Use the **Queue file path** setting to determine the location for the persistent queue files. The default is `$CRIBL_HOME/state/queues`. When writing data, Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this path.

For queuing to operate properly, you must provide sufficient disk space. In Distributed mode, this minimum disk space configuration is set on each Worker Group/Fleet. You can access this setting at **Group/Fleet settings** > **General Settings** > **Limits** > **Min free disk space**.

If available disk space falls below this minimum threshold, Cribl Stream/Edge will stop maintaining persistent queues, and data loss will begin. The default minimum is 5 GB.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Stream/Edge will append `/<worker-id>/<output-id>`.

What Happens to Data when the Queue Reaches Its Configured Limits

You can use the **Queue-Full Behavior** setting to determine what happens when the persistent queue reaches its **Queue size limit** and runs out of space. There are two options:

Setting	Description
Block	Blocks all data until the backpressure event has resolved. If set to Block, the output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
Drop new data	The Destination will discard all new events until the backpressure event has resolved and the receiver is ready.

How to Drain Persistent Queues When Backpressure Events End

When a backpressure event ends, the persistent queue begins to drain to the downstream Destination. You can configure the order of event delivery and the rate at which Cribl Stream forwards events.

Use the **Strict Ordering** setting to configure the order that Cribl Stream sends data to the Destination. Toggle **Strict Ordering** on (default) to use FIFO (first in, first out) processing. This means Cribl prioritizes earlier queued events before sending newly arrived data. Toggle **Strict Ordering** off to change this behavior, prioritizing new data over the events already in the queue.

If you toggle **Strict Ordering** off, you must configure the **Drain rate limit (EPS)**. This setting allows you to throttle the rate at which events drain from the persistent queue to the Destination. The default value of `0` disables throttling. Throttling the drain rate helps Cribl manage the incoming stream of live data more effectively, preventing delays caused by queue processing. It also improves the throughput of active connections by reserving additional resources for them.

The Drain rate limit (EPS) is set in Events Per Second (EPS). To determine your system's EPS value:

1. Open the Monitoring page. From Cribl Stream's sidebar, select **Monitoring** to access dashboards displaying data for all Worker Groups and all nodes.
2. Filter by a specific node. Use the **Groups** menu at the top to restrict monitoring data to a single Worker Node.
3. Adjust the time granularity. Use the time menu change the display granularity from the default `15 min` to `1 day` for better accuracy.
4. Locate the EPS metrics. On the Monitoring page, find the **Events In and Out** metrics group. Copy the value listed under THROUGHPUT IN (AVG). For example, a typical value might be `31,000 EPS`.

Cribl recommends setting the **Drain Rate Limit** to 10% of the Worker Process EPS to prioritize live data processing. To calculate an appropriate drain rate:

1. Determine EPS per Worker Process. Divide the Worker Process EPS by the number of Worker Processes (WPs). For example: `31,000 EPS / 14 WPs = 2,200 EPS per WP`.
2. Calculate 10% of EPS per Worker Process. Multiply the result by `0.10` to find the recommended drain rate. For example: `10% of 2,200 EPS = 220 EPS`.
3. Configure the **Drain Rate Limit**. In the persistent queue settings for the Destination, enter this value in the **Drain rate limit (EPS)** field. For example: `220`.

After applying this setting, monitor the queue's drain rate. If the queue is draining too slowly, carefully increase the **Drain rate limit (EPS)** while ensuring it doesn't interfere with live data processing. Avoid setting the limit too high, as this can impact the performance of live streams. If needed, consider optimizing Worker startup connections and managing CPU load to further enhance performance at **Group Settings** > Worker Processes.

Cribl's guarantee for data delivery is that all data is delivered at least once, but not exactly once. Sometimes Cribl Stream sends duplicate data events when the persistent queue drains.

Steps to Safely Disable and Clear Persistent Queues

If you want to disable persistent queuing, always wait for the queue to fully drain. The **Clear Persistent Queue** button is available as a destructive fallback. This action frees up disk space, but it also deletes the queued data *without* sending it on to receivers.

After the queue has drained, then you can select a different backpressure behavior. Save the configuration after changing it.

Destination Persistent Queue Notifications

Some Cribl licenses allow you to configure Notifications for Destination persistent queues for on-prem deployments. In general, Cribl recommends setting Notifications for these events when using persistent queue to ensure you are aware of important system events. These Notifications always appear in Cribl Stream's user interface and internal logs. You can also send them to external systems.

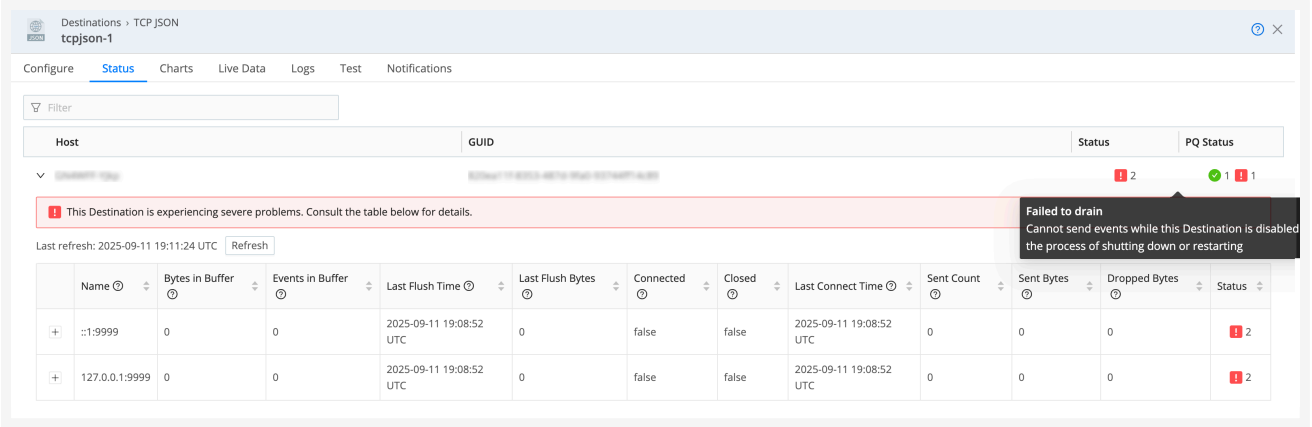
You can set notifications for these scenarios:

- Persistent queue files exceed a configurable percentage of allocated storage.
- A Destination reaches the queue-full state, meaning it is running out of available disk space.
- A Destination backpressure engages, causing blocked or dropped events.
- Persistent Queue Usage (saturation).

See About Notifications for information about adding Notifications for Destinations.

Monitor Destination Persistent Queues

Cribl Stream provides metrics and health indicators to monitor your Destination persistent queue through the **Status** tab on your Destination. Cribl Stream provides metrics and health indicators to monitor your Source persistent queue through the **Status** tab on your Source. The **Status** tab aggregates metrics and health from all Worker Processes, allowing you to assess the health of your persistent queues and the status of the Destination in real time.



Example of the Destination Status tab

To view the Destination persistent queue metrics:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Data**, select **Destinations**.
2. From the sidebar, select the type of Destination you want to view.
3. Select the Destination from the list of currently configured Destination.
4. In the resulting modal, select the **Status** tab.

Inside this view, you can expand individual Worker Nodes for more details.

For additional analysis, you can also use Monitoring dashboards:

1. Navigate to **Monitoring** on the product sidebar.
2. Navigate to **System** > **Queues (Sources)** and view relevant data.

Troubleshooting Tools

Cribl internal logs for Cribl-managed Workers might include entries labeled `Revived PQ Worker Process`. These indicate where a Cribl-managed Worker was newly assigned to drain a persistent queue left over from a shut-down Worker Node. You can use these log events to troubleshoot Cloud PQ issues.

Reference: Destination Persistent Queue Fields

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues

- Optimize Destination Persistent Queues (dPQ)
- Destination Backpressure Triggers

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Stream or Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Backpressure duration Limit: When **Mode** is set to `Backpressure`, this setting controls how long to wait during network slowdowns before activating queues. A shorter duration enhances critical data loss prevention, while a longer duration helps avoid unnecessary queue transitions in environments with frequent, brief network fluctuations. The default value is `30` seconds.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Stream/Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are

8.3.4. About Destination Backpressure Triggers

This page describes the conditions that can trigger backpressure in Cribl Stream Destinations. Backpressure exists when a destination receives more data than it can currently send. It typically results from network connectivity problems or when a Destination is receiving data faster than it can forward that data to the downstream service.

When a Destination signals backpressure, it notifies the Sources generating data that its buffers are full and that the incoming data flow should pause until there is room for more data.

You can configure your desired behavior through a Destination's **Backpressure Behavior** drop-down. Where other options are not displayed, Cribl Stream's default behavior is **Block**. For details about all the above behaviors and options, see Persistent Queues.

HTTP-Based Destinations

HTTP-based Destinations trigger backpressure when they encounter errors while connecting or when they receive certain HTTP response codes. If the HTTP call returns a `500` series (`500-599`) HTTP code, the Destination adds the events in the buffer back to its internal buffer and tries to send them again. The retry attempt can also trigger backpressure, depending on the frequency at which this happens.

If the Destinaton receives a `400` series response code, it will drop (not retry) the events, because these response codes indicate an error in payload or formatting (for example). See this Mozilla page on the `400 Bad Request` code for more information.

Finally, HTTP-based Destinations trigger backpressure when their processing loads exceed the specified limit. HTTP-based Destinations handle requests by creating a connection, sending the request payload, and receiving and parsing a response. Because this process can take time, HTTP Destinations allow more than one request to be in progress at a time. When the number of requests in flight exceeds the value set in **Advanced Settings** > **Request concurrency**, the Destination will trigger backpressure.

The following conditions will trigger backpressure:

- Connection failure.
- Connection or request timeouts.
- Data overload, such as when the Source sends more data than the Destination will accept.
- Reaching the limit on concurrent (in-flight) requests.
- HTTP `500` series responses.

You can set the number of in-flight or concurrent requests in **Advanced Settings** > **Request concurrency**.

See Available Destinations for information about which Destinations are HTTP-based.

Filesystem-Based Destinations

Filesystem-based Destinations that send data to cloud-based services trigger backpressure when Cribl Stream can't move a file or upload it to the cloud.

Filesystem-based Destinations queue events in files on disk in a staging directory. When a batch of events is ready for transmission, Cribl Stream closes the file, optionally compresses it, and transmits the file to the downstream service.

For the Filesystem Destination, the batch simply moves from the staging directory to the output directory.

For other filesystem-based Destinations, Cribl Stream uploads the file to a cloud service, such as AWS S3, Azure Blob Storage, or other. For these Destinations, a failure to upload the file will trigger backpressure.

These scenarios include:

- Permissions problem writing to the staging directory, such as when the user running the Cribl Stream process does not have permission to write to the staging directory.
- The filesystem for the staging or output directory is full (impacts Filesystem Destination only).
- The credentials provided for the cloud service are invalid.
- The Destination doesn't have the permissions required to upload to the cloud service.
- Cloud service permissions issue, such as when an upload fails because the cloud user (identified in credentials) does not have write permissions.
- Network connectivity - The Destination can't communicate with the cloud service due to network connectivity issues.

Object Storage Destinations and Backpressure

Object-based Destinations, such as Amazon S3, Azure Blob Storage, Google Cloud Storage, and similar services, do not support Destination persistent queues. Instead, these Destinations use a local staging directory to buffer files before uploading them to cloud storage.

Resilience for object storage Destinations depends on staging disk capacity and upload success. Unlike streaming Destinations with persistent queues, there is no separate queue to absorb prolonged outages.

When configuring the **Backpressure behavior** setting for object storage Destinations, consider the impact on other Destinations receiving the same input data:

- If **Block** is selected and the Destination becomes unhealthy (for example, due to credential issues or network problems), it can stall delivery to all other Destinations that receive the same events.

- If **Drop** is selected, Cribl Stream discards events for the affected Destination while other Destinations continue to receive data.

For archival or less-critical paths, **Drop** may be preferable to **Block** to avoid stalling more important downstream Destinations. However, this means accepting potential data loss on the archive path during outages.

For sizing and configuration guidance, see S3 Better Practices.

See Available Destinations for information about which Destinations are filesystem-based.

TCP-Based Destinations

TCP Sources establish a persistent connection with a Destination and send data. These Sources maintain connection to the Destination and will re-establish that connection if they detect a close or write timeout.

If the connection fails, Cribl Stream uses a backoff algorithm to avoid spiking the CPU. This backoff logic makes the first retry at 2 seconds, then gradually increases the time between retries up to a maximum of 60 seconds.

The following conditions can trigger backpressure from a TCP-based Destination:

- Connection failure.
- Authentication failure.
- Write timeout, where a Source sends data but doesn't receive an `ack` at the TCP layer. In this case, Cribl Stream closes the connection to the Destination and tries to re-establish it.
- The Destination receives data from the Source faster than it can send data over the network to the downstream service, causing internal buffers to fill up. This condition can occur due to a slow network connection or slow processing on the downstream service.When space in the internal buffers becomes available, backpressure is relieved, allowing the Source to send more data.

See Available Destinations for information about which Destinations are TCP-based. Some Destinations use either TCP or UDP to send messages, but they trigger backpressure and use the backoff algorithm described above only when used with the TCP protocol.

Kafka

Kafka is a binary protocol that runs over TCP. The protocol defines three roles - producers, consumers, and brokers.

Producers send data to a Kafka topic (think of it as a message queue). Kafka consumers read data from Kafka topics. Brokers receive data from topic producers and send data to topic consumers, meaning they serve as go-betweens for producers and consumers.

Cribl Stream's Kafka-based Destinations are producers. They send data to Kafka brokers. Since the protocol is TCP-based, the conditions that trigger backpressure are similar to those of Cribl Stream's TCP Destinations.

The specifics for connection and request retries are defined by the Kafka JS library in conjunction with the configuration parameters defined for each Destination. In all cases, the Destinations have internal buffers that are sent to the Broker when they're considered full (on a size and time basis).

The following conditions can trigger backpressure for Kafka-based Sources:

- Failure to connect to the broker, lack of network connectivity, or the broker is down.
- Invalid credentials - Destination connects successfully, but the connection is rejected due to a failure to authenticate.
- Invalid permissions - The credentials assigned do not have proper permissions to send events to the topic.
- The Destination is attempting to send data faster than the broker can receive it. Backpressure will be relieved when internal buffers have room for more events.

Kafka Retries and PQ

In some situations, Kafka Destinations may take a long time to engage the PQ (1 to 6 minutes by default).

This delay can result from the default settings used with the Kafka Destination. The relevant settings are all in the **Advanced Settings** UI:

- **Connection timeout (ms)**: Defaults to `10000`,
- **Request timeout (ms)**: Defaults to `60000`.
- **Retry limit**: Defaults to `5`.

These default settings mean that Cribl Stream will retry five times after a failed connection, with a 10-second timeout between each attempt. It will also retry five files after a failed request, with a timeout of 60 seconds between each attempt.

For faster PQ engagement, update these values. You can use smaller values for **Connection timeout** and **Request timeout** to decrease the interval between retries. You can also use smaller values for **Retry limit** or even set it to `0` to eliminate retries altogether.

UDP

UDP is a connectionless protocol, so there is no concept of backpressure at the network layer. As a result, UDP Destinations will never trigger backpressure.

See Available Destinations for information about which Destinations support UDP. Except for SNMP Trap, these Destinations also support TCP, but the UDP versions do not trigger backpressure.

SQS

The SQS (Simple Queue Service) Destination uses the AWS SQS library to send events to the Destination's configured queue. Like Kafka, this Destination acts as a producer that publishes messages to the provisioned SQS queue.

This Destination has five buffers with 10 events per buffer for a total of 50 events that can be queued before backpressure is enabled. The reason that backpressure might be generated for this Destination include:

- Invalid credentials.
- Invalid permissions.
- Queue does not exist and **Create Queue** is disabled.
- Lack of network connectivity.

Amazon Kinesis

Kinesis runs over HTTPS and behaves like Pub/Sub Destinations.

This Destination serializes and publishes events in a newline-delimited JSON format. In the context of the Kinesis Destination, it behaves as a producer where a Kinesis source is considered a consumer. Since the protocol is HTTP-based, the conditions that trigger backpressure are similar to those of other Cribl Stream HTTP Destinations.

The Kinesis library defines the specifics for connection and request retries in conjunction with the configuration parameters defined for each Destination. In all cases, the Destinations have internal buffers that are sent to the Broker when they're considered full (on a size and time basis).

The following conditions can trigger backpressure for Kinesis-based Destinations:

- Failure to connect to the Kinesis service, network connectivity, or the service is down.
- Invalid credentials - Connects successfully but connection is rejected due to a failure to authenticate.
- Invalid permissions - The credentials assigned do not have proper permissions to send events to the Kinesis stream.
- The Destination is attempting to send data faster than the service can receive it. Backpressure will be relieved when internal buffers have room for more events.

Google Cloud Pub/Sub

Google Cloud Pub/Sub is similar to Kafka and Kinesis in that there are producers that send data and consumers that receive data. The Cribl Stream Google Cloud Pub/Sub Destination is a producer that sends data to the

Google Cloud Pub/Sub service. Google Cloud Pub/Sub leverages gRCP, however, which uses protocol buffers as both its interface definition language (IDL) and as its underlying message interchange format.

The conditions that trigger backpressure for a Google Cloud Pub/Sub Destination are:

- Failure to connect to the Google Pub/Sub service, network connectivity, or the service is down.
- Invalid credentials - Connects successfully but connection is rejected due to a failure to authenticate.
- Invalid permissions - The credentials assigned do not have proper permissions to send events to the topic.
- The Destination is attempting to send data faster than the service can receive it. Backpressure will be relieved when internal buffers have room for more events.

OpenTelemetry

OpenTelemetry supports gRPC or HTTP to send messages. For the gRPC protocol, the same rules described for other TCP Destinations generally apply to OpenTelemetry. The key difference is that this Destination uses the OpenTelemetry library, which handles write timeouts and reconnection logic.

For the HTTP protocol, the same rules apply to our HTTP Destinations for retries based on connectivity or `500` series response codes.

Load-Balanced Destinations

HTTP-Based Load-Balanced Destinations

Some HTTP-based Destinations support two modes - single host and multiple load-balanced hosts.

With a load-balanced version of an HTTP Destination, Cribl Stream spreads events across all configured Destinations, using a weighted algorithm. Under normal circumstances, this algorithm spreads the load across the configured Destinations according to the weight assigned to the Destination.

When one of the load-balanced Destinations is out of service (due to a write timeout or `500` series response code - buffers full), Cribl Stream removes that Destination from the list of hosts and moves any in-flight buffers to the next available host. Cribl Stream will try to resend events to the downed host in the background, and it will resume sending data to that host once the connection is restored.

See Available Destinations for information about which HTTP-based Destinations support load balancing.

TCP Load-Balanced Destinations

Some TCP-based Destinations support two modes - single host and multiple load-balanced hosts.

With a load-balanced TCP Destination, Cribl Stream spreads events across all configured Destinations using a weighted algorithm. Under normal circumstances, this algorithm spreads the load across the configured Destinations according to the weight assigned to each Destination.

When one of the load-balanced Destinations is out of service (due to a write timeout or connection failure), Cribl Stream removes that Destination from the list of hosts and moves any in-flight buffers to the next available host. Cribl Stream will try to reconnect to the downed host and will resume sending data to that host once the connection is restored.

TCP load-balanced Destinations can be configured with one or multiple receivers. If one or more receivers go down, Cribl Stream will continue sending data to any healthy receivers.

See Available Destinations for information about which TCP Destinations support load balancing.

Output Router

The Output Router is a wrapper destination that groups together 1..*N* Destinations. It's used in conjunction with event filters to route data to a selected Destination. The Output Router Destination emits backpressure only when one of its downstream Destinations is blocking.

External Load Balancers

External load balancers placed in front of Worker Nodes generally do not detect backpressure states within the data Pipeline. If a Worker Node still accepts network connections, the load balancer typically considers it healthy, even when event flow is blocked by downstream backpressure.

This means:

- Load balancing alone should not be treated as protection against blocked Destinations.
- A Worker Node under backpressure may continue to receive new data from the load balancer, potentially leading to dropped events if Source buffering is exhausted.
- Health checks based solely on TCP connectivity or HTTP endpoints may not reflect the Worker Node's ability to process and deliver events.

To detect backpressure conditions, use Cribl Stream's built-in Notifications for **Destination Backpressure Activated** or monitor Destination health directly.

8.3.5. Backpressure Impacts To Sources

When a Destination experiences backpressure, Cribl Stream must manage the incoming data flow to prevent overwhelming the system. If persistent queue (PQ) is not enabled, backpressure propagates back through the data Pipeline to the Sources, which can impact data flow in different ways depending on the Source type.

This page explains how backpressure affects Sources when PQ is not in use and the **Backpressure behavior** is set to **Block**. For information about backpressure behavior options, see Data Delivery to Unreachable Destinations.

How Backpressure Propagates Without PQ

When a Destination signals backpressure and PQ is not enabled, the Cribl Stream event processors stop accepting new data. This creates a chain reaction that propagates back through the Pipeline:

1. The Destination internal buffers fill up.
2. The event processors stop reading from Source buffers.
3. Source buffers fill up.
4. The Source signals backpressure to upstream senders (when supported).

The speed at which this propagation occurs depends on buffer sizes throughout the Pipeline. A brief backpressure event might not immediately affect all Sources, but sustained backpressure will eventually impact all connected senders. For Sources that support backpressure signaling, senders are blocked and data queues on the sender side. For Sources that do not support backpressure signaling (such as UDP-based Sources), data is dropped.

The Destination does not directly notify individual Sources about backpressure. Instead, for Sources that support backpressure signaling, backpressure propagates indirectly when the Cribl Stream event processors stop reading from Source buffers, causing those buffers to fill. The specific mechanism varies by Source type. See the sections below for details.

The following sections describe how this backpressure propagation affects different Source types when PQ is not enabled.

TCP-Based Sources

For TCP-based Sources (such as Splunk TCP, Syslog over TCP, TCP JSON, and TCP Raw), backpressure propagates through the following mechanism:

1. When the Destination buffers fill, the Cribl Stream event processor stops reading from the TCP socket buffer.
2. When the TCP socket buffer fills, the TCP/IP stack notifies the sender to stop sending data.
3. The sender pauses transmission until the socket buffer has capacity again.

This mechanism relies on TCP flow control, which is built into the protocol. When Cribl Stream stops acknowledging received data, the TCP stack on the sender automatically slows or pauses transmission. During this time, the sender's outbound data queues in its local TCP buffer. When Cribl Stream resumes reading from the socket (because the Destination has capacity again), the TCP stack automatically resumes transmission and the sender's buffer drains.

Per-Connection Behavior

When the TCP socket buffer fills, the TCP/IP stack signals the sender to stop sending data. Because this occurs at the individual socket level, some senders may experience blocking sooner than others, even if they are sending data to the same Destination.

This means:

- Different senders connected to the same Source may experience backpressure at different times.
- Senders transmitting higher volumes of data will fill their socket buffers faster and experience backpressure sooner.
- Senders with slower network connections may have smaller effective buffer capacities and experience backpressure sooner.

Only TCP-based Sources support this flow control mechanism. UDP-based Sources (such as UDP Raw and SNMP Trap) do not have built-in backpressure support because UDP is a connectionless protocol. For UDP Sources, Cribl Stream drops incoming data when buffers are full.

Pull-Based Sources

For pull-based Sources, Cribl Stream has built-in intelligence to detect backpressure and pause data retrieval. When backpressure is detected, pull-based Sources stop or slow their data collection activities.

The following pull-based Sources are affected:

Source Type	Backpressure Behavior
S3, Azure Blob Storage, and other object storage Sources	File downloads pause when backpressure is detected.

Source Type	Backpressure Behavior
Database Collectors	Results streaming pauses during backpressure.
REST Collectors	GET requests pause during backpressure.
Kafka, Confluent Cloud, Amazon MSK	Polling from Kafka-based Sources stops during backpressure.
Amazon Kinesis Data Streams	Stream reads pause during backpressure.
Amazon SQS, Google Cloud Pub/Sub	Message retrieval pauses during backpressure.

Side Effects of Pausing Pull-Based Sources

While pausing data collection prevents overwhelming the Pipeline, it can introduce side effects.

File Download Timeouts

Backpressure causes file downloads from object storage (such as S3 or Azure Blob Storage) to pause. If backpressure persists for too long, the download may time out. This can result in:

- **Duplicate data**: If Cribl Stream retries the download after a timeout, you may ingest the same data twice.
- **Data loss**: If the source data is purged or expires before Cribl Stream can recollect it, that data is lost.

To mitigate this risk, consider increasing the **Socket timeout** setting in **Advanced Settings** for the Source, or enable persistent queue to prevent prolonged backpressure events.

Database Resource Consumption

When Database Collectors pause results streaming due to backpressure, the database query remains active on the database server. This means:

- The database server continues to consume resources (CPU, memory, connections) for the paused query.
- Database connections remain held, which can exhaust the connection pool and block other database operations.
- The Database Collector runs on only one Worker Process at a time, so if that process is blocked, the entire Database Collector job run is affected.

For long-running database queries, monitor your database server resources and connection pool usage during backpressure events.

Kafka Consumer Group Rebalancing

When Kafka-based Sources pause polling for extended periods, the Kafka broker may consider the consumer inactive and trigger a consumer group rebalance. This can cause:

- Temporary disruption to other consumers in the same consumer group.
- Potential duplicate processing when the consumer rejoins.

Impact on Multi-Destination Routing

When a sender is blocked due to backpressure from one Destination, it affects data delivery to all Destinations receiving data from that sender, even Destinations that are not experiencing backpressure.

This occurs because event cloning for multi-Destination routing happens after data passes through the Routes. If a sender is blocked:

1. Data from that sender cannot flow through the Routes.
2. The Clone Function or Output Router cannot create copies for other Destinations.
3. All Destinations expecting data from that sender stop receiving data.

Example Scenario

Consider a configuration where:

- A Syslog Source sends data to two Destinations via an Output Router.
- Destination A experiences backpressure.
- Destination B is healthy and can accept data.

When Destination A blocks and the sender is affected:

- No new data from that sender reaches Destination B either.
- This occurs even though Destination B has capacity.
- The block persists until backpressure on Destination A resolves.

To prevent one Destination from blocking all data flow, set non-critical Destinations to **Drop** or enable persistent queue.

8.4. About Load Balancing

Cribl Stream will attempt to load-balance outbound data as fairly as possibly across all endpoints. For example, if FQDNs/hostnames are used as the Destination addresses, and each resolves to 5 (unique) IPs, then each Worker Process will have its # of outbound connections = {# of IPs x # of FQDNs} for purposes of the Destination.

Data is sent by all Worker Processes to a randomly selected endpoint, and the amount sent to each connection depends on these parameters:

1. Respective destination **weight**: If a **Load Weight** is set to `0`, Cribl Stream will not try to connect to that IP (nor to any IPs resolved for that FQDN). When a connection is blocked, Cribl Stream will apply a 10% penalty to the load weight, and will select the connection with the lower adjusted load.
2. Respective destination **historical data**: By default, historical data is tracked for 300s. Cribl Stream uses this data to influence the traffic sent to each destination, to ensure that differences decay over time, and that total ratios converge towards configured weights.

Sources share a single Worker Process for load balancing, so you don't need to dedicate a separate Worker Process for load balancing for each Source. Load balancing Worker Processes have a high throughput rate because they only handle Event Breakers.

On Destinations that support load balancing, Cribl recommends enabling the feature, even if you only have one hostname - because this hostname can expand to multiple IPs. If you must disable load balancing, then to ensure robust connections, enable the alternative **Advanced Settings** > **Round-robin DNS** option. This will allow Cribl Stream to follow the DNS host's IP rotation, preventing connection pinning.

If a request fails, Cribl Stream will resend the data to a different endpoint. Cribl Stream will block only if **all** endpoints are experiencing problems.

Example: Equal Distribution

Suppose we have two connections, A and B, each with weight of `1` (i.e., they are configured to receive equal amounts of data). Suppose further that the load-balance stats period is set at the default `300s` and - to make things easy - for each period, there are 200 events of equal size (bytes) that need to be balanced.

Interval	Time Range	Events to balance
1	*time=0s —> time=300s*	**200**

Both A and B start this interval with 0 historical stats each.

Let's assume that, due to various circumstances, 200 events are "balanced" as follows: `A = 120 events` and `B = 80 events` - a difference of **40 events** and a ratio of **1.5:1**.

Interval	Time Range	Events to balance
2	*time=300s —> time=600s*	**200**

At the beginning of interval 2, the load-balancing algorithm will look back to the previous interval stats and carry **half** of the receiving stats forward. In other words, connection A will start the interval with **60** and connection B with **40**. To determine how many events A and B will receive during this next interval, Cribl Stream will use their weights and their stats as follows:

Total number of events: `events to balance + stats carried forward = 200 + 60 + 40 = 300`.

Number of events per each destination (weighted): `300/2 = 150` (they're equal, due to equal weight).

Number of events to send to each destination `A: 150 - 60 = 90` and `B: 150 - 40 = 110`.

Totals at the end of interval 2: `A=120+90=210`, `B=80+110=190`, a difference of **20 events** and a ratio of **1.1:1**.

Over the subsequent intervals, the difference becomes exponentially less pronounced, and eventually insignificant. Thus, the load gets balanced fairly.

Example: Unequal Distribution

Suppose you have three connections, A, B, and C, weighted to receive unequal amounts of data:

- A: 1
- B: 2
- C: 7

Assume that the load-balance stats period is set at the default `300s` and for each period, 200 events of equal size (bytes) need to be balanced:

Interval	Time Range	Events to balance
1	*time=0s —> time=300s*	**200**

All three connections (A, B, and C) start this interval with 0 historical stats each.

Let's assume that 200 events are "balanced" as follows: `A = 30 events`, `B = 50 events`, and `C = 120 events` - a difference of **90 events** and a ratio of **3:5:12**.

Interval	Time Range	Events to balance
2	*time=600s —> time=600s*	**200**

At the beginning of interval 2, the load-balancing algorithm will look back to the previous interval stats and carry **half** of the receiving stats forward. This means that connection A will start the interval with **15**, connection B with **25**, and connection C with **60**. To determine how many events each connection will receive during this next interval, Cribl Stream will use their weights and their stats as follows:

Total number of events: `events to balance + stats carried forward = 200 + 15 + 25 + 60 = 300`.

Number of events per each destination (weighted): `300 / (1 + 2 + 7) = 300 / 10 = 30`.

Number of events to send to each destination `A: 30 - 15 = 15`; `B: 60 - 25 = 35`; `C: 210 - 60 = 150`.

Totals at the end of interval 2: `A: 30 + 15 = 45`; `B: 50 + 35 = 85`; `C: 120 + 150 = 270`.

The difference between the highest connection (C) and the lowest (A) is **225 events**. The ratio at the end of interval 2 is approximately **1:1.89:6**.

Over the subsequent intervals, the difference becomes exponentially less pronounced, and eventually insignificant. Thus, the load gets balanced fairly.

8.5. Configure Host Metadata

Cribl Stream can add a `__metadata` property to every event produced from every enabled Source. You can view the metadata collected for a Worker Node by selecting the Worker Node on the **Workers** page.

The metadata surfaced by a Worker Node can be used to:

- Enrich events (with an internal `__metadata` field).
- Display metadata to users as a part of instance exploration.

You can customize the type of metadata collected at **Group Settings** > **General Settings** > **Limits** > **Metadata**. Add and select metadata sources by selecting **Add Source** and choosing an option from the list.

In Cribl Stream, all the **Event metadata sources** are disabled by default.

The sources that you can select here include:

Source	Description
`os`	Reports details for the host OS and host machine, like OS version, kernel version, CPU and memory resources, hostname, network addresses, and so on.
`cribl`	Reports the Cribl Stream version, Distributed mode, Worker Nodes (for managed instances), and configuration version.
`aws`	Reports details on an EC2 instance, including the instance type, hostname, network addresses, tags, and IAM roles. For security reasons, we report only IAM role **names**.
`env`	Reports environment variables.
`kube`	Reports details on a Kubernetes environment, including the node, Pod, and container. For details, see __metadata.kube Property.

When these metadata sources are enabled (and can get data), Cribl Stream will add the corresponding property to events, with a nested property for each enabled source.

Some metadata sources work only in configured environments. For example, the `aws` source is available only when running on an AWS EC2 instance. And `kube` applies only to on-prem deployments.

If your security tools report denied outbound traffic to IP addresses like `169.254.169.168` or `169.254.169.254`, you can suppress these by removing `aws` from the metadata sources described

above. If you have a proxy setup, Cribl recommends adding these IP addresses to your `no_proxy` environment variable.

`__metadata.kube` Property

For the `__metadata.kube` property (displayed as `kube` in the list of event metadata sources) to report details on a Kubernetes environment, Cribl Stream needs to know where it is running. Set the `KUBE_K8S_POD` environment variable to the name of the Pod in which Cribl Stream is running. This gives the `__metadata.kube` property the information it needs to report on the `node` and `pod` properties.

If `/proc/self/cgroup` is working, the `container` property information will be available, too.

8.6. Cribl Edge To Cribl Stream

Cribl Edge automatically discovers logs, metrics, application data, and so on - in real time - from your configured endpoints, and delivers them to Cribl Stream or any supported destination. Meanwhile, Cribl Stream can help collect, reduce, enrich, transform, and route data from Cribl Edge to any destination. And using a Cribl HTTP Source, you can collect and route data from Edge Nodes to Stream Worker Nodes without incurring additional cost.

For more information about sending data between organizations and Workspaces without paying for data twice, see Transfer Data Between Workspaces or Environments.

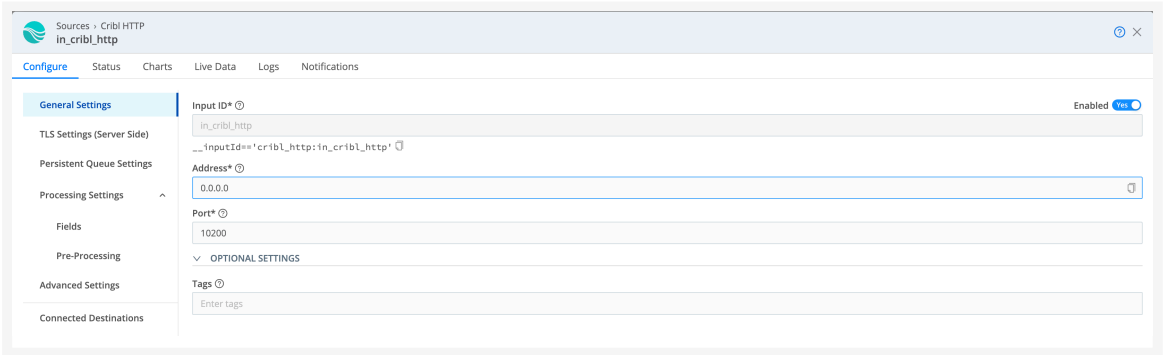
This guide outlines how to route data from an Edge Node (or an entire Fleet) to an existing Stream Worker Group for additional processing. We will walk you through the following:

- Configure Cribl HTTP Source on Cribl Stream to receive data from the Edge Node.
- Configure the Exec Source on Cribl Edge to collect data on the Edge Node.
- Configure the Cribl HTTP Destination on Cribl Edge to send data to Cribl Stream.
- Configure a Route to Send the Data.

And finally, we will confirm the data flow.

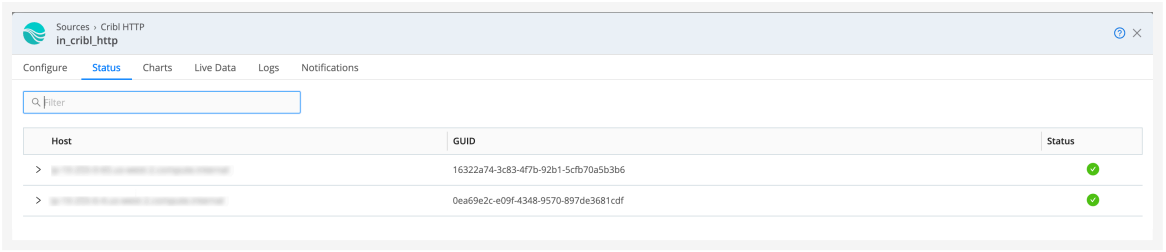
Configure the Cribl HTTP Source on Cribl Stream

In Cribl Stream, start by configuring and enabling a Cribl HTTP Source. The key requirement here is to set the **Port** to listen on. For this example, we'll use the default `10200`. (Optionally, you can also configure TLS, enable persistent queue, and/or a pre-processing Pipeline.)



Configuring a Cribl HTTP Source

When done, **Commit** and **Deploy** your changes. Before moving on to the next step, confirm that your Source is healthy.



Status of the Cribl HTTP Source

On Cribl-managed Workers in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl HTTP Source and the Cribl HTTP Destination it's receiving data from, or enabled on both. Otherwise, no data will flow. In the Source, TLS is enabled by default.

Configure the Exec Source on Cribl Edge

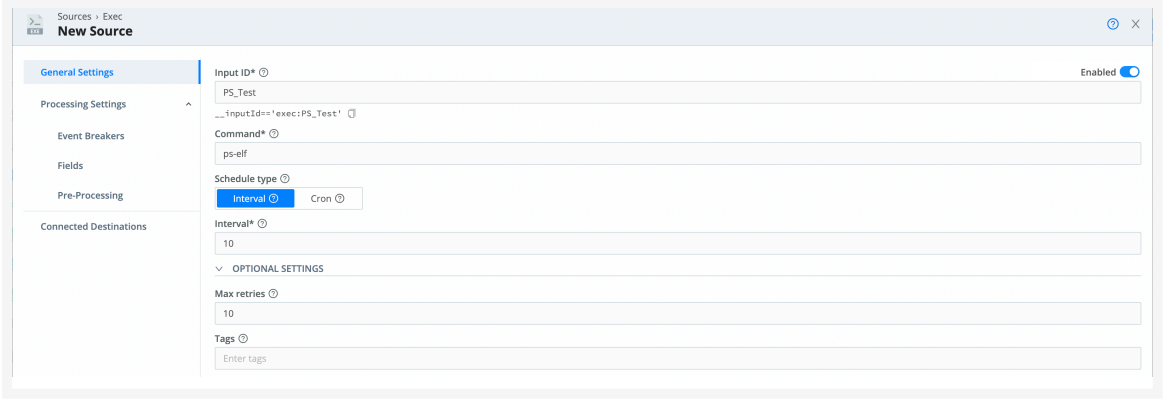
Next, we'll configure the Exec Source on your Edge Node. This Source will break the incoming streams of data into discrete events, and send them to Cribl Stream.

In this step, you can swap out the Exec Source by instead configuring a System Metrics or File Monitor Source. Or, configure multiple Sources to connect to the same Destination.

The Exec Source enables you to periodically execute a command and collect its `stdout` output. In the Exec Source's configuration modal, specify:

- Which command to execute.
- The number of times to attempt running the command.
- The interval between attempts.

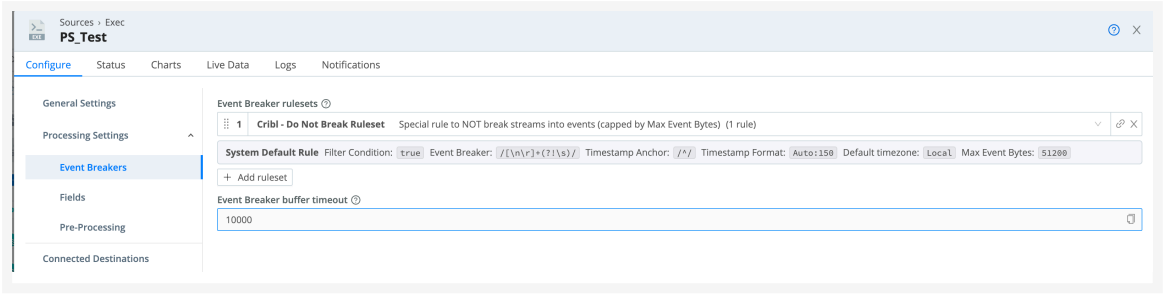
In our example, we are running the `ps` command to list and retrieve running processes every `10` seconds.



Configuring an Exec Source

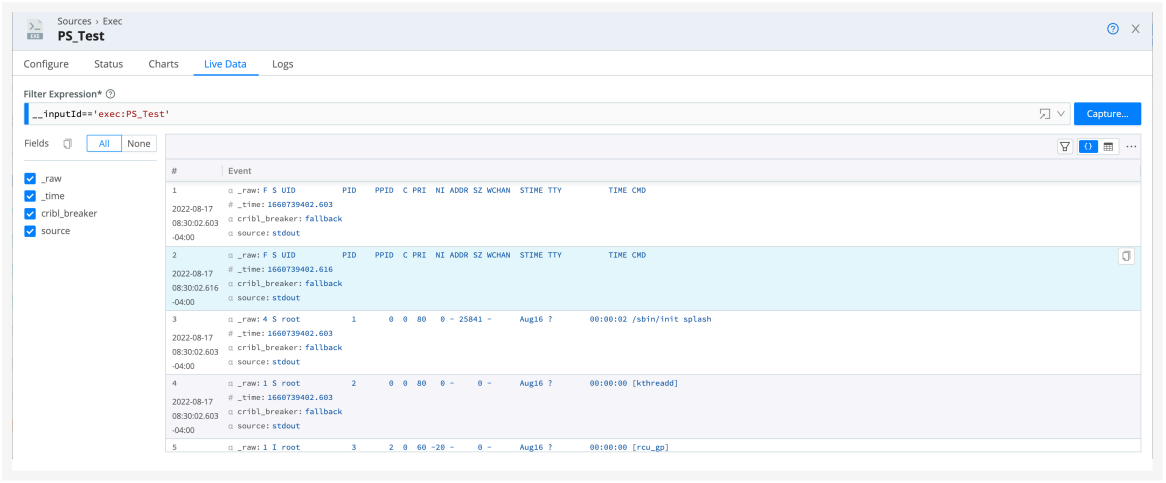
If we don't configure an Event Breaker, then with each capture we run on the dataset, each process will be ingested as its own event, without the header information. So to structure the data, we'll add an Event Breaker.

On the Exec Source configuration modal's left tab, select **Event Breaker**. In the **Event Breaker rulesets** drop-down, select `Cribl - Do Not Break Ruleset`.



Apply an Event Breaker

Next, preview your data on the modal's **Live Data** tab.



Preview Live Data

Configure the Cribl HTTP Destination on Cribl Edge

To get the data flowing, we'll configure the Cribl HTTP Destination on your Edge Node. A few things to note when configuring this Destination:

- The Cribl endpoint field in this Destination must point to the **Address** and **Port** you entered on the Cribl HTTP Source you configured in the first step.
- Optionally, define your **Compression**, **Throttling**, and **Backpressure behavior** requirements.
- On Cribl-managed Worker/Edge Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl TCP Destination and the Cribl TCP Source it's sending data to, or enabled on both. Otherwise, no data will flow. In the Destination, TLS is disabled by default.

Once you've configured your Destination, test it to verify that your Edge Node can communicate with the Stream Worker Group.

Configure a Route to Send the Data

Finally, configure a Route to send your data to Cribl Stream. For this example, we can use the `passthru` Pipeline.

Confirm the Data Flow

To confirm that your data is flowing, navigate back to Cribl Stream's Cribl HTTP Source. Run a **Live Data** capture on the Source.

You can also check the Monitoring page > **Data** submenu, to isolate the throughput on your Source.

8.7. Transfer Data Between Workspaces Or Environments

Cribl Stream provides you with the ability to transfer data between Cribl Worker Nodes that report to the **same** Leader or different Leaders, via the Cribl TCP and Cribl HTTP Source and Destination pairs.

You can enable data sharing across Worker Nodes that do not share a Leader as long as both Organizations have **active, paid Cribl.Cloud plans** or **active, paid licenses**.

We designed this workflow to support scenarios where you can't or don't want to create a direct connection between Leader Nodes, such as:

Use case	Description
High/Low Security Environments	Isolated and protected network environments that handle sensitive data (for example, air-gapped networks managed by Cribl Edge) sending data to an external Cribl Stream processing tier.
Cribl Stream to Cribl Stream	Send data between Cribl Stream environments or Workspaces that exist within the overall Cribl system that you own and pay for.
Decentralized Management	Cribl Edge environments managed by separate Leaders forwarding data to a central Cribl Stream instance.

Key Aspects of Data Transfer Between Environments

Understand how you're billed for data transfers between environments and separate, paid Organizations.

Connectivity

The sending and receiving Organizations do not need to share a Leader. Use a paired **Cribl HTTP** or **Cribl TCP** Source/Destination.

Trust and Billing

- The **single ingest** benefit applies only when Workspaces are in the same **Cribl.Cloud Organization**, or when on-prem Leaders have the exact same paid license key installed.
- You can transfer data between separate paid **Cribl.Cloud Organizations**, but the receiving Organization will incur ingest charges.

Example: Customer to MSSP across separate Cloud Organizations

> An enterprise customer (paid Cribl.Cloud Organization A) can send data via **Cribl HTTP** or **Cribl TCP** to their MSSP (paid Cribl.Cloud Organization B). This setup is supported. Because the Organizations are different, the **single ingest** benefit does not apply across them; the MSSP Organization will be billed for the received data.

Understand Environment Compatibility

Sender → Receiver	Org/Workspace scenario	Cribl HTTP/TCP Support	Receiver Billed for Ingest?	Example Deployments	Notes
Same Leader	Same Workspace		No	• On-prem Worker Group A → Worker Group B under the same on-prem Leader. • Cribl.Cloud hybrid Worker Group A → Cribl.Cloud managed Worker Group B in the same Workspace. • Cribl Edge Fleet → Cribl Stream Worker Group.	This is the default Cribl to Cribl pattern.
Different Leaders	Same on-prem license key		No	• Two on-prem Stream deployments sharing a license key. • Edge Fleet under Leader 1 → Stream Worker Group under Leader 2, same key.	Treated as a single paid environment via shared key.

Sender → Receiver	Org/Workspace scenario	Cribl HTTP/TCP Support	Receiver Billed for Ingest?	Example Deployments	Notes
Different Leaders	Two Workspaces in the same Cribl.Cloud Org		No	• Cribl.Cloud-managed hybrid Worker Group in Workspace A → Cribl.Cloud-managed Worker Group in Workspace B. • Edge → Stream across Workspaces in the same Org.	Requires supported versions and shared Org – uses auth tokens on 4.15+.
Different Leaders	Different Cribl.Cloud Orgs		Yes	Enterprise customer Org A → MSSP Org B via Cribl HTTP/TCP.	Supported, but the receiving Org is billed. No single-ingest across Orgs.
On-prem → Cribl.Cloud	No Connected Environments or Universal Subscription. Same paid Org/license.		No	On-prem Cribl Stream or Edge → Cribl.Cloud-managed Worker Group for central processing (same license/org).	Standard Edge → Stream or Stream → Stream “hub” architectures.
On-prem → Cribl.Cloud	Different paid Orgs, no Universal Subscription.		Yes	Hybrid Worker Group for Customer A → Managed Worker Group in MSP Org B.	Counts as two separate paid environments.
Hybrid Worker Group → Cribl.Cloud Hybrid or Managed Worker Group	Same Organization		Yes	Cribl.Cloud Hybrid Worker Group in Workspace A → Cribl.Cloud-managed Worker Group in Workspace B.	Typical “hybrid WG in Workspace A → Cloud WG in Workspace B” expansion path.

Sender → Receiver	Org/Workspace scenario	Cribl HTTP/TCP Support	Receiver Billed for Ingest?	Example Deployments	Notes
Hybrid Worker Group → Cribl.Cloud Hybrid or Managed Worker Group	Different Organization		Yes	Hybrid Worker Group for Customer A → Managed Worker Group in MSP Org B.	Counts as two separate paid environments.
On-prem Cribl Edge or Stream → Cribl.Cloud Hybrid Worker Group	Same Org with Universal Subscription		Yes	On-prem Edge Fleet with Universal Subscription → Cribl.Cloud Hybrid Worker Group	Not supported for single-ingest billing. Treated as separate environments.
On-prem Cribl Edge or Stream → Cribl.Cloud-managed Worker Group	Same Org with Universal Subscription		Yes	On-prem Worker Group with Universal Subscription → Cribl.Cloud-managed Worker Group in a Workspace.	US governs billing of on-prem env; Cloud ingest is billed normally unless also covered by shared key/Org rules.
Cross-environment flow on free tier	N/A		Not supported	Free-tier Workspace ↔ paid Org.	Free tier license or subscriptions don't qualify for single-ingest benefit.

Requirements and Caveats

- Both Organizations must have active, paid Cribl.Cloud plans or paid licenses.
- Workers on 4.11.1 and older can't share data with Workers on 4.12.0 and newer.
- For Cribl-managed Workers using **Cribl HTTP** in Cribl.Cloud, ensure **TLS settings match** between the Cribl HTTP Source and Destination (the Source enables TLS by default).

Limitations

You **can't** transfer data across Organizations in these scenarios:

- Workers on 4.11.1 and older communicating with Workers on 4.12.0 and newer.
- Free tier Workers communicating between themselves within the same Workspace.

How We Secure the Data Transfer

A shared-key mechanism validates and establishes trust between Leaders. The shared key will apply when the Leader of the sending environment has the exact same license key installed as the receiving environment, or when any Cribl.Cloud environment has Workspaces set up in the same Organization.

Set up Sources and Destinations to Transfer Data

Prerequisites / Before You Begin

Ensure the following criteria are met before configuring:

- Both of the environments for which you want to transfer data have an active billing contract or paid license.
- You have Leader networking configured to allow cross-environment communication between Worker Nodes.
- You have a Source configured to collect data (events, logs, metrics, files, etc). This Source will send the data to the Cribl TCP or Cribl HTTP Destination on the receiving Organization.
- On Cribl-managed Worker Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl HTTP Source and the Cribl HTTP Destination it's receiving data from, or enabled on both. Otherwise, no data will flow. In the Source, TLS is enabled by default.

Choose Your Source and Destination Pair

You can send data between Organizations using one of these Source and Destination pairs:

- Cribl TCP Destination and Cribl TCP Source.
- Cribl HTTP Destination and Cribl HTTP Source.

For more information about these two options and how to decide which one is right for your Organization, read Interoperation Protocols.

Configure Cross-Workspace Data Collection

This guide will cover the Cribl TCP setup, but the general workflow is the same for the Cribl HTTP Source

and Destination.

This workflow assumes you already have data ingested in Cribl Stream, and you want to move the data to a Worker Node in another Organization:

1. Configure the Cribl TCP Source in the Organization where you want to **receive** data.
2. Configure the Cribl TCP Destination in the second Organization. This Destination will **send** data to the receiving Organization.
    - In the **Cribl Endpoint** field, enter the Leader hostname in the **Address** field, in one of these formats:
        - Cribl.Cloud: `https://<your-workspace-name>.cribl.cloud`
        - On-prem: `http://localhost:<port>`
3. If your setup meets the criteria (see Key Aspects of Data Transfer for a refresher), you will see data flowing into the Cribl TCP Source from Workers that are not connected to the same Leader. Next!

8.8. Integrating With Other Services

The following topics provide detailed guides and better practice for integrating with different external services.

Source	Description
AWS Cross-Account Data Collection	Collecting and writing data across multiple AWS accounts
Amazon S3 Better Practices	Read, write, and replay with S3
Amazon Security Lake Integration	Integrate Cribl Stream's Amazon Security Lake Destination with its Namesake Service
Collecting Logs from Amazon ECS Containers	Collect logs from Amazon Elastic Container Service (ECS)
Preparing the Azure Workspace	Preparing the Azure Workspace for Cribl Integrations
Azure Event Hubs Integrations	Ingest data from an Azure Event Hub
Microsoft Sentinel Integration	Set up Cribl to send data to the Microsoft Sentinel SIEM
Splunk Cloud Platform and BYOL Integrations	Integrating with the Splunk Cloud Platform by using the Splunk HTTP Event Collector
Switch Cribl Stream Destinations from S2S to Splunk HEC	How to switch your data collection from Splunk to Splunk (S2S) to HTTP Event Collector (HEC)
Splunk to Elasticsearch	Routing data from Splunk to Elasticsearch services
Splunk to Exabeam	Exporting parsed data to Exabeam
Splunk Stream to Cribl Stream	Sending data from Splunk Stream packages to Cribl Stream
Decryption of Data in Splunk	Decrypting data with Splunk
Stream-to-Splunk Encryption	Encrypting and decrypting data moving from Cribl Stream to Splunk
Syslog Best Practices	Best practices for processing syslog events
Palo Alto Syslog to Cribl.Cloud	Palo Alto Syslog Forwarding to Cribl.Cloud
Configure Upstream Logging Agents	Connect common logging agents to Cribl Stream
BigPanda/Webhook Integration	Configure Cribl Stream to send Webhook notifications to the BigPanda IT Ops platform

Source	Description
Gigamon to Cribl Stream	Sending data from Gigamon to Cribl Stream
System Metrics to Grafana	Sending data from System Metrics to Grafana
Kafka Authentication with Kerberos	This topic describes a procedure for configuring Kafka Sources and Destinations for Kerberos authentication.
Moogsoft/Webhook Integration	Configure Cribl Stream to send Webhook notifications to Moogsoft
Nightfall Integration	Integrating Cribl Stream with Nightfall to detect and redact sensitive information
Managing QRadar Licenses	Reduce QRadar costs with fine-grained control over events sent
Slack/Webhook Integration	This page describes how to integrate Cribl Stream with Slack via the Cribl Stream Webhook Destination.
Zscaler NSS Virtual Machine	Reduce the size of ZScaler logs with Cribl Stream
Tanium to Cribl Stream	Sending data from Tanium to Cribl Stream

8.8.1. Amazon

The following topics provide detailed guides and better practice for integrating with Amazon services.

Source	Description
AWS Cross-Account Data Collection	Collecting and writing data across multiple AWS accounts
Amazon S3 Better Practices	Read, write, and replay with S3
Amazon Security Lake Integration	Integrate Cribl Stream's Amazon Security Lake Destination with its Namesake Service
Collecting Logs from Amazon ECS Containers	Collect logs from Amazon Elastic Container Service (ECS)

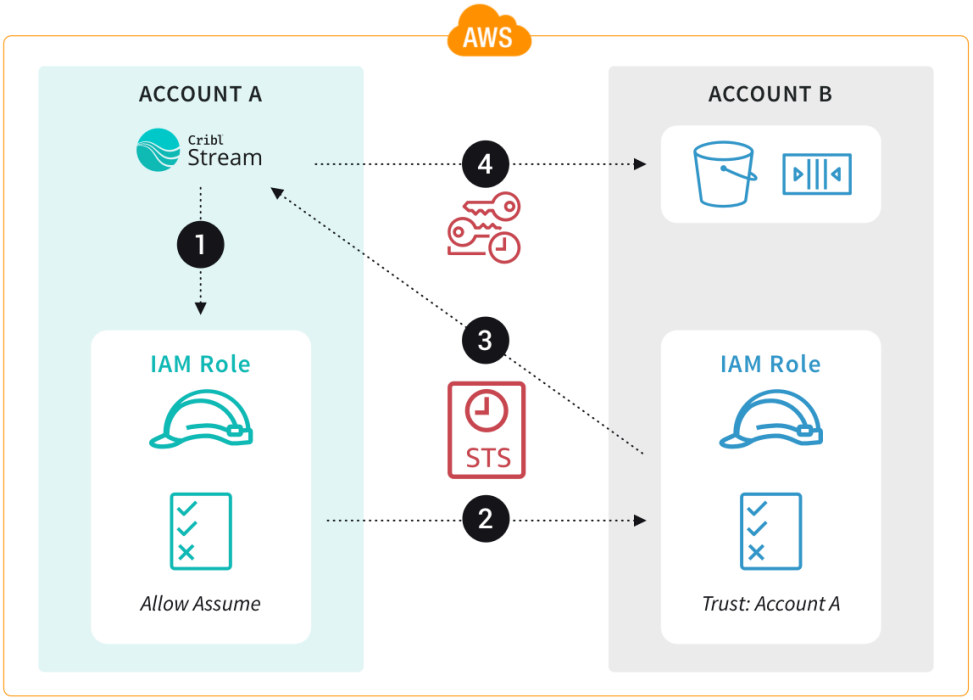
8.8.1.1. AWS Cross-Account Data Collection

Cribl uses multiple AWS accounts for different purposes, including our public Cribl.Cloud service (deployment details here). We built our account strategy from the ground up using the AWS Control Tower framework, as summarized in our Logging in a Multi-Account AWS Environment blog post.

However, some organizations use a legacy account structure that doesn't consolidate logs to a single account. This creates a challenge in collecting data or logs from peer accounts, as permission boundaries now need to be crossed. Whether you need to collect data from, or write data to, another account, the `AssumeRole` permission allows for cross-account access without the need to generate static IAM keys.

AssumeRole Example

A usage example is a central logging account that has access to other organization accounts to consume logs, but not to perform other actions. Let's say we have two AWS accounts, A and B. We want account A to be able to access resources in account B. We can build a policy inside account B that allows permissions to access the target resources. We can then specify, in account B, that we trust account A to be allowed to use this role. The diagram below illustrates how the `AssumeRole` action permits the Trusted Account (A) access to resources in the Trusting Account (B).



Using STS and temporary credentials to access an S3 bucket and SQS queue across accounts

Here's how Cribl Stream would work with `AssumeRole` permissions inside AWS:

1. The Cribl Stream Worker has an EC2 instance role attached.
2. The IAM role in Account A permits the EC2 instance to assume the role in Account B (and Account B trusts Account A).
3. Temporary IAM credentials are returned to the EC2 instance.
4. Cribl Stream uses the temporary IAM credentials to access the resources in Account B.

Since this guide's original publication, we've updated `logstream` to `cribl-stream` in example ARNs below, to match our renamed product.

Configure IAM AssumeRole Permissions

First, in account A, we build a policy that allows only the ability to assume the role inside account B. This policy restricts users from being able to access any resources that they don't need to see. We can also revoke this trust relationship at any time, without having to worry about an account still having keys and (therefore) access to the data.

In our example, we want to access VPC Flow logs inside an S3 bucket in account B (ID 222222222222) from account A (ID 111111111111). We'll start building the two policies in account B, and then move to account A.

Account B Configuration

In account B, we build a policy to enable access to the S3 bucket (`vpc-flow-logs-for-cribl`) with the least privileges required for Cribl Stream. This policy is the one that changes depending on what you need to accomplish - e.g., reading from an S3 bucket, writing to Amazon Kinesis Data Streams, etc.

```
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Action": "s3:GetObject",
     "Resource": "arn:aws:s3:::vpc-flow-logs-for-cribl/*"
   },
   {
     "Effect": "Allow",
     "Action": "s3:ListBucket",
     "Resource": "arn:aws:s3:::vpc-flow-logs-for-cribl"
   }
 ]
}
```

Copy

Next, we need to attach a Trust Relationship to Account B's IAM role to permit the `AssumeRole` action from account A:

```
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Principal": {
       "AWS": "arn:aws:iam::111111111111:role/account-a-cribl-stream-assumerole-role'
     },
     "Action": "sts:AssumeRole",
     "Condition": {
       "StringEquals": {
         "sts:ExternalId": "cribl-s3cre3t"
       }
     }
   }
 ]
}
```

Copy

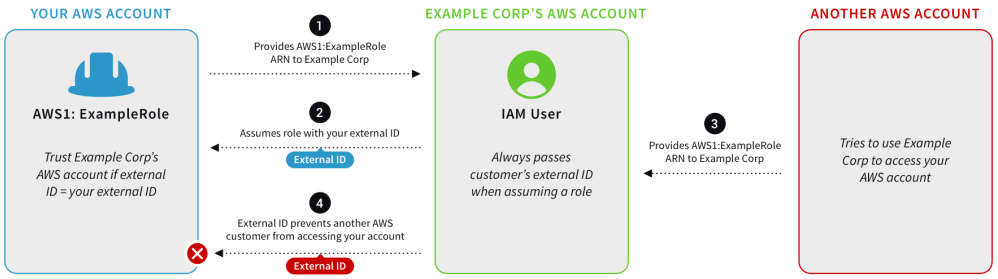
If you are creating a Trust Relationship for a Cribl.Cloud Worker managed by Cribl, you would instead paste the AWS Worker's role ARN in the format shown below. This option applies only to Cribl-managed Workers, not to customer-managed (hybrid or on-prem) Workers:

```
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Principal": {
       "AWS": "arn:aws:iam::111111111111:role/main-default"
     },
     "Action": "sts:AssumeRole",
     "Condition": {
       "StringEquals": {
         "sts:ExternalId": "cribl-s3cre3t"
       }
     }
   }
 ]
}
```

Copy

Why an External ID Condition in the Trust Policy?

It is important to configure an AWS External ID, especially if you have third parties accessing your AWS accounts. The External ID protects from the confused deputy problem, where a third party obtains access through an intermediary. The External ID is not a password or secret, but it should still be protected from accidental sharing.



Mitigating the confused deputy vulnerability

Account A Configuration

In account A, we next configure a new IAM role with the following policy.

> If you are creating a Trust Relationship for a Cribl-managed Cloud Worker, skip this section. Cribl has implicitly preconfigured Account A for you.

For our example, we only want the role to be able to use the `AssumeRole` action, but you can add additional statements to meet your needs:

```
{
 "Version": "2012-10-17",
 "Statement": {
   "Effect": "Allow",
   "Action": "sts:AssumeRole",
   "Resource": "arn:aws:iam::222222222222:role/account-b-cribl-stream-role-to-assume'
 }
}
```

Copy

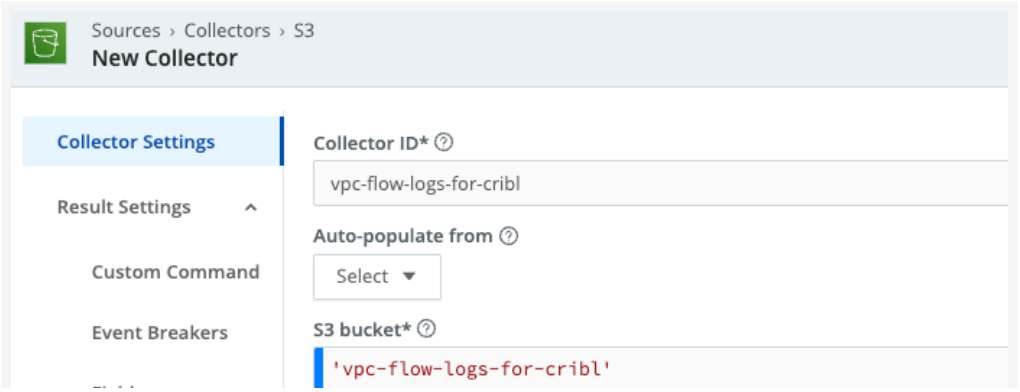
Since we need our EC2 instance to be able to assume this role, we will configure the Trust Relationship as follows:

```
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Principal": {
       "Service": "ec2.amazonaws.com"
     },
     "Action": "sts:AssumeRole"
   }
 ]
}
```

Copy

Configure Cribl Stream

Now that our `AssumeRole` policies have been built, we can configure Cribl Stream to assume the correct role to access the resources we need. Configure your Source, Collector, or Destination with the appropriate `AssumeRole` ARN and External ID. While this screenshot shows an S3 collector specifically, all AWS sources and destinations support Assume Role functionality.



8.8.1.2. Integrate Cribl Stream With AWS Security Hub

You can integrate Cribl Stream with AWS Security Hub to enable your security teams to ingest, standardize, and route Security Hub findings in near real time. This integration streamlines security operations by providing a unified, flexible, and extensible data pipeline for AWS security events, leveraging the Open Cybersecurity Schema Framework (OCSF) v1.6 for consistent data structure and interoperability.

Key features include:

- Near real-time ingestion of AWS Security Hub findings via AWS EventBridge and Cribl Stream Webhook.
- Standardization of findings to OCSF v1.6, including support for AWS-specific extensions.
- Flexible routing to multiple destinations, including Cribl Lake, SIEMs, and data warehouses.
- Support for transforming and enriching third-party security findings.
- Secure, scalable architecture with recommended authentication and IAM permissions.

Architecture and Data Flow

This integration uses an event-driven architecture to deliver Security Hub findings to Cribl Stream for processing and routing:

1. AWS Security Hub generates a finding.
2. AWS EventBridge captures the finding event.
3. An EventBridge Rule filters and forwards events to a target.
4. The target is typically an AWS SNS Topic, which pushes the data to a Cribl Stream HTTP Endpoint (Webhook).
5. Cribl Stream receives the data, processes and standardizes it (for example, to OCSF v1.6), and routes it to one or more Destinations.

Configure Event Streaming from AWS Security Hub to Cribl Stream

The workflow to configure event streaming from AWS Security Hub to Cribl Stream consists of four parts:

1. Create an Amazon SNS topic.
2. Configure a Cribl Stream HTTP Endpoint as an SNS subscription.
3. Create an EventBridge rule in the AWS Management Console.

4. Enable the Webhook in Cribl Stream.

Create an Amazon SNS Topic

1. In the AWS Management Console, go to **Simple Notification Service (SNS)**.
2. Create a new topic (for example, `Cribl-SecurityHub-Findings`).

Configure a Cribl Stream HTTP Endpoint as an SNS Subscription

1. In Cribl Stream, navigate to Sources and enable an HTTP Endpoint (Webhook). Copy the unique URL.
2. In AWS SNS, create a subscription for the topic created above. The Protocol is `HTTPS`. For the URL, paste the Cribl Stream HTTP Endpoint URL.

Create an EventBridge Rule

1. In the AWS Management Console, go to **Amazon EventBridge**.
2. Select **Create rule** and provide a descriptive name (for example, `SecurityHub-to-Cribl`).
3. Define the event pattern as follows:
    - **Event source**: `AWS services`
    - **AWS service**: `Security Hub`
    - **Event type**: `Security Hub Findings - Custom Action` or `Security Hub Findings - Imported`
      Example format:

```
{
 "source": ["aws.securityhub"],
 "detail-type": ["Security Hub Findings - Imported"]
}
```

Copy

    - Set the target to the SNS Topic created in Step 1.

Enable the Webhook in Cribl Stream

1. In Cribl Stream, go to **Data > Sources**.

2. Select **Add new** and select **HTTP Endpoint**.
    - **Input ID**: Provide a unique ID (for example, `securityhub_webhook`).
    - **Authentication**: Configure Shared Secret authentication for security.

For advanced customization, consider using an intermediate Lambda or API Gateway.

    - **Output**: Connect the source to a specific pipeline (for example, `securityhub_pipeline`) for OCSF conversion and routing.

Process and Standardize Data in Cribl Stream

Next, you can pre-process the data, standardize the JSON payload, and optionally enrich data with external or internal events.

1. Handle the SNS envelope/wrapper if present.
2. Convert the Security Hub JSON payload to OCSF v1.6 format, adding AWS context/extensions as needed.
3. Optionally add external or internal data (for example, CMDB lookups, CloudTrail events).

Route Findings and Manage Destinations

After processing, you can route Security Hub findings to multiple destinations:

Destination Service	Cribl Stream Destination Type	Purpose
Cribl Lake	Amazon S3 (managed by Cribl)	Long-term, cost-effective storage for historical analysis and compliance.
SIEM Platform	Splunk HEC, Kafka, ElasticSearch	Real-time security analysis, alerting, and incident response.
Data Warehouse	Amazon S3, Snowflake, Google BigQuery	Business intelligence and operational reporting on security trends.

This flexible routing ensures Security Hub findings are immediately available for analysis and archival across your security ecosystem.

Transform Third-Party Findings

Cribl Stream can also convert third-party security findings into OCSF v1.6, including AWS-specific extensions. This enables a unified approach to security data management, regardless of the original source format.

Original Source	Original Format	Cribl Stream Action	Output Format
Third-Party Tool 1	Proprietary	Convert and Add AWS Extensions	OCSF v1.6 with AWS Extensions
Third-Party Tool 2	Custom JSON	Convert and Add AWS Extensions	OCSF v1.6 with AWS Extensions

Required Identity Access Management (IAM) Permissions

To enable robust integration, ensure the IAM role associated with your Cribl deployment has the following permissions (at minimum):

Endpoint	Permission(s)
`ec2_instances`, and so forth	`ec2:DescribeInstances`, `ec2:DescribeVolumes`, `ec2:DescribeSecurityGroups`, and so forth
`lambda_functions`	`lambda:ListFunctions`
`iam_*`	`iam:ListPolicies`, `iam:ListRoles`, `iam:ListUsers`, `iam:ListGroups`, `iam:ListMFADevices`
`cloudformation_*`	`cloudformation:ListExports`, `cloudformation:ListStacks`, `cloudformation:ListStackSets`
`dynamodb_backups`	`dynamodb:ListBackups`
`rds_*`	`rds:DescribeDBInstances`, `rds:DescribeDBClusterEndpoints`, and so forth
`cloudtrail_events`	`cloudtrail:LookupEvents`
`vpc_*`	`ec2:DescribeNetworkInterfaces`, `ec2:DescribeVpcs`, `ec2:DescribeSubnets`
`efs_file_systems`	`elasticfilesystem:DescribeFileSystems`

For a full list and details, see the Cribl documentation on AWS API permissions.

Security Best Practices

We recommend following these best practices to keep your AWS Security Hub integration safe:

- Always use Shared Secret authentication for HTTP Endpoints.

- Limit IAM permissions to the minimum required for your use case.
- Use AWS CloudFormation templates provided by Cribl for automated, secure setup of IAM roles and trust relationships.

Getting Started

If you are new to AWS Security Hub or Cribl Stream, refer to the following resources:

- Enable Security Hub in AWS
- Configure Cribl Stream

8.8.1.3. Amazon S3 Better Practices

The “better practices” in this guide all apply to Cribl Stream’s Amazon S3-based Sources and Destinations. Many also apply to other object stores, like Azure Blob Storage, MinIO, and Google Cloud Storage.

View the AWS S3 with Cribl Best Practices video presentation from Cribl Community Office Hours.

Foundations: Cribl Stream and Object Storage

In this first section, we’ll lay out four basic factual underpinnings:

- How Cribl writes to object storage.
- Write to a Cribl Amazon S3 Destination.
- Read from Cribl’s Amazon SQS Source.
- Replay from Amazon S3 buckets, via Cribl’s S3 Collector.

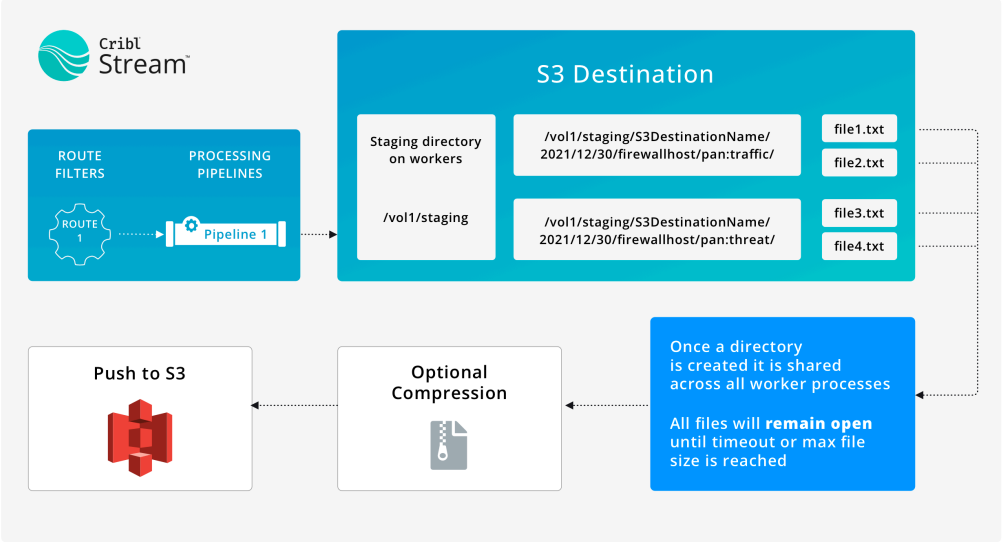
Then, this guide will go on to detail 10 “better practices” (and a bonus one!) as we cover four broad topics:

- Write to object storage, generically.
- Cardinality and partitioning expressions.
- Amazon S3-specific optimization.
- Better partitioning expressions.

How Cribl Writes to Object Storage

Cribl does not write data **directly** to its object storage Destinations, which include Amazon S3; any solution with an S3 API; and other object storage Destinations, like Azure Blob Storage, MinIO, and Google Cloud Storage.

Data persists locally to a “staging location” on the Workers. The Worker Processes append new data to the staging location based on partitioning expressions and configurations such as file size and max timeout settings. Each Worker Process, governed by its own specific settings, creates and maintains its own set of files.



Write to object storage - example

Write to a Cribl Amazon S3 Destination

When writing to our Amazon S3 Destination, or any object storage, consider two main settings: **File name prefix expression** and **Partitioning expression**.

Cribl allows a maximum of 2000 open files per Worker Process per S3 Destination. On a system with 14 Worker Processes, that translates to a maximum of 28,000 open files per S3 Destination. On a system with 30 CPUs, that translates to 60,000 open files.

When a specific Worker Process hits the maximum open files, it closes all open files, moves them to the final output location, and creates new ones. If you have multiple object storage Destinations configured in Cribl, ensure that the total maximum open files across all these Destinations is less than your system's configured maximum open files. To figure out this maximum, multiply the number of file-based Destinations by max open file limit for each such Destination and by number of Worker Processes (Destinations x max open file limit x Worker Processes).

The default maximum open file settings on many Linux systems are too low for Cribl Stream when writing to an object storage Destination. You'll need to increase your system max open files and/or process max open files settings, as explained below.

Additionally, to limit the number of files in each directory, **Partitioning expression** should specify dates down to the hour or minute.

Read from Cribl's Amazon SQS Source

When reading data using Cribl Stream's Amazon SQS Source, a few settings can greatly speed up data retrieval. These are:

- **General Settings** > **Queue**, a.k.a. the file name filter.

- **Advanced Settings** > **Max messages**.
- **Advanced Settings** > **Num receivers**.

Even more importantly, data retrieval speed is also governed by Destination settings and Pipeline efficiency.

Replay from Amazon S3 Buckets

When replaying from S3 via Cribl's S3 Collector, optimize your performance by adjusting the following:

- **Optional Settings** > **Path**, a.k.a. the filter.
- Pipeline efficiency.
- Destination settings.
- Destination health.

The **Path** should specify the time down to the hour, or in some cases, down to the minute.

Also, consider the API limits for your object storage bucket. AWS sets a limit of 3,500 writes/second and 5,500 reads/second per S3 prefix. An S3 prefix is a path on Amazon S3, including bucket name and any subdirectories up to but not including the object name. The S3 prefix always ends in (and includes) the slash before the object name. In its simplest form, the S3 prefix is just `BucketName/`.

AWS API limits apply to all attempted access to these prefixes, cumulatively. You probably won't hit the write limits while putting the "better practices" in this guide into effect. However, populating too many files in any one directory might trigger throttling when reading and performing replays.

Some Cribl Destinations have **File prefix expression** and/or **Partitioning expression** settings. Do not confuse these with the AWS prefix.

Write to Object Storage, Generically

When you deploy a Cribl Amazon S3 Compatible Stores Destination, start with a simple global **Partitioning expression** and the default **File name prefix expression**.

This will work as long as cardinality remains below 2,000 during the max timeout period. Also, apply the procedures to increase the system max open file settings, as described later in this guide.

Better Practice 1: Mind the Partitioning Expression

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}/${index ? index
```

Copy

If cardinality exceeds 2,000, you can either:

- Remove the less-important fields from the expression; or
- Create different partitioning expressions for different event types, categories, etc.

On the **Advanced Settings** tab:

- Match the **Max open files** to cardinality, without exceeding 2,000.
- Toggle **Remove staging dirs** on.
- Set the **Storage class** to `Intelligent Tiering`.

Still in **Advanced Settings**, keep the default settings for:

- **Max file size (MB)**: `32`.
- **Max file open time (sec)**: `300`.
- **Max file idle time (sec)**: `30`.

As you gain deeper understanding of the data, consider the following options:

- Create a set of different S3 Destinations, each with its own **Partitioning expression**. They can all point to the same S3 bucket. Be aware that doing so will increase the number of API requests because events will be spread over more files.
- If the numbers of open files becomes too large, discuss alternative architectures (e.g., creating additional Worker Groups) with your Cribl Account team or Support.

Better Practice 2: Optimize System Settings for Max Open Files

Consider the workflow for writing to Cribl S3 Destinations:

- Each Cribl Worker Process creates its own set of files in a staging directory based on **Partitioning expression** and **File name expression**.
- The maximum partitioning expression cardinality allowed is 2,000. This translates to a maximum of 2,000 open files per Worker Process per object storage Destination.
- Each Destination writes files to its staging directory until the number of files exceeds the configured maximum, or the Destination reaches any of the following limits: **File size limit (MB)**, **Idle time limit (sec)**, or **File open time limit (sec)**.

When writing to an object store, more Worker Nodes with fewer CPUs is better than fewer Worker Nodes with more CPUs (e.g., 5 Workers with 12 vCPUs is better than 2 systems with 32 vCPUs).

You should apply this principle to realize two benefits:

- To maximize the number of open files.
- To have more S3 Destinations with more precisely-focused partitioning expressions.

Linux defaults for maximum open files tend to be too low for writing to Cribl S3 Destinations, but the 65,536 limit recommended by Cribl is a good starting point. When setting the maximum open files substantially higher than 65,536, you should track system health.

You can further increase the maximum number of open files allowed by your system based on the number of S3 Destinations you are planning to use and the number of Worker Processes on each Node. The table below provides some examples:

# of S3 Destinations in Cribl	Max cardinality per Dest.	Open file limit in Cribl Dest.	# Worker Process on each Worker Node	Min Linux per-process open file limit	Min Linux system plus Cribl user open file and 1k reserved for the system
1	2,000	2,000	10	3,000	21,000
1	2,000	2,000	14	3,000	29,000
1	2,000	2,000	22	3,000	45,000
2	2,000	2,000	10	5,000	41,000
2	2,000	2,000	14	5,000	57,000
2	2,000	2,000	22	5,000	89,000
5	2,000	2,000	10	11,000	101,000
5	2,000	2,000	14	11,000	141,000
5	2,000	2,000	22	11,000	221,000

Better Practice 3: Update Max Open File Settings on Hosts

Here are basic instructions that cover many Linux distributions. (Check the documentation for your specific Linux distribution and version for any variations required.)

Edit the following settings. You will be required to reboot.

```
# Update `fs.file-max` to a very large value run (as root):
sysctl -w fs.file-max=<open-files-limit>

# or edit sysctl.conf (as root):

vi /etc/sysctl.conf
fs.file-max = <open-files-limit>
```

Copy

```
# vi /etc/security/limits.conf (as Cribl user)
* soft nproc 65536
* hard nproc 65536
* soft nofile 65536
* hard nofile 65536
```

Copy

After you reboot, verify the settings:

```
# sysctl -p
# cat /proc/sys/fs/file-max
# sysctl fs.file-max
```

Copy

Cardinality and Partitioning Expressions

As we've seen, partitioning expressions and file expressions interact to determine cardinality. In this section, we'll examine this interaction more closely and learn better practices based on what we find.

Where Cardinality Begins

Partitioning expressions specify the directory structure that Cribl adds when writing to an object storage Destination.

For example, the following partitioning expression extracts the `year`, `month`, `day`, `hour`, `minute`, `index`, `host`, `sourcetype`, `server_ip`, `status_code`, and `Method`, and populates them as the directory structure.

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')
/${index ? index : 'no_index'}
/${host ? host : 'no_host'}
/${sourcetype ? sourcetype : 'no_sourcetype'}
/${server_ip}
/${status_code}
/${Method}/`
```

Copy

A file expression prefix comes into play next. The default file expression is just a random file name. However, an expression like this would create files that also include the hour and minute in each file name. This reflects the time the file was created, not the time of each event.

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%H%M')}
```

Together, the partitioning expression and the file expression must not produce a cardinality greater than 2,000.

Calculate Cardinality

Cardinality is the quantity of combinations of unique values, within a time period, for each parameter in the expressions.

For example, a partitioning expression could specify the following:

- Within an hour.
- 5 unique sourcetype values.
- 10 unique host values.
- 2 unique source values for each host.

For this example, we could calculate the maximum cardinality as `(5*10*2)=100`.

It's important to also consider the timeframe this is calculated within. That cardinality might be 100 over a 1-minute period, but might be 500 over a 5-minute period.

If we further add a file name prefix expression, this increases the cardinality. For example, let's add the method and top-level URI as file name prefix parameters. If there are 3 possible methods, and 10 URIs, the cardinality just went up from 100 to `100*3*10=3,000`.

Cardinality has the greatest impact on how you should configure an object storage Destination in Cribl Stream. For every combination of partitioning expressions, file prefix expressions, and Worker Processes, there can be an open file on the Worker Node's system.

A partitioning expression and file prefix expression should produce fewer than 2,000 potential combinations. When a Worker Process exceeds the configured **Open file limit**, this generates errors; all open files for that Worker Process are simultaneously closed; and, new files will be created.

The Worker Process might experience some extra load while all files are processed. If this occurs infrequently, that's generally okay. But if it happens several times per hour, you should consider how to improve the combination of partitioning and file expressions.

As a starting point, consider these two strategies:

1. Write to one S3 bucket, incorporating parameters common to each event.

For example, here's a partitioning expression that specifies year, month, day, hour, minute, index, sourcetype, source, and host:

```
${C.Time.strftime(_time ? _time:Date.now()/1000,'%Y/%m/%d/%H/%M')/${index}/${host}/${
```

Copy

2. Dedicate different S3 Destinations to different event types. During replays, this makes searching specific data faster. However, this benefit comes at the expense of needing a larger number of open files. Should you pursue this option, test large numbers of open files on a test system in your environment. Such testing is especially crucial in virtualized environments with shared disk, CPU, and memory resources.

Better Practice 4: Select Fields for Partitioning and File Expressions

The main factors to consider when selecting fields for a partitioning or file name prefix expression are:

- Configure Time-based filtering: All partitioning expressions should include `year`, `month`, `day`, `hour`, and optionally, `minute`. This facilitates filtering during replays. It also limits the files in any one directory, so that replays are not throttled when returning large volumes of files.
- Identify Universal fields: Fields that users will typically search on during replays across all datasets. Examples include `sourcetype`, `host`, `source`, `category`, and `index`.
- Optionally, configure specific fields for different datasets.
  Examples include:
  - Web logs: server IP, method, status code.
  - Firewall logs: source zone, destination zone, accept/deny status.
  - Flow logs: protocol, accept/deny status.

Be careful when pursuing this option as the number of open files can grow exponentially with too many multiple partition and file name prefix expressions.

Analyze Partitioning Expressions

Let's work through some examples of partitioning expressions, with hypothetical possible values for each parameter, to see what cardinalities they produce.

Example 1

This one produces reasonable results.

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}
/${sourcetype}/${host}/${AttackType}`
```

Copy

Possible values:

- `sourcetype`: 5.
- `host`: 100.
- `AttackType`: 5.

Potential cardinality: `5 x 100 x 5 = 2,500`.

Example 2

Here, too, cardinality is kept commendably low.

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}/${state}/${inte
```

Copy

Possible values:

- `state`: 2.
- `interface`: 50.
- `dest_ip`: 20.

Potential cardinality: `2 x 100 x 10 = 2,000`.

Example 3

This is a bad partitioning expression which produces out-of-control cardinality. Back to the drawing board!

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}/${state}/${inte
```

Copy

Possible values:

- `state`: 2.
- `interface`: 100.
- `src_ip`: 65,535.

Potential cardinality: `2 x 100 x 65,535 = 13,107,000`.

For more examples like these, see Better Partitioning Expressions.

See How Cardinality Changes Over Time

In the examples so far, we've assumed typical expected values for parameters. Another useful exercise is to estimate the maximum possible values of each parameter, and multiply each value to obtain maximum theoretical cardinality.

You should also investigate how cardinality changes depending on when and how long you measure it. To do this, query/search your analytic tool to determine cardinality for different durations over several days.

Run the searches over different duration spans (e.g., 1 minute, 3 minutes, 5 minutes) to determine the best timeout period. For example, your cardinality might be 2,000 over a 2-minute span, but 10,000 over a 5-minute span. In this case, it is most certainly beneficial to set the maximum file timeout to 2 minutes.

Below are examples of Splunk searches over different span periods, with maximum open file time set to 3 minutes. Change the fields to the ones you'd prefer to incorporate into a partition and/or file name prefix expression, and try running them in your environment.

Here's an example using a "traditional" search method:

```
earliest=-24h index=*
|bin _time span=3m
| stats dc(source) as dc by host, sourcetype _time
| stats sum(dc) by _time
```

Copy

Here's an example using `tstats`:

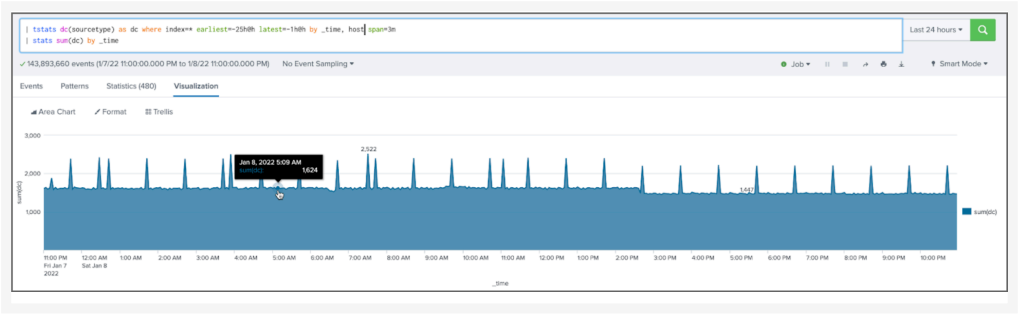
```
| tstats dc(source) as dc where index=* earliest=-25h@h latest=-1h@h by _time, host,
| stats sum(dc) by _time
```

Copy

The `tstats` search produces the results shown in the diagram below.

- Cardinality mostly stays below 1,625.
- There are some hourly peaks around 2,500. These spikes, which exceed the max allowed cardinality of 2,000, are infrequent.

All of this is generally acceptable.



cardinality Check Results

Better Practice 5: Size a Separate Fast(er) Disk for Staging Location

The system's ability to handle enough open files is a key factor that drives performance. This requires:

- Setting **Open file limit** high enough.
- Ensuring that the staging directory on the Workers can handle simultaneous writing tens of thousands of open files. The metric to use here is Input/Output Operations per Second (IOPS). A good starting point is 2,000 IOPS.

Cribl recommends that you allocate a separate disk for the staging directory on Workers, especially when you have configured multiple object storage Destinations. Follow these general, conservative guidelines:

- Toggle **Advanced Settings** > **Remove staging dirs** on. This means that any empty directory that has not been written to for an hour, is deleted.
- Disk size of 500 GB should be adequate, since the Workers need only enough disk capacity for a few minutes' worth of data. 500 GB errs on the side of caution, allowing us to store as much as 4 hours of data to disk. See the formula and examples below.
- Because Cribl writes to the staging directory only when the object storage Destinations are healthy, disk size does not usually become an issue. If the Worker encounters or triggers a backpressure situation, it stops writing to the staging directory.

- The staging directories are not intended for high availability, but rather to support creation of large-enough files to write to object storage.

Replay from a dedicated Worker Group. Do not compete for resources against production, real-time, streaming resources to perform replays!

Determine Staging Directory Disk Size

You can calculate an optimal size for your staging directory disk using the following formula:

- `Data Volume` (GB/day) you expect to ingest, times `1.25` metadata factor; divided by
- `1440` (minutes in a day), times
- `Duration` (minutes) you want to store data on disk; divided by
- `Number of Workers` writing to a staging directory.

The result will be disk size per Worker.

The figure below illustrates the formula.

$$\frac{Data\ Volume\ (GB/day) \times 1.25\ metadata\ factor}{1440\ mins/day} \times mins\ to\ store\ data\ to\ disk \div number\ of\ Workers$$

Here are some examples:

Data Volume	Number of Workers	Duration (Minutes)	Disk Size per Worker
1 TB/day	3	120	35 GB
10 TB/day	5	240	417 GB
50 TB/day	45	240	232 GB

Amazon S3 Optimization

Once you configure your Amazon S3 permissions, verify access, and (if applicable) discover your Cribl.Cloud Organization's AWS ARN, you can start applying some more better practices.

Amazon S3 Permissions

If your Workers are hosted outside AWS, you will need an access key and secret key to access the S3 bucket. If the Workers are EC2 instances or in AWS EKS, it's most ideal to assign an EC2 service role to the instances. The

role will need access to the S3 bucket. For policies for reading and writing to/from Amazon S3, see AWS Cross-Account Data Collection.

Here's a policy to grant a role, or user access, with read and write permissions the S3 bucket. Just change the bucket name in this policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::bucketname/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::bucketname"
    }
  ]
}
```

Copy

If `assumeRole` is required, here's a sample policy to assume the role that has access to the S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111111111111:role/account-a-cribl-stream-assumerole-role
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "sts:ExternalId": "cribl-s3cre3t"
        }
      }
    }
  ]
}
```

Copy

Test your policy with AWS's IAM policy simulator to ensure there are no boundary policies that might conflict with this policy.

Verify S3 Access

To troubleshoot access to your S3 bucket, install the AWS CLI on one of the Workers. Log in using your AWS user and Region. Assume the role if necessary. Then, attempt to download a file from the bucket or write a new file to the bucket.

Example of assuming a role:

```
aws sts assume-role --role-arn "arn:aws:iam::123456789012:role/example-role" --role-s
```

Copy

Example of validating the role you'll use to run subsequent commands:

```
aws sts get-caller-identity
```

Copy

Example of listing files in a bucket:

```
aws s3 ls s3://s3-bucket-name
```

Copy

Example of sending stdin to a specified bucket:

```
aws s3 cp - <target> [--options]
```

Copy

Example of writing a local file to the bucket:

```
aws s3 cp localfilename.txt s3://bucket-name
```

Copy

Example of reading a file from S3:

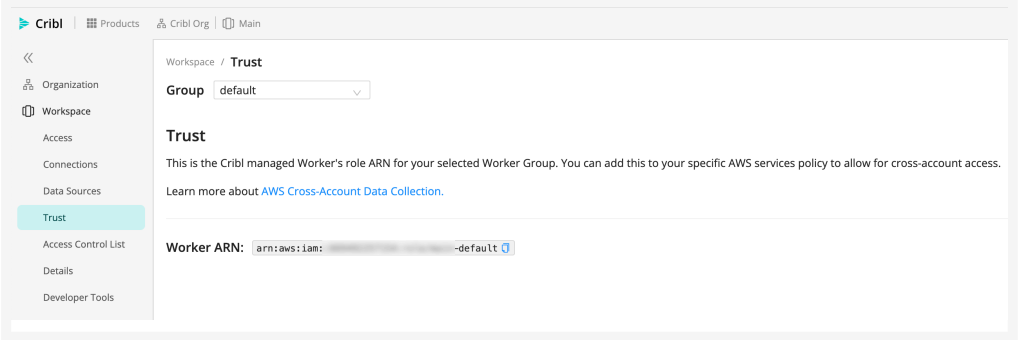
```
aws s3 cp s3://bucket-name localfilename.txt
```

Copy

Access Amazon S3 from Cribl.Cloud

Every Cribl.Cloud Organization exposes its own unique AWS ARN.

From the main Cribl.Cloud portal, navigate to the **Workspace** you are working in, and select **Trust** from the sidebar to expose the Cribl.Cloud ARN.



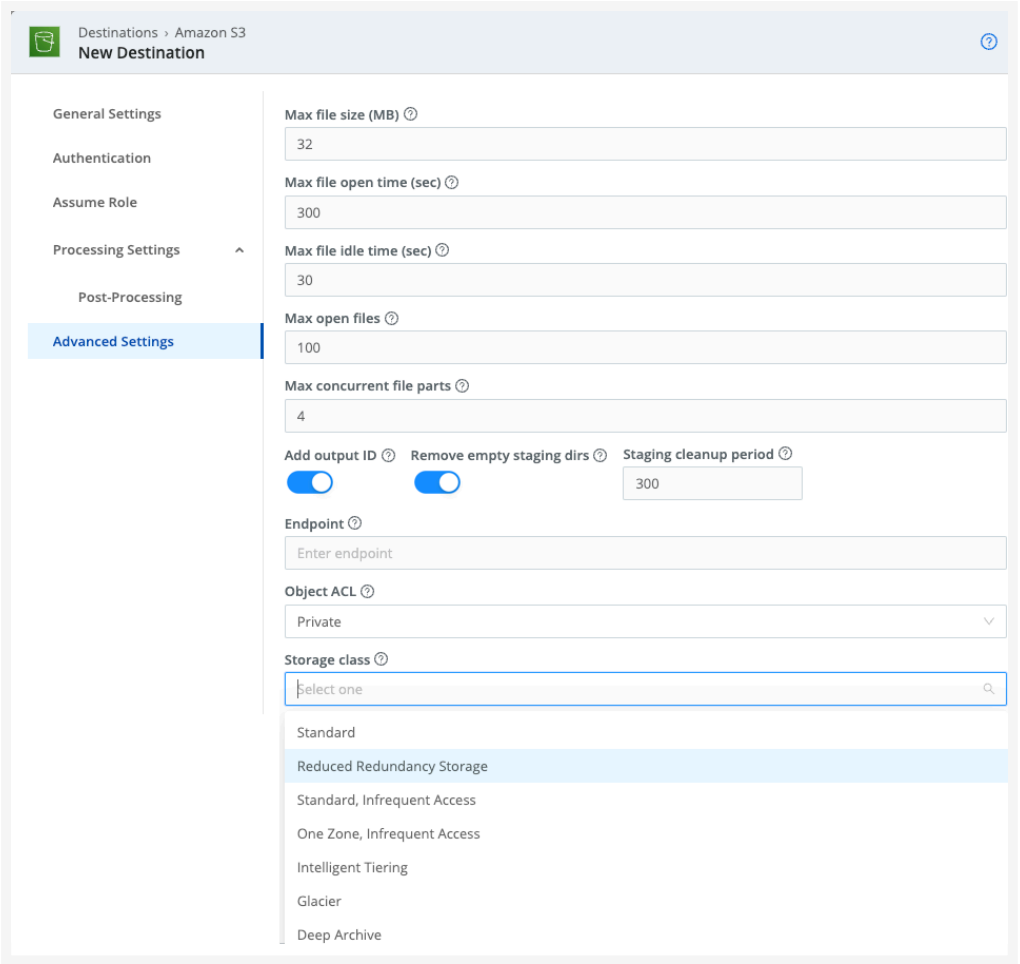
Configure your AWS account with access to the S3 bucket, to allow Cribl.Cloud to assume that role, as illustrated above in Amazon S3 Permissions.

Better Practice 6: Tuning Amazon S3 Destination Settings

Under the Amazon S3 Destination's **General Settings** and **Advanced Settings** tabs are several settings for tuning your Amazon S3 Destination. Below are some recommendations for tuning those settings, in order of importance:

1. **Staging Location**: Change this to a directory on the Workers with increased IOPS, to accommodate thousands or tens of thousands of simultaneous open files. (Cannot be configured on Cribl.Cloud-managed Workers.)
2. **Remove staging dirs**: This setting must be enabled, so as not to leave millions of empty directories on the system over time.
3. **Compress**: Always enable compression, to reduce the size of files uploaded and downloaded from S3. This can reduce your S3 bill by 8-15x. Note that compression does add to the processing time - but transfer time will be substantially faster.
4. **Max open files**: Adjust this to be slightly larger than the data's cardinality, but not greater than 2,000. Also, ensure that the system can support the number of open files for all Worker Processes, and across all configured S3 Destinations. This value is set per process. 32CPUs*100 - 3200 max open files. Increase this value to avoid "Too many open files" errors. Default open file limit on Linux is 1024/process.
5. **Max file size (MB)**: If you have a separate S3 Destination for high-volume data sources, such as VPC Flow Logs or firewall logs, consider raising this value in order to create fewer files. Start with 64 MB. Otherwise, the default 32 MB setting is generally acceptable.
6. **Max file open time (sec)**: First, determine your cardinality over 1 minute, 3 minutes, 5 minutes, and 10 minutes. Adjust this setting to match the lowest-cardinality period. E.g., if cardinality is 10,000 over 5 minutes, but 2,000 over 90 seconds, change this setting to 90 seconds. If cardinality is 2,000 over 5 minutes, then the default 5 minutes (300 seconds) is acceptable.
7. **Max idle time (sec)**: The default 30 seconds is generally acceptable. In cases with high cardinality, lowering this setting can result in fewer open files when processing bursty data.
8. **Data format**: If using a Passthru Pipeline, change this setting to `Raw`. Otherwise, leave it at the JSON default to preserve all metadata added to the events.
9. **Storage class**: For Amazon S3 Destinations, consider the "infrequent access tier" or "intelligent tier" to reduce overall cost if the data will be rarely searched. Examples of rarely-searched data include threat-hunting or compliance-reporting use cases. "Standard, Infrequent Access" and "Intelligent Tiering" options should be used on low-access use cases such as threat hunting or compliance audit.

10. **AWS Region**: Leave this field blank for non-AWS Destinations, unless instructed otherwise. For AWS, set this to the nearest geographic location to the Workers.

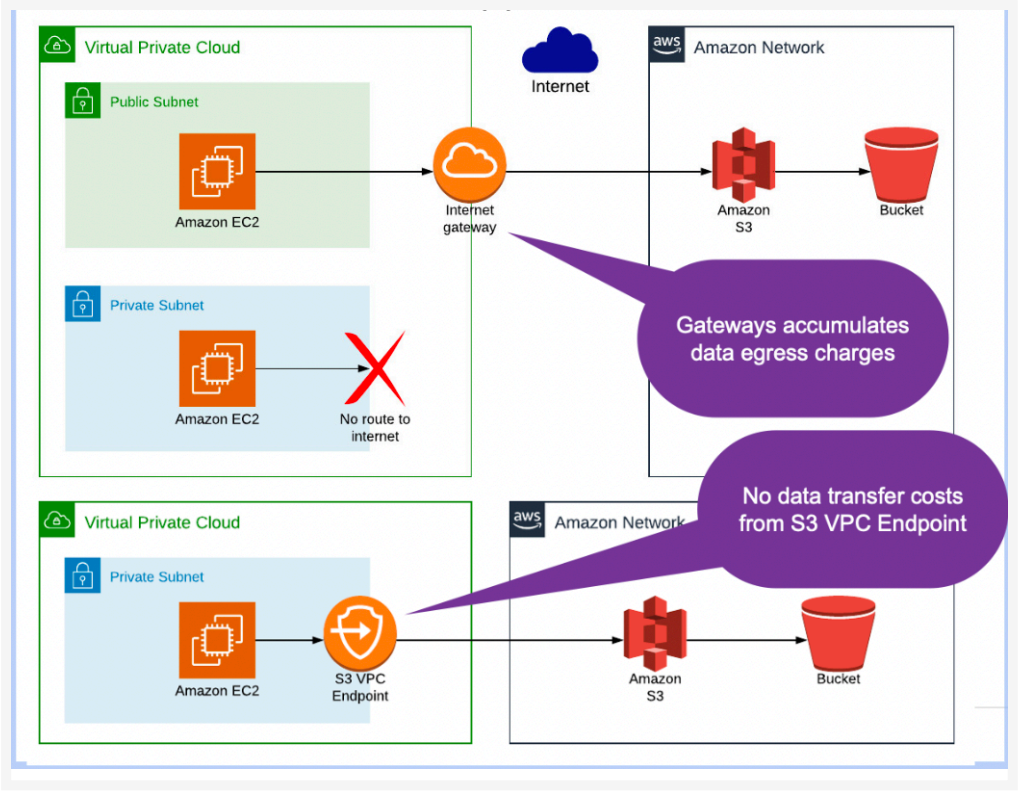


Configuring S3 Destination Settings

Better Practice 7: Lower AWS Costs

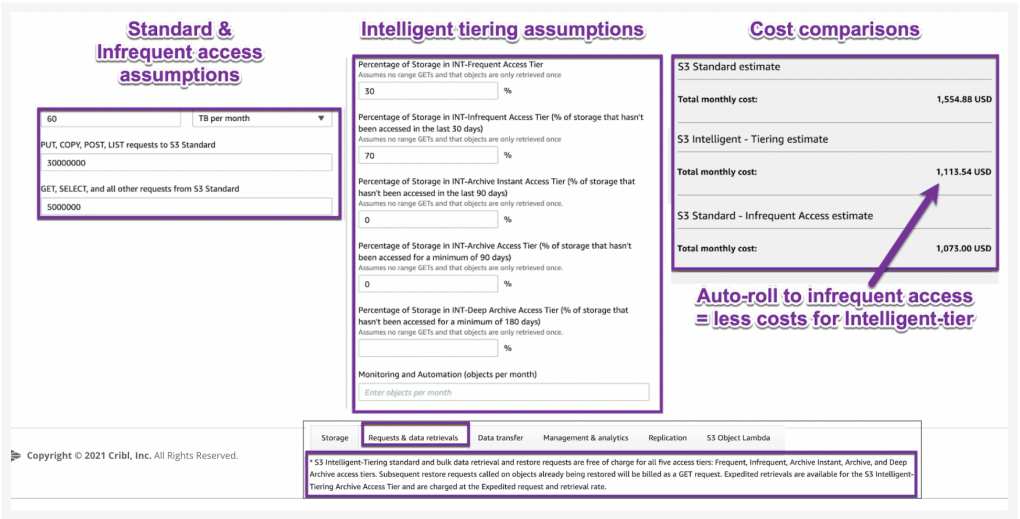
Lowering AWS costs can be achieved by a few means. First and foremost, ensure that compression is enabled on your Cribl S3 Destination and set to `gzip`. This will reduce both egress costs and S3 storage costs.

To eliminate egress costs from your Workers to S3, map a VPC endpoint on the S3 bucket to the VPC where your Workers reside.



Mapping a VPC endpoint to an S3 bucket

Writing to S3's Intelligent storage class, or infrequent access tier, can reduce long-term costs. Intelligent storage automatically routes data to cheaper S3 tiers when it is not searched or touched for certain periods of time. Consult the AWS Cost Estimator to calculate the differences. Old data can also be rolled off to a much cheaper option such as Glacier Instant Retrieval or Glacier Deep Archive. Below are sample cost comparisons:



AWS Cost Comparison

Cribl Stream Collectors and Replay features don't support S3 Glacier or S3 Deep Glacier due to long retrieval times for those storage classes.

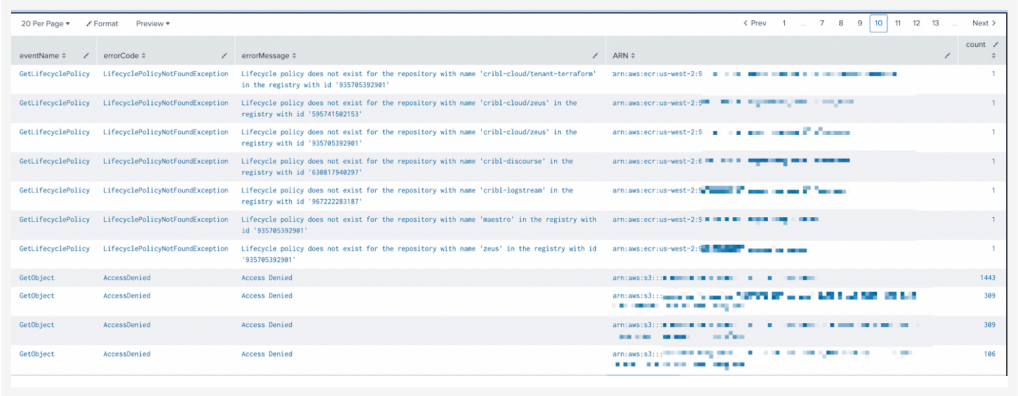
> Collectors and Replay features do support S3 Glacier Instant Retrieval when you're using the S3 Intelligent-Tiering storage class.

Better Practice 8: Monitor Amazon S3 Buckets

AWS may limit S3 access if cumulative API writes are greater than 3,500 writes/second, or cumulative API reads are greater than 5,500 reads/second for a prefix (a.k.a., directory within S3). While it would be impossible to track every single AWS prefix's API requests, Cloudtrail offers "rate exceeded" events if you are ever over the API request limits.

Here's a Splunk search to report on all Cloudtrail events for S3. Filter or look for rate exceeded within the `errorMessage` field:

```
index=aws sourcetype=aws:cloudtrail errorCode=* "resources{}.ARN"=* | rename "resources{}.ARN" as ARN | stats count by eventName errorCode errorMessage ARN
```



Cloudtrail Logs Search

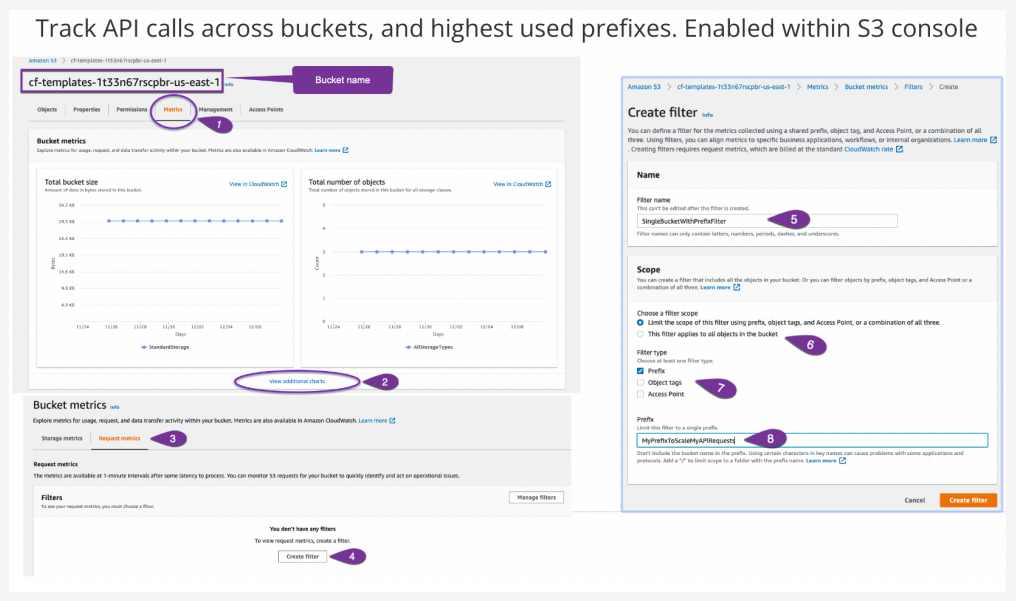
If there are `rate exceeded` messages from writing to Amazon S3, then a new strategy for partition and file name prefix expressions might be warranted. You will want to create fewer files, so consider one or more of the following options:

- Increasing timeouts.
- Eliminating file name expression prefixes.
- Updating partitioning expressions.

If there are rate exceeded messages on reading from Amazon S3, then you should likely apply better filtering. This might also warrant a new strategy for how files are written to S3.

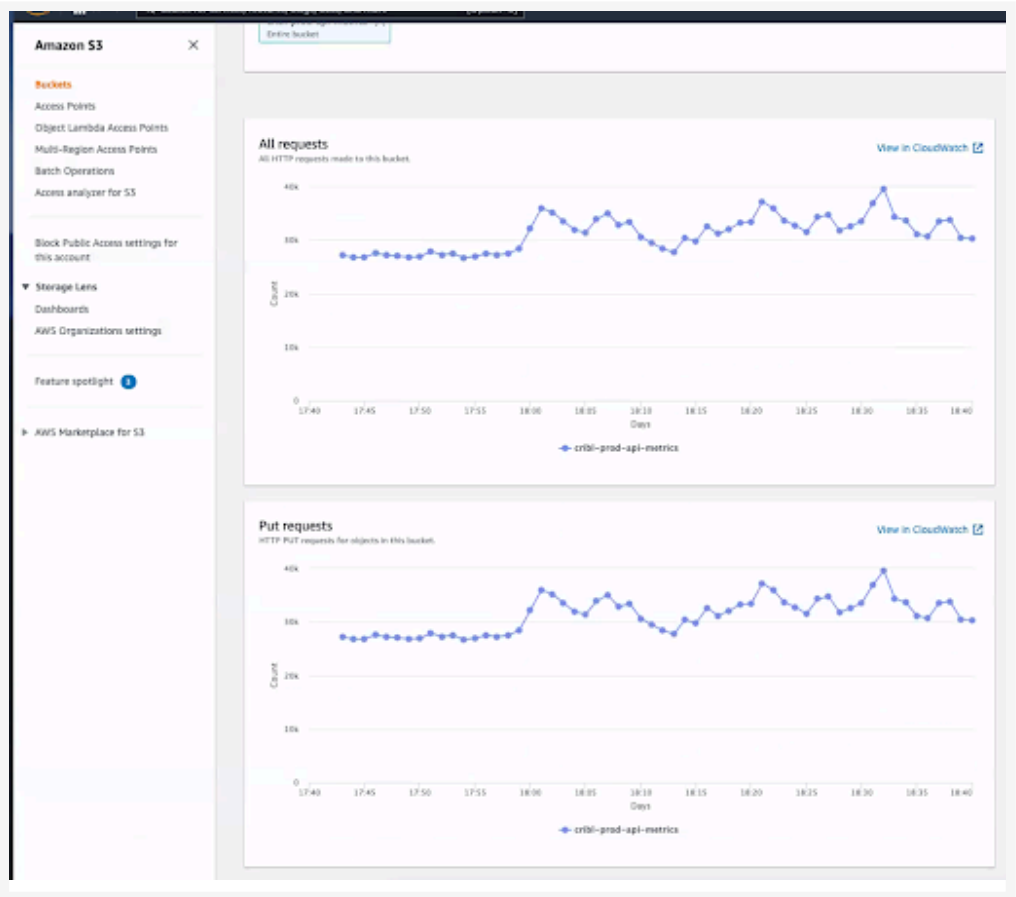
For trending API calls, you'll need to focus on a specific prefix. This might be useful for specific AWS prefixes, as there will be hundreds of thousands or millions. API calls can be tracked via AWS Cloudwatch, but first need to be enabled for tracking within the S3 bucket. See AWS' Creating a Metrics Configuration that Filters by Prefix, Object Tag, or Access Point topic.

The screenshot below illustrates the locations to enable tracking API calls for a specific prefix:



Enable Monitoring in S3

Here's a Cloudwatch chart trending all requests, and write requests, for an S3 prefix. This is granular to 1 minute. Because the API limits are per second, some extrapolations are necessary to estimate per-second values.



Cloudwatch Chart

Consider both the write and read behavior when designing your partitioning expressions and file name prefix expressions.

Better Practice 9: Monitor Worker Node Performance, and Enable Notifications

Aside from the standard CPU load, disk space, memory usage metrics, consider tracking some additional metrics. If the Worker Nodes are deployed as EC2 instances, track the Cloudwatch metrics for the EC2 instances and associated disks. Cribl Support will ask for these metrics to track Amazon S3 issues:

- `BurstBalance`
- `VolumeReadBytes`
- `VolumeWriteBytes`
- `VolumeReadOps`
- `VolumeWriteOps`
- `VolumeQueueLength`

On the Linux host, the following command allows you to track the number of open files. This would be another useful metric to track over time:

```
lsof | grep <common_upperlevel_staging_dir> | wc -l
```

You can also configure Notifications in Cribl Stream when the S3 Destination is unhealthy or triggering backpressure. Once the S3 Destination is enabled, and a Notification target is set, you need to:

- Edit Cribl Stream's S3 Destination to configure Notifications.
- Add Notifications for different conditions.

Better Practice 10: Dedicate a Separate Worker Group for Replays

Execute Replays from a dedicated Worker Group. Streaming real-time data needs dedicated Worker Groups. You do not want CPU or memory conflicts on production systems that are streaming mission-critical, real-time machine data. Kubernetes or AWS spot instances are good options for on-demand Worker Processes that are needed only for infrequent replays.

Bonus Better Practice: Tune Amazon S3 Source Settings

For Cribl Stream's SQS-based Amazon S3 Source (as opposed to our S3 Collector), a few settings can speed up processing of new files added to an S3 bucket:

1. Under **General Settings**, apply a **Filename filter** if you want to pull only a subset of files from the S3 filter. The value is a regular expression (e.g., *suricata*)
2. Under **Advanced Settings**, set **Max messages** as high as 10 to fetch more SQS messages from the queue at once.
3. Under **Advanced Settings**, set the **Num receivers** to vertically scale the number of simultaneous processes pulling SQS messages and downloading S3 files. For S3 buckets with centralized Cloudtrail logs, or VPC flows across multiple accounts, raise the setting to 5 or 10.

Improve Partitioning Expressions

Creating partitioning expressions is an art. To get a sense of the possibilities and risks, let's consider both positive and negative examples.

Partitioning Expression 1: The Good

```
${C.Time.strftime(_time ? _time : Date.now()/ 1000, '%Y/%m/%d/%H/%M')}
```

Copy

Key Questions	Answers
Potential cardinality every *minute*?	1
How many open files if there are 30 Worker Processes?	30 open files
How many files in the S3 prefix, if the timeout is the default 60 seconds (assuming no file size limit)?	30 * 1 = 30 files
What if there are 10 Nodes in the Worker Group? How many files in each S3 prefix?	30 * 10 = 300 files
What happens when a replay fetches data for this hour?	Under API limit of 5,500 reads/sec

Result

- A good partitioning expression.

Partitioning Expression 2: The Ambiguous

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}
/${index ? index : 'no_index'}
/${host ? host : 'no_host'}
/${sourcetype ? sourcetype : 'no_sourcetype'}
```

Copy

Key Questions	Answers
Potential cardinality every 3 minutes?	3,000
How many active subdirectories in the staging dir?	3,000
What is the excess cardinality?	3,000 - 2,000 = 1,000
What are maximum open files if there are 14 Worker Processes on a Worker ?	14 * 2,000 = 28,000 open files
What happens when maximum open files of 2,000 is reached for any one Worker Process? What happens if it happens too frequently?	All files closed & written to S3 at once = 2,000 writes. Potential for backpressure if Cribl Stream takes long enough to write the files.
What's the maximum number of files in any S3 prefix?	14 * 10 Worker Process * (60min/3min) = 2800 files max in any S3 prefix

Additional assumptions:

- Cardinality of 3,000 every 3 mins.
- File write timeout of 3 minutes.
- File size limit never reached.
- 10 Worker Process in group.

Result

- Proceed with caution.

Solution

- Track the occurrences of `max open files reached` messages
- If the `max open files reached` message occurs too frequently, consider reducing the cardinality. You might achieve this by lowering the timeout period to 2 minutes or 1 minute.

Partitioning Expression 3: The Bad

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}
```

Copy

Key Questions	Answers
Potential cardinality every hour?	1
How many open files if there are 30 Worker Processes?	30 open files.
How many files in the S3 prefix, if the timeout is the default 60 seconds (assuming no file size limit)?	(30 * 60) = 1800 files
What if there are 10 Nodes in the Worker Group? How many files in each S3 prefix?	(1,800 * 10) = 18,000 files
What happens when a replay fetches data for this hour?	Could exceeed the API limit of 5,500 reads/sec.

Result

- A bad partitioning expression.

Solution

- Change the timeout to 1800 seconds to allow files to grow in size.

Partitioning Expression 4: The Terrible

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d')}
/${index ? index : 'no_index'}
/${host ? host : 'no_host'}
/${sourcetype ? sourcetype : 'no_sourcetype'}
```

Copy

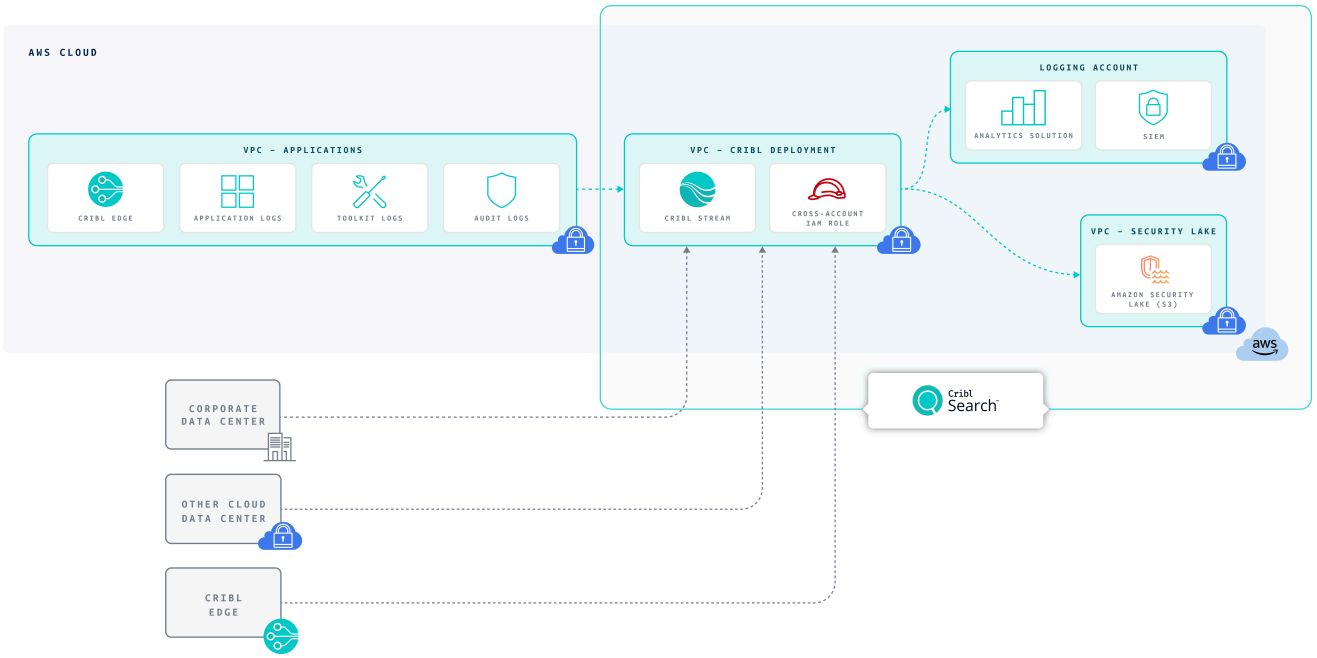
Filename Prefix Expression:

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%H%M')}
```

Copy

8.8.1.4. Amazon Security Lake Integration

Cribl Stream supports sending data to Amazon Security Lake as Parquet files that adhere to the Open Cybersecurity Schema Framework (OCSF). The diagram below illustrates the all-AWS variant of this architecture.



Integrating Cribl Stream with Amazon Security Lake

This guide walks you through an example where Cribl Stream, running in Cribl.Cloud, sends Palo Alto Networks logs to Amazon Security Lake. The workflow starts with a Cribl Stream Syslog Source, which ingests the Palo Alto data and routes it to a Cribl Stream Amazon Security Lake Destination, which then writes Parquet files to Amazon Security Lake. These Parquet files organize the data according to the OCSF schema for the appropriate OCSF Event Class, in this case Network Activity [4001].

You can work with other data sources besides Palo Alto Networks, and other OCSF Event Classes besides Network Activity [4001]. See Going Beyond This Example below.

If you want to use Amazon Security Lake with a Cribl Stream instance deployed on-prem or in your private cloud, the setup procedures will differ from those documented here. Please contact Cribl via the `#packs` channel of Cribl Community Slack.

Set Up Amazon Security Lake

Complete the Amazon Security Lake Getting Started instructions, paying particular attention to the following actions:

1. Enable Amazon Security Lake for your AWS account.

2. Define the **collection objective** and **target objective**.
3. Select the Regions where you want to create S3 buckets to store the data in OCSF format.

Note your Amazon Security Lake S3 bucket name for use later in the setup process.

Set Up Cribl Stream

Complete the procedures in this section before doing anything else in Cribl Stream.

First, find and note the Amazon Resource Name (ARN) that enables AWS to locate your Cribl Stream instance.

1. Log in to Cribl.Cloud.
2. In the sidebar, select **Workspace**, and then select **Trust**.
3. Select the copy icon next to the **Worker ARN**, and paste the ARN into a local text editor.
4. Copy the 12-digit number in the middle of the ARN. This is the AWS Account ID you'll need later in the setup process.

For example:

- If your ARN is `arn:aws:iam::222233334444:role/main-default`, then …
- Your AWS Account ID will be `222233334444`.

Next, install the Cribl Pack that Cribl Stream will use to send data to Amazon Security Lake in the required OCSF format. (As the reference shows, the Palo Alto Networks data chosen for this example requires the **OCSF Post Processor Pack**.)

1. On the top bar, select **Products**, and then select **Cribl Stream**.
2. Select the name of the Worker Group whose Worker Nodes you want to send data to Amazon Security Lake. (For this example, we'll use the `default` Worker Group.)
3. Navigate to **Processing** > **Packs** (Stream) or **More** > **Packs** (Edge) and select **Add Pack**. From the drop-down, select **Import from Git**.
4. For the **URL**, enter:

```
https://github.com/asc-me-cribl/cribl_ocsf_postprocessing
```

Copy

5. For the **New Pack ID**, enter:

```
Cribl-OCSF_Post_Processor
```

Copy

6. Select **Import** to close the modal. Cribl Stream will take a little time to finish importing the Pack.

At the bottom of the list of Packs, you should now see your newly imported Pack, listed with the display name of **OCSF Post Processor**.

Finally, you will need the Parquet schema that supports the OCSF Event Class you're working with. In this example, that's OCSF Event Class 4001, so as shown in the reference below, you'll need the `OCSF 4001 Network Activity` Parquet schema.

- First, download the Parquet schema from this GitHub repo.
- Then, upload the schema to the Cribl Stream Parquet schema library as described in Parquet Schemas.

Once this is done, the Parquet schema you need should be available when you configure the **Parquet Settings** for your Cribl Stream Amazon Security Lake Destination.

Please post any questions you have about these procedures to the `#packs` channel of Cribl Community Slack.

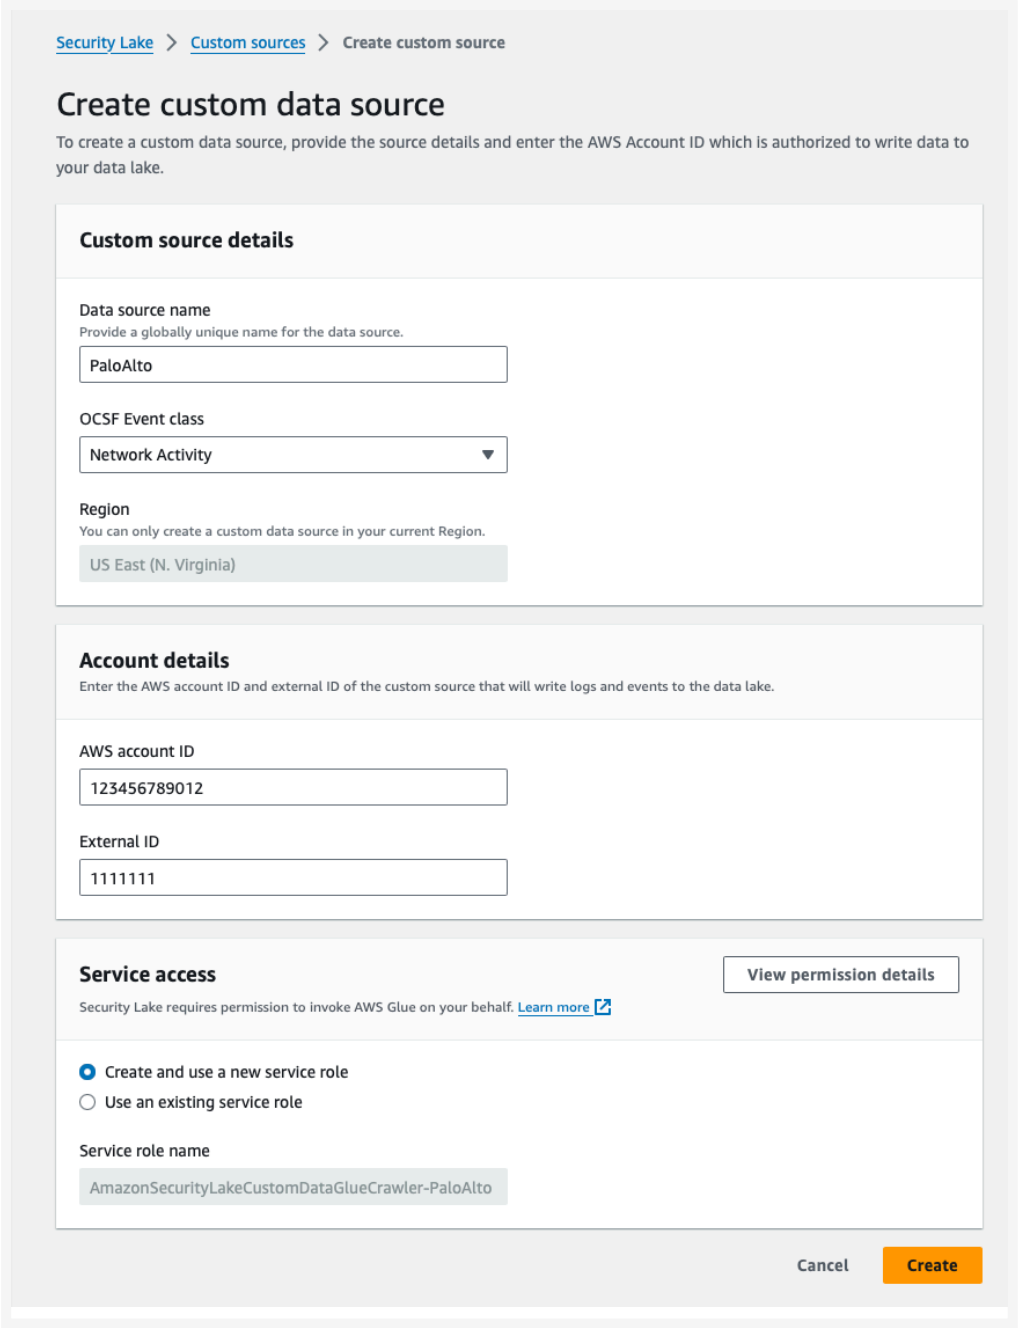
Create an Amazon Security Lake Custom Source

Because Cribl is not a native Amazon service, you'll configure what Amazon calls a **Security Lake custom source**, and the Cribl Stream Amazon Security Lake Destination will write to that.

Before you begin:

1. Have your Cribl.Cloud AWS account ID, which you identified earlier, handy.
2. Ensure that you have permissions in AWS Lake Formation to create AWS Glue databases and tables. For more information, see Granting and revoking permissions using the named resource method in the AWS docs.

Then complete the instructions here in the AWS docs. These docs will take you through the **Create custom data source** template show below.



Creating an Amazon Security Lake custom source

Once the custom source has been created, still in AWS, navigate to **Security Lake** > **Custom sources** and you should see your new custom source in the list.

Now locate the **Provider role ARN**. This is the ARN that Cribl Stream will use to declare its role to AWS.

1. Select the copy icon next to the **Provider role ARN** to add it to your clipboard. Keep the ARN handy for use later in the setup process.
2. Navigate to the **Identity and Access Management (IAM)** screen.
3. From the left menu, select **Access management** > **Roles**.
4. In the **Roles** search box, paste the part of the ARN that begins `AmazonSecurityLake` and ends with the Region.

5. When the role name appears below, select the link.
6. In the **Trust relationships** tab, view the `ExternalId` element in the JSON object that appears there.

This is the External ID for the trust relationship, which you created when went through the template. You will need this ID later in the setup process.

Create a Cribl Amazon Security Lake Destination

Back in Cribl Stream, create a new Amazon Security Lake Destination in the Routing UI as described in the Destination topic. In the **New Destination** modal, configure the settings specified below. For all settings **not** mentioned in the following notes, you can keep the defaults.

General Settings

S3 Bucket name: The S3 bucket name you noted when setting Up Amazon Security Lake.

Region: Select the Region where the S3 bucket is located.

Optional Settings

File name prefix expression: Keep the default (`CriblOut`) if it satisfies your requirements; otherwise, edit to suit your needs.

Authentication

Authentication method must be set to `Auto` (the default).

Assume Role

Cribl strongly recommends using the **Auto** authentication method in conjunction with the **Assume Role** settings as described below. Both Cribl and Amazon discourage the use of other approaches.

When using **Assume Role** to access resources in a different Region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that Region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. To specify a custom STS endpoint, set the `CRIBL_AWS_STS_ENDPOINT` environment variable. If both are set, `CRIBL_AWS_STS_ENDPOINT` takes precedence. Setting an invalid Region or endpoint results in a fallback to the global STS endpoint.

AssumeRole ARN: This is the **Provider role ARN** you copied after creating your custom source in Amazon Security Lake.

External ID: Enter the ID that you specified when creating your Amazon Security Lake custom source.

Processing Settings Post-Processing

Pipeline: From the drop-down, select the Pack you installed earlier:

```
PACK Cribl-OCSF_Post_Processor (OCSF Post Processor)
```

Copy

System fields: Remove any fields specified here.

Parquet Settings

Parquet schema: From the drop-down select `OCSF 4001 Network Activity`, since OCSF Event Class 4001 describes the events coming from Palo Alto Networks in this example.

At this point, you can select **Save**; the defaults for **Advanced Settings** should work fine for this example. Then, **Commit** and **Deploy**.

You must create one Cribl Stream Amazon Security Lake Destination for **each unique pairing** of a data source with an OCSF Event Class.

- In this example, we're ingesting Palo Alto Networks Threat and Traffic data, which requires the OCSF Network Activity [4001] Event Class. That's one pairing.
- If you also wanted to ingest CrowdStrike Network Activity data, that would be a new data source paired with the same OCSF Event Class - such as, **that would be a second unique pairing**. You would need to create a **separate** Cribl Stream Amazon Security Lake Destination for that pairing.

The reference below shows all the possible pairings of data sources and OCSF Event Classes.

Connect a Cribl Source to the S3 Destination

We'll now configure a Cribl Stream Syslog Source to ingest Palo Alto Networks system logs, using the QuickConnect UI. (The reference below shows what Cribl Stream Source to use for each supported data source.)

Navigate to QuickConnect as described here. After selecting the Syslog Source tile, select **Select Existing**, then select the preconfigured `in_syslog` Source. When prompted to `Switch in_syslog to send to QuickConnect instead of Routes?`, select `Yes`.

Select + and drag the connection line to the S3 Destination you created above.

The connection between the Syslog Source and the S3 Destination should now be enabled.

Commit and **Deploy** the changes.

Send Data to Amazon Security Lake

Return to your AWS Console. You should see Parquet files landing in the S3 bucket. These files should contain the Palo Alto Networks syslog data you sent through Cribl Stream.

Troubleshooting and Testing

Good things to double-check:

- Are you sending the events to your Amazon Security Lake in Parquet format?
- Are your permissions set properly for your IAM role to write to the S3 bucket?

If the answer to either question is "No," your data will not make it into Amazon Security Lake.

To send sample events from the GitHub repo, using netcat:

1. Download the `oYLbFU.json` sample file.
2. Run the following command, replacing `<cribl_org_id>` with your Cribl.Cloud Organization ID:

```
cat oYLbFU.json | nc default.main.<cribl_org_id>.cribl.cloud 10070
```

Copy

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to `<groupName>.main` when sending to other Worker Groups.

Beyond This Example

If you want to send data from sources other than Palo Alto Networks, you can adapt the above instructions to use the appropriate Source and Pack (and/or modifications to the OCSF Post Processor Pack) in Cribl Stream. This holds true as long as the OCSF Event Classes you want to work with are among those supported by Cribl Stream. For each unique pairing of a data source with an OCSF Event Class, you'll need to create a separate Amazon Security Lake Destination.

In the next section is a list of the supported data sources, what OCSF Event Classes they handle, and what Packs and Parquet schemas you need to work with them.

Reference: Supported Data Sources

Data Source	OCSF Event Classes Handled	Cribl Source	Cribl Pack Display Name	Parquet Schema(s)

Azure Audit Logs	3002, 3004	REST Collector against Microsoft Graph API	Azure Audit Logs to OCSF	`OCSF 3002 Authentication`
				
				`OCSF 3004 Entity Management`

Azure NSG Flow Logs	4001	Azure Blob Storage Source, run as scheduled jobs, not as a Pull Source	Azure NSG Flow Logs	`OCSF 4001 Network Activity`
Cisco ASA	4001	Syslog	Cisco ASA	`OCSF 4001 Network Activity`
Cisco FTD	4001	Syslog	Cisco FTD	`OCSF 4001 Network Activity`
CrowdStrike Account Change	3001	CrowdStrike FDR	Crowdstrike FDR Pack	`OCSF 3001 Account Change`
CrowdStrike Authentication	3002	CrowdStrike FDR	Crowdstrike FDR Pack	`OCSF 3002 Authentication`
CrowdStrike Network Activity	4001	CrowdStrike FDR	Crowdstrike FDR Pack	`OCSF 4001 Network Activity`
GCP Audit Logs Account Activity	3001	Google Cloud Pub/Sub	Google Cloud Audit Logs	`OCSF 3001 Account Change`
Palo Alto Networks (PAN) Threat and Traffic	4001	Syslog	OCSF Post Processor Pack	`OCSF 4001 Network Activity`

SentinelOne	1001, 2001, 3002, 4001	Amazon S3	SentinelOne Cloud Funnel	`OCSF 1001 File System Activity`
				
				`OCSF 2001 Security Finding`
				
				`OCSF 3002 Authentication`

	OCSF Event			

8.8.1.5. Collecting Logs From Amazon ECS Containers

When using the Amazon Elastic Container Service (ECS), Cribl Stream can eliminate the additional expense of CloudWatch Logs by selecting an alternative Docker logging driver.

By default, the `awslogs` driver will forward all container logs to CloudWatch Logs. This requires an additional Amazon service, such as Amazon Data Firehose or AWS Lambda, to export logs to the desired destination.

But by using Docker's `splunk` logging driver, you can forward the ECS container logs directly to a Cribl Stream Worker Group, bypassing CloudWatch Logs.

For example, when using Cribl.Cloud, you can forward logs to your Organization's Splunk HEC endpoint. This endpoint information can be found in your Cloud Organization's Data Onboarding configuration.

Example Task Definition

Below is a sample JSON task definition with the required `logConfiguration` section configured to forward Splunk HEC payloads to Cribl Stream:

```
{
    "containerDefinitions": [
        {
            "name": "my-example-container",
            "essential": true,
            "image": "public.ecr.aws/my/containerimage:latest",
            ...
            "logConfiguration": {
                "logDriver": "splunk",
                "options": {
                    "splunk-url": "https://main-default-<org>.cribl.cloud:8088",
                    "splunk-token": "176FCEBF-4CF5-4EDF-91BC-703796522D20",
                    ...
                }
            }
        }
    ],
    ...
}
```

Copy

Additional Details

For additional configuration options on the `splunk` logging driver, see Docker's documentation.

For additional details on the `LogConfiguration` section, see the Amazon ECS documentation.

8.8.2. Azure

The following topics provide detailed guides and better practice for integrating with Azure services.

Source	Description
Preparing the Azure Workspace	Preparing the Azure Workspace for Cribl Integrations
Azure Event Hubs Integrations	Ingest data from an Azure Event Hub
Microsoft Sentinel Integration	Set up Cribl to send data to the Microsoft Sentinel SIEM

8.8.2.1. Prepare The Azure Workspace For Cribl Integrations

This guide walks you through configuring Azure to receive data from Cribl Stream. Currently, Cribl Stream supports sending data to **custom tables** and some **native tables** in Azure Log Analytics workspaces. For more information, see Azure's Supported Tables topic.

Before You Begin

To send data to custom tables, you need to configure a Data Collection Rule (DCR) with Stream definitions. We provide example DCR templates in our Cribl-Microsoft GitHub repository to simplify this process, and recommend using the Syslog template as the starting point. Note that the Syslog template is provided under the `DataCollectionRules` path and is intended for the **DCR kind:direct** approach.

Choose Your Data Collection Method

Decide which method best suits your deployment:

- **Method 1: DCR kind:direct (Recommended)**: This is the simplest approach. The `logIngestion` URL is embedded directly in the DCR, so a separate Data Collection Endpoint (DCE) is not needed. This is ideal if you don't require Private Link connectivity or complex network routing.
- **Method 2: Data Collection Endpoint (DCE)**: Use this method if you need **Private Link connectivity** for network isolation, specific data routing, or a single ingestion endpoint for multiple DCRs.

For most deployments, DCR `kind:direct` is the recommended approach due to its simplicity. Only use a DCE if you have specific networking requirements such as Private Link connectivity, network isolation, or centralized endpoint management across multiple regions.

Deployment Approaches

This guide covers **manual configuration** using the Azure portal. For automation and templates, refer to the Cribl-Microsoft GitHub repository. The GitHub repository contains various resources and approaches that can simplify and automate the deployment process, which is particularly useful for production environments or repeated deployments.

The following sections walk through manual Azure portal configuration for those who prefer or need to understand the step-by-step process.

Prepare the Azure Workspace

First, you must prepare the Azure Workspace to receive data from Cribl Stream by registering Cribl Stream as an authorized application with the Microsoft Identity Platform.

Use Copy buttons, where available, to copy complete values for later use without truncation.

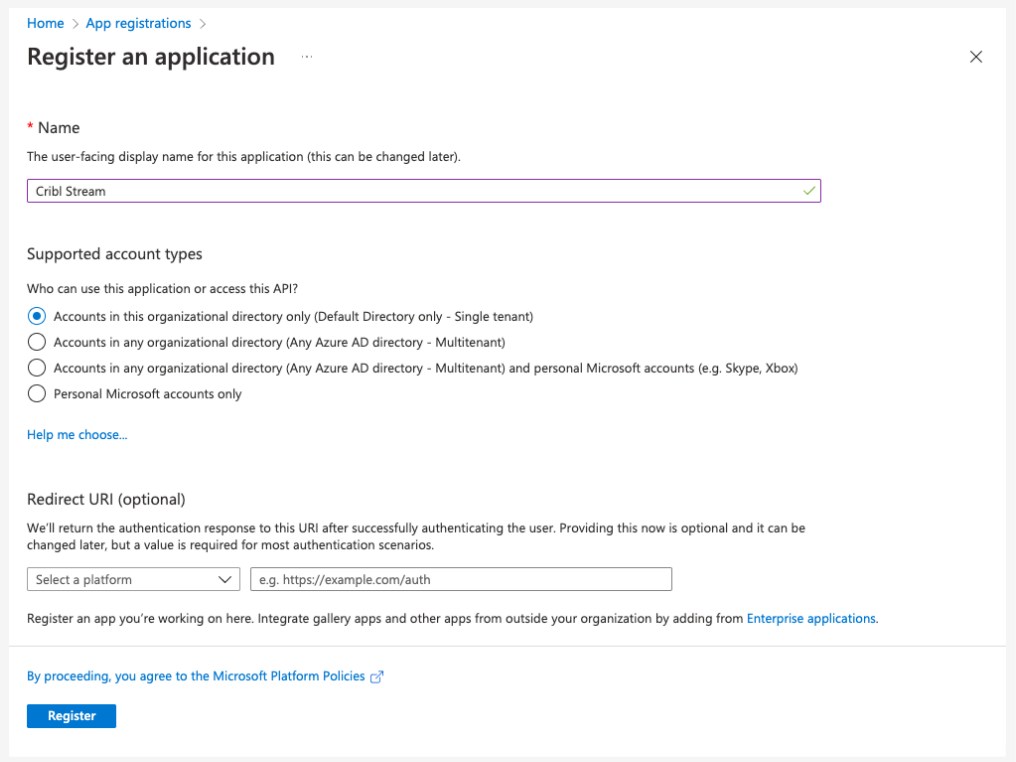
Common Setup Steps

Regardless of which configuration path you choose, you'll need to complete these initial steps.

Create Credentials for a New Azure Application

Register Cribl Stream as an authorized application with the Microsoft Identity Platform.

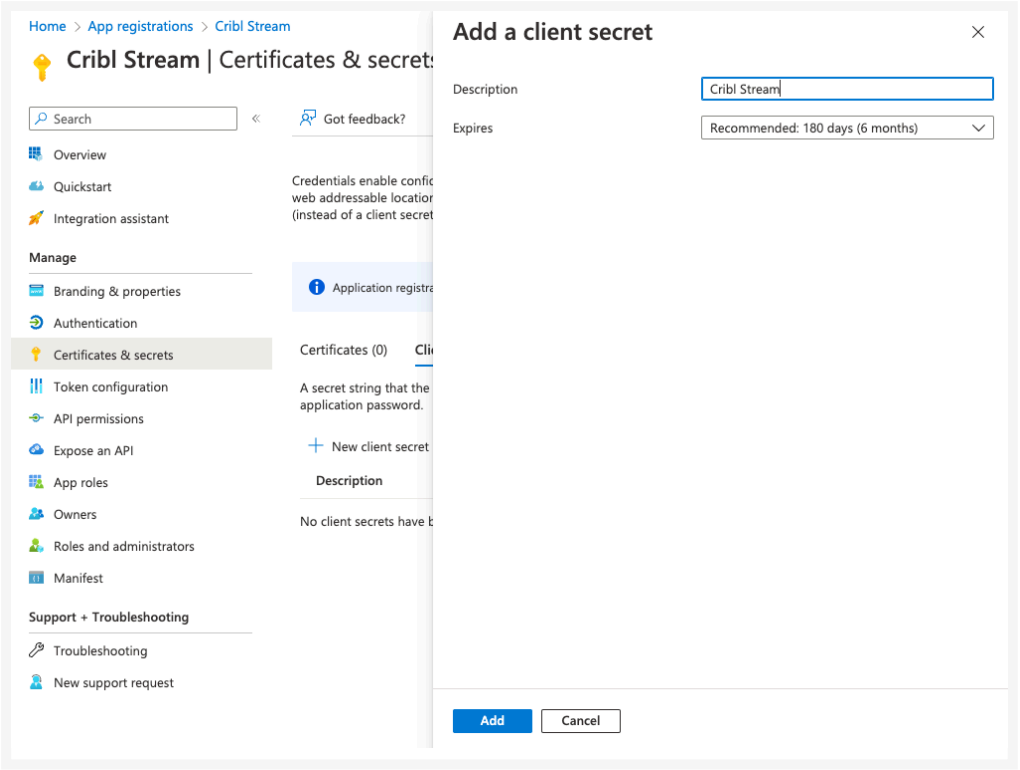
1. Log into the **Azure** portal as an `Administrator`.
2. Navigate to the portal's **App registration** section.
3. Click **New registration** to register an application.
4. Register a new application with the name `Cribl Stream`.



Registering an Application

5. Click **Register**.

6. Store the **Application (client) ID** and **Directory (tenant) ID** for later steps.
7. In your newly registered application, select the **Certificates & secrets** tab.
8. Create a **New client secret**.
9. Store the secret **Value** for later steps.



Creating a client secret

Find the Log Analytics Workspace Resource ID

1. Navigate to the Azure portal's **Log Analytics workspaces** service.
2. Select the workspace that will receive data.
3. From the **Overview** page, select **JSON view**, and store the value of the **Resource ID** (gray box at the top) for later use.

Configure Data Collection (Choose Your Path)

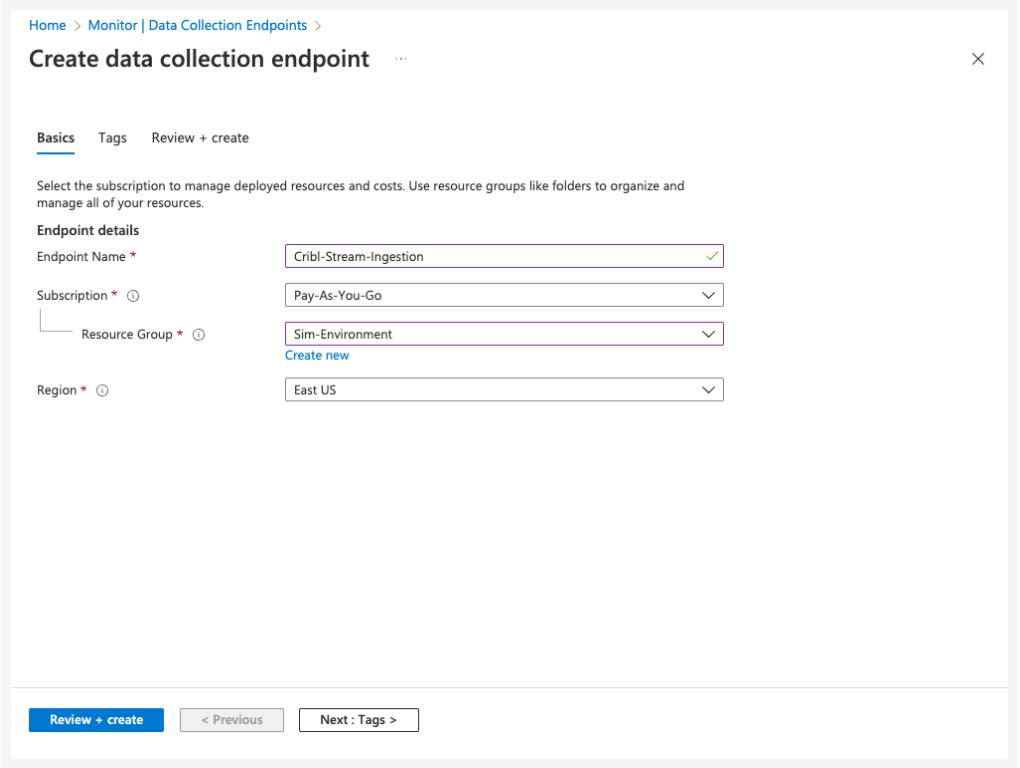
Path A: Using DCR `kind:direct` (Recommended)

If you chose the DCR `kind:direct` method, you can skip directly to Create and Configure the Data Creation Rule. The `logIngestion` URL will be embedded automatically.

Path B: Using a DCE

If you need a DCE, create it first.

1. Navigate to the Azure portal's Monitor service.
2. Under **Settings**, select **Data Collection Endpoints**.
3. Select **Create** and name the endpoint `Cribl-Stream-Ingestion`.
4. Select the appropriate Subscription and Resource Group used by your organization.
5. Select **Review + create**, review your changes, then select **Create**.
6. In the list of **Data Collection Endpoints**, open the newly created endpoint. (You might need to refresh the page to see it.)
7. Navigate to the **Overview** page, and copy and store the **Logs Ingestion** URL.
8. Select **JSON view**, and store the value of the **Resource ID** (gray box at the top) for later use.



Creating a DCE

After creating the DCE, proceed to **Create and Configure the Data Collection Rule**.

Create and Configure the Data Collection Rule

Both configuration paths require a DCR, but they use different templates:

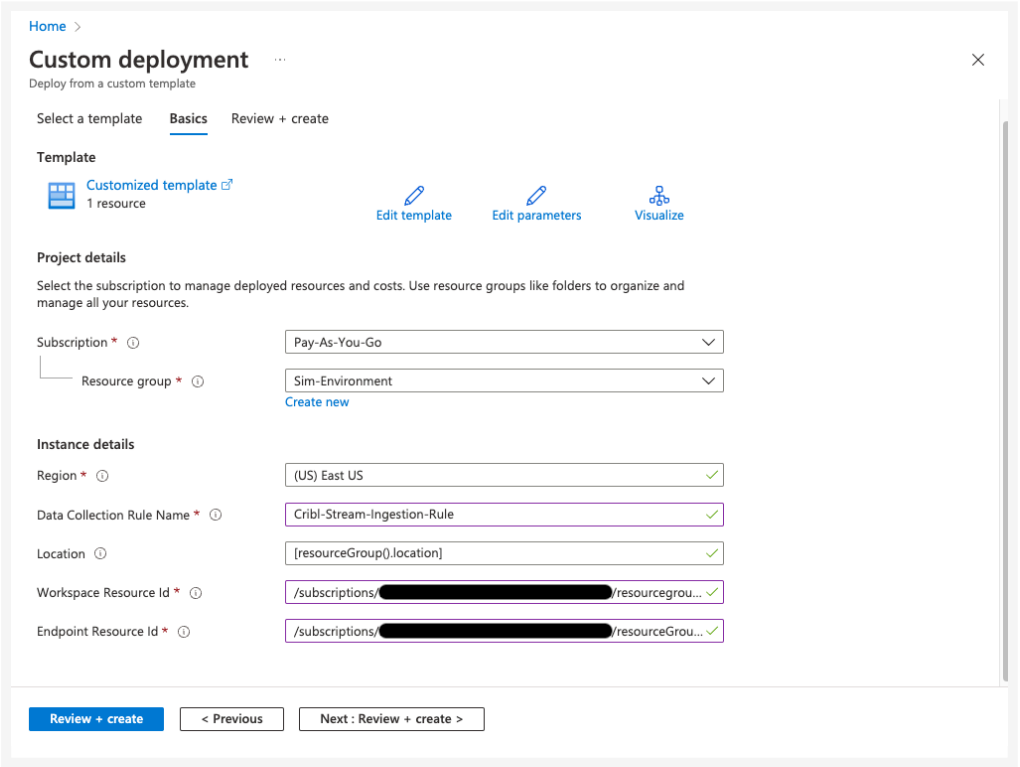
- **DCR `kind:direct`**: Creates a DCR with `kind:direct` that includes an embedded `logIngestion URL`.

- **DCE method**: Creates a standard DCR that references the DCE.

Both templates are available in the Cribl-Microsoft GitHub repository. Browse to the appropriate template for your use case.

Deploy the DCR Template

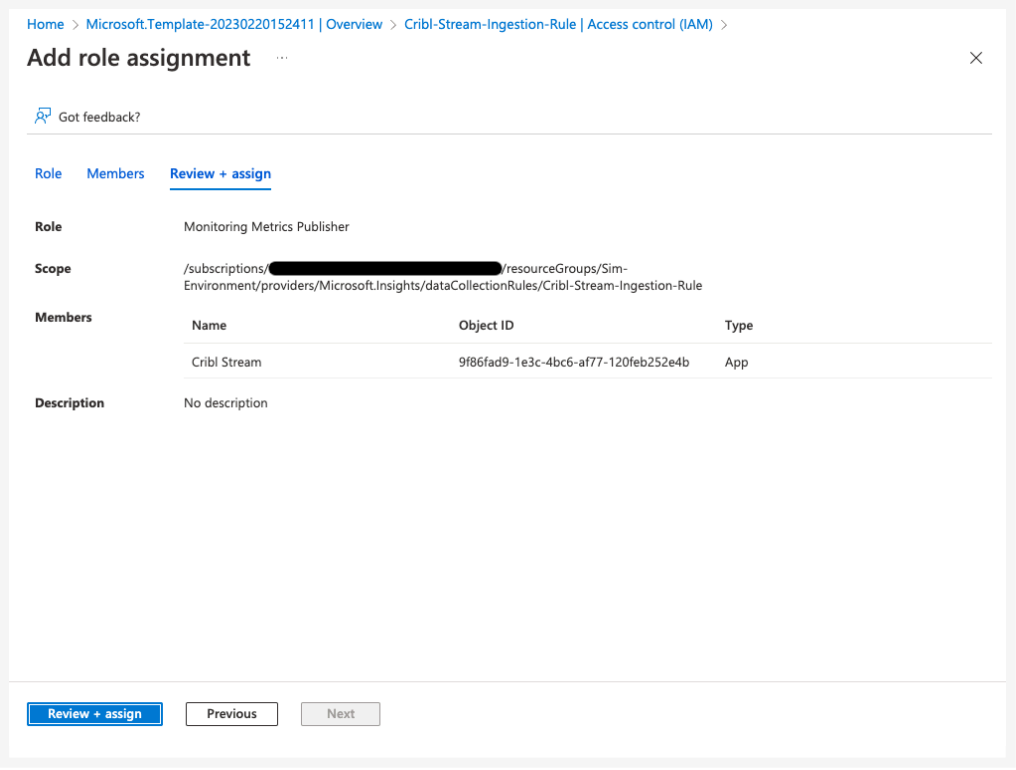
1. Navigate to **Deploy a custom template**.
2. Select **Build your own template in the editor**, then **Load file** to upload the appropriate DCR Template from the Cribl-Microsoft repository.
3. Click **Save**.
4. Select the appropriate Subscription and Resource Group used by your organization.
5. Name the rule `Cribl-Stream-Ingestion-Rule`.
6. Enter the required parameters based on your configuration path:
    - **For DCR kind:direct configuration:** Enter only the Log Analytics **Workspace Resource ID**.
    - **For DCE configuration:** Enter the Log Analytics **Workspace Resource ID**, and the **Endpoint Resource ID**.
7. To create the Data Collection Rule, select **Review + create**, followed by **Create**.



Deploy the DCR Template

Configure Permissions: Add Role Assignment

1. Once the template has been deployed, select **Go to resource**.
2. From the Overview page, select the **JSON view**, and store the **immutableId** from the JSON body (without quotes) for later use.
3. Click the Data Collection Rule's **Access control (IAM)**.
4. Click **Add role assignment**.
5. Select the **Monitoring Metrics Publisher** role, then select **Next**.
6. Click **+ Select members**.
7. Search for and select `Cribl Stream` (the app you created earlier), then select **Select** to confirm the selection.
8. Click **Review + assign** to review changes.
9. Click **Review + assign** again to implement the permissions update.



Adding a Role Assignment

Required Fields for Cribl Stream Configuration

After completing this setup, configure your Cribl Stream Azure Destination using the values in the following fields:

- `Application (client) ID`
- `Directory (tenant) ID`
- `Client secret value`
- `Log Analytics Workspace Resource ID`
- `Data Collection Rule immutableId`

Additional fields for DCE configurations:

- `Data Collection Endpoint Resource ID`
- `Logs Ingestion URL`

Next Steps

1. Configure your Cribl Stream Azure Destination using the collected credentials.
2. Test the Pipeline.
3. Monitor data flow in your Log Analytics workspace.

Additional Resources

- Cribl-Microsoft GitHub Repository - DCR templates and integration artifacts
- Azure Monitor data collection
- Data Collection Rules overview

8.8.2.2. Azure Event Hubs Integrations

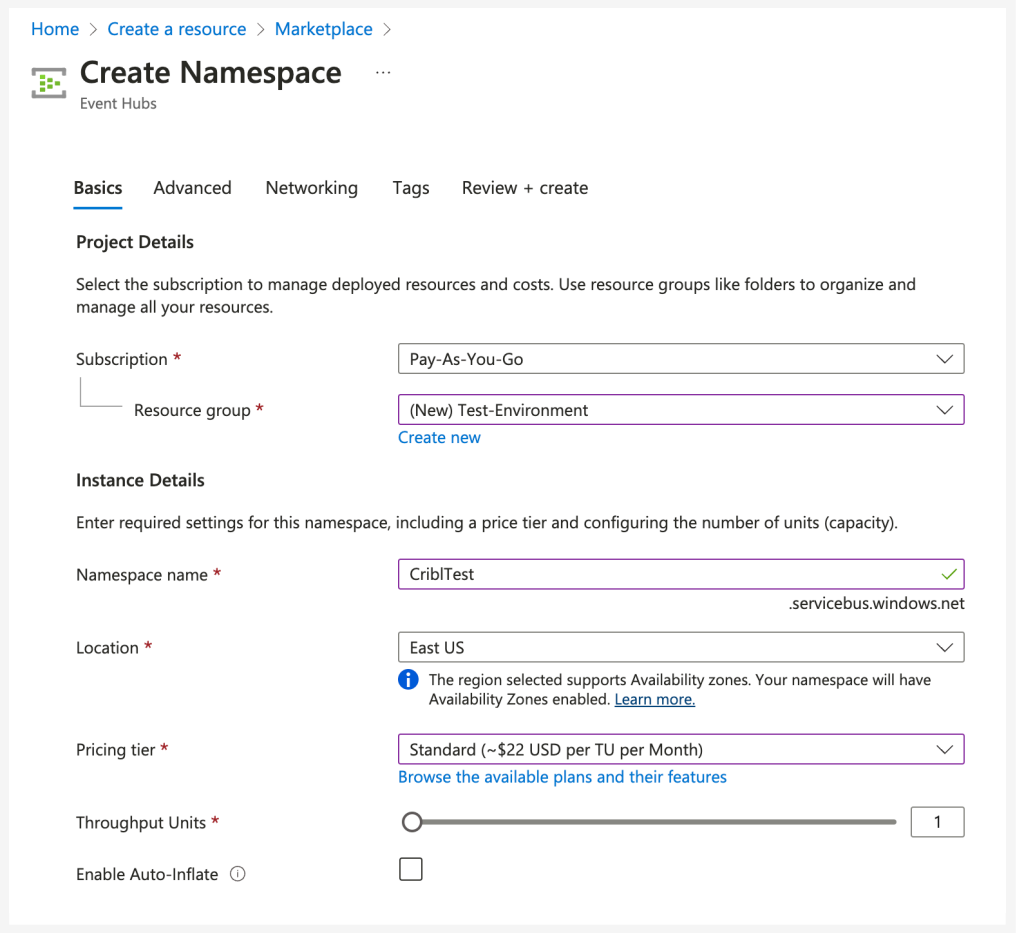
To ingest data from an Azure Event Hub, you can create an Event Hub and a Cribl Stream Azure Event Hubs Source configured to consume data from the Event Hub. This page documents that integration.

Your Azure Event Hubs account must be at the Standard (or a higher) pricing tier, because the Basic pricing tier does not support the PLAIN authentication method Cribl Stream uses for Event Hubs.

Prepare Azure Event Hubs to Send Data to Cribl Stream

First, create an Azure Event Hub as described in the Azure documentation.

In this tutorial, we use `CriblTest` as the **Namespace name**. You can use any **Namespace name** you like, as long as it is unique across Azure.

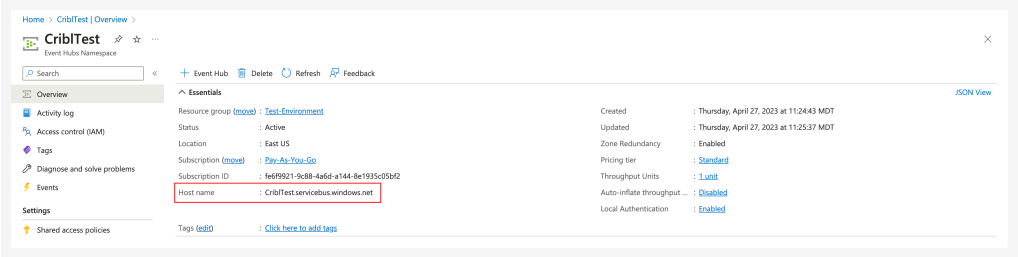


Creating an Event Hubs Namespace

Collect the information you will need when configuring Cribl Stream:

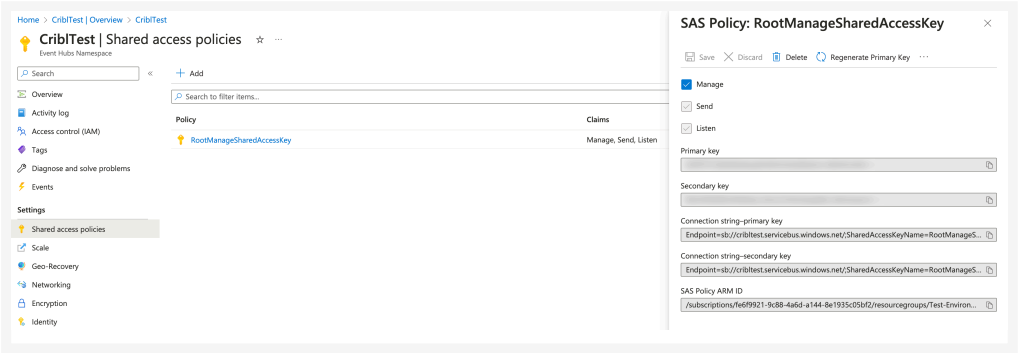
1. In the **Deployment** page, click **Go to Resource**.

2. Copy the **Host Name** and store it.



Finding the Host name and Shared access policies

3. Click **Shared Access Policies** to open the page where you can select policies for your Event Hubs Namespace, and then click `RootManageSharedAccessKey` to show details for that policy.



Viewing Shared access policies

4. Copy and securely store the **Connection String-primary key**.
5. Click on Event Hubs on the left-hand column and copy the Event Hubs name you want to ingest.

Restricting Public Network Access for Cribl.Cloud Deployments

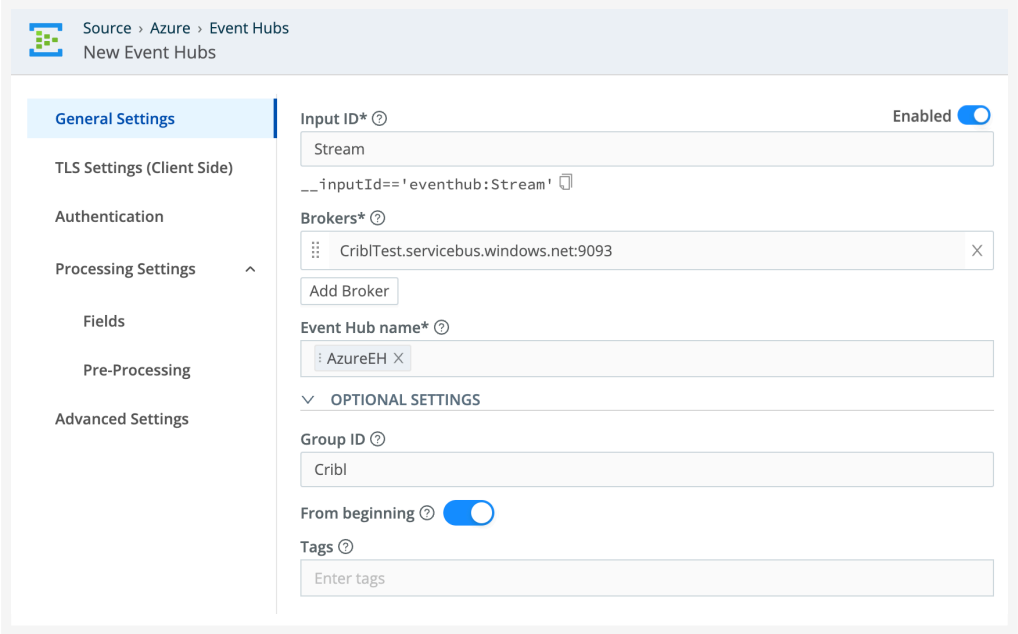
If you are using a Cribl.Cloud deployment, you have the option of restricting public network access to the Event Hubs environment.

To restrict access, you will need to obtain the egress IP in your Cribl.Cloud portal, then use it to configure public network access in the Event Hubs environment.

1. To obtain the egress IP, click **Access Details** and copy the **Egress IP** of your Cribl.Cloud Organization.
2. In the Azure Event Hubs environment, select **Networking** > **Public network access** > **Selected networks**.
3. On that same page, paste the Cribl.Cloud egress IP into the **Address range** field in the Event Hubs environment.

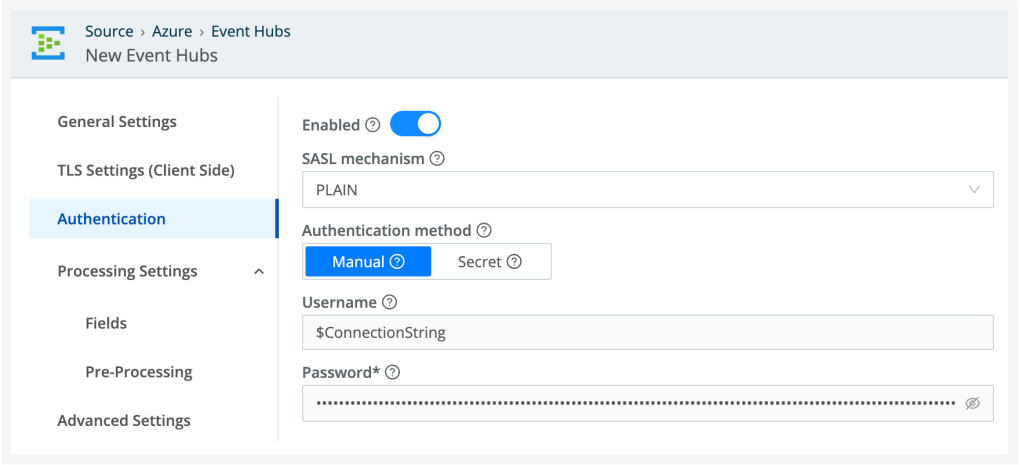
Configure the Azure Event Hubs Source in Cribl Stream

1. From a Cribl Stream instance's or Group's **Manage** submenu, select **Data** > **Sources**, then select **Azure Event Hubs** from the **Manage Sources** page's tiles or left nav. Click **New Source** to open the **Azure Event Hubs** > **New Source** modal.
2. In the **General Settings** tab, enter the following values:
    - **Input Id**: A unique ID of your choice. For example: `Stream`.
    - **Brokers**: End the Host Name you wrote down earlier and append port `9093`. For this example: `CriblTest.servicebus.windows.net:9093`.
    - **Event Hub name**: The name of your Azure Event Hub. For this example: `AzureEH`. The **Event Hub Name** is equivalent to a Kafka topic. It should not be the same as the Azure Event Hubs namespace value you created above.
    - **Group ID**: This value can be `Cribl`, but the **Group ID** cannot be shared with other technologies. Sharing this value across technologies may cause unexpected behavior, such as failing to collect logs reliably.



The General Settings tab

3. In the **Authentication** tab, enter or select the following values:
    - **SASL mechanism**: Options include `PLAIN` and `OAUTHBEARER`.
    - **Username**: `$ConnectionString` (the default generated by Azure).
    - **Authentication Method**: Select `Manual` to use the Connection String Key generated by Azure Event Hubs.
    - **Password**: Enter the **Connection String-primary key** that you copied earlier.



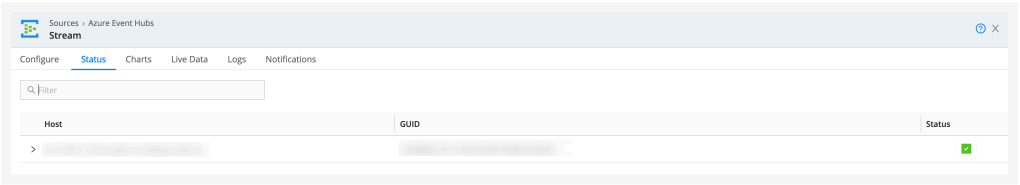
The Authentication tab

Verify that Data is Flowing from Your Azure Event Hub to Cribl Stream

Before you can verify that data is reaching Cribl Stream, you must ensure that it is flowing out of your Azure Event Hub in the first place.

One option is to configure a Datagen and a Route to send data to the Event Hub destination. We'll assume you have done that, or gotten data flowing from your Azure Event Hub in some other way.

1. In Cribl Stream, open the **Sources** > **Azure Event Hubs** > **Cribl Stream** page. This should show your Source, with a message confirming that it is working properly.



A working Source

2. Open the **Live Data** tab. You should see the data that is flowing from your Azure Event Hub to Cribl Stream.

8.8.2.3. Microsoft Sentinel SIEM Integration

You can send events through Cribl Stream Microsoft Sentinel Destinations to the Microsoft Sentinel SIEM in Azure.

This use case demonstrates how to send data from Cribl Stream to Microsoft Sentinel in various Azure environments, including Azure Public Cloud, Azure US Government Cloud, and Microsoft Azure operated by 21Vianet. While we'll cover key points about the Cribl Stream Microsoft Sentinel Destination here, you should refer to the Sentinel Destination topic for complete UI details.

Before You Begin

Ensure that you have prepared your Azure Workspace. You must complete this step before you can send events through the Microsoft Sentinel Destination to the Microsoft Sentinel SIEM.

If you do not yet have Microsoft Sentinel up and running, please join us on Cribl's Community Slack at https://cribl-community.slack.com/ and let us know; very likely, a wise goat will offer time-saving suggestions.

Event Types

Of the many event types (also called "tables") present in the Microsoft ecosystem, this topic provides a starting point for integrating Cribl with Sentinel. For the complete list of supported tables and their schemas, refer to the Microsoft documentation for supported tables.

To plan your Cribl/Sentinel integration, start by deciding which event types (a.k.a. tables) you want to send to Sentinel. Common event types you might work with include:

- `CommonSecurityLog`
- `SecurityEvent`
- `Syslog`
- `WindowsEvent`

Choosing a Data Collection Strategy

When sending data to Sentinel, you have a decision to make that balances ease of troubleshooting with the number of Cribl resources you'll need:

- **One Cribl Destination for a single Data Collection Rule (DCR)**: This approach minimizes the number of Destinations you need in Cribl. You can send all data to a single Sentinel Destination, which is configured

to use a single DCR that handles all of your event types. While this reduces Cribl resource overhead, it can make troubleshooting more complex as all data flows through a single point.

- **A unique Cribl Destination for each DCR**: This approach simplifies troubleshooting and provides greater control over your data. By creating a unique Sentinel Destination for each DCR, you can easily isolate and debug issues related to a specific data type. This is the recommended approach for most deployments, as it makes managing your data flows easier.

Creating Data Collection Rules

In Cribl Stream 4.1.4 and later, DCRs (data collection rules) support direct log ingestion URLs. This update means that DCEs (data collection endpoints) are no longer needed unless your Log Analytics workspace has restricted public access, such as with private endpoints.

The Sentinel SIEM can have multiple ingestion endpoints, called Data Collection Endpoints (DCEs). In turn, each DCE can have multiple Data Collection Rules (DCRs). A DCR can dictate the structure of the data flowing into one table, or multiple tables.

For ready-to-use DCR templates and automation options covering all supported tables, visit the Cribl-Microsoft GitHub repository. Cribl provides DCR templates for various tables. You can use these templates to quickly set up your DCRs.

Ensure that the field names in your data match the schema defined in the Data Collection Rule (DCR) for Microsoft Sentinel. The DCR specifies the expected structure, including field names and types. Mismatched field names can result in dropped fields.

To determine which Sentinel table should ingest a specific data source, review the Microsoft Sentinel Content Hub catalog. For instance, the Palo Alto Sentinel Solution sends all Palo Alto Firewall data to the `CommonSecurityLog` table. In contrast, the Crowdstrike Solution uses multiple tables, including custom ones, for data ingestion.

Besides the Azure documentation, you can study the Cribl template to understand how DCRs are structured. For example, each table's columns are defined in a sub-element of the `resources` > `properties` > `streamDeclarations` element. The `dataFlows` element - at the same level as `streamDeclarations` - specifies the table that a given type of data should populate, via the `outputStream` sub-element. It also specifies the query that will translate incoming fields into values in the table's columns, via the `transformKql` sub-element.

Read more about DCRs in the Microsoft Sentinel documentation.

Custom DCR Template Errors

> If you get an error such as `Table for output stream 'Microsoft-CommonSecurityLog' is not available for destination 'logAnalyticsWorkspace'`), it is probably because you don't have Sentinel assigned to your Log Analytics workspace. Please add Microsoft Sentinel to your Log Analytics Workspace to correct this error.

Preparing Your Azure Environment

To configure your Cribl Stream Microsoft Sentinel Destination, you must provide your log ingestion URL. This resides either in a Data Collection Endpoint, or in a Data collection Rule of `kind:Direct` and a Data Collection Rule (DCR) immutable `ID`. You configure this in **General Settings** > **Endpoint configuration**. Cribl recommends the `ID` option, as it automatically generates the correct URL format, and is more reliable than manually constructing URLs.

The ID format follows this pattern:

- **Data Collection Rule ID**: The immutable ID of your DCR.
- **Stream Name**: The specific stream within the DCR you're targeting.

In most respects, Cribl Stream's Microsoft Sentinel and Webhook Destinations are alike. This section notes the few differences, while highlighting key points about configuring Microsoft Sentinel Destinations.

In Microsoft Sentinel Destination, **General Settings** > **Authentication** offers fewer options than the Webhook Destination. This is because OAuth is Cribl Stream's only supported option for Microsoft Sentinel, for now. Some fields that present in other Destinations always have the same values for Microsoft Sentinel, and Cribl Stream fills those out for you without exposing them in the UI.

The Microsoft Sentinel Destination does not support client-side TLS.

The value for **Advanced Settings** > **Body size limit (KB)** value defaults to `1000`. The intent here is to keep request bodies from exceeding Microsoft Sentinel's limit of 1 MB, meaning 1024 KB including headers. If necessary, you can lower the **Body size limit (KB)** even further.

8.8.3. Splunk

The following topics provide detailed guides and better practice for integrating with Splunk services.

Source	Description
Splunk Cloud Platform and BYOL Integrations	Integrating with the Splunk Cloud Platform by using the Splunk HTTP Event Collector
Switch Cribl Stream Destinations from S2S to Splunk HEC	How to switch your data collection from Splunk to Splunk (S2S) to HTTP Event Collector (HEC)
Splunk to Elasticsearch	Routing data from Splunk to Elasticsearch services
Splunk to Exabeam	Exporting parsed data to Exabeam
Splunk Stream to Cribl Stream	Sending data from Splunk Stream packages to Cribl Stream
Decryption of Data in Splunk	Decrypting data with Splunk
Stream-to-Splunk Encryption	Encrypting and decrypting data moving from Cribl Stream to Splunk

8.8.3.1. Splunk Cloud Platform And BYOL Integrations

The Splunk HTTP Event Collector (HEC) is the preferred method for integrating with the Splunk Cloud Platform. It's easy to set up, offers superior compression, and efficiently load balances data across multiple indexers in a distributed Splunk environment. While Splunk-to-Splunk (S2S) can be used for specific scenarios, such as legacy integrations or granular data distribution, HEC generally provides a more straightforward and efficient integration process.

Cribl Stream provides multiple integrations for sending data to the Splunk Cloud Platform. The following table outlines the supported Cribl Stream Destinations and Splunk protocols for different Splunk Cloud Platform deployment scenarios:

Cribl Stream Destination	Splunk Protocol	Splunk Deployment
Splunk HEC Destination	Splunk HEC	- Distributed Splunk Cloud Platform - Bring Your Own License (BYOL) deployment (either in a non-Splunk cloud or on-prem)
Splunk Load Balanced Destination	S2S	- Distributed Splunk Cloud Platform - BYOL deployment
Splunk Single Instance Destination	S2S	- Single-instance Splunk Cloud Platform (trial or smaller deployments)

For BYOL deployments, leverage the `.pem` and `outputs.conf` files already in use on your Splunk Universal Forwarders to maintain consistency and simplify the security setup. The Splunk documentation has detailed instructions on securing your Splunk indexers to ensure the overall security of your deployment.

8.8.3.2. Switch Cribl Stream Destinations From S2S To Splunk HEC

This guide is for users that want to change their Splunk data flow from using Splunk to Splunk (S2S) to HTTP Event Collector (HEC). The guide will provide step-by-step instructions for making this change.

Prerequisites

You must have the following prerequisites before following this guide:

- A Cribl Stream instance
- A Splunk instance

Configure the queue Setting

If your Splunk Technology Add-ons (TAs) include many index-time operations like SEDCMD or TRANSFORMS, be aware of potential data quality impacts. By default, Splunk HEC sends data through a queue where these operations (often referred to as extractions) may be applied, potentially altering your original data.

To bypass these index-time operations (extractions) and ensure data integrity, configure the `queue` setting in the `inputs.conf` file in Splunk to use the `rulesetQueue` on a per-token stanza level. This approach allows for newer Ingest Actions to be applied through the Ruleset queue.

Modifying the `queue` setting in the **global** stanza of `inputs.conf` will impact all HEC tokens and may have unintended consequences for other HEC-based integrations.

1. Locate and open the `inputs.conf` file on your Splunk instance. This file is typically located in the `$SPLUNK_HOME/etc/system/local` directory.
2. Add or modify the following within the file:

```
[http://cribl]
disabled = 0
index = main
token = ${SPLUNK_HEC_TOKEN}
queue = rulesetQueue
```

Copy

3. Replace `${SPLUNK_HEC_TOKEN}` with your actual HEC token.
4. Save the `inputs.conf` file and restart the Splunk instance for the changes to take effect.

If you are using Splunk Cloud, you must open a ticket with Splunk to request a change to the `inputs.conf` file. Make sure you request that they change the `queue` setting only for the Cribl integration, not on a global level.

Create the Splunk HTTP Event Collector Token

Once you complete this section, you will have a new HEC token in Splunk that can receive data from Cribl Stream.

1. Log in to Splunk.
2. Navigate to **Settings** then **Add Data**.
3. Select **Monitor** from the **Add Data** menu.

Select a Source

1. Choose **HTTP Event Collector**.
2. Enter a name for your token (`cribl-HEC` for example).
3. Click **Next**.

Validate Input Settings

1. For **Source type**, select **Automatic** (unless you are setting this token for a specific Sourcetype).
2. For **Index**, select your desired Allowed Indexes.

If you want to send Splunk logs such as data from `_internal`, set the Allowed Indexes to `N/A`. You may want different tokens for different types of data.

3. Click **Next**.

Review HEC Settings

1. Ensure that **Allowed indexes** it set to `N/A`, unless you want to restrict users to only send data to specific indexes using this token.

2. Click **Submit**.

You should now have a new, valid HTTP Event Collector (HEC) token that you can use with Cribl Stream. This token allows Cribl Stream to receive events for any index that is available in Splunk.

Create a Splunk HEC Destination in Cribl Stream

Using the token you just created in Splunk, create a Splunk HEC Destination in Cribl Stream.

1. Log in to Cribl Stream.
2. Click **Data** then **Destinations**.
3. From the resulting page's tiles or the **Destinations** left nav, select **Splunk**, then > **HEC**
4. Click **Add Destination** to open a **New Destination** modal and fill in the required fields:

Field	Configuration
Output ID	Enter a descriptive name for your Destination.
Load balancing	Decide whether to enable Load Balancing for this Destination.
Splunk HEC Endpoints	Enter the endpoint for your Splunk instance, in the following format: `https://http-inputs-<CLOUD_ORG>.splunkcloud.com/services/collector/event`
Authentication method	Set to **Manual**.
HEC Auth token	Enter the Splunk HEC API access token from the Create the Splunk HTTP Event Collector Token section.

5. Depending on your data volume and event size, you may also want to tune Advanced Settings (**Body size limit**, **Request concurrency**, **Flush period (sec)**). See Splunk HEC Advanced Settings for specific guidance.
6. Click **Save**.
7. In a Distributed deployment, you'll also need to **Commit & Deploy** to push the configurations to your Workers.

Test the Destination Connection

1. Open the Splunk HEC Destination you just created and click the **Test** tab.
2. Add the index field to **Test input** and click **Run test**.
3. Check the bottom of the **Test** tab. If the banner shows a green Success indicator, your endpoint and token are valid.

Switch from S2S to Splunk HEC

Now, you can switch from Splunk S2S to HEC Destination.

1. In Cribl Stream, navigate to **Data** then **Destinations**.
2. Choose either **Splunk Single Instance** or **Splunk Load Balanced** depending on which applies to you.
3. Open the Splunk S2S Destination and check for any **QuickConnects** Sources.
4. Click directly on a Source in this column to it.
5. Switch all **QuickConnects** Sources from the Splunk S2S Destination to the Splunk HEC Destination.

Check Routes and Packs

Once you've switched all QuickConnects references to Splunk HEC:

1. Navigate to **Processing**, **Packs** and **Routing**, **Data Routes** and look for references to the Splunk S2S Destinations:
    - On the **Data Routes** page.
    - On the **Routes** page for the Pack.
2. Change the Splunk S2S Destinations you find to the Splunk HEC Destination.
3. Once you're finished, **Commit & Deploy** the changes. In standalone instances, the changes take place as soon as you save them.

We recommended that you make these changes incrementally and validate each change inside of your Splunk instance for any data irregularities before you move on.

Now, you've successfully switched all Splunk S2S Destinations in Cribl Stream to the Splunk HEC Destination.

8.8.3.3. Splunk To Elasticsearch

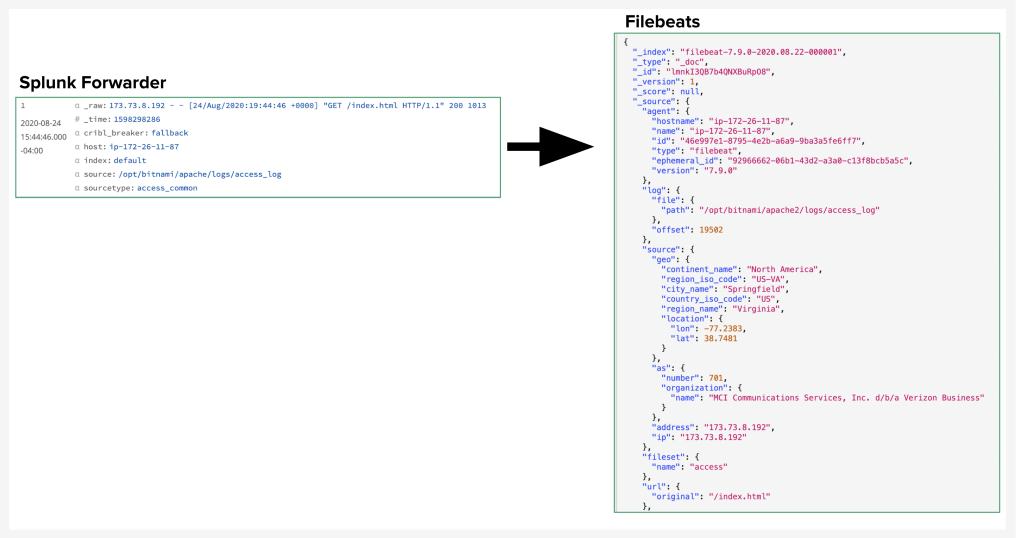
To route data from existing Splunk infrastructure to Elasticsearch services, you might face a daunting task: re-architecting your entire forwarding tier. This could require retooling lots of servers - up to hundreds, or thousands - to uninstall their Splunk forwarders, and swap in Elastic-compatible agents.

Cribl Stream can reduce this effort to just a few hours: Configure one Splunk `outputs.conf` stanza to output to Cribl Stream, and propagate that across all your Splunk servers. Done!

Next, you can easily configure Cribl Stream to listen for Splunk data on one port, and to route that data to all the Elasticsearch destinations you want to feed.

Transforming Data from Splunk to Elastic Format

Also, in Cribl Stream's core, you can easily design a Pipeline that modifies the original Splunk event into Elastic's Common Schema - making it look exactly like an event generated by an Elastic agent. These transformations help you make the most of Elastic's offerings, like Filebeats, etc.



Transforming to Elastic Common Schema

Some of the Cribl Stream Functions useful in transforming Splunk-generated events into Elastic's format are:

- Regex Extract: Extract a portion of the raw event, and place it into a specified field.
- Lookup: key off the host IP to add fields like `hostname`, `name`, `id`, and `type`.
- Eval: Turn key-value pairs into nested JSON objects.
- GeoIP: Correlate source IP to a geographic database.

We'll show all four in our example Pipeline below, although you might need only a subset.

Goat Rid of Some Guesswork

Cribl Stream will offer you further time savings as you configure the internal data transformation. Cribl Stream's Pipeline Data Preview features enable you to test transformations' results as you build your Pipeline, before you commit or run it.

This eliminates blind guesswork in Splunk configuration files to specify source -> index transformations, check the results, and then start all over again. In particular, Cribl Stream's Regex Extract Function provides a regex101-like UI, to facilitate precisely designing and debugging your regex expressions.

Let's goat started on the example.

Configure Splunk Forwarder

First, in a Splunk App, configure a Splunk forwarder (UF or HF) to specify your Cribl Workers as destinations. Use outputs.conf stanzas of this form:

.../outputs.conf

```
[tcpout]
disabled = false
defaultGroup = cribl, <optional_clone_target_group>, ...

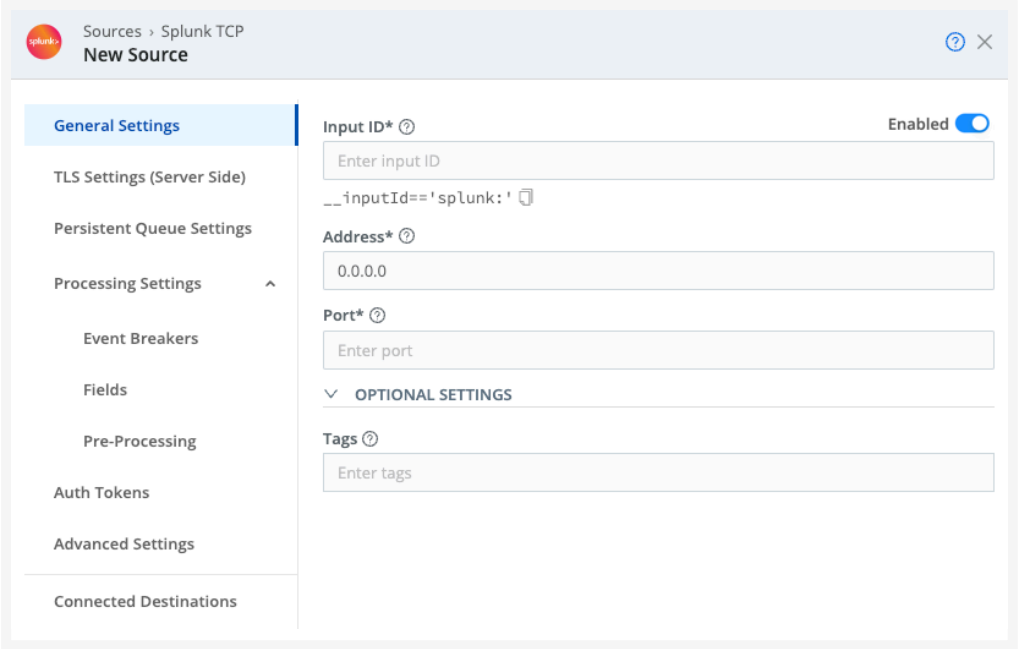
[tcpout:cribl]
server = [<cribl_ip>|<cribl_host>]:<port>, [<cribl_ip>|<cribl_host>]:<port>, ...
sendCookedData=true
```

Copy

Push the app using the deployment server.

Configure Splunk Source in Cribl Stream

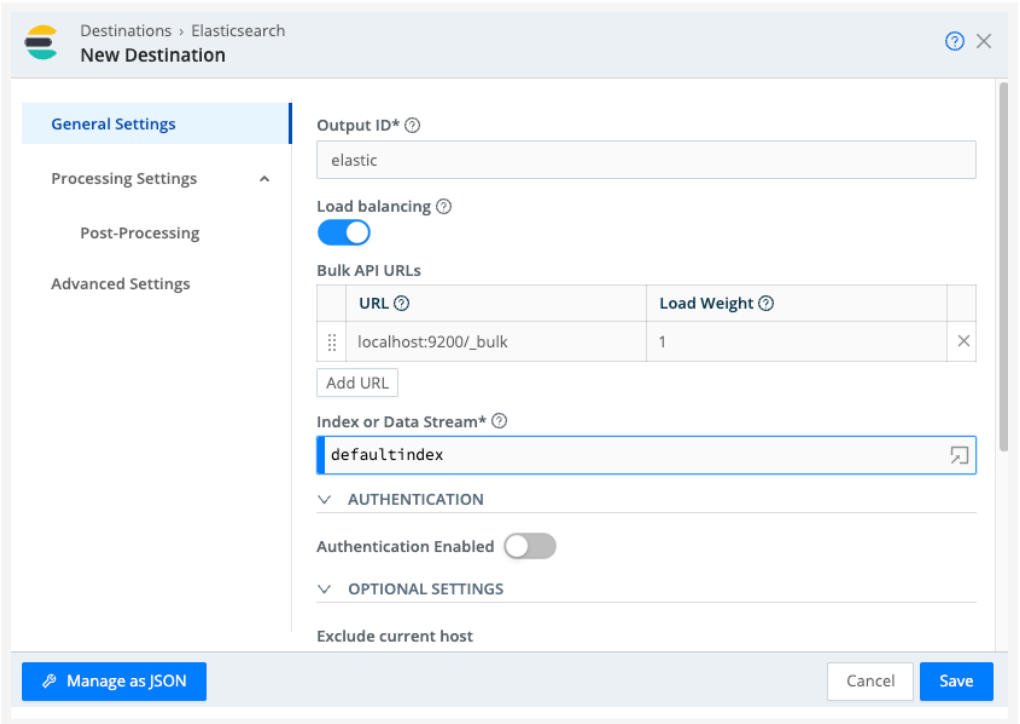
Next, in Cribl Stream, configure a Splunk Source. The key requirement here is to set the **Port** to listen on. (Optionally, you can also configure TLS, Event Breakers, metadata fields, and/or a pre-processing Pipeline.)



Splunk Source configuration

Configure Elasticsearch Destination

To configure Cribl Stream's output, set up an Elasticsearch Destination by specifying the **Bulk API URL** and **Index**.



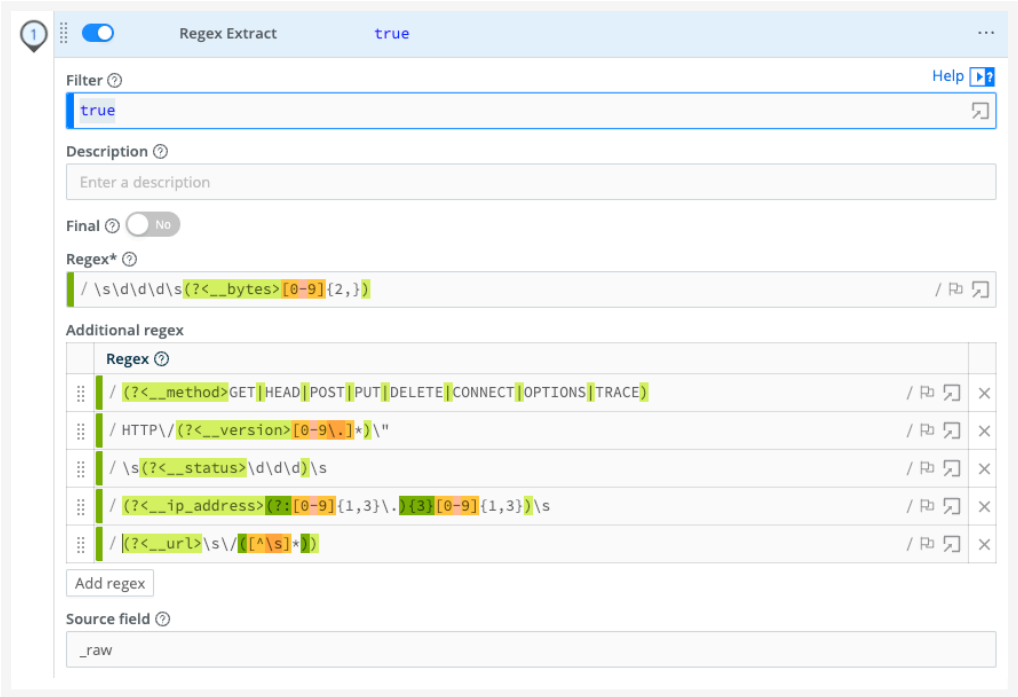
Elasticsearch Destination configuration

Configure Pipeline

Next, this section shows several Functions that you can assemble into a Pipeline to transform incoming Splunk events to match the Elastic Common Schema.

Regex Extract Function

First, use a Regex Extract Function to break the Splunk events into fields. Try the sample configuration shown below:



Regex Extract Function

Here are the six rows of regex in this example:

Regex; Additional Regex

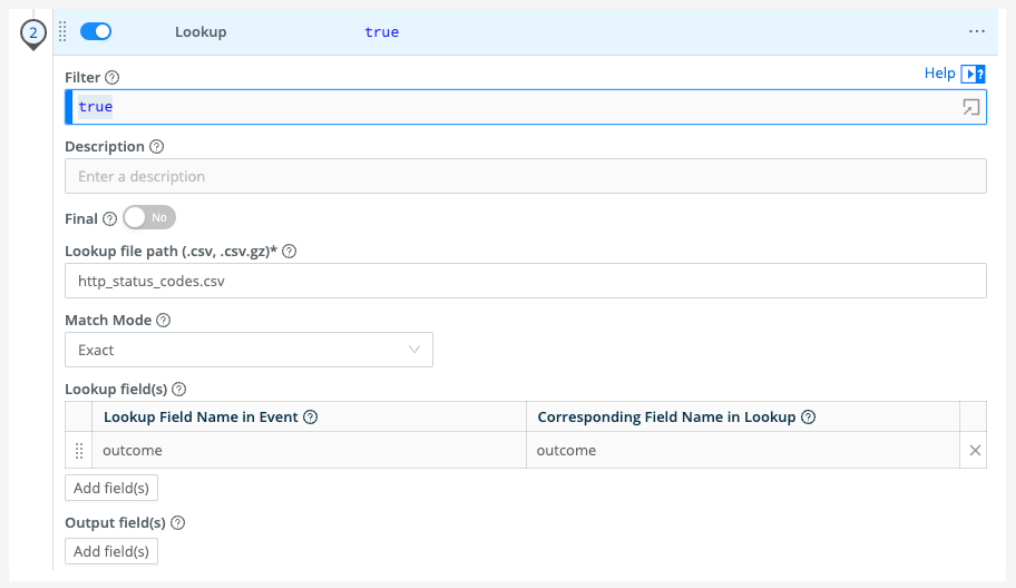
```
/\s\d\d\d\s(?<__bytes>[0-9]{2,})/
/(?<__method>GET|HEAD|POST|PUT|DELETE|CONNECT|OPTIONS|TRACE)/
/HTTP\/(?<__version>[0-9\.]*)\"/
/\s(?<__status>\d\d\d)\s/
/(?<__ip_address>(?:[0-9]{1,3}\.){3}[0-9]{1,3})\s/
/(?<__url>\s\/([^\s]*))/
```

Copy

As you refine your expression, capture a sample of incoming Splunk data to test your regex's results in Cribl Stream's right Preview pane.

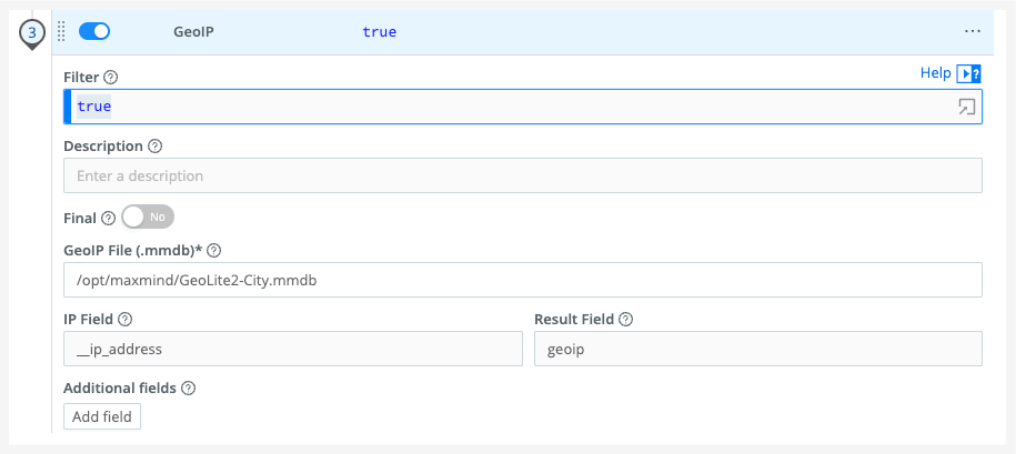
Lookup Function

In this example, we next add a Lookup Function, to translate HTTP error codes to readable text. Note this Function's optional **Reload Period** field, in which you can define a reload interval for a lookup file whose contents refresh frequently.



GeoIP Function

To enrich the Splunk data, we next use a GeoIP Function. This a specialized lookup against a database of IP addresses by geographic location. This Function's output can provide Elasticsearch with `location` fields like `lat` and `long`.



GeoIP specialized lookup

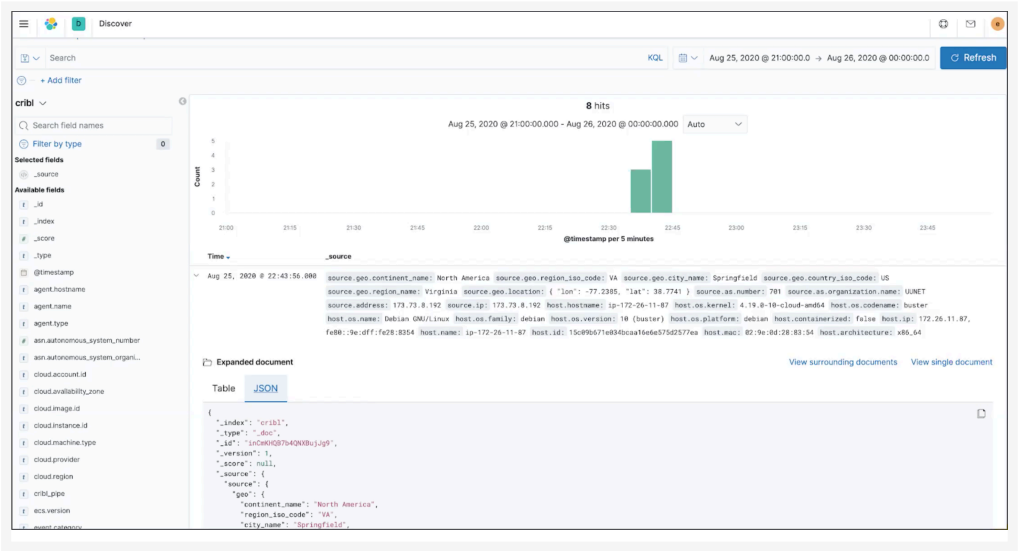
Eval Function

Finally, to further enrich the outbound events, the Pipeline uses an Eval Function. This adds multiple key-value pairs that define and populate fields conforming to the Elastic Common Schema.

Eval Function

Results

After attaching your Pipeline to a Route, here's an an exported event, all happy in Elasticsearch with nested JSON.



Event as exported to Elasticsearch

For More Info

8.8.3.4. Splunk To Exabeam

In many organizations, the IT department uses a tool like Splunk for operational logging, while the Security team relies on Exabeam to prevent insider threats. These tools use separate agents to access the same data, leading to some data-sharing conundrums:

- Installing the Exabeam agent in parallel with Splunk would duplicate the data.
- Some servers, like domain controllers, allow only a single agent. In this case, you can't feed two platforms with the same data.
- Querying Splunk for the data would introduce extra latency and overhead costs.
- Forwarding data directly from Splunk Universal Forwarders (UFs) is a nonstarter. Classic logs from Splunk UFs embed newlines and special characters, which break Exabeam's parser.

Cribl Stream can help you unblock these issues: Ingest data directly into Cribl Stream from Splunk UFs running on the domain controller, and transform the events in Stream before routing them to Exabeam.

While this example is written around a Splunk-to-Exabeam scenario, you can use the same general techniques to connect and transform data between several other upstream and downstream services.

Transform Data from Splunk to Exabeam's Format

In Cribl Stream's core, you can easily design a Pipeline that modifies the original Splunk event to fit the format that Exabeam expects. Some Cribl Stream Functions useful for this transformation are:

- Serialize: Remove all of the newlines and spaces, and then transform the data into `JSON` format.
- Mask: Remove the special characters, and replace them with space.
- Eval: Create a new field called `Message`, and remove everything else using the **Remove Fields** option.

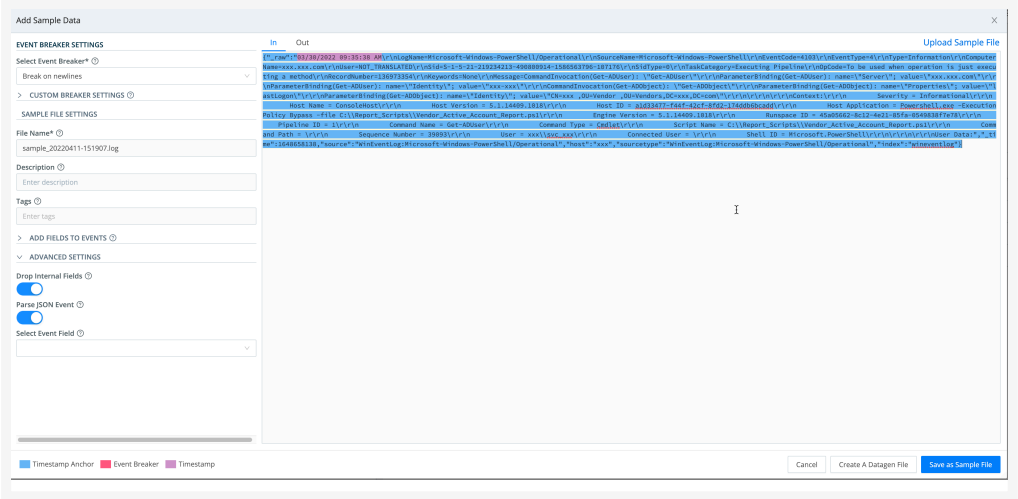
In this guide, we'll show you how to:

1. Capture sample logs.
2. Apply the Functions (outlined above) to transform the sample log into Exabeam's expected format.
3. Validate your fields with Exabeam Parsers.
4. Stream your event to Exabeam to test the entire sequence.

Capture Sample Logs

Start with sample logs of the event data you plan to work with. In our example, we'll copy and paste the log sample straight into Cribl Stream.

Once you've pasted the log sample, enter a unique **File Name** on the modal's left side, then select **Save as Sample File** at right.



Saving captured data

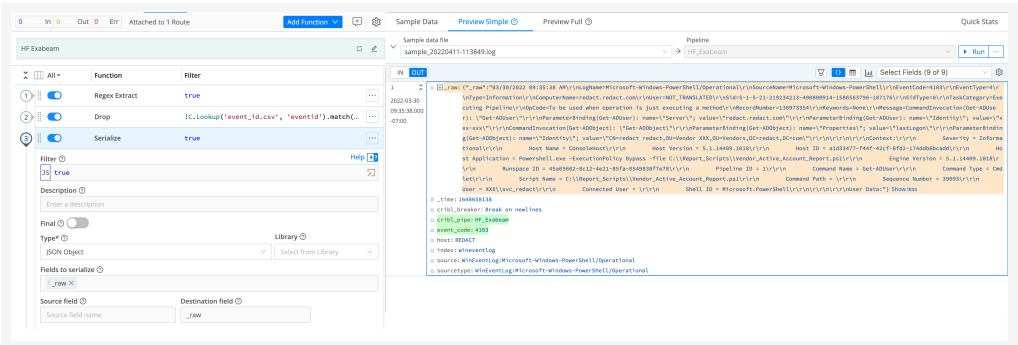
In your production environment, you can filter incoming events in real time (e.g., using a filter expression like `Windows Security logging`) to identify your in-scope Exabeam data.

Configure Pipeline

Next, this section shows relevant Functions that you can assemble into a processing Pipeline to transform the sample log into Exabeam's expected format.

Serialize Function

First, use a Serialize Function to change the event's format into `JSON`. Then, remove the extra lines and spaces, because Exabeam treats each newline as a separate event.

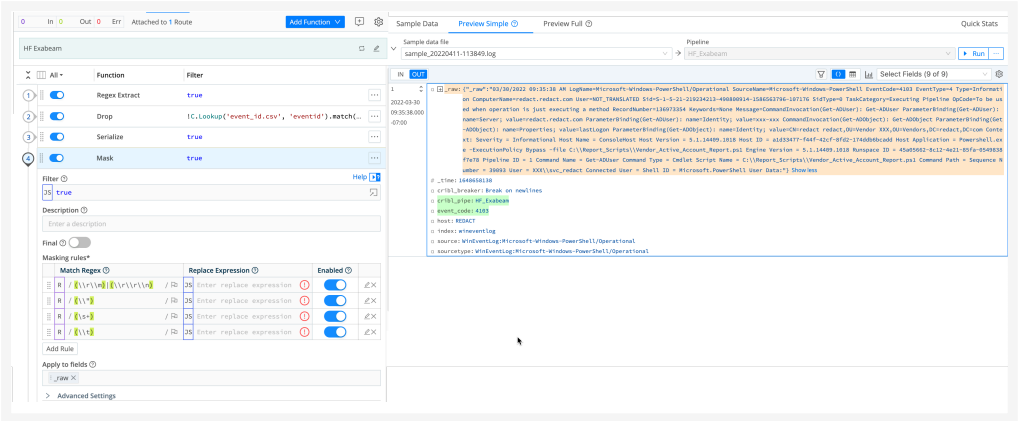


Reformatting the event

Mask Function

Next, use a Mask Function to remove extra `\n` and `\r` characters. (Otherwise, Exabeam's regex filter would reject the characters and drop whole fields that need to be matched and extracted.)

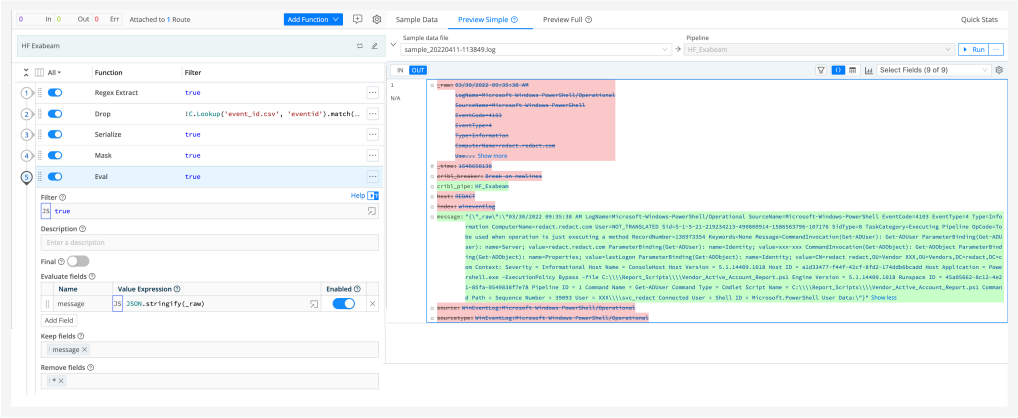
In this example, we are using a Mask Function to remove these special characters and replace them with spaces.



Extraneous newlines/returns to remove

Eval Function

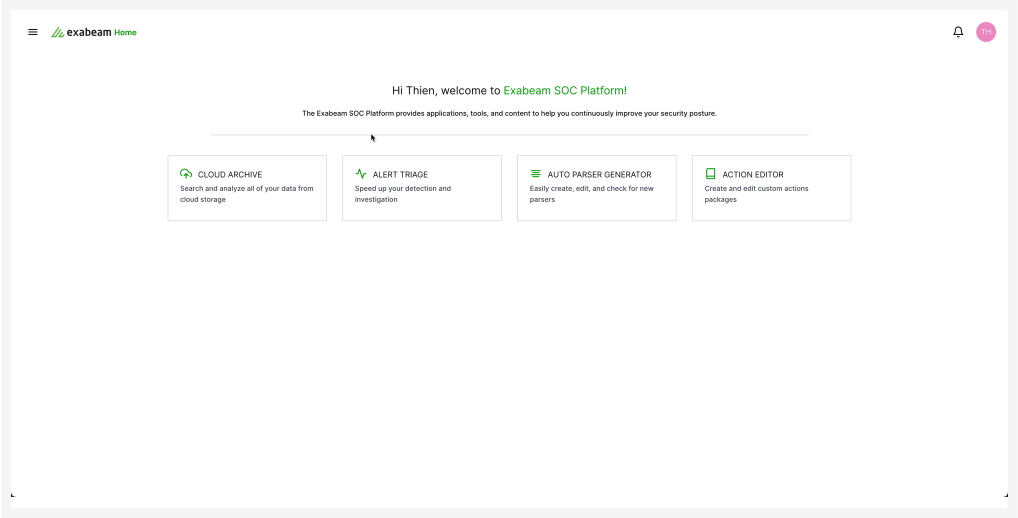
As the last step in Cribl Stream, use an Eval Function to enrich the outbound events, by adding key-value pair that defines and populates a field conforming to the Exabeam schema. Name the new field `Message`. (The `Message` field will populate `Raw Message` in the Exabeam Data Lake.) Remove everything else using **Remove Fields**.



Eval Function to add an Exabeam-specific field

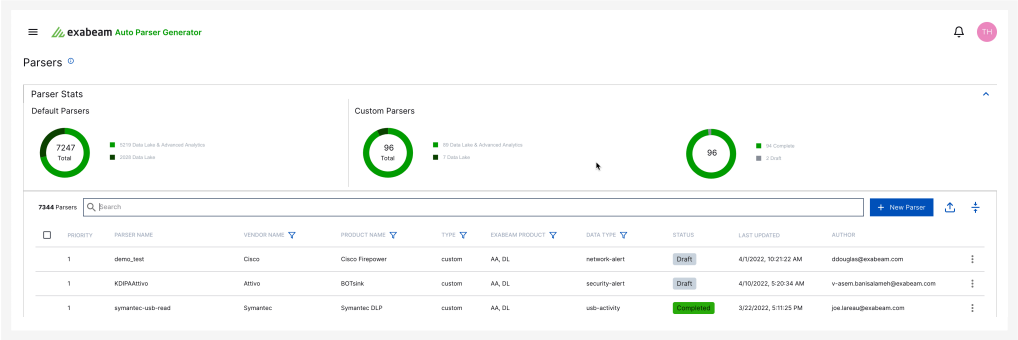
Goat the Fields?

Use Exabeam's Auto Parser Generator (APG) tool to validate your fields. If you don't have the APG tool, contact Exabeam support to request access via your ECP account. This tool validates matching parsers based on your event.



APG tool access in Exabeam

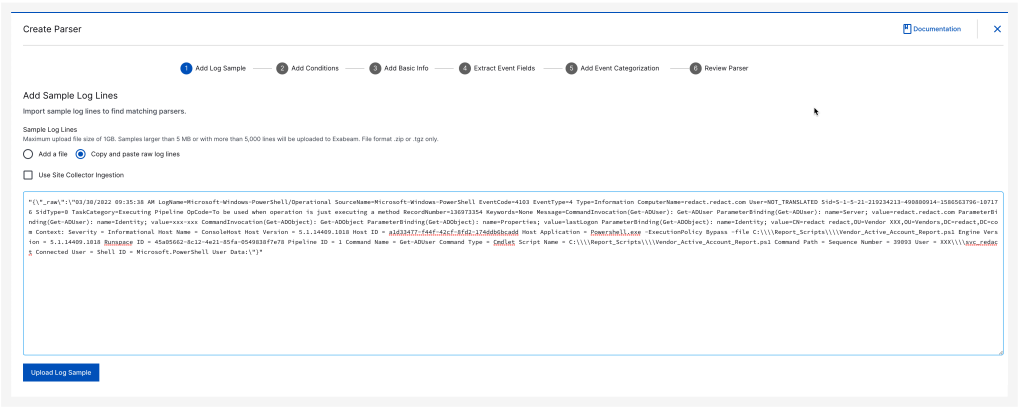
In the APG tool, select **New Parser**.



New Parser option

On the **Create Parser** page, select **Copy and paste raw log lines**.

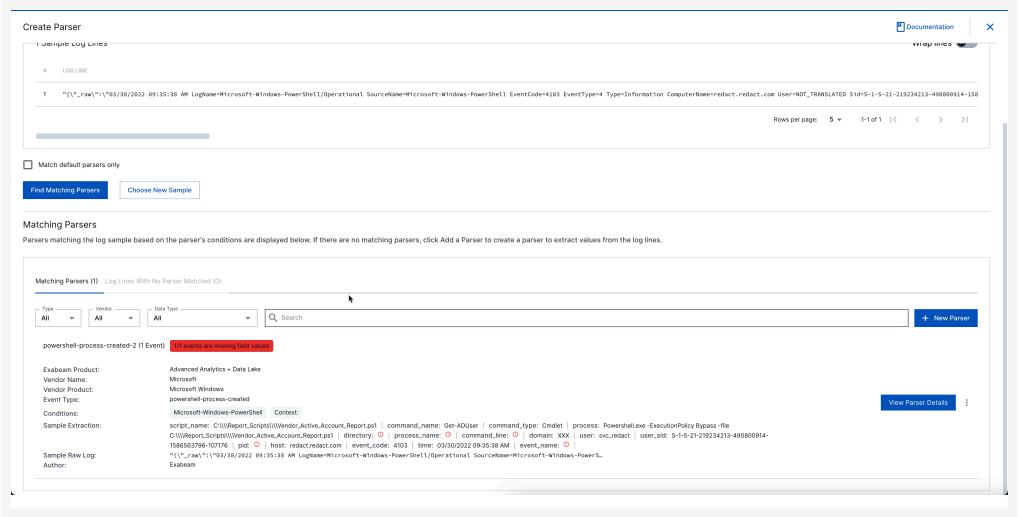
In the text box, paste the **Message** field value from the your sample file and select **Upload Log Sample**.



Paste Message Field

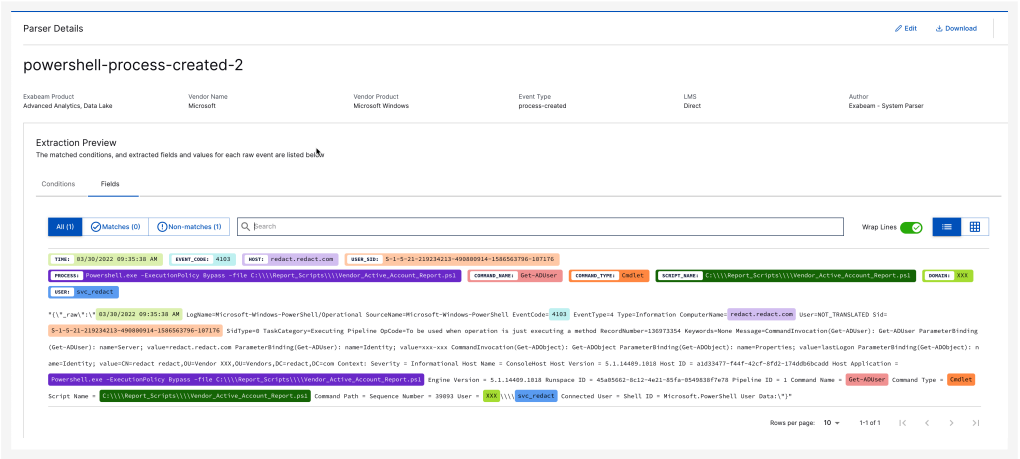
Copy the *Message** field value to your clipboard for a later step in Stream it to Exabeam.

Select **View Parsing Details** to view parsers matching this event type.



New Parser option

Validate that all the fields you need are populated: `src_ip`, `dest_host`, `user`, etc.



Paste Message Field

Do not change Field Names in Exabeam (e.g., `src_ip` to `source_IP`). Exabeam has its own Field Name format that matches its Advanced Analytics template.

At the bottom of the **Extraction Preview** page, select **Configuration Files** to inspect the parsers. If required, you can download the parser to change the regex configurations.

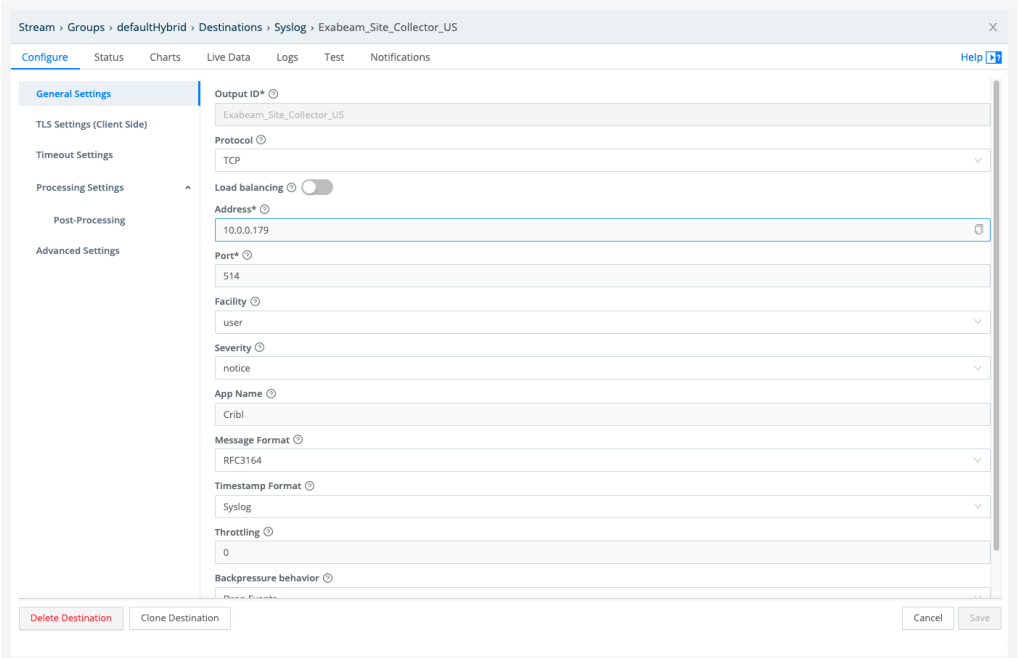
Parser Details

Stream It to Exabeam

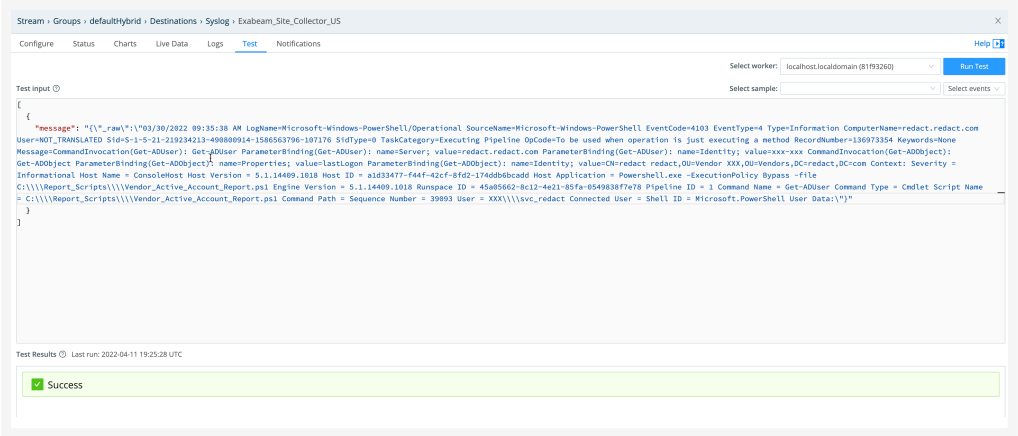
Our final test is to send a single event to Exabeam, and validate the results in Exabeam's Data Lake or Advanced Analytics.

Before testing, configure your Exabeam implementation's `Asset Name` and `Username` to a dummy account. Exabeam's Advanced Analytics has hundreds of models out of the box, and you do not want to ruin these models while testing out your data.

1. From Cribl Stream Home, select a Worker Group, and then select **Data** > **Destinations** > **Syslog**.
2. Select **Add Destination** to configure and save a new Syslog Destination to export data to Exabeam. Configure the **Address**, **Port**, **Message format**, **Timestamp format**, and other options to match your Exabeam implementation.

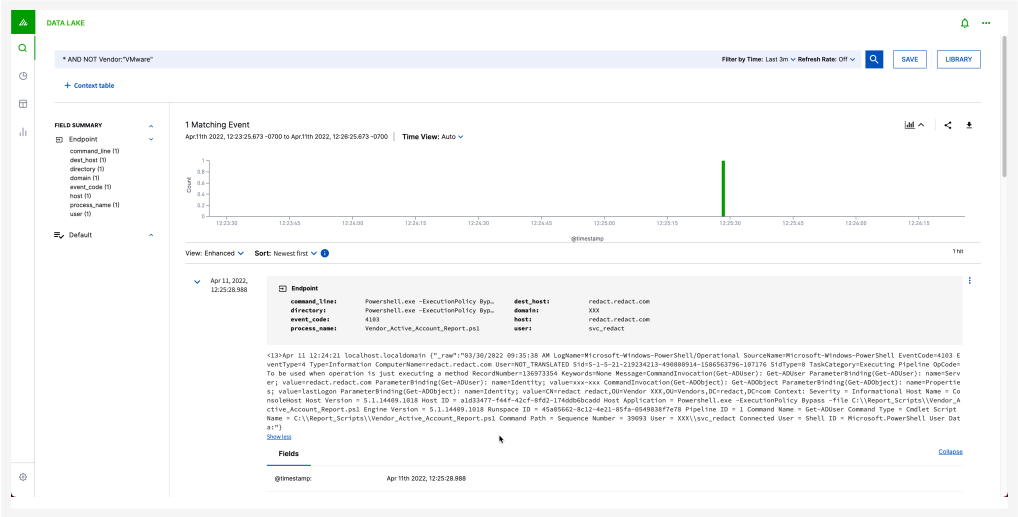


3. Reopen the Syslog Destination. On its **Test** tab, copy and paste the **Message** field's value you copied onto your clipboard above.



Syslog Test tab

4. Within a few seconds, you should see your event display in the Exabeam Data Lake. Search for your forwarder IP/Host (Example syntax: `Forwarder:"IP/host`).



Validating event in Exabeam

5. You can validate that you have the right parser by matching the `exa_parser_name` with the parser in the Auto Parser Generator.

8.8.3.5. Splunk Stream To Cribl Stream

Splunk Stream is a set of three Splunk packages that, combined, enable you to capture and work with streams of network event data. This adds up to a collector for streaming data. You can deploy Splunk Stream in either of two forms:

- As part of a Splunk Universal Forwarder (we'll call this the forwarder-based config), sending data to a Cribl Stream Splunk TCP Source; or
- As an independent stream forwarder (we'll call this the ISF config), running on a compatible Linux machine, and sending data to a Cribl Stream Splunk HEC Source.

In either case, the collector process (not to be confused with a Cribl Stream Collector) will need to call home to a Splunk Enterprise process with the Splunk Stream app installed. You'll manage the collector's settings in Splunk Enterprise.

For the broader Splunk configuration story, see Splunk's documentation. Here, we'll explain one small part of the Splunk configuration process: how to configure Splunk Stream to send the data it captures to Cribl Stream. See the section below - either Forwarder-based or ISF - that corresponds to your use case.

Setting Up the Forwarder-Based Config

Install the Stream TA on the Universal Forwarder targets, either manually or via the deployment server. You'll need to add a new `inputs.conf` stanza pointing to your Splunk Stream App management instance. Adapt the example stanza below, replacing the placeholder with the hostname or IP address of your management host.

New stanza in config file

```
[streamfwd://streamfwd]
splunk_stream_app_location = https://<your_management_host>:8000/en-us/custom/splunk_
disabled = 0
```

Copy

The `outputs.conf` for the Universal Forwarder with Splunk Stream App is the same as for a Universal Forwarder with a non-streaming collector. See these examples.

To verify that your setup is working, run a Live Capture in your Cribl Stream Splunk TCP Source with appropriate filters. Once the Universal Forwarder is sending data to your Cribl Stream Workers, you're ready to begin working with sample captures, Routes, and Pipelines.

If no data seems to be coming through, check the logs located at `/opt/splunkforwarder/var/log/splunk/splunkd.log` on each machine where your Forwarder is running.

Setting Up the ISF Config

Splunk Stream as an independent stream forwarder (ISF) can run only on Ubuntu- or RHEL-based x64 Linux machines that have bzip2 installed.

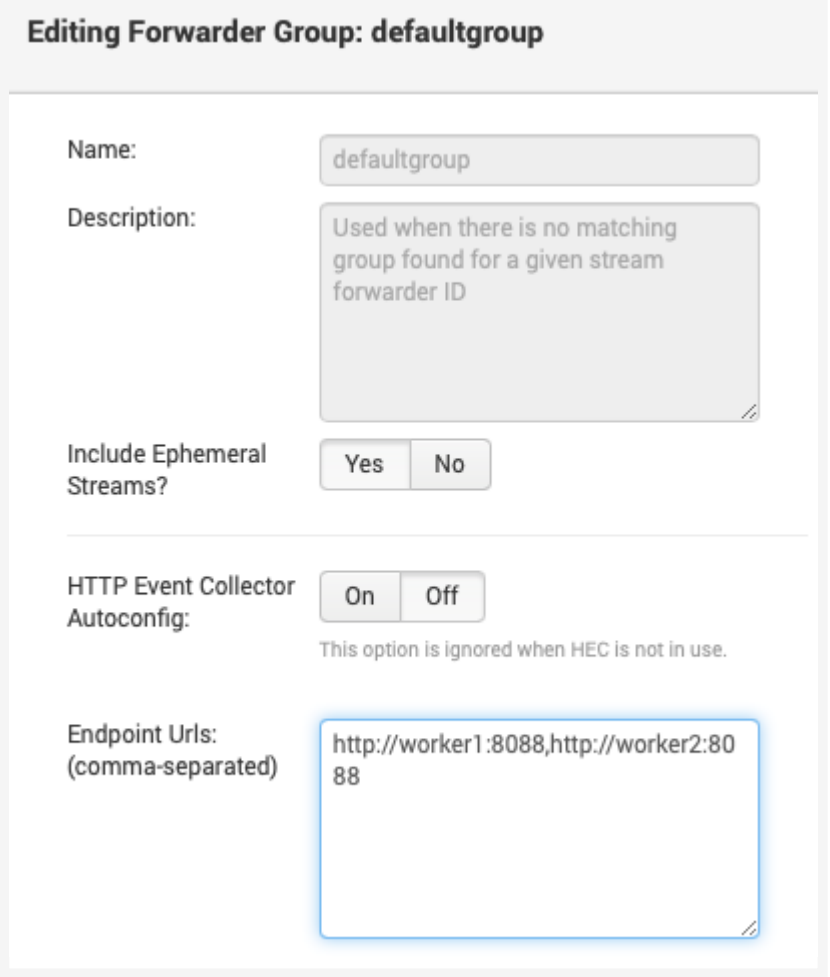
To install Splunk Stream, begin in the Splunk UI:

- In the Stream App, navigate to **Configuration** > **Distributed Forwarder Management**.
- Click the **Install Stream Forwarders** button.
- In the resulting modal, under the text `To get data from other machines, run this command on your data source machine`, copy the `curl` command. E.g.:
  `curl -sSL http://DellT20:8000/en-us/custom/splunk_app_stream/install_streamfwd | sudo bash`

On each Linux machine where you want to install Splunk Stream, run the `curl` command that you copied. Installation will fail if the machine lacks `bzip2`.

Once installation is complete, return to the Splunk UI.

1. To update the HEC endpoint URL, navigate to **Actions** > **Edit Forwarder Group** for the desired group.
2. Toggle **HTTP Event Collector Autoconfig** off.
3. In the **Endpoint URLs** field, list your Cribl Stream Worker URLs, as shown here:



Editing forwarder group to specify Cribl Worker URLs

4. Click **OK**.

Finally, on each Linux machine where you're running Splunk Stream, update the ISF settings with the proper HEC token. (While it is technically possible to run without a token, Cribl strongly recommends against this practice.)

1. In Cribl Stream, copy the HEC token from your Cribl Stream Splunk HEC Source definition (the value of the `__hecToken` internal field).
2. On the desired Linux machines, open `/opt/streamfwd/local/streamfwd.conf` in a text editor.
3. Add the following stanza, substituting your HEC token for the placeholder:

```
[streamfwd]
httpEventCollectorToken = <HEC_token_from_your_Cribl_Stream_Source>
```

Copy

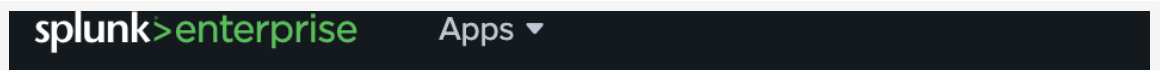
4. Run the following command to restart the ISF:

```
systemctl restart streamfwd
```

Copy

To verify that your setup is working, run a Live Capture in your Cribl Stream Splunk HEC Source with appropriate filters.

You can also check ISF status in Splunk. Navigate to **Apps** > **Splunk Stream** > **Admin Dashboards** > **Stream Forwarder Status**:



8.8.3.6. Decryption Of Data In Splunk

Currently, Cribl Stream supports decryption only when Splunk is the end system. In Splunk, decryption is available to users of any role with permissions to run the `cribldecrypt` command that ships with Cribl App for Splunk. Further restrictions can be applied with Splunk **capabilities**. This page provides details.

For clarity, Cribl introduced the `cribldecrypt` as an alias to the original `decrypt` command. Use this alias to avoid conflicts with Splunk's internal commands. (We show it in the examples below.) Both are, in fact, aliases to the actual command: `/path/2/cribl --splunk-decrypt`. You can use both aliases.

Usage

The `cribldecrypt` command is used to display Cribl-encrypted fields in cleartext. It is an alias to the `decrypt` command. This command decrypts fields only for the encryption keys that the user can access.

The example below retrieves data from a Splunk index with Cribl-encrypted data, and pipes it to the `cribldecrypt` command:

```
index=index_with_encrypted_fields | cribldecrypt
```

Copy

Decrypting in Splunk

Decryption in Splunk is implemented via a custom command called `cribldecrypt`. To use the command, users must belong to a Splunk role that has permissions to execute it. Capabilities, which are aligned to Cribl Key Classes, can be associated with a particular role to further control the scope of `cribldecrypt`.

Decrypt Command Is Search Head ONLY

To ensure that keys don't get distributed to all search peers - including peers that your search head can search, but you don't have full control over - `cribldecrypt` is scoped to run locally on the installed search head.

Restricting Access with Splunk Capabilities

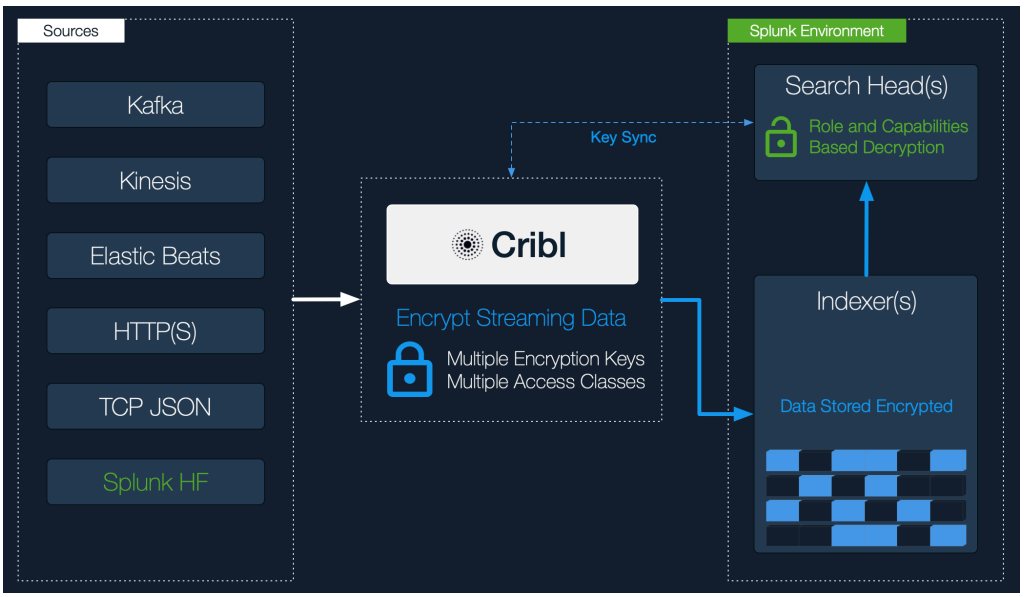
In Splunk, capability names should follow the format `cribl_keyclass_N`, where `N` is the Cribl Key Class. For example, a role with capability `cribl_keyclass_1` has access to all key IDs associated with key class `1`.

Capability Name	Corresponding Cribl Key Class

`cribl_keyclass_1`
`cribl_keyclass_2`
`...`
`cribl_keyclass_N`
	`1`
	`2`
	`...`
	`N`

Configuring Splunk Search Head to Decrypt Data

You set up decryption in Splunk according to this schematic:



1. Download the Cribl Stream App for Splunk from Cribl's Download Cribl Stream page: In the **Select Release Version** dropdown, select the Cribl App for Splunk option.

2. To install the Cribl Stream App for Splunk on your search head, untar the package into your `$SPLUNK_HOME/etc/apps` directory.
   The app will run in search head mode by default. If the app has previously been installed and later modified, you can convert it to search head mode with the command: `$CRIBL_HOME/bin/cribld mode-searchhead`. (When installed as a Splunk app, `$CRIBL_HOME` is `$SPLUNK_HOME/etc/apps/cribl`.)

3. Assign permissions to the `cribldecrypt` command, per your requirements.

4. Assign capabilities to your roles, per your requirements. If you'd like to create more capabilities, ensure that they follow the naming convention defined above.

5. In the `$SPLUNK_HOME/etc/apps/cribl/local/cribl/auth/` directory, sync `cribl.secret` | `keys.json`. (To successfully decrypt data, the `cribldecrypt` command will need access to the same keys that were used to encrypt, **in the Cribl instance where encryption happened**.)
   - In a single-instance deployment, the `cribl.secret` and `keys.json` files reside in: `$CRIBL_HOME/local/cribl/auth/`.

- In a distributed deployment, these files reside on the Leader Node in: `$CRIBL_HOME/groups/<group-name>/local/cribl/auth/`.
- When using Cribl Stream's UI, you can download these files by clicking the **Get Key Bundle **button.

Sync/copy these files over to their counterparts on the search head (decryption side). In a non-Splunk integration, you would copy these assets to wherever decryption will take place.

Modifying Keys

When you update keys by editing the `keys.json` file, you must add them back to the directories above (respectively, on a single instance or on a distributed deployment's Leader Node).

8.8.3.7. Stream-To-Splunk Encryption

Encrypt at Ingest-Time and Decrypt in Splunk

With Cribl Stream, you can encrypt your sensitive data in real time before it's forwarded to and stored at a destination. Using the out-of-the-box Mask function, you can define patterns to encrypt with specific key IDs or key classes. To decrypt in Splunk, you will need to install Cribl App for Splunk on your search head. (The app will default to `mode-searchhead`.)

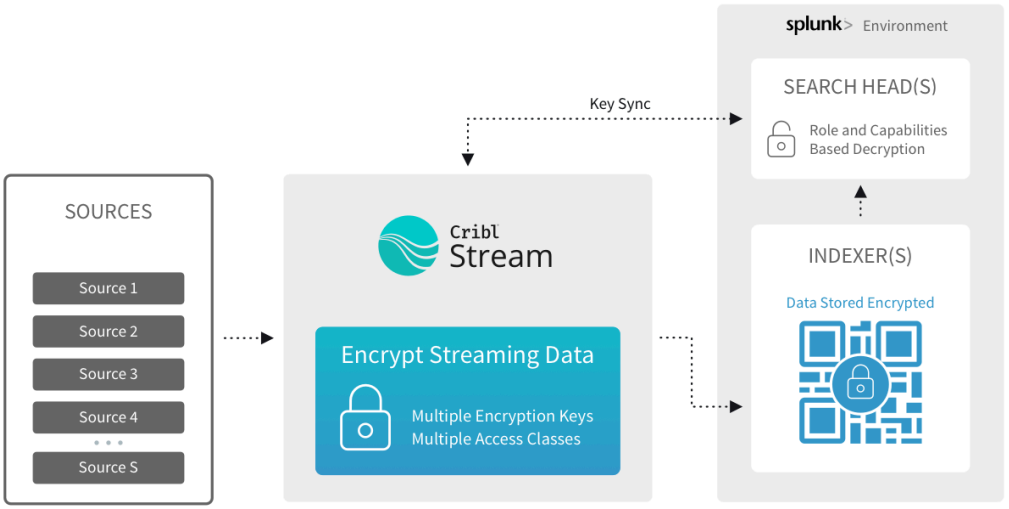
Keys and Key Classes

Symmetric encryption keys can be configured through the CLI or the UI. They're used to encrypt the patterns, and users are free to define as many keys as required.

Key classes are collections of keys that can be used to implement multiple levels of access control. Users (or groups of users) that have access to data with encrypted patterns can be associated with key classes. You can use these classes to provide more-granular access rights, such as read versus decryption permissions on a dataset.

Encrypt in Cribl Stream and Decrypt in Splunk

1. Define one or more keys and key classes on Cribl Stream. (See UI- and CLI-based instructions.)
2. Sync `auth` with the decryption side (Splunk Search Head). (The Splunk-side directory is `$SPLUNK_HOME/etc/apps/cribl/local/cribl/auth/`.)
3. Apply the Mask function to patterns of interest, using C.Crypto.encrypt().
4. Decrypt on the Splunk search head, using Role-Based Access Control on the `decrypt` command.



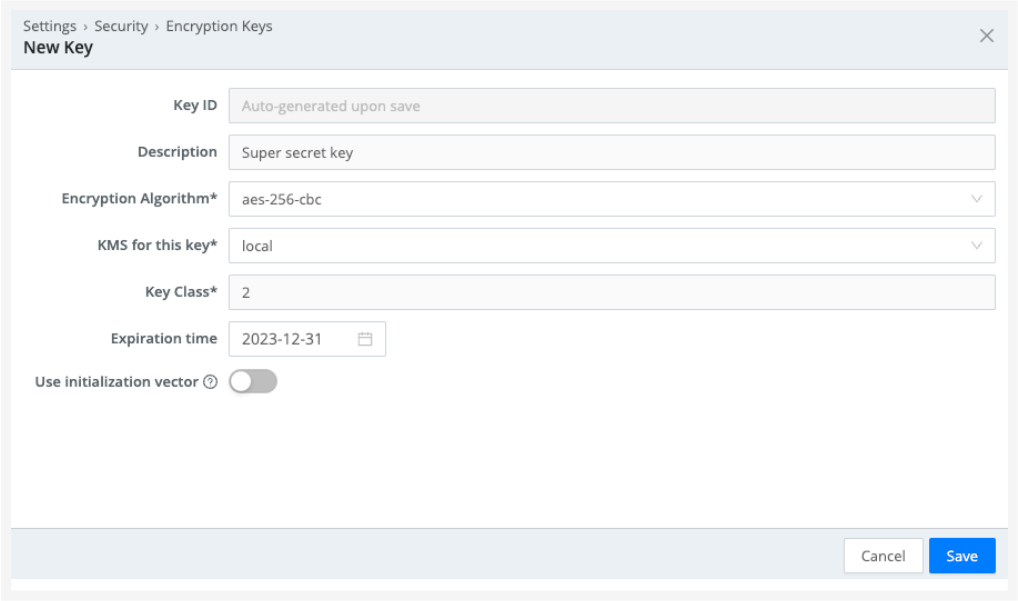
Encrypting in Cribl Stream, decrypting in Splunk

Examples

Encryption Side

You can generate keys via the UI or the CLI.

To generate keys via the UI, access **Group Settings** > **Security** > **Encryption Keys**:



Adding a new encryption key

To generate one or more keys via the CLI, pattern your commands after these examples.

In a single-instance deployment:

```
$CRIBL_HOME/bin/cribl keys add -c 1 -i ... $CRIBL_HOME/bin/cribl keys add -c <N> -i
```

In a distributed deployment, to generate keys on a Worker Group named `uk`:

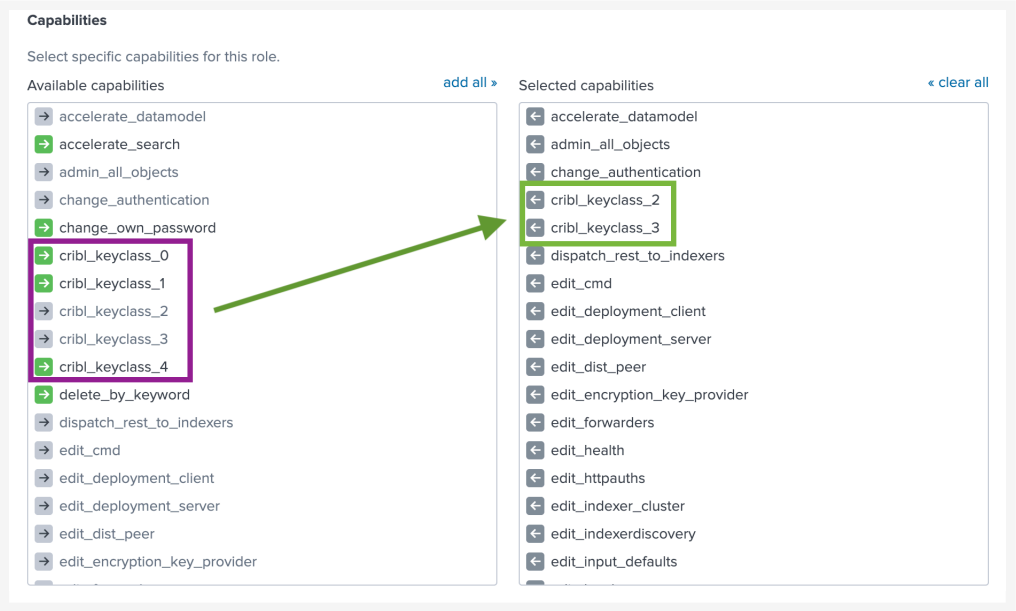
```
$CRIBL_HOME/bin/cribl keys add -c 1 -i -g uk ... $CRIBL_HOME/bin/cribl keys add -c <N> -i -g uk
```

Add `-e <epoch>` to the above commands if you'd like to set expiration for your keys.

For all command/syntax options, see Adding Keys.

Decryption Side

- Download the Cribl Stream App for Splunk from Cribl's Download Cribl Stream page: In the **Select Release Version** dropdown, select the Cribl App for Splunk option.
- To install the Cribl Stream App for Splunk on your search head, untar the package into your `$SPLUNK_HOME/etc/apps` directory. The app will default to `mode-searchhead`.
- Assign permissions to the `decrypt` command, per your requirements.
- Assign capabilities to your Roles, per your requirements. Capability names should follow the format `cribl_keyclass_N`, where `N` is the Cribl Key Class. For example, a role with capability `cribl_keyclass_1` has access to all key IDs associated with key class `1`. You can use more capabilities, as long as they follow this naming convention.



Selecting capabiities

- In the `$SPLUNK_HOME/etc/apps/cribl/local/cribl/auth/` directory, sync `cribl.secret` | `keys.json`. (To successfully decrypt data, the `decrypt` command will need access to the same keys that were used to encrypt, **in the Cribl instance where encryption happened**.)

- In a single-instance deployment, the `cribl.secret` and `keys.json` files reside in: `$CRIBL_HOME/local/cribl/auth/`.
- In a distributed deployment, these files reside on the Leader Node in: `$CRIBL_HOME/groups/<group-name>/local/cribl/auth/`.
- When using Cribl Stream's UI, you can download these files by clicking **Get Key Bundle**.

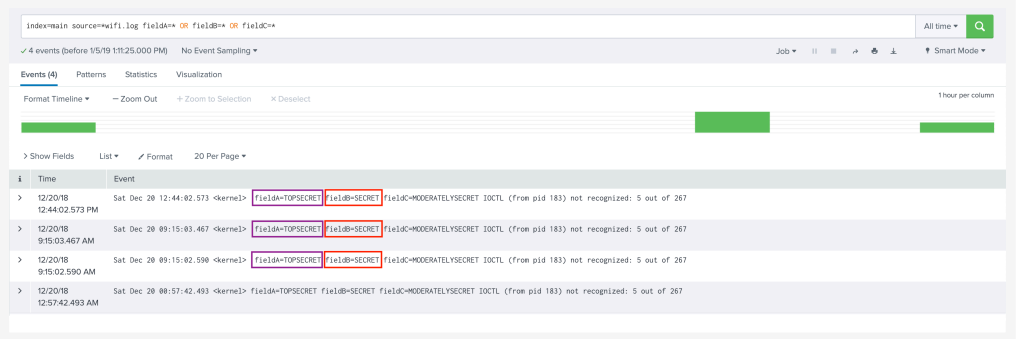
Sync/copy these files over to their counterparts on the search head (decryption side). In a non-Splunk integration, you would copy these assets to wherever decryption will take place.

Modifying Keys

When you update keys by editing the `keys.json` file, you must add them back to the directories above (respectively, on a single instance or on a distributed deployment's Leader Node).

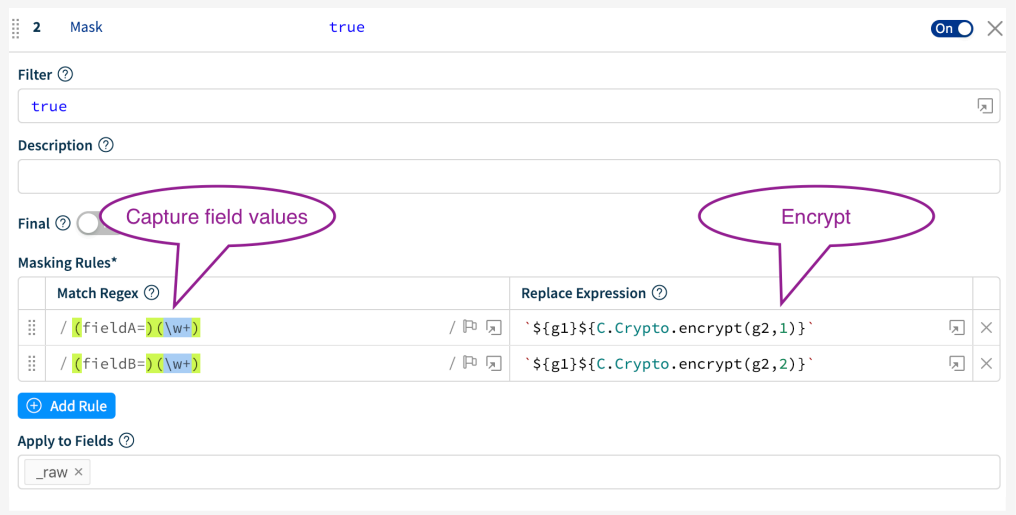
Usage

Before Encryption: Sample un-encrypted events. Notice the values of `fieldA` and `fieldB`.



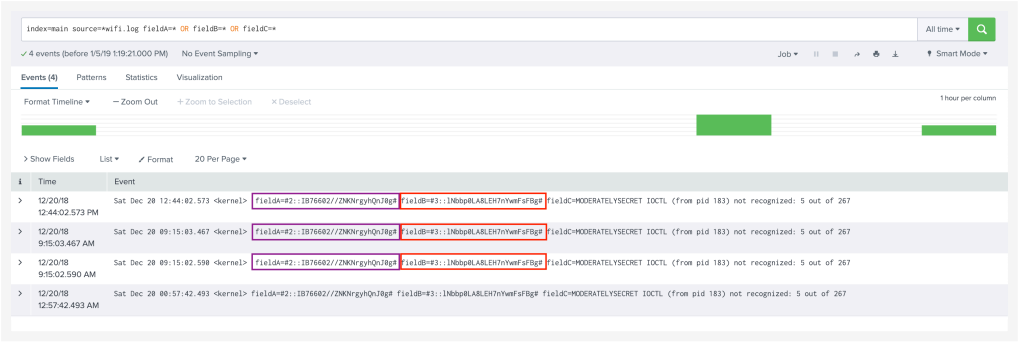
Events before encryption

Next, encrypt `fieldA` values with key class `1`, and `fieldB` with key class `2`.



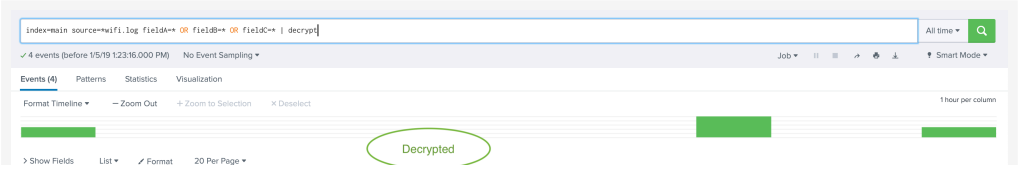
Encrypting two fields with separate key classes

After Encryption: again, notice the values of `fieldA` and `fieldB`.



Both fields encrypted

Here, we've decrypted `fieldB` but not `fieldA`. This is because the logged-in user has been assigned the capability `cribl_keyclass_2`, but not `cribl_keyclass_1`.



8.8.4. Syslog

The following topics provide detailed guides and better practice for integrating with Syslog services.

Source	Description
Syslog Best Practices	Best practices for processing syslog events
Palo Alto Syslog to Cribl.Cloud	Palo Alto Syslog Forwarding to Cribl.Cloud

8.8.4.1. Syslog Best Practices

Cribl Stream can process a syslog stream directly. Moving to Cribl Stream from existing syslog-ng or rsyslog servers fully replaces those solutions with one that is fully supported and easily managed.

Processing syslog in Cribl Stream allows you to readily address these common challenges of ingesting data from syslog senders:

- **Architecture**: Cribl Stream routes the syslog stream directly, immediately, and securely to the destinations of your choice, reducing latency and management overhead.
- **Volume**: Removing redundant data and unnecessary fields in Cribl Stream typically reduces volume 20-30% overall. It also optimizes the data for downstream services like Splunk or Elasticsearch.
- **Timestamp handling**: Cribl Stream intelligently processes events sent from different time zones. It can embed a new, consistent timestamp, and can auto-correct timestamps that are off by an exact number of hours.
- **Severity/Facility accuracy**: Each syslog event begins with a bracketed integer that represents Facility and Severity, as defined in the Syslog Protocol. Cribl Stream translates this code (e.g., `<165>`, `<0>`) into the correct Facility and Severity values.
- **Metadata**: Cribl Stream can automatically set metadata fields, including `sourcetype` and `index`.

This tutorial outlines best practices for replacing your syslog server with Cribl Stream. To go even a bit deeper, check out this Cribl Office Hours video.

The Goal: Optimizing Syslog Events

By default, a Cribl Stream Syslog Source produces eight fields: `_time`, `appname`, `facility` (numeric), `facilityName` (text), `host`, `message`, `severity` (numeric), and `severityName` (text).

Default, parsed syslog event

While this default parsing makes the output much more readable, we haven't saved any volume - and we now have redundant pairs of fields (numeric versus text) that represent facility and severity.

Our next logical step is to streamline syslog events to something more like this:

```
3
2021-11-18
16:33:06.000
-08:00
  _raw: dropbear[25092]: Child connection from 222.186.30.76:19708
  _time: 1637281986
  cribl_pipe: CriblSyslogPreProcessing
  facility: 10
  facilityName: authpriv
  host: 66.241.71.15
  index: syslog
  message: dropbear[25092]: Child connection from 222.186.30.76:19708
  severity: 6
  severityName: info
  source: syslog:in_syslog:udp
  sourcetype: syslog
```

Default, parsed syslog event

This accomplishes all of the following:

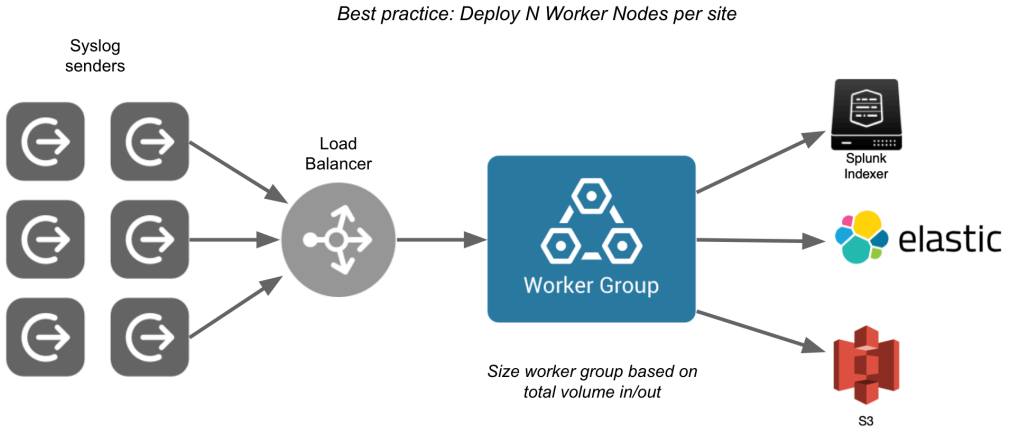
- Extracts the essentials.
- Removes the redundancies.
- Adds a new field to identify the Cribl Stream Pipeline (which we're about to build).
- Adds metadata that the Destination needs.
- Shrinks the outbound `_raw` payload to just its `message` component.

Once we optimize syslog in this way, we can achieve still further efficiencies by dropping or downsampling frequent events, and by balancing high-volume syslog inputs across Cribl Stream worker processes.

Architecture: On-Prem Cribl Stream Deployments

Syslog data, especially when sent via UDP, is best collected as close to the source as possible. Ideally, you should capture syslog data **at its origin**. (This is true of syslog in general, not just syslog processed in Cribl Stream.)

Also, because syslog senders have no built-in load balancing, Cribl strongly recommends using a load balancer to distribute the load across multiple Worker Nodes.



Example architecture for a single site or location

The load balancer shown above is dedicated only to communication between the syslog senders and the Stream Worker Nodes. Any load balancing between the Worker Group and its Stream Leader would be handled by a separate load balancer.

Load Balancers

The load balancer in front of the Leader UI can be an Application Load Balancer or a Network Load Balancer.

The load balancer between the Cribl Workers and the Cribl Leader listening on port 4200 must be a Network Load Balancer or other load balancer that supports health checks.

For load balancer configuration examples showing how to distribute syslog traffic across multiple Cribl Stream Worker Nodes, see Third-Party Load Balancer Example Configurations for Cribl Stream Syslog.

High-Volume Syslog Senders

For general guidance on handling high-volume senders in Cribl Stream, see Scaling for High-Volume Syslog Senders for details on capacity planning, TCP load balancing, and other performance considerations.

For individual high-volume syslog senders sending via TCP above 300 GB/day, it is recommended to enable the TCP Load Balancing function (available in Cribl Stream single-instance and Distributed deployments). This feature prevents "TCP pinning" by distributing the syslog traffic across all Worker Processes, improving overall performance. When enabled, a dedicated load balancer process distributes incoming data via IPC sockets. For details, see TCP Load Balancing.

UDP Versus TCP

For any given syslog device, you might need to choose between using UDP or TCP. Which is best depends on the characteristics of the sender. Here are some basic guidelines:

- For both the sender and Cribl Stream, UDP imposes lower overhead than TCP. The stateless nature of UDP allows each log event to be directed to a different worker thread than the last. This ensures maximum utilization of the Worker Nodes. See Sizing and Scaling for more details.
- For lower-volume senders, use TCP if the sender supports it.
- For all other use cases, use UDP.

Optimize Syslog with Cribl.Cloud

When deploying syslog solutions with Cribl.Cloud, consider these recommendations for optimal performance and security.

Prioritize Hybrid Stream Workers for On-Premise Syslog

For syslog senders located within your on-premise environment, deploying Cribl Hybrid Stream Workers is strongly recommended. Place two or more Workers in the same network proximity as your syslog devices, managed by your Cribl.Cloud Leader. This strategy offers significant advantages:

- **Enhanced UDP delivery**: We recommend local processing due to UDP's "best-effort" nature and lack of encryption. Hybrid Workers improve delivery reliability and prevent sensitive data from traversing the internet unencrypted.
- **Robust Security**: By keeping unencrypted TCP traffic within your local network (especially from senders lacking TCP/TLS support), you maintain data security. Cribl Stream can then encrypt data in transit between hybrid Workers and Cribl.Cloud.
- **Simpler Port Management**: Hybrid Workers provide flexible port configuration, enabling dedicated ports per device type for streamlined management and monitoring.
- **Improved Monitoring**: Dedicated ports enable the Cribl Monitoring dashboards to report volumes for each major type of syslog sender. While this benefit technically applies to Cribl.Cloud deployments as well, the number of available ports is limited. See the next section for additional details on Cribl Cloud port limitations.

If your environment does not allow for the deployment of Hybrid Cribl Stream Workers, the details below will help you optimize delivery to Stream Workers hosted in Cribl Cloud.

Port Considerations in Cribl.Cloud

Cribl.Cloud provides a limited selection of pre-configured ports for common use cases, primarily for receiving Syslog data.

In addition to the pre-configured Syslog ports, Cribl.Cloud offers a range of configurable TCP ports from `20000` to `20010`. These ports can be assigned to **any push-based Source** (including but not limited to Syslog) to receive **any supported data type**.

Pre-configured Syslog Ports

Cribl.Cloud provides the following fixed ports specifically for Syslog traffic:

Port	Protocol	Usage	Notes
6514	TCP + TLS	Encrypted Syslog	Standard for Syslog over TCP + TLS.

Port	Protocol	Usage	Notes
9514	TCP or UDP	Unencrypted Syslog	
514	TCP or UDP	Unencrypted Syslog	Redirected internally to `101514`. This port is available for devices that cannot be configured to use a non-default Syslog port.

For unencrypted **UDP** delivery of Syslog traffic, only ports `514` and `9514` are available.

Port Flexibility with Hybrid Stream Workers

For maximum port flexibility, **Hybrid Stream Workers** support any port, offering a significant advantage over the standard, more restricted port options available directly in Cribl-managed Workers.

Important Security Considerations

Avoid sending unencrypted traffic over the Internet. When using Cribl.Cloud, using syslog with TLS is strongly recommended. Unencrypted options accommodate senders lacking TLS support. For such senders, consider deploying Hybrid Stream Workers on the same LAN to keep unencrypted traffic on private networks.

Pipeline Planning

In Cribl Stream, we speak of **pre-processing Pipelines**, **processing Pipelines** (or just plain **Pipelines**), and **post-processing Pipelines**. Cribl recommends combining the first two in an arrangement that we've found to be optimal for syslog.

Pre-Processing Syslog Sources

Pre-processing Pipelines are useful for standardizing or normalizing incoming data from multiple Syslog Sources. Pre-processing can ensure consistency, streamline ingest-time processing for syslog events, and reduce the need to replicate the functionality and logic in each processing Pipeline that is associated with a Syslog Source.

However, pre-processing may not be necessary or desirable in every case. For example, if you have unique processing requirements for different subsets of data, it may be more effective to configure separate processing Pipelines according to your needs.

The Cribl Pack for Syslog Input provides a pre-processing Pipeline that modifies the data that Cribl Stream delivers. Before you deploy the pre-processing Pipeline, review the Pipeline's comments as described in Importing the Pre-Processing Pipeline to understand the available functions and options and enable or disable them as desired.

If your syslog senders produce events with embedded newline or carriage-return characters (multi-line or otherwise malformed syslog), treat them as malformed syslog rather than standard single-line events. In those cases, consider ingesting the data via a Raw TCP or Raw UDP Source with a custom Event Breaker, as described in Alternative Sources for Malformed Syslog .

Pipeline for Selected Syslog Data Subsets

Configure dedicated Pipelines (and Routes!) for each distinct subset of data that arrives via syslog senders. These subsets might include DHCP logs from the router, traffic logs from the firewall, operational logs from load balancers, and virtualization logs from on-prem virtualization hypervisors.

Certain kinds of subset-specific processing have become Cribl Stream best practices. These include:

- For ESXi or other hypervisor logs, use the Drop Function to drop `debug`-level logs.
- For firewall logs, enrich with DNS names, GeoIP fields, and lookups from a threat list.
- For load balancer logs, use the Suppress Function to reduce volume.

Unless you're new to Cribl Stream, you've already created your own Pipelines, so we're not going to review that here. (If you are new to Cribl Stream, consider running through the free Cribl Stream Overview sandbox course ASAP.)

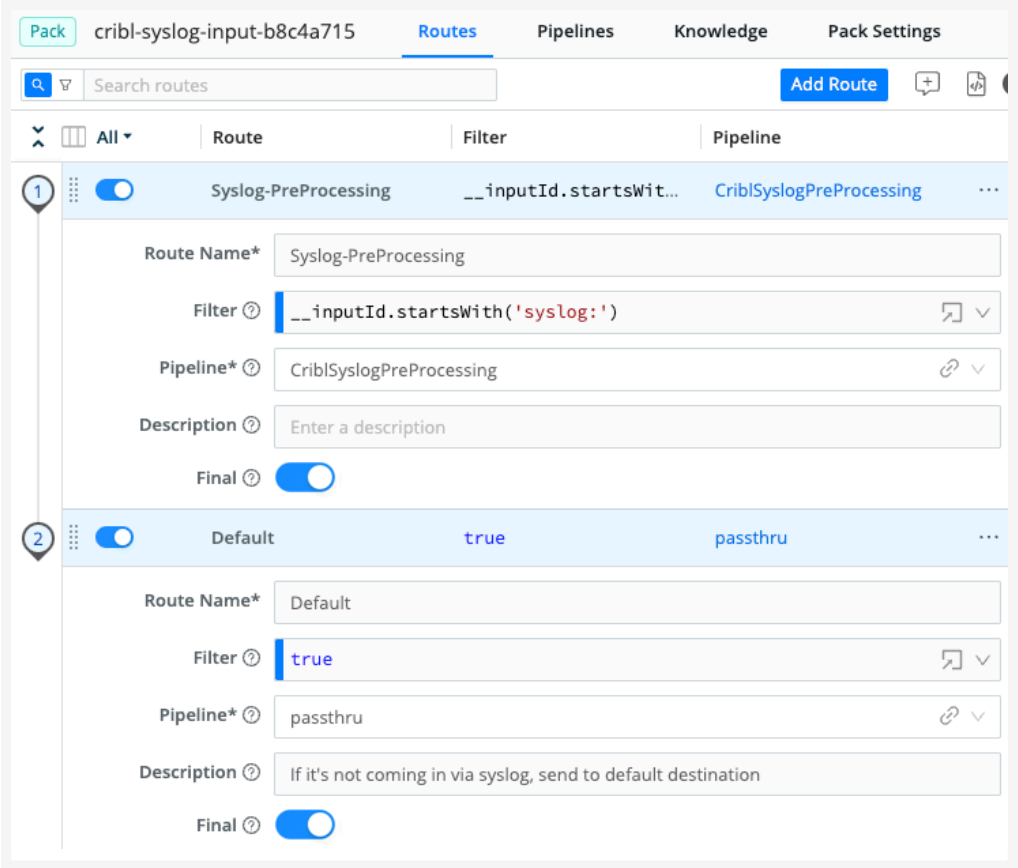
Importing the Pre-Processing Pipeline (Optional)

Even before setting up a Cribl Stream Syslog Source, you have the option to install the Cribl Pack for Syslog Input (a.k.a. `cribl-syslog-input` Pack), which provides the pre-processing Pipeline for mixed-use Syslog Cribl Sources. This is particularly helpful when you have various types of syslog devices sending data to a single port, such as port 514. When you configure dedicated ports for each type of device, it's generally best to use a Pipeline or Pack that is specifically tailored to that type of data.

If this is your first time installing from the Cribl Dispensary, see the full directions with screenshots. Otherwise:

1. Open the Cribl Pack Dispenary's Cribl Pack for Syslog Input page.
2. Under **Releases** at right, click the link for the latest release.
3. In the resulting **Assets** section, right-click the `.crbl` file to download it locally.
4. In Cribl Stream, select a Worker Group, then select **Processing** > **Packs**.
5. Click the **Add New** button, and select **Import from file**.
6. Select the Pack you downloaded, and follow the prompts from there. In most cases, when installing a Dispensary Pack, you should not enter an override value for **New Pack ID**.
7. Review the Pack's `README` file, available in the Pack's **Settings** link and also online.

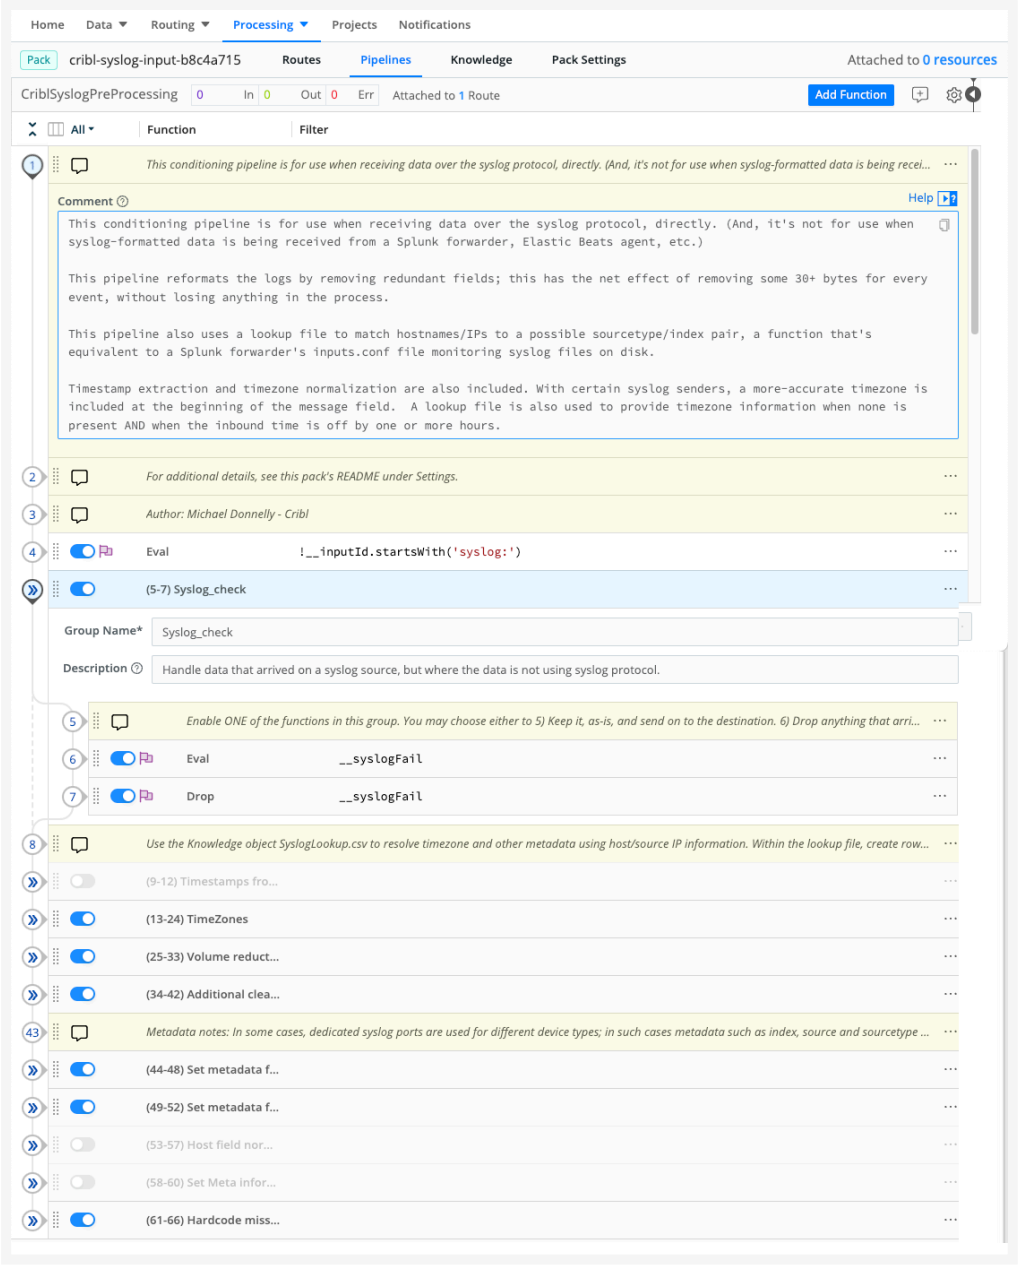
Let's examine what this Syslog Input Pack provides, starting with the Routes page.



Routes page in the Cribl Pack for Syslog Input

The first Route matches based on `inputId`. Anything arriving via a Cribl Stream Syslog Source will match this filter, as long as you've configured the Source to use the Pack, as shown below.

On first installation of the Pack, the Pipeline defaults to commonly used configurations. Cribl **strongly** recommends reviewing the Pipeline's internal documentation to understand which features are enabled. This documentation consists of Comments for each section, and a Description for each Function to explain what's happening in that step.

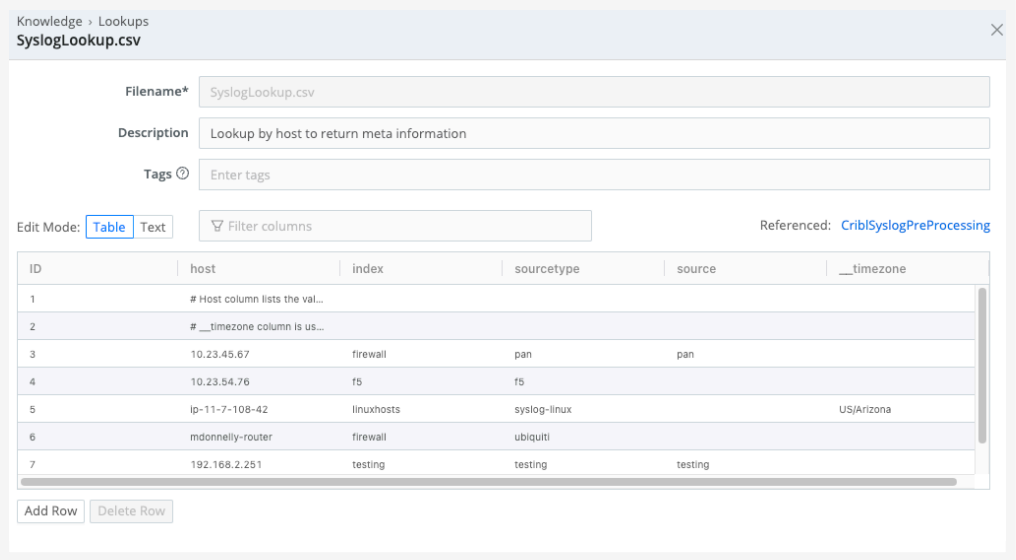


The Pipeline's internal documentation

Examining this documentation should make it clear what changes (if any) are needed to suit your deployment environment. Go ahead and make those changes now.

The Lookup File

The Pack ships with a lookup file called `SyslogLookup.csv`, whose contents you should replace as necessary. To access the file, navigate to **Processing** > **Packs**, select the `cribl-syslog-input` Pack, and click **Knowledge**.



Stock `SyslogLookup.csv` file, to be filled with customer data

Creating Syslog Sources

Now that you've imported the pre-processing Pipeline, the next step is to ensure that you have the Syslog Sources you need.

Configure the `in_syslog` Source

Cribl Stream ships with a Syslog Source named `in_syslog`, which is preconfigured to listen for both UDP and TCP traffic on Port 9514. You can clone or directly modify this Source to further configure it, and then enable it.

Use the `in_syslog` Source for syslog senders that are hard-coded to send to port 514, as described above. In the **QuickConnect** UI: Click **Add Source**. From the resulting drawer's tiles, select [**Push** >] **Syslog**. Click **Select Existing**, then `in_syslog`.

Or, in the **Data Routes** UI: From the top nav of a Cribl Stream instance or Group, select **Data** > **Sources**. From the resulting page's tiles or the **Sources** left nav, select [**Push** >] **Syslog**. In the **Manage Sources** page, click `in_syslog`.

Configure the fields and options as follows:

General Settings

- **Enabled**: Toggle on.

- **UDP Port** and **TCP Port**: Assuming you're following the guidelines in this tutorial, you'll have a load balancer relaying incoming traffic from port 514 to port 9514. Therefore, leave the `in_syslog` Source configured to listen on its default port, 9514, for both TCP and UDP.

TLS Settings (TCP Only)

- Enabling TLS is strongly recommended if the Source will be receiving data across the Internet.

Processing Settings

- **Metadata**: There is no need to add fields here, because for generic senders coming in on 9514, the Pack will set the meta-information via the `SyslogLookup.csv` file. What you need to do is edit the lookup file to add content appropriate to your deployment.
- **Pre-processing**: From the **Pipeline** drop-down, select `PACK: cribl-syslog-input (Syslog Preprocessing)`.

Create a Source for Each Device Class

As explained above, you should now create a Syslog Source for each vendor/class of syslog sender. Create each Syslog Source as follows:

In the QuickConnect UI: Click **Add Source**. From the resulting drawer's tiles, select [**Push** >] **Syslog**. Click **Add New**.

If you use QuickConnect, remember that each Source/Destination pair will be parallel and independent.

Or, in the **Data Routes** UI: From the top nav of a Cribl Stream instance or Group, select **Data** > **Sources**. From the resulting page's tiles or the **Sources** left nav, select [**Push** >] **Syslog**. Click **New Source** to open a **New Source** modal.

Configure the fields and options as follows:

General Settings

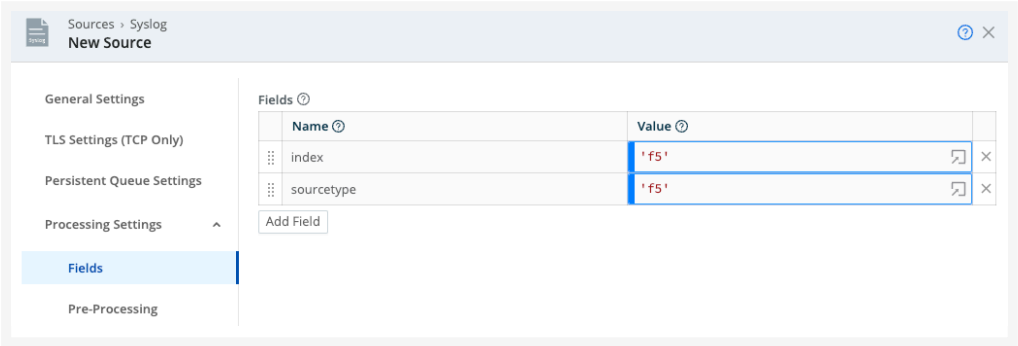
- **Input ID**: This field specifies the name for the Source, which will appear in the `__inputId` field as well as on Monitoring pages that show Source information. Common examples include `in_syslog_cisco_switch` for Cisco switches, `in_syslog_f5` for F5 load balancers, and so on.
- **UDP Port** and **TCP Port**: Enter the dedicated port you have chosen for the device class, and use UDP or TCP according to the recommendations above.

TLS Settings (TCP Only)

- Enabling TLS is strongly recommended if the Source will be receiving data across the Internet.

Processing Settings

- **Metadata**: Select **Fields (Metadata)** and add the fields appropriate for the intended Destination(s), such as `sourcetype`, `index`, `__timezone`, and any other meta-information you want to tie to the sender's hostname or IP address.



Metadata fields tied to a dedicated-port Syslog source

- **Pre-processing**: From the **Pipeline** drop-down, select `PACK: cribl-syslog-input (Syslog Preprocessing)`.

Adding Processing Pipelines

Congratulations! You've gotten a nice grounding in syslog processing, and you've seen methods with which you can:

- Properly architect the deployment environment, where syslog sender data travels through a load balancer, which then distributes it across a Cribl Stream Worker Group.
- Import a Pack from the Cribl Pack Dispensary.
- Create new Cribl Stream Syslog Sources which use the **Cribl Pack for Syslog Input**.
- Hard-code meta-information for specific ports, or use the lookup file to map meta-information for specific hosts.

Your logical next step: using Pipelines and Routes, transform syslog data in a way that makes sense for your particular syslog sender(s).

We'll look at two use cases:

- QuickConnect a Syslog Sender to a Source

- Route Multiple Syslog Senders to a Source

The point is to see how Cribl Stream offers different approaches for different scenarios. For configuring one dedicated Source to receive a given, single dataset, QuickConnect is ideal. But to accommodate a mix of data arriving on the same Source and port, and needing to be divided into subsets, and processed differently by different Pipelines - that is where we need Routes.

Use Case A: QuickConnect a Syslog Sender to a Source

> This use case includes receiving input data on the `1517` port, which is not available on Cribl.Cloud. The scenario presented here will only work in an on-prem deployment.

Of the many possible examples, we'll focus on reducing the volume of VMware ESXi syslog data by dropping events of `debug` severity.

Data reduction will be significant, because `debug` severity events can make up 80-90% of syslog data sent from ESXi servers. Not only that: Reducing the data volume reduces the CPU load and storage used to process the data, and searches will respond faster. In a world where we're searching for needles in a haystack, dropping 80% of the hay makes everything better.

To set this up:

1. In your Worker Group, navigate to **Pipelines**, click **Add Pipeline**, then click **Add Pipeline**.
2. Name the new Pipeline `DropNoisySyslog` or something similar.
3. Click **Comment** and enter a good description of what you're doing. (This is an important best practice!)
4. Add a Drop Function with filter `severityName=='debug'`. (You could also use sampling, or dynamic sampling if you wanted to be fancy about this.)
5. Click **Save** and we're done.

Next, we need to direct VMware ESXi data to our Pipeline. We'll do this using QuickConnect, which is the fastest way to configure a new Source, tie it to a Destination, and assign pre-processing and processing Pipelines to that Source. (We could also do this with Routes; that simply requires a few more configuration steps.)

In the **QuickConnect** UI:

1. Click **Add Source**.
2. From the resulting drawer's tiles, select [**Push** >] **Syslog**.
3. Click **Add New**.
4. Configure the fields and options as follows:
    - **Name**: `in_syslog_ESXi`.

- **TCP**: `1517`. This is the TCP port on which ESXi servers send their logs.
- **Pre-Processing** > **Pack**: Select `cribl-syslog-input`.
- **Fields (metadata)**: Add a `sourcetype` field with value `esxilogs`, and an `index` field with value `vmware-esxi`.

Adding metadata appropriate for ESXi

5. Click **Save**.
6. On the main **QuickConnect** page, drag a connector from `in_syslog_ESXi` to each Destination you want to receive these events. When prompted, select **Pipeline**, select your `DropNoisySyslog`, and click **Save**.
7. Commit and deploy, and you're all set!

Use Case B: Route Multiple Syslog Senders to a Source

Let's imagine you have incoming data from a router. This data is tagged with `sourcetype=myrouter`, and it includes a mix of DHCP actions, login/authentication attempts, and firewall traffic logs.

Our goal is to send each of the three data subsets of data - DHCP, login, and firewall - to its own Pipeline.

We know that the **Cribl Pack for Syslog Input** has a Lookup Function that - for data arriving on the default port - should return meta-information such as `sourcetype` or `index`. We can combine this metadata with some matching of strings within the data, in Route filters that direct the right data to the right Pipeline.

Although in reality, the `myrouter` firewall does not exist, the example that follows shows the art of the possible. We'll spell out the procedures as if the scenario were real. Perhaps one day you'll use it as a template for an actual deployment.

Create a Pipeline for Each Data Subset

- Create three Pipelines, naming each one for a data subset: `myrouter-dhcp`, `myrouter-auth`, and `myrouter-fw-traffic`.
- Leave the Pipelines empty for now; we'll add Functions later on.

Create a Route for Each Data Subset

1. Navigate to **Routing** > **Data Routes**.
2. Click **Add Route**.
3. Configure a Route as specified in the table below:

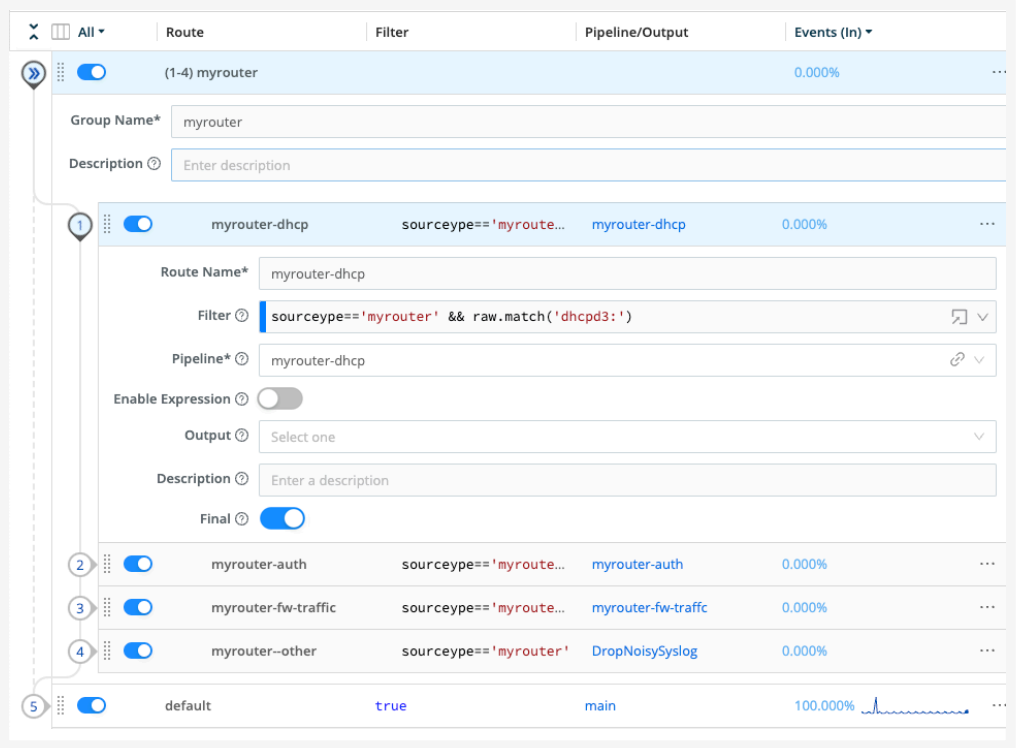
Name	Filter	Pipeline
`myrouter-dhcp`	`sourcetype=='myrouter' && raw.match('dhcpd3:')`	`myrouter-dhcp`
`myrouter-auth`	`sourcetype=='myrouter' && raw.match('login')`	`myrouter-auth`
`myrouter-fw-traffic`	`sourcetype=='myrouter' && raw.match('TRAFFIC')`	`myrouter-fw-traffic`
`myrouter-other`	`sourcetype=='myrouter'`	`DropNoisySyslog`

4. Repeat the preceding steps until you have configured four new Routes - one for each of the three data subsets, plus a final Route to drop events that don't match our Filters (i.e., noise).

For all Routes, toggle **Final** on and set the output to whatever Destination you think is appropriate for the given data subset.

5. Click the `myrouter-dhcp` Route's ••• (Options) menu, then select **Group Actions** > **Create Group**.
6. Name new Group `myrouter`.
7. Drag the Routes you created above into the new Group. (Be sure that `myrouter-other` is listed last.)
8. Drag the new Group to whichever vertical position makes the most sense for your deployment.

Once you've completed all the above steps, then after collapsing your new Routes, you should see something like this:



All
Route
Filter
Pipeline/Output

8.8.4.2. Syslog TLS To Cribl.Cloud (Palo Alto Example)

This guide explains how to securely forward syslog data to your Cribl.Cloud instance using Transport Layer Security (TLS). Properly configured TLS encryption ensures that sensitive log data is protected during transmission across networks.

Benefits of TLS-Encrypted Syslog

- **Data Security**: Encrypts sensitive log data during transmission.
- **Integrity Verification**: Ensures data hasn't been tampered with during transit.
- **Compliance**: Helps meet security requirements for regulated industries.
- **Authentication**: Verifies the identity of your Cribl.Cloud instance.

General Configuration Steps

Follow these steps to set up your connection.

Determine Your Cribl.Cloud Ingest Address

Before configuring your syslog sender, you'll need to identify your Cribl.Cloud ingest address:

1. Log into your Cribl.Cloud portal.
2. From the top nav, select **Workspace**.
3. In the sidebar, select **Access**.
4. Note the **Public Ingress address** (for example, `default.main.<organizationId>.cribl.cloud`).

Obtain Cribl.Cloud CA Certificates

Cribl.Cloud uses Google Trust Services (GTS) certificates to secure connections. You have the following two options.

Use Trusted Public Certificate Authorities (Recommended)

Most systems already trust Google Trust Services certificates, so no additional certificate configuration may be necessary if your system's trust store is up to date.

Manually Import Google Trust Services Certificates

Google Trust Services publishes the necessary certificates in a user-friendly repository. Follow these steps to download the required certificates:

1. Visit the Google Trust Services Root Repository.
2. Download the following certificates:
    - `GTS Root R1` (PEM format): This is the root certificate for Google Trust Services.
        - **Fingerprint**: `d9:47:43:2a:bd:e7:b7:fa:90:fc:2e:6b:59:10:1b:12:80:e0:e1:c7:e4:e4:0f:a3:c6`
    - `WR1` (PEM format): This is the intermediate certificate issued by Google Trust Services.
        - **Fingerprint**:: `b1:0b:6f:00:e6:09:50:9e:87:00:f6:d3:46:87:a2:bf:ce:38:ea:05:a8:fd:f1:cd:c4`

You only need to download these certificates once.

Next, import these certificates into your syslog sender's trust store.

Configure Your Syslog Sender

The following are general steps for configuring a syslog sender (specific steps vary by vendor):

1. Configure a new syslog server profile/destination.
2. Set the protocol to `TLS/SSL` (not TCP).
3. Use port `6514` for TLS-encrypted syslog.
4. Set the destination address to your Cribl.Cloud ingest address.
5. Configure the appropriate log format (typically BSD syslog).
6. Enable certificate validation using your system's trust store or imported certificates.

Vendor-Specific Configuration: Palo Alto Example

Panorama management appliances give you insights into what is happening behind your Palo Alto Networks firewalls, including details about applications, URLs, threats, data files, and patterns. By forwarding logging data directly from Palo Alto firewalls or Panorama management appliances to your Cribl.Cloud instance, you can shape, process, search, and route the data to the analytics platform of your choice.

This section outlines how to configure your Palo Alto Networks firewalls or Panorama management appliances to connect securely to your Cribl.Cloud instance using Google Trust Services (GTS) as the Certificate Authority

(CA).

Import Trusted Roots into PAN

Download the GTS certificate certificate as outlined above. Next, import the certificates into PAN. In the PAN OS:

1. Go to **Device** > **Certificate Management** > **Certificates**.
2. Select the **Import** button at the bottom.
3. The **Import Certificate** configuration modal appears. Import both downloaded certificates (`GTS Root R1` and `WR1`).
4. Once you have imported both certificates, go to the **Device Certificates** table and select the blue link for each certificate you just imported.
5. Select the **Trusted Root CA** check box for each certificate.

Configure the Syslog Server Profile

Now that you've imported the trusted certificates, proceed with creating a new Syslog Server Profile:

1. After importing the certs, navigate to **Device** > **Server Profiles** > **Syslog**.
2. Create a new Syslog Server Profile.

   If you're using Syslog over TLS, make sure to set the profile to use SSL instead of TCP.

   Even if a PAN rule does not explicitly reference the TLS certificate that you added from Cribl, TLS will detect the certificate information and use it correctly.

3. Configure the Syslog server field with your Cribl.Cloud Organization's ingest address. To find your ingest address, navigate to your Cribl.Cloud portal and select the gear on the top bar.
4. Select **Network Settings** and choose the Worker Group you're sending data to. For example, sending to the default Group your ingest address would look like: `default.main.<organizationId>.cribl.cloud.`

Configure Log Settings to Use the Syslog Profile

Next, configure your log settings to use the Syslog Profile.

1. Go to **Device > Log Settings**.
2. Ensure the desired log types are configured to use the newly created Syslog Server Profile.

Configure Firewall Rule Log Forwarding

To selectively forward specific log types, create a Log Forwarding Profile and define the rules for which traffic should be forwarded.

1. Use the **Log Forwarding Profile** to create a ruleset and configure the appropriate log types to be forwarded.
2. Go to **Objects** > **Log Forwarding** and configure each relevant section with the appropriate settings.

Forward Admin Activity Logs

For additional context, you can forward your admin activity logs:

1. Go to **Device** > **Setup** > **Management**, and select the gear in the **Logging and Reporting** settings.
2. Enable the **Debug and Operational Commands** and **UI Actions**, and choose the appropriate Syslog server.

Customize OCSP Validation Settings for the `syslog-ng` Process

If the certificate validation fails, follow these steps to customize the validation settings for the `syslog-ng` process. This requires shell access to your device.

These commands are for an individual PAN OS device and might differ for Panorama. Refer to the official PAN-OS documentation for specific instructions on your version.

```
set syslogng ssl-conn-validation all-conns skip
set syslogng ssl-conn-validation explicit OCSP skip CRL skip EKU skip
```

Copy

Validation

To validate whether you have successfully set up the TLS-encrypted Syslog, check the logs on your PAN OS.

Troubleshooting

If you run into issues not anticipated above, you can use some of the following commands to further diagnose them:

```
# restart the syslog-ng process
debug syslog-ng restart

# see syslog-ng process logs
tail follow yes mp-log syslog-ng.log

# get stats for processes
debug log-receiver statistics
debug syslog-ng stats

# tcpdump activity on the syslog port and view the results
# note: control-c to exit the tcpdump, it will not show anything on the cli when runr
tcpdump filter "port 6514" snaplen 0
view-pcap mgmt-pcap mgmt.pcap
```

Copy

8.8.5. Configure Upstream Logging Agents

This page explains how to quickly connect a wide selection of common logging agents and other log sources to Cribl Stream. The examples below are equally valid for Cribl.Cloud and on-prem Cribl Stream instances.

Whichever source you choose, start by doing a live capture on the corresponding Source in Cribl Stream. Verify that data is coming in. Then save your capture to a sample file, which will help you build your Pipelines.

Fluent Bit and Fluentd

Both Fluent Bit (written in C) and fluentd (written in Ruby) are open-source log collectors, processors, and aggregators.

Fluent Bit to HEC

Of Fluent Bit's many output options, several work with Cribl Stream. Here's how to connect a Cribl Stream Splunk HEC Source to Fluent Bit with the Splunk HEC formatting option.

You'll need to copy and paste the following:

- From the Cribl.Cloud sidebar, select **Workspace** > **Data Sources** and copy the `in_splunk_hec` ingest address.
- From a Cribl Stream instance or Worker Group, select **Data** > **Sources** > **Splunk HEC** > `<source_name>` > **Auth Tokens**, and copy the HEC token.

Decide how to adjust the `match` parameter for your use case. For example, an asterisk (wildcard) value will send **all** events to Cribl Stream.

Edit the Fluent Bit settings accordingly. They're usually in `/etc/td-agent-bit/td-agent-bit.conf`, in a form similar to this:

```
[OUTPUT]
    name         splunk
    match        *
    host         in.main-default-<organization>.cribl.cloud
    port         8088
    splunk_token <HEC_token>
    tls          on
    # optional
```

Copy

Save the changes and restart the `td-agent-bit` service.

Fluent Bit to Elastic Sources

You can also connect Cribl Stream to Fluent Bit, using an Elastic Source.

```
[OUTPUT]
    name          es
    match         *
    host          10.0.21.134
    port          9200
    index         my_index
    type          my_type
```

Copy

Fluentd to HEC

If you don't already have it, install the `splunk_hec` fluentd mod:

```
sudo gem install fluent-plugin-splunk-hec
```

You'll need to copy and paste the following:

- From the Cribl.Cloud sidebar, select **Workspace** > **Data Sources** and copy the `in_splunk_hec` ingest address.
- From a Cribl Stream instance or Worker Group, select **Data** > **Sources** > **Splunk HEC** > `<source_name>` > **Auth Tokens**, and copy the HEC token.

Decide how to adjust the `match` parameter for your use case. Use an asterisk (wildcard) if you want to send **all** events to Cribl Stream.

Edit the `<match` section of the fluentd settings accordingly. They could be in `/etc/fluent/fluent.conf` or another location, as described in the fluentd docs.

```
<match **>
  @type splunk_hec
  @log_level info
  hec_host in.main-default-<organization>.cribl.cloud
  hec_port 8088
  hec_token <HEC_token>
  index <index_name>
  source_key <file_path>
  <format>
    @type json
  </format>
</match>
```

Copy

Save the changes and restart fluentd.

Splunk

Cribl Stream can directly ingest the native Splunk2Splunk (S2S) protocol. As a result, both Splunk universal and heavy forwarders can send log data to Cribl Stream.

Splunk Forwarder (Universal or Heavy) to Splunk TCP

See how to configure a Splunk Forwarder in the Splunk TCP Source document.

Elastic

In the Elastic ecosystem, Elastic Filebeat is an agent that functions as a lightweight shipper for forwarding and centralizing log data.

Elastic Filebeat

Cribl Stream can ingest the native Elasticsearch streaming protocol directly.

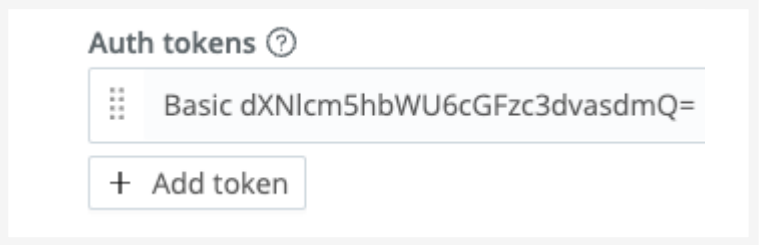
Cribl recommends setting an authorization token so that your receiver will accept only your traffic. This setting is in the **Auth Tokens** field of Cribl Stream's **Sources** > **Elasticsearch API** > **General Settings** tab.

If you want to enable Basic authentication:

- Concatenate your username and password with a colon in between, like this: `username:password`.

- Encode the `username:password` string using base64.
- Prepend the string `Basic ` (including the trailing space) to the encoded string.
- Enter the resulting string in the **Auth tokens** field as described above.

You'll see something like this:



Basic auth in the Cribl Stream Elasticsearch API Source

```
output.elasticsearch:
  hosts: ["in.main-default-<organization>.cribl.cloud:9200/search"]
  protocol: "https"
  ssl.verification_mode: "full"
  username: <some_username>
  password: <some_password>
```

Copy

syslog

To receive syslog data in Cribl Stream, create a native Syslog Source. See Cribl's best practices for working with syslog data.

Cribl recommends not using UDP over the public internet. UDP examples are included here for test purposes only.

UDP, by definition, does not guarantee delivery. While TCP mitigates this problem, using either UDP or TCP without TLS over the public internet exposes unencrypted data.

syslog-ng (TLS over TCP)

Cribl recommends using TLS over TCP to send data from syslog-ng to Cribl Stream.

Here's an example of `syslog-ng.conf` edited such that all event data will be encrypted on the way to Cribl.Cloud. Adapt the snippet to your use case and edit `syslog-ng.conf` accordingly.

```
destination d_syslog {
    syslog("in.main-default-<organization>.cribl.cloud"
        transport("tls")
        port(6514)
        tls(
            peer-verify(required-trusted)
            ca-dir("/etc/syslog-ng/ca.d")
        )
    );
};

log {
    source(s_network);
    destination(d_syslog);
};
```

Copy

Save the changes and restart the syslog-ng service.

syslog-ng (UDP or TCP)

Here's an example of `syslog-ng.conf` - for test purposes only, because it does not use TLS.

Adapt the snippet to your use case, and edit `syslog-ng.conf` accordingly. You can change `tcp` to `udp` to switch protocols.

```
destination d_syslog {
    syslog("in.main-default-<organization>.cribl.cloud"
        transport("tcp")
        port(9514)
    );
};

log {
    source(s_network);
    destination(d_syslog);
};
```

Copy

Save the changes and restart the syslog-ng service.

syslog-ng with Load-Balanced Outputs

You can forward logs from syslog-ng to multiple Cribl Stream Workers through a redundant, load-balanced output by using the syslog-ng `elasticsearch-http` output module. With this arrangement, syslog-ng receives syslog messages over TCP and/or UDP and outputs events over the Elasticsearch HTTP Bulk API to Cribl Stream Workers.

Forwarding to Cribl Stream from the syslog-ng `elasticsearch-http` output module requires syslog-ng version 3.19 or higher.

To check your syslog-ng version, run the following command:

```
syslog-ng -V
```

Copy

Adapt the snippet to your use case, and edit `syslog-ng.conf` accordingly. To learn more about syslog-ng destination flags, see the syslog-ng Administration Guide.

```
@version: 3.33
@include "scl.conf"

# Inputs
source s_network {
    # flags(no-parse) disables syslog-ng parsing of syslog messages (raw passthru)
    network(transport("tcp") port("9514") flags(no-parse));
    network(transport("udp") port("9514") flags(no-parse));
};

destination d_elasticsearch_tls {
    # https://www.syslog-ng.com/technical-documents/doc/syslog-ng-open-source-editior
    elasticsearch-http(url("https://worker1:9200/_bulk" "https://worker2:9200/_bulk"
        batch-lines(100)
        batch-bytes(512Kb)
        batch-timeout(2500)
        persist-name("d_elasticsearch-http-load-balance")
        type("")
        index("syslog")
        # Auth token
        #headers("Authorization: <token from Stream>")
        # or Basic Auth
        #user("username")
        #password("password")
    );
};

log {
    source(s_network);
    destination(d_elasticsearch_tls);
};
```

Copy

Save the changes and restart the syslog-ng service.

rsyslog (TLS over TCP)

You'll need to install the `rsyslog-gnutls` package if it's not already on your system. E.g.:

```
apt install rsyslog-gnutls
```

If the `rsyslog-gnutls package` is not already on your system, run the following command (or equivalent) to install it:

```
apt install rsyslog-gnutls
```

Cribl recommends using TLS over TCP to send data from rsyslog to Cribl Stream.

Here's an example of `rsyslog.conf`, edited such that all event data will be encrypted on the way to Cribl.Cloud. Adapt the snippet to your use case, and edit `rsyslog.conf` accordingly:

```
# path to the crt file.
# You will need a valid ca cert file. Most linux distros come with this
$DefaultNetstreamDriverCAFile /etc/ssl/certs/ca-certificates.crt

*.*     action(
         type="omfwd"
         target="in.main-default-<organization>.cribl.cloud"
         port="6514"
         protocol="tcp"
         action.resumeRetryCount="100"
         queue.type="linkedList"
         queue.size="10000"
         StreamDriver="gtls"
         StreamDriverMode="1" # run driver in TLS-only mode
)
```

Copy

Save the changes and restart the rsyslog service.

rsyslog (UDP or TCP)

Here's an example of `rsyslog.conf` - for test purposes only, because it does not use TLS.

Adapt the snippet to your use case, and edit `rsyslog.conf` accordingly. You can change `tcp` to `udp` to switch protocols.

```
*.*     action(
         type="omfwd"
         target="in.main-default-<organization>.cribl.cloud"
         port="9514"
         protocol="tcp"
         action.resumeRetryCount="100"
         queue.type="linkedList"
         queue.size="10000"
)
```

Copy

Save the changes and restart the rsyslog service.

Appliances that Send syslog

Many appliances emit syslog data. At a minimum, configure your appliance(s) to send syslog over TCP with TLS enabled, if possible.

Even better, stand up a Cribl Stream instance close to the appliances in your network topology. Have the appliances send syslog to the nearby Cribl Stream, which can optionally transform, filter, and/or enhance the data, and then send it to a more centralized Cribl Stream cluster in Cribl.Cloud or an one-prem location.

The Cribl Stream worker that's closest to the appliance will use TCP JSON, with TLS enabled, to send syslog to the second Cribl Stream instance:

Sending syslog from an appliance to Cribl Cloud

The benefits of placing the first Cribl Stream instance close to the log producer include:

- Since there are fewer network hops, UDP becomes a more viable option, if you want it.
- If you're using TCP, that can be more performant here than it would be across the internet.
- The first Cribl Stream instance can do data reduction and/or compression. These operations reduce the volume of the data hitting the wire on the way to the next hop.
- This can help keep data egress costs under control.

Vector

Vector is Datadog's tool for building observability pipelines.

Vector to HEC

Vector supports Splunk's HTTP Event Collector (HEC). Here's how to connect a Cribl Stream Splunk HEC Source to Vector.

For Cribl.Cloud especially, Cribl recommends setting an authorization token so that your receiver will accept only your traffic. This setting is in Cribl Stream's **Sources** > **Splunk HEC** > **Auth Tokens** tab.

The snippet below references a random syslog generator called `dummy_logs` for testing purposes. Adapt the snippet to your use case and edit `vector.toml` (or `vector.yaml` or `vector.json`) accordingly.

```
[sinks.my_sink_id]
type           = "splunk_hec"
inputs         = [ "dummy_logs" ]
endpoint       = "https://in.main-default-<organization>.cribl.cloud:8088"
compression    = "gzip"
token          = "<optional-but-recommended>"
encoding.codec = "json"
```

Copy

Vector to Elasticsearch

Vector supports Elasticsearch API. Here's how to connect a Cribl Stream Elasticsearch API Source to Vector.

The snippet below references a random syslog generator called `dummy_logs` for testing purposes. The snippet also specifies Basic authentication. Follow the procedure for enabling Basic authentication described in the Elastic Filebeat example above.

Adapt the snippet to your use case and edit `vector.toml` (or `vector.yaml` or `vector.json`) accordingly.

```
[sinks.elastic_test]
type          = "elasticsearch"
inputs        = [ "dummy_logs" ]
endpoint      = "https://in.main-default-<organization>.cribl.cloud:9200/search"
compression   = "gzip"
index         = "my_es_index"
auth.user     = "<some_username>"
auth.password = "<some_password>"
```

8.8.6. BigPanda/Webhook Integration

You can configure Cribl Stream to send Webhook notifications to the BigPanda IT Ops platform. These notifications arrive in BigPanda as Alerts, which BigPanda correlates into Incidents.

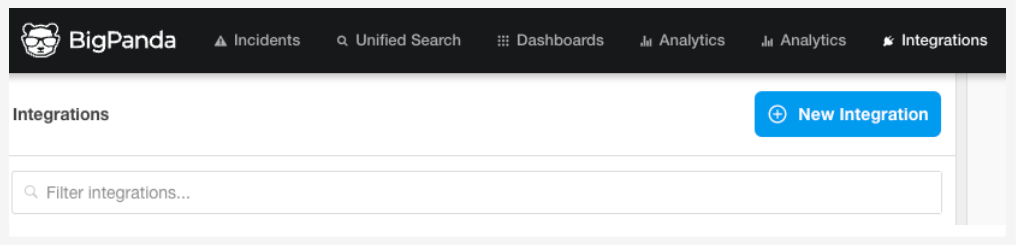
Before you begin, you should have an Admin account on a BigPanda Cloud instance.

To supplement this guide, reference the Cribl Integration document from BigPanda.

Prepare BigPanda to Receive Data from Cribl Stream

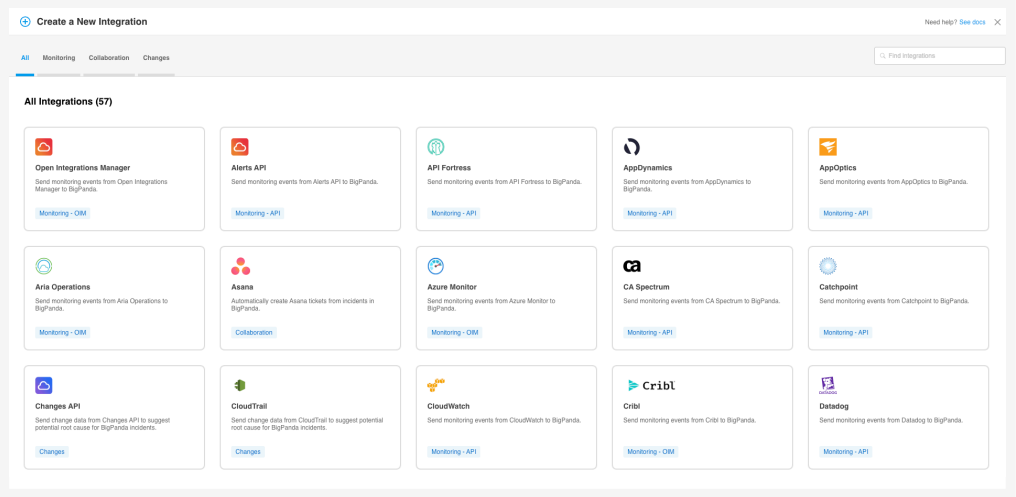
The BigPanda **App Key** and **Access Token** are separate and independent. The **Access Token** is a 32-character string that is part of the value that BigPanda generates for the `Authorization` HTTP header. (It functions like an auth token or bearer token.)

1. Log into your BigPanda Cloud instance as an Admin.
2. In the **Integrations** tab, select **New Integration**.



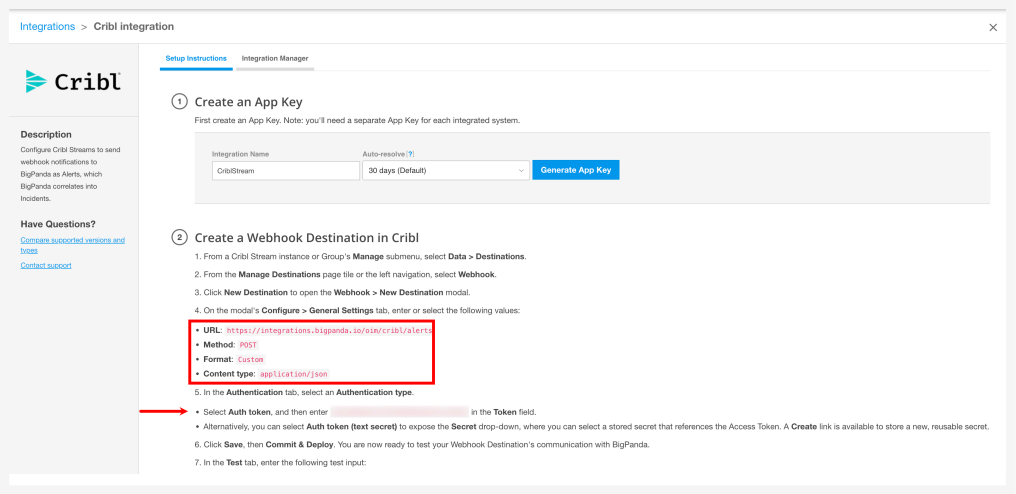
The **Integrations** tab

3. In the **Create a New Integration** modal, select the Cribl tile.



The **Create a New Integration** modal

- This opens the **Cribl Integration** page.



The **Cribl Integration** page

4. In the **Create an App Key** section, generate an App Key named `Cribl Stream`. You'll need the App Key when configuring Cribl Stream in the next section. Cribl Stream will insert the App Key into every event it sends to BigPanda.
5. BigPanda will generate a page containing setup instructions for the Cribl Stream Webhook Destination. Store the following information:
    - **URL**: `https://integrations.bigpanda.io/oim/cribl/alerts`.
    - **Method**: `POST`.
    - **Format**: `Custom`.
    - **Content Type**: `application/json`.
    - **Authentication token**: A 32-character `<auth-token>`.

The BigPanda page will also contain test code. You'll need the preceding information and the test code when configuring Cribl Stream in the next section.

Configure the Webhook Destination in Cribl Stream

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Destinations**. Then select **Webhook**. Next, select **Add Destination**.
2. On the modal's **Configure** > **General Settings** tab, enter or select the following values:
    - **URL**: Enter the Alerts API endpoint URL, for example: `https://integrations.bigpanda.io/oim/cribl/alerts`.

- **Method**: `POST`.
- **Format**: `Custom`.
- **Content type**: `application/json`.

3. In the **Authentication** tab, select an **Authentication type**.
   - You can select **Auth token** and provide the 32-character **Authentication token** you got from BigPanda after creating the App Key in the **Token** field.
   - Alternatively, select **Auth token (text secret)** to expose the **Secret** drop-down, in which you can select a stored secret that references the Access Token. A **Create** link is available to store a new, reusable secret.
4. Select **Save**, then **Commit & Deploy**. You are now ready to test your Webhook Destination's communication with Big Panda.
5. In the **Test** tab, enter the test code from the BigPanda setup instructions. It will look like this:

```
[
        {
                "app_key": "<your_app_key>",
                "status": "critical",
                "host": "production-database-1",
                "timestamp": 1402302570,
                "check": "CPU overloaded",
                "description": "CPU is above upper limit (70%)",
                "cluster": "production-databases",
                "my_unique_attribute": "myUniqueValue987654321"
        }
]
```

Copy

6. Select **Run Test**.

This should send an alert to BigPanda.

BigPanda Alerts API Requirements

HTTP payloads sent to the BigPanda Alerts API must satisfy rules that are beyond the scope of this topic. For details, see the BigPanda documentation about Parameters and Troubleshooting an Integration.

However, at at minimum, three fields are required:

1. `app_key`.

2. `status`.
3. `host` OR `service` OR `application` OR `device`.

Thus, the test input shown above works even if you omit all but the first three fields.

There are other possibilities for the third field, but they require understanding how BigPanda determines the `primary_property` of an Alert, plus some additional BigPanda configuration. See the BigPanda links above for details.

BigPanda Alert Deduplication

BigPanda processes an alert's Primary and Secondary properties on ingestion. These properties default to `host` and `check`.

When an alert has the same Primary and Secondary properties as those received in previous alerts, the Incident Console shows only the timestamp from the initial event.

For more information on this functionality, see the BigPanda pages Deduplication and Incident Identifier.

Verify that BigPanda is Receiving Notifications and Events

In the BigPanda **Incidents** tab, you should see an Incident whose Source is `Cribl Stream`. The details of the test input you sent from the Webhook Destination should appear in an Alert within that Incident. If so: It works!

8.8.7. Gigamon To Cribl Stream

Gigamon and Cribl have integrated the Gigamon GigaVUE Cloud Suite with Cribl Stream to optimize telemetry intelligence delivery across hybrid cloud infrastructures. This integration enables seamless data formatting and routing, enhancing the value of existing tools by providing comprehensive observability and security.

Gigamon's Deep Observability Pipeline, with GigaVUE Cloud Suite, delivers deep visibility into hybrid cloud traffic, improving security and performance by addressing East-West application traffic blind spots. Cribl's data management solution enhances threat detection and incident response through seamless access, enrichment, and routing of telemetry data from multiple sources.

In this integration, data is sent from the Gigamomn Application Metadata Exporter to a Cribl Stream HTTP Raw Source.

Prerequisites

- Your Gigamon GigaVUE Cloud Suite has the AMI module enabled.
- You've enabled the appropriate Application Metadata Intelligence attributes.
- You know your Cribl Stream Worker Group ingress address, shown on the **Overview** page under **Group Information**.

Configuring Cribl Stream

1. In your Cribl Stream account, select the Worker Group that will receive the data.
2. Select **Processing**, then **Packs**. Add the **Gigamon** Pack from the Dispensary to your Worker Group.
3. Select **Routing**, then **QuickConnect**. Select **Add Source** and add a new **Raw HTTP** Source.
4. Configure the new Raw HTTP Source as follows:
    - **General Settings**:
        - **Input ID**: Enter a unique name to identify this Raw HTTP Source definition. Such as `Raw HTTP`.
        - **Address**: Enter the address to bind on. Use `0.0.0.0` to bind on all addresses.
        - **Port**: Enter `20001`. This port number is used in the Cribl Stream Worker Group ingress address you'll provide to Gigamon.
    - **Authentication**:

        - Select **Add token** and **Generate** an **Auth token**. You'll provide this token to Gigamon when configuring your **Monitoring Session**.
5. Click **Save**.
6. Use QuickConnect to connect your new Raw HTTP Source to Cribl Destinations. Be sure to use the Gigamon Pack for the connection configuration.
7. **Commit & Deploy** your changes.

Configuring Gigamon to Export Data to Cribl Stream:

1. In your Gigamon instance, navigate to the **Traffic** section from the FM instance.
2. Select the location of your deployment, like `AWS`.
3. Choose and edit your **Monitoring Instance**.
4. Select the **Details** for your AMX instance.
5. Create a new Cloud Tool Export as follows:
    - **Alias**: `Cribl`
    - **Cloud Tool**: `Other`
    - **Endpoint**: Provide your Cribl Stream Worker Group ingress address with port `20001`. For example, `https://workergroup.main.orgname.cribl.cloud:20001`.
    - **Headers**:
        - **Authorization**: Provide the **Auth token** you generated when configuring the Cribl Stream **Raw HTTP Source**.
        - **Content-Type**: `application/json`
    - **Enable Export**: Check the box to enable.
    - **Format**: `JSON`
6. Click **Save** and **Deploy** the changes.

Verifying Data Flow

There are many ways to monitor the status of your Source. Navigate to the Source and use the available tabs.

- Use the **Live Data** tab to capture metadata received by Cribl Stream.
- The **Charts** tab displays throughput details.
- The **Status** tab provides details about the Workers in the group and their status.

You can also monitor Source throughput on the Monitoring page.

8.8.8. System Metrics To Grafana

Cribl Stream can collect metrics from the host on which it is running, and can populate some standard metrics dashboards right out of the box. For metrics details, see Linux System Metrics Details. While, Grafana is a multi-platform open source analytics and interactive visualization web application. It provides charts, graphs, and alerts for the web when connected to supported data sources.

Cribl has configured a Prometheus dashboard to display Cribl Stream System Metrics, and shared the dashboard in the Grafana library, which is public. This is a relatively simple dashboard suitable for showing aggregate metrics.

Another useful dashboard is the one that's commonly used with Prometheus and their Node Exporter agent, found here. This dashboard can handle the highly detailed metrics.

In this guide, we will show you how to route system metrics to a Grafana dashboard for both basic and highly detailed metrics visualizations.

We will walk you through the following:

- Configure System Metrics Source on Cribl Stream to receive metrics from the host.
- Configure the Prometheus Destination to send data to Grafana Cloud.
- Access Grafana Cloud to see the metrics and visualizations.

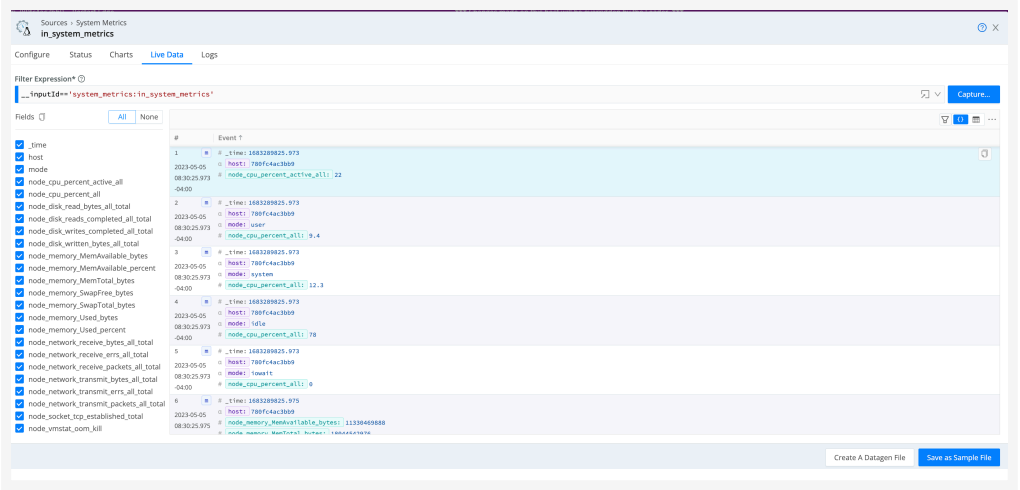
Configure the System Metrics Source on Cribl Stream

In Cribl Stream, start by configuring and enabling a System Metrics Source. The key requirement here is to to decide on the level of details for the metrics you want to collect. In the **Host Metrics** and **Container Metrics** tabs:

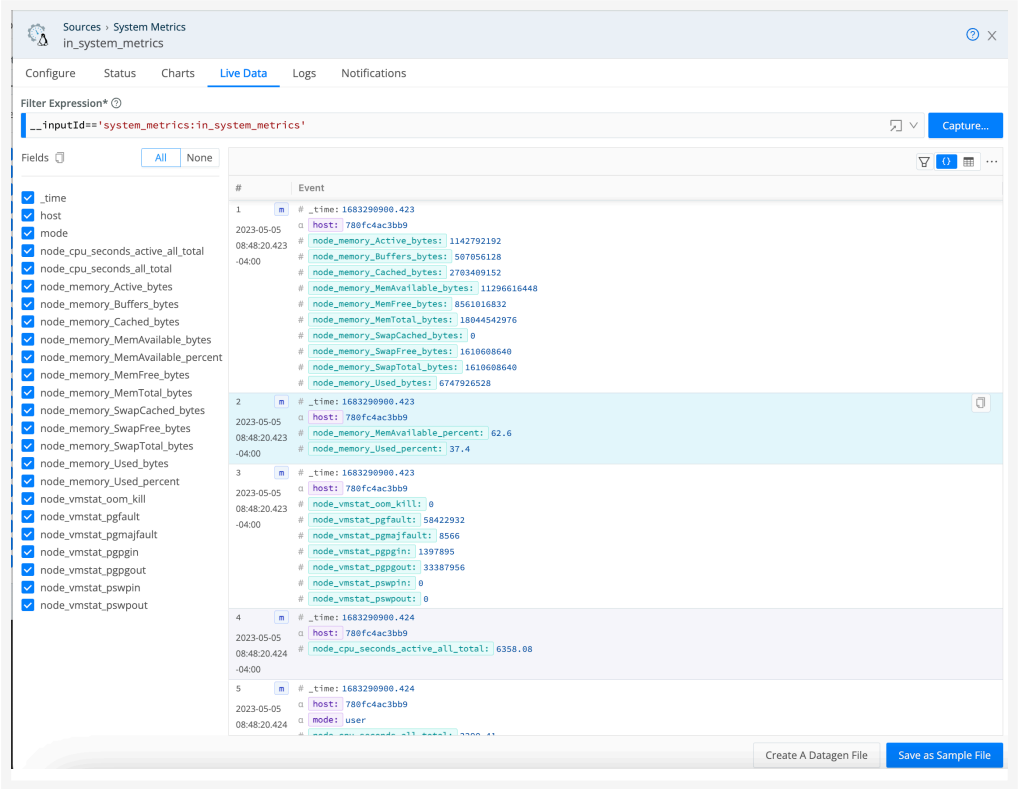
- For the relatively simple dashboard showing aggregate metrics, choose the **Basic** mode for most of your metrics.
- For the highly detailed metrics visualizations dashboard, choose the **All** mode for all of your metrics.

In the **Pre-Processing** tab, select the `prometheus_metrics` **Pipeline**.

When done, **Commit** and **Deploy** your changes. Before moving on to the next step, check the **Live Data** tab to make sure the metrics are generated.



Basis System Metrics

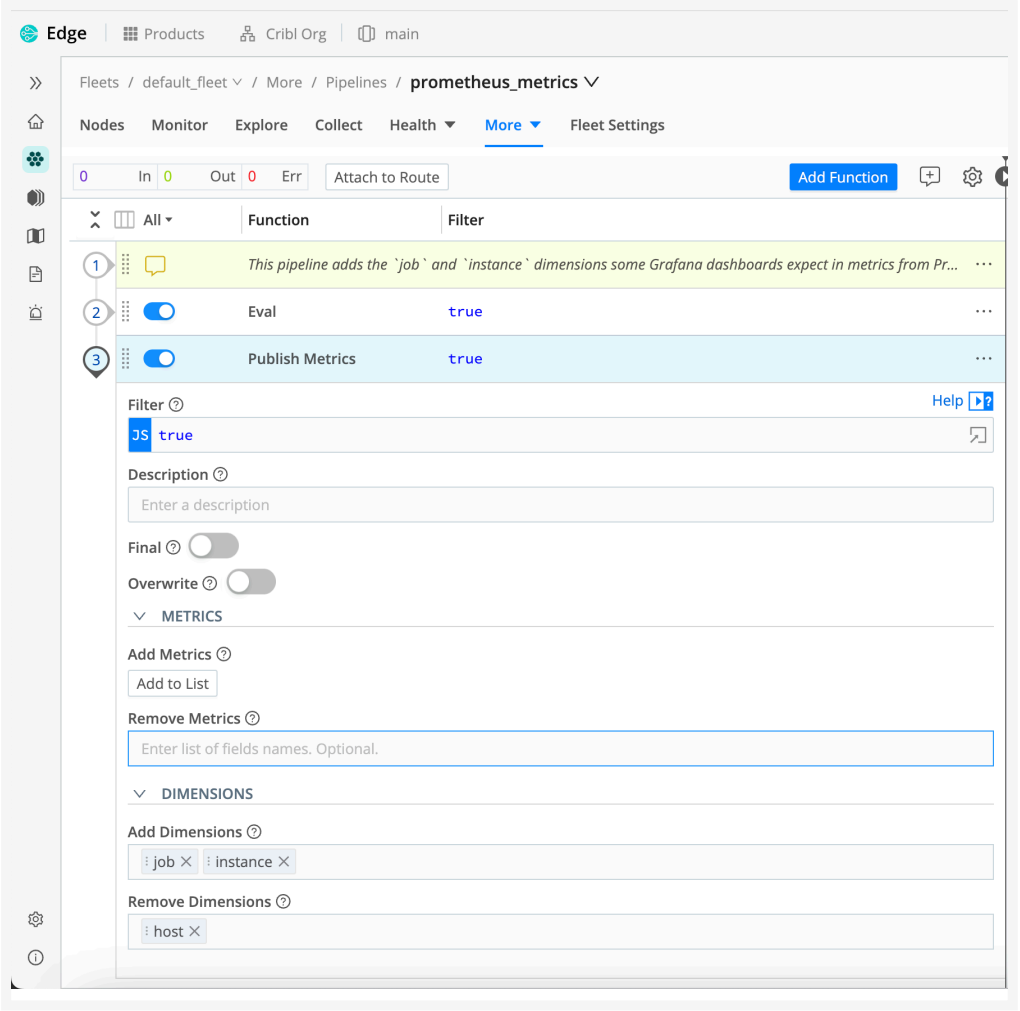


Detailed System Metrics

(Optional) Adjust the `prometheus_metrics` Pipeline

Optionally, you can adjust the `prometheus_metrics` Pipeline to include the `host` dimension or add/remove more dimensions.

Select a **Fleet** to configure. From the Fleet's submenu, select **More** > **Pipelines**.

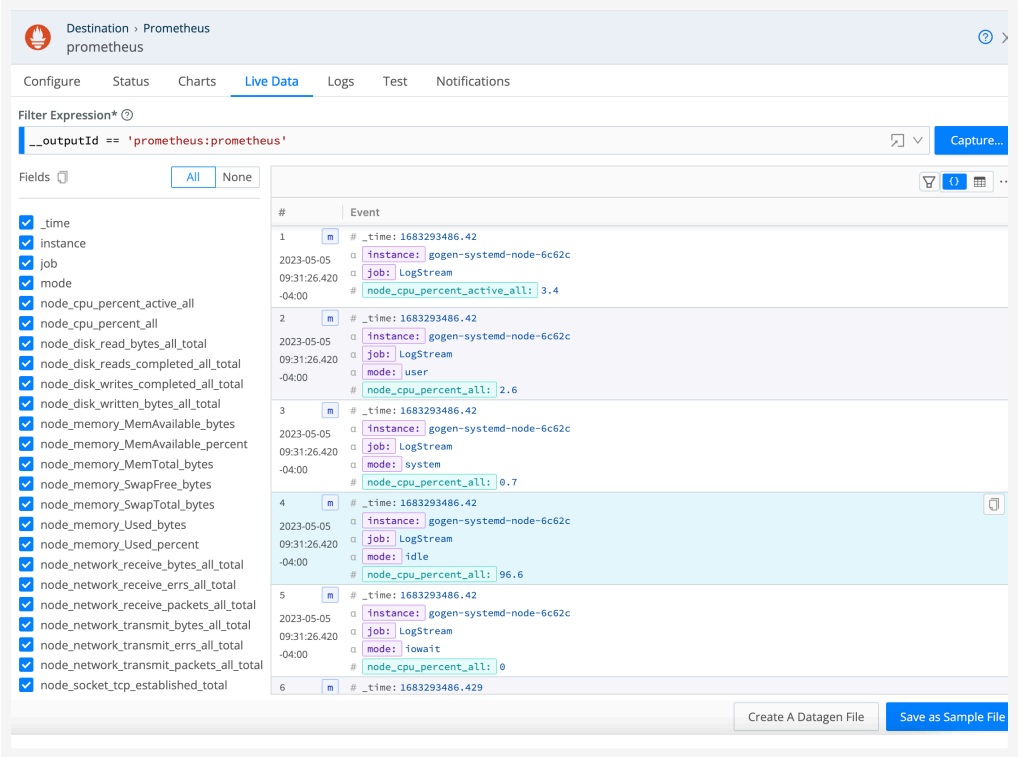


Adjust the Pipeline

Configure the Prometheus Destination

Next, we'll configure the Prometheus Destination to send data to Grafana Cloud.

Next, preview your data on the modal's **Live Data** tab.

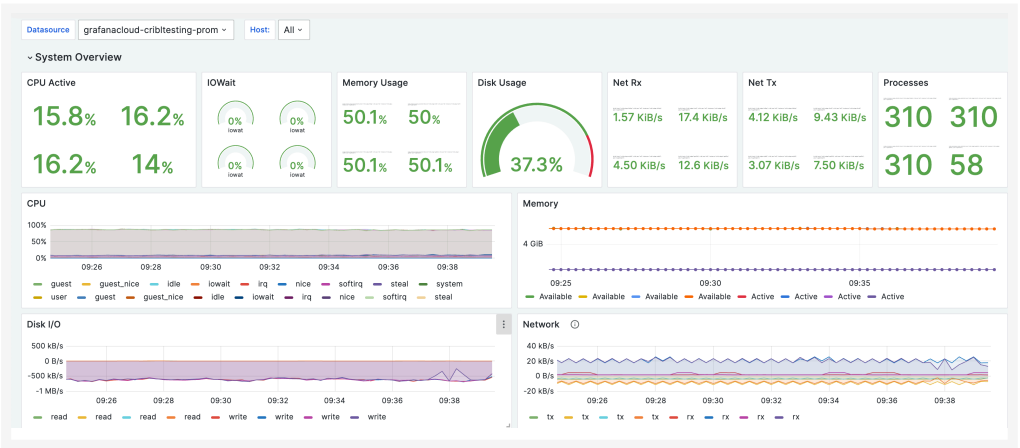


Preview Live Data

Visualize the Data in Grafana

Navigate to your Grafana Cloud instance, and select **Explore** on the left panel to review the node metrics. Selecting metrics and running the query will produce a chart and table of metric events that can be added to new or existing dashboards for analysis. If you are missing some expected metrics, you might need to adjust the variables in your Grafana Cloud instance. For details, see Variables.

Use the Grafana **Filter** option to browse the dashboards for your Prometheus data. Below are the Cribl dashboards with the basic and detailed metrics shown.



Cribl Node Observability

8.8.9. Kafka Authentication With Kerberos

This page describes how to configure a Kafka Source and Destination to use Kerberos authentication. It also documents the verification steps to test your setup.

Availability:

- Kerberos is available only on Linux, so you'll have to use a Linux host or Linux container to work through this procedure.
- Kerberos is not supported for Cribl-managed Cribl.Cloud Workers, but it is enabled for customer-managed (hybrid or on-prem) Worker Groups, whether the Leader is based in Cribl.Cloud or on-prem.

For additional information on Kafka configuration, see also our Kafka Source or Kafka Destination reference topics.

Set up the Cribl Stream Host

Once you have set up an instance of Kafka with Kerberos, perform the following steps on the same host where Cribl Stream is running:

1. Install `krb5-user` (or the equivalent for non-Ubuntu systems) on your Worker Node.
2. Ensure that you have a valid `/etc/krb5.conf` file. Consult your Kerberos admin if you don't have one. Kerberos authentication with Kafka specifically requires `rdns = false` in this config, but no other special settings. Cribl Stream supports the file and directory cache types.
3. Ensure that the keytab path in your configuration points to a valid keytab on each Worker Node.

Configure the Kafka Destination

Create a new Kafka Destination with the following settings:

General Settings

- **Brokers**: `broker.kerberos-demo.local:9092`
- **Topic**: `Cribl`

Authentication Settings

- **Enabled**: Toggle on.
- **SASL mechanism**: `GSSAPI/Kerberos`
- **Keytab location**: `/<path-to-client-keytab>/kafka-client.key`. This path to the valid keytab file must be available on all Worker Nodes.
- **Principal**: `kafka_producer@TEST.CONFLUENT.IO`
- **Broker service class**: `kafka`

Configure the Kafka Source

Create a new Kafka Source with the following settings:

General Settings

- **Brokers**: `broker.kerberos-demo.local:9092`
- **Topic**: `Cribl`
- **Group ID**: `Cribl`

Authentication Settings

- **Enabled**: Toggle on.
- **SASL mechanism**: `GSSAPI/Kerberos`
- **Keytab location**: `/<path-to-client-keytab>/kafka-client.key`
- **Principal**: `kafka_producer@TEST.CONFLUENT.IO`
- **Broker service class**: `kafka`

Verify the Setup

1. Open the **Live Data** tab and start a capture with **Capture Time (sec)** and **Capture Up to N Events** set to high values (for example, `1000`).
2. In a separate browser tab, navigate to the Destination modal's **Test** tab and select **Run Test** a few times.
3. Return to the Source's **Live Data** tab and verify that the Source is capturing events.

8.8.10. Moogsoft/Webhook Integration

Written for Cribl by Douglas Bothwell, formerly of Moogsoft.

You can configure Cribl Stream to send Webhook notifications to Moogsoft, using custom integrations. A custom integration is a user-defined Moogsoft endpoint that ingests JSON payloads, and converts them to Moogsoft events or metrics.

Note these options:

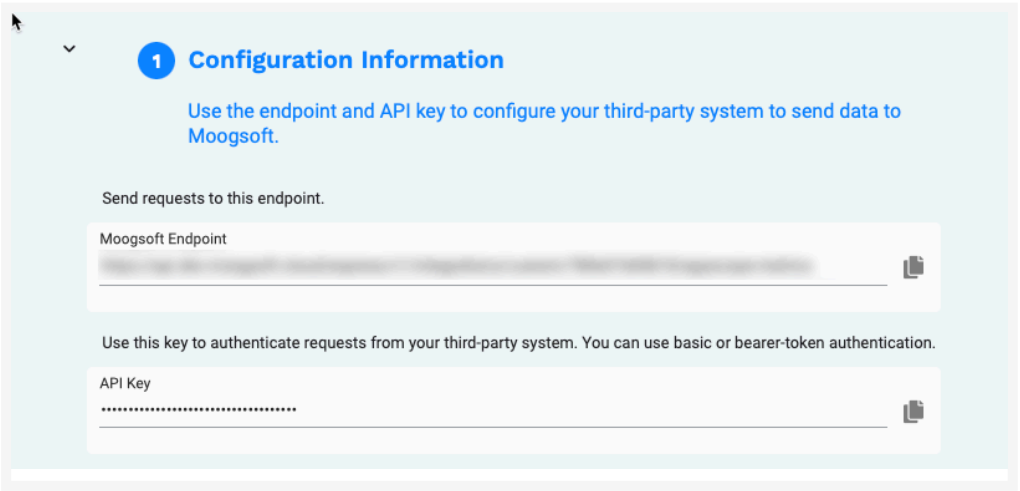
- A Moogsoft custom integration can ingest either events or metrics. Each custom integration has its own separate API key, and its own Cribl-to-Moogsoft mappings.
- There is no limit to the number of custom integrations you can create.
- The examples below illustrate simple event and metric mappings. You can define your own mappings for each endpoint, based on the data types and payloads you want to send. For details, see Moogsoft's Create Your Own Integration documentation.

Create the Moogsoft Custom Integration

Log into your Moogsoft SaaS instance as an Owner or Administrator, and then:

1. Choose **Data Config** > **Ingestion Services** > **Create Your Own Integration**.
2. Select **Add New Integration**.
3. Specify an integration endpoint and description.
4. Specify the data type to send to the endpoint: **Events** or **Metrics**.

The integration setup screen appears, with the URL and the API key for the new endpoint.



The Moogsoft integration setup screen

Configure the Webhook Destination

Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Destinations**. Select **Webhook**. Next, select **Add Destination** to open the **Webhook** > **New Destination** modal, and configure the following.

General Settings

URL: The URL for the new custom integration (copy this from the Moogsoft UI).

Method: `POST`.

Format: `Custom`.

Content type: `application/json`.

Advanced Settings

Extra HTTP Headers: Select **Add Header** to define this extra header:

Name	Value
`apiKey`	The API key for the new custom integration (copy this from the Moogsoft UI).

Select **Save**, then **Commit** and **Deploy**. Now you are ready to map your events and/or metrics.

Mapping Cribl Data to Moogsoft

Your mappings will differ, depending on the data you want to send. However, the simple examples below, in which we map a Cribl Stream payload to a Moogsoft custom integration, illustrate principles that apply to all custom mappings:

- Moogsoft has a defined event schema and metric schema. Each schema includes a set of required fields. Your custom integration must include mappings for all required fields.
- You can define custom tags for Cribl Stream fields that do not have Moogsoft equivalents.
- You can also specify default values in case Cribl Stream sends an object with a missing field.
- The Moogsoft event schema includes a `severity` field. You can map Cribl Stream fields and values to Moogsoft severities, or define a default severity if a payload does not include this information.

Define and validate your mappings based on the type of data you plan to send to Moogsoft:

- Event Mapping
- Metric Mapping

Event Mapping

To illustrate how to map Cribl Stream payloads to Moogsoft events, we'll walk through an example with a payload of Cribl Stream syslog messages. You'll follow the same overall workflow for any events payload.

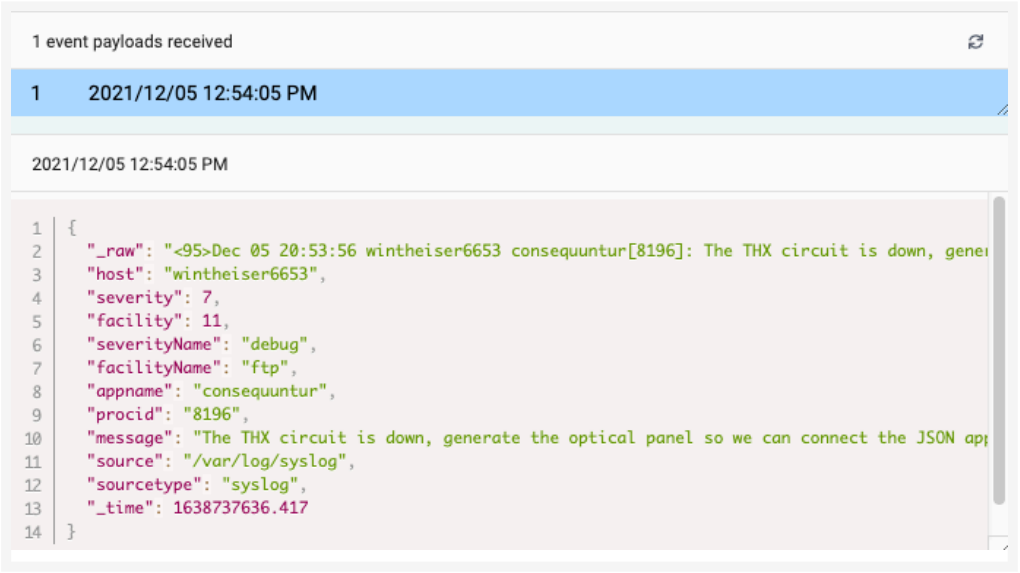
Send a Sample Payload to Moogsoft

In Cribl Stream, navigate to your Webhook Destination's configuration modal, select the **Test** tab, then:

1. In the **Test input** field, define one or more JSON payloads for the Cribl data you want to send. To map syslog events, set the **Select sample** drop-down to **syslog.log**.
2. Select **Test**.

Map the Event Fields

In Moogsoft, view the custom integration's config screen. Under **Map Your Data**, you should now see the payload you just sent.



The event payload appears in Moogsoft

Select the payload, and then define your Cribl-to-Moogsoft mappings. Your Cribl Stream data will largely determine the mappings you want. See Events Object in the Moogsoft API docs.

Here are some reasonable mappings for the syslog payload in this example:

Cribl Source Field(s)	Moogsoft Target Field
`message`	`description`
`appname`	`service`
`facilityName`	`check`
`severity`, `severityName`	`severity`
`procid`	`tag.process-id`

Map the Severities

The Moogsoft event schema has a severity field. You can specify integers or strings, from `0`, meaning Clear, to `5`, meaning Critical. Here are some reasonable mappings.

Syslog Severities	Moogsoft Severities
Emergency (`0`), Alert (`1`), Critical (`2`)	Critical (`5`)
Error (`3`)	Major (`4`)
Warning (`4`)	Warning (`2`)
Informational (`6`), Debug (`7`)	Unknown (`1`)
Notice (`5`)	Clear (`0`)

Verify your Mappings

Once you save and apply your mappings in Moogsoft, do the following:

1. In Cribl Stream, return to the **Test** tab for the Webhook Destination. Select **Test** again to send another payload.
2. In Moogsoft, go to the **Alerts** screen. You should now see a new alert based on the payload you just sent.

Metric Mapping

To illustrate how to map Cribl Stream payloads to Moogsoft events, we'll walk through an example with a payload of Cribl Stream syslog messages. You'll follow the same overall workflow for any metrics payload.

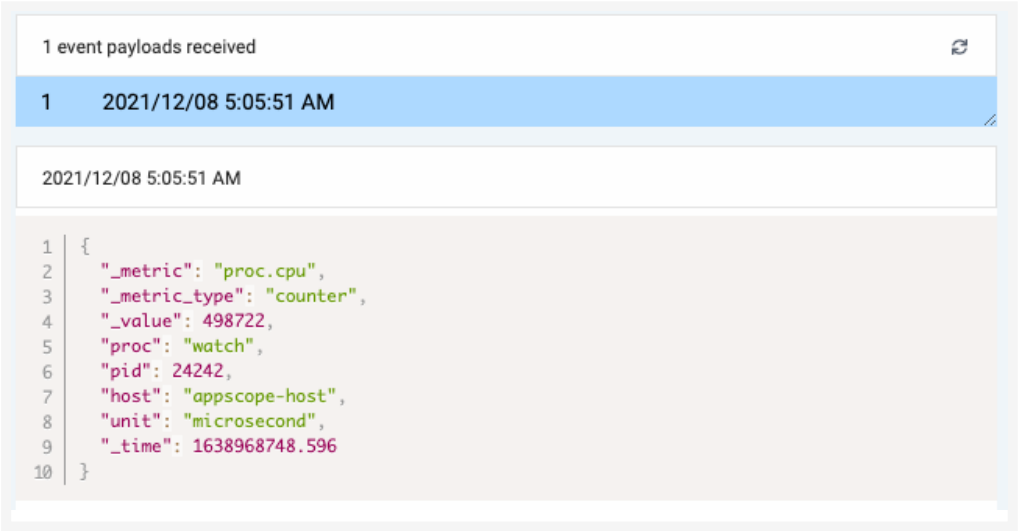
Send a Sample Payload to Moogsoft

In Cribl Stream, navigate to your Webhook Destination's configuration modal, select the **Test** tab, then:

1. In the **Test input** field, define one or more JSON payloads for the Cribl data you want to send. To map syslog events, set the **Select sample** drop-down to a metrics-based sample file available in your deployment.
2. Select **Test**.

Map the Metrics Fields

In Moogsoft, view the custom integration's config screen. Under **Map Your Data**, you should now see the payload you just sent.



The metrics payload appears in Moogsoft

Select the payload and then define the Cribl-to-Moogsoft mappings you want. Your Cribl data will largely determine these mappings. See Metric Datum Object in the Moogsoft API docs.

Here are some reasonable mappings for the metrics payload you just sent:

Cribl Source Fields	Moogsoft Target Field
`_metric`	`metric`
`_value`	`data`
`host`	`source`
`unit`	`tag.unit`

Cribl Source Fields	Moogsoft Target Field
`pid`	`tag.pid`

Verify Your Mappings

After you save and apply your mappings in Moogsoft, test them like this:

1. In Cribl Stream, return to the Webhook Destination's **Test** tab. Select **Test** again to send another payload.
2. In Moogsoft, go to the **Metrics** screen. You should now see a new alert, based on the payload you just sent.

8.8.11. Nightfall Integration

Thanks to Nightfall for contributing this page and the corresponding Nightfall Pack, which you can install in Cribl Stream and customize as described below.

The Nightfall Pack relies on Nightfall's Data Loss Prevention (DLP) engine, which uses machine learning to detect sensitive information in events streamed through Cribl. The Pack enables you to monitor your Pipelines in real time for PII, PHI, PCI, and other sensitive data. Nightfall discovers and automatically redacts the sensitive content before it can reach any Destination. Aside from redaction, you can use the Pack to automatically label problematic event data.

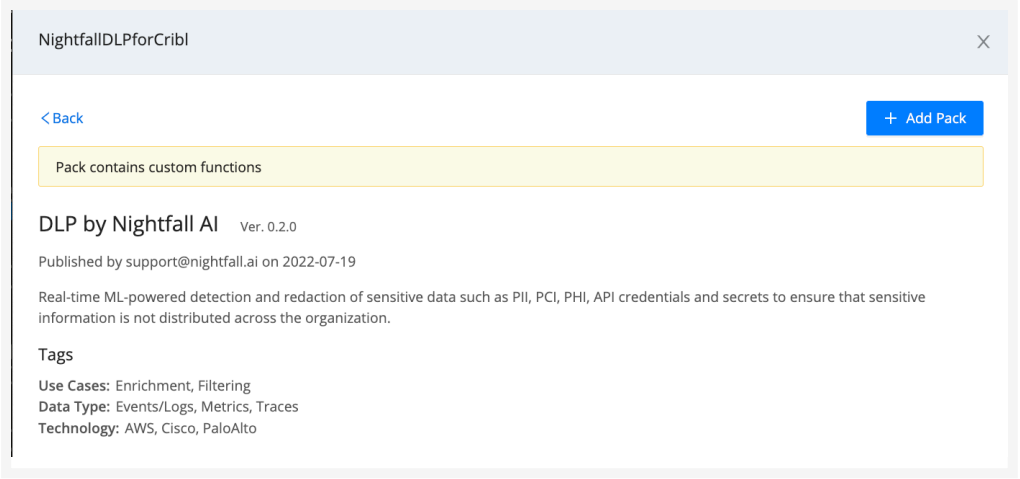
The risk of sensitive data spreading across data pipelines grows as organizations work with data from more sources. Nightfall can help ensure that sensitive data doesn't accumulate in the first place, facilitating compliance with data-security regulations. This is important for Cloud-first organizations that must scale observability while complying with regional or industry-specific compliance regimes.

Configure the Detection Engine

1. Sign up for a free Nightfall Developer Platform account, if you have not already done so. This entitles you to scan up to 3GB of event data per month for free.
2. Log in to the Nightfall Dashboard.
3. Create an API Key.
4. Create the Detection Rules and/or Policy that you want Nightfall to scan with.
   Detection Rules enable you to specify which Detectors will scan each event. A Detection Rule simply redacts sensitive information from events.
   A **Policy** governs alerts, which Nightfall can send via email, Slack, or webhook. (Assuming that you want to send data to a Cribl Stream Destination and/or a SIEM, use a webhook.) A Policy can include up to 20 previously defined Detection Rules. It can also turn redaction off, if desired.

Install the Nightfall Pack

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Processing** > **Packs**.
2. Select **Add Pack**, then select **Add from Dispensary** to open the Packs Dispensary drawer.
3. Navigate to the **DLP by Nighfall AI** Pack's tile.
4. Select the Nightfall Pack's tile to display its details page.

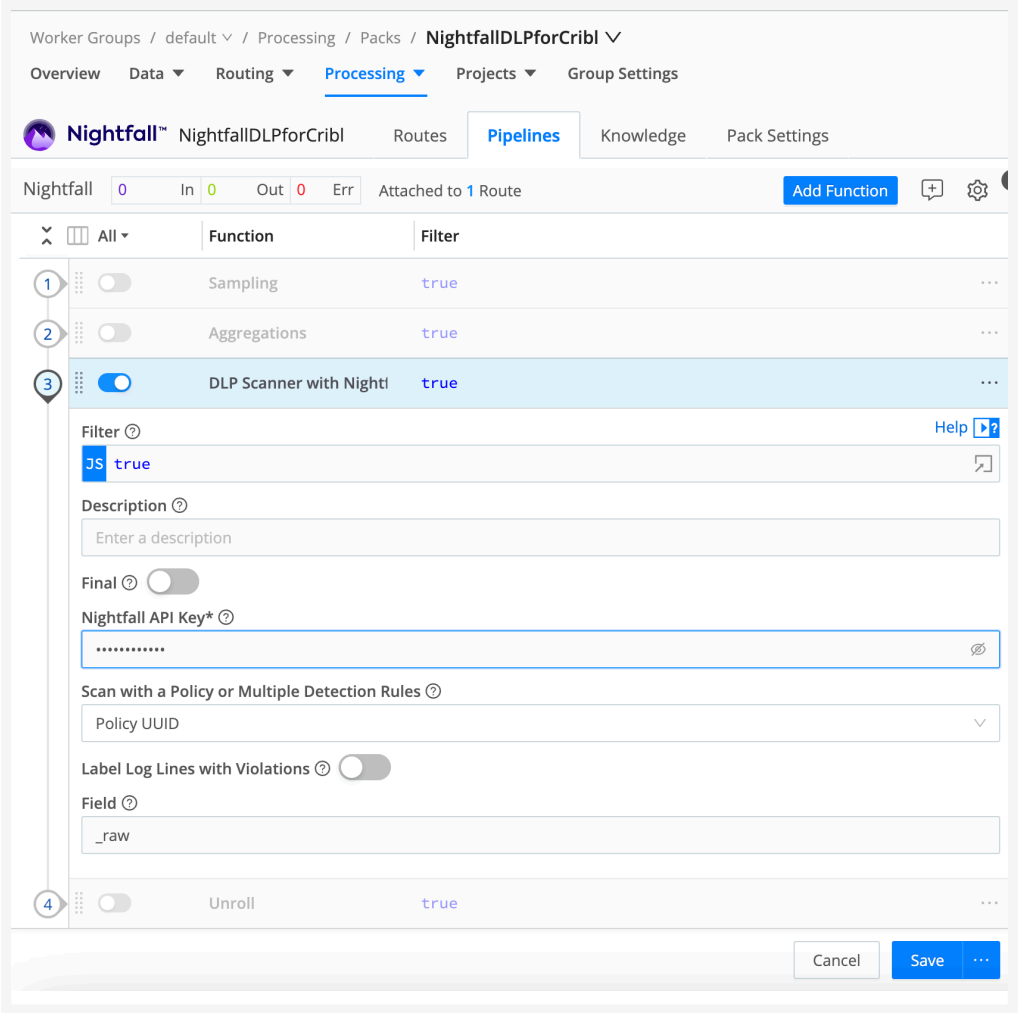


The Nightfall Pack details page

5.Select **Add Pack**. Shortly, you'll see a banner confirming that the Pack is installed.

Configure the Nightfall Pack

1. From the **Packs** page, select the new Pack. This opens the Pack's **Routes** tab.
2. In the **Pipeline** column, select `Nightfall`.
3. From the resulting Nightfall Pipeline configuration, expand the **DLP Scanner with Nightfall AI** Function.



Selecting the Nightfall Pipeline

4. In the **Nightfall API Key** field, enter the API key you created in the Nightfall Dashboard.
5. Set the **Scan with a Policy or Multiple Detection Rules** drop-down to match your detection engine configuration.
   Selecting **Policy UUID** exposes a corresponding field to enter the single UUID.
   Selecting **Detection Rule UUID** exposes a **Add Rule**. Click this to enter as many Detection Rule UUIDs as you want to specify.
6. (Optionally:) Label sensitive events. If you toggle **Label Log Lines with nightfall_violations** on, each event where Nightfall has detected sensitive information will have an added `nightfall_violations: true` field.

Advanced Features

The Nightfall Pipeline also includes three limiting Functions, described here. These are disabled by default, but you can enable them as needed.

8.8.12. Managing QRadar Licenses

If you're using a SIEM (security information and event management) system like QRadar that's subject to an events-per-second (EPS) licensing model, managing license costs can be an issue. Cribl Stream enables you to proactively manage your license by slowing EPS growth.

Cribl Stream does so by offering fine-grained control over what events to send to the QRadar Event Processor, without breaking the expected LEEF (Log Event Extended Format) data format. You can report on event codes, and make decisions about what to drop, based on the data in the events. Some of what we discuss here also applies to SIEMs generally, not just QRadar.

Confronting QRadar Constraints

QRadar imposes constraints on data through several of its components:

- QRadar Event Collectors can send data only to QRadar. Elastic and other systems of retention or analysis are not an option.
- QRadar Event Collectors can send data only in LEEF format. The pipeline cannot provide additional streams of data in different formats such as JSON or syslog.
- Incoming data must adhere to a predefined schema, based on IBM LEEF format. You can't reformat events, nor reduce the size of an event, without breaking the correlation rules within the QRadar Event Processor.
- When incoming data exceeds the EPS license limits, QRadar will drop or stop ingesting data. Meanwhile, since the license is based on EPS event velocity, license costs increase linearly: the higher the EPS count, the higher the cost.

If your event velocity approaches the license limit, your options are unappealing:

- You can try to exclude some data, but the correlation rules and constraints on data formatting restrict your ability to be selective. You can drop only broad categories of data, such as an entire Windows Event ID, leaving you at a risk of missing something important.
- You can hope that you never actually exceed the EPS limit, but if you guess wrong, QRadar dropping or not ingesting data can be disruptive and compromise your enterprise security posture.

Cribl Stream enables you to surgically minimize these risks, and get the most out of your existing licenses.

Dropping Events Selectively

A common tactic to avoid exceeding an EPS license limit is to start dropping an entire class of events. This is a crude approach that carries its own risks. With Cribl Stream, you can analyze the data within the event, and decide what to keep based on your priorities.

Analyzing a Windows Event

Here's an example of how to analyze and selectively drop Windows Security Event ID 4674. This event documents operations attempted on a privileged object. While it's commonly discarded when admins are feeling pressed to drop events, 4674 is actually a critical ID that should be kept some, or most, of the time.

Event ID 4674 includes the logon types shown in the table below.

Logon Type	Logon Title	Description
2	`Interactive`	Activity on the system's keyboard and screen.
3	`Network`	Connection to a shared folder on this computer from elsewhere on the network.
4	`Batch`	Processes might be executing on behalf of a user without their direct intervention.
5	`Service`	Service startup by the Service Control Manager.
7	`Unlock`	An unattended workstation with password-protected screen saver.
8	`NetworkCleartext`	Logon with credentials sent in cleartext. Most often indicates a logon to IIS with "basic authentication".
9	`RemoteInteractive`	Logon with RunAs, or mapping a network drive with alternate credentials.
10	`CachedInteractive`	Logon with cached domain credentials, such as when logging on to a laptop when away from the network.

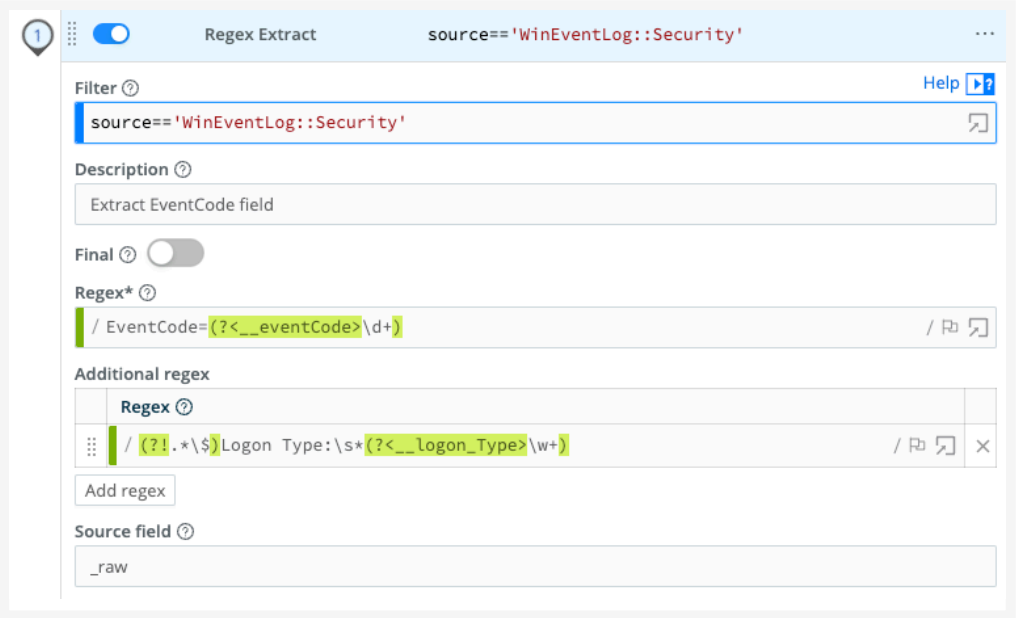
Each logon type is assigned a different security value.

Let's suppose that your QRadar deployment is in an enterprise where inbound file sharing is disabled. In that case, you don't need logon type 3 events. So let's see how to use Cribl Stream to keep all ID 4674 events except logon type 3 events, which we'll' drop.

Dropping the Excess Baggage

Use sample data to validate the reduction methods described below. Don't apply these methods to your production SIEM until you are confident they won't interfere with the usability of your system.

1. Save your Windows Events to Cribl Stream using Live Capture.
2. Create a Pipeline and name it `Windows_Event_Reduction`.
3. Add the Regex Extract Function to your Pipeline to create fields for `EventCode` and `Logon Type`. These fields will be the foundation for a Filter that drops only Windows events of ID 4624, logon type 3.

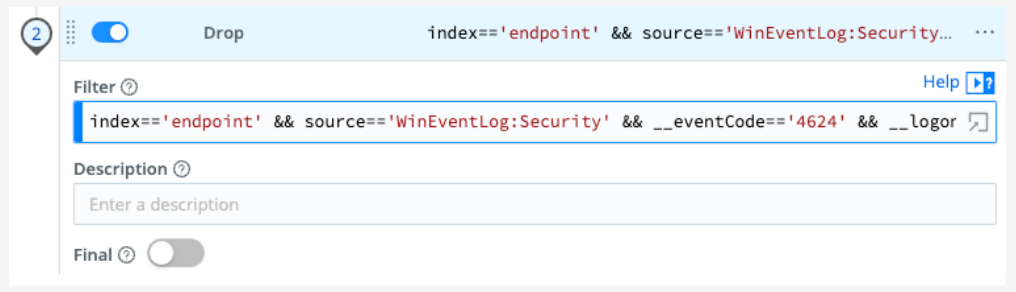


Regex Function on Pipeline

4. Add the Drop Function to your Pipeline using the Filter below.

```
index=='endpoint' && source=='WinEventLog:Security' && __eventCode=='4624' && __logor
```

Copy



Drop Function

5. Apply the Pipeline to your Windows Sources. Cribl Stream will then start dropping the unneeded events.

Other Reduction Examples

Apply the options in this section only after careful analysis of your own environment and priorities. Even if you choose to exclude these events from QRadar, you might want to send them to an object store for later auditing and/or replay.

WinEvents

- Event ID 4624: Look for Subtypes (Logon Type) that can be dropped.
- Event ID's 4634 and 4674: An account was logged off. Most security use cases don't require Logoff events.
- Event ID 4673: A privileged service was called. This event rarely contains actionable intel. It's a large-volume data source that can be dropped, in exchange for other, more-valuable event IDs.
- Event ID 4674: An operation was attempted on a privileged object. Similar to Event ID 4673, this event is largely considered "noise," providing little value. Consider dropping.
- Event ID 4689: A process was exited. This source, when paired with Event ID 4688, can tell you "how long a process was running." Typically, this is unimportant information, and can be omitted from your event collection.

Palo Alto

The following filters can be helpful to reduce the noise:

- All external-to-internal traffic AND `action=deny`: `Ingress traffic && action=deny`
- `PAN Traffic logs && application=ping|ibm-bigfix|outlook-web-online|google-base|traceroute|ms-teams|ic mp|outlook-web-online|ms-office365-base|crowdstrike`

Cisco ASA

- All external-to-internal traffic AND `action=deny`: `Ingress traffic && action=deny`
- Teardown UDP Connection && Event ID 302016
- Teardown TCP connection && Event ID 302014
- Teardown ICMP connection && Event ID 302021
- Teardown Translation && Event ID 305010|305012

8.8.13. Slack/Webhook Integration

You can configure Cribl Stream to send simple Notifications to Slack via a Webhook URL. These Notifications arrive in Slack as messages in a channel that you choose. For more information, see our Slack Notifications topic.

However, if you have specific event data such as alert-based or conformance data that you want to route to Slack for prompt attention, you can use Cribl Stream's Webhook Destination to route or filter this data.

You can also enhance your messages with more advanced formatting. Consult the Slack documentation for detailed information.

Cribl Stream does not currently support the use of special characters in Slack notifications sent via a Webhook Destination.

Creating a Slack/Webhook integration is a three-step process:

1. Create a Slack demo app.
2. Configure the Webhook Destination.
3. Verify that Slack is receiving messages.

Create a Slack Demo App

1. Create a Slack app by following these Slack instructions on sending messages with incoming webhooks.
2. Test the cURL command supplied when setting up the Slack app. For example:

```
curl -X POST "https://hooks.slack.com/services/T00000000/B0000000000/XXXXXXXXXX
-H "Content-Type: application/json" \
-d '{
  "text": "Hello, World!"
}'
```

Copy

Configure a Webhook Destination

Configure a Webhook Destination in Cribl Stream as described in Webhook. However, you must override some of the default settings:

- In **General Settings**, use the **URL** provided for your Slack demo app.
- In **General Settings** > **Optional Settings**, set **Format** to `Custom`.
- In **General Settings** > **Optional Settings**, set **Source expression** to `` `{"text":"${_raw}"}` `` (with literal backticks).
- In **Advanced Settings**:
  - Toggle **Validate server certs** off.
  - Toggle **Compress** off.
  - Set **Events-per-request limit** to `1`.

Verify That Slack Is Receiving Messages

To verify that Slack is receiving message, send a test message, using the **Test** UI. For example:

```
[
  {
    "_raw": "Hello, World!"
  }
]
```

Copy

If the integration is working correctly, this test message will arrive in the Slack channel you're using for your demo app.

8.8.14. Zscaler NSS Virtual Machine

Zscaler Nanolog Streaming Service (NSS) uses a VM to stream traffic logs in real time from the Zscaler Nanolog to a SIEM. Cribl Stream can take the place of the SIEM in this arrangement. Then you can use Cribl Stream to greatly reduce the size of ZScaler logs.

For Zscaler Cloud NSS, use the Zscaler Cloud NSS Source, which uses HTTP/HTTPS.

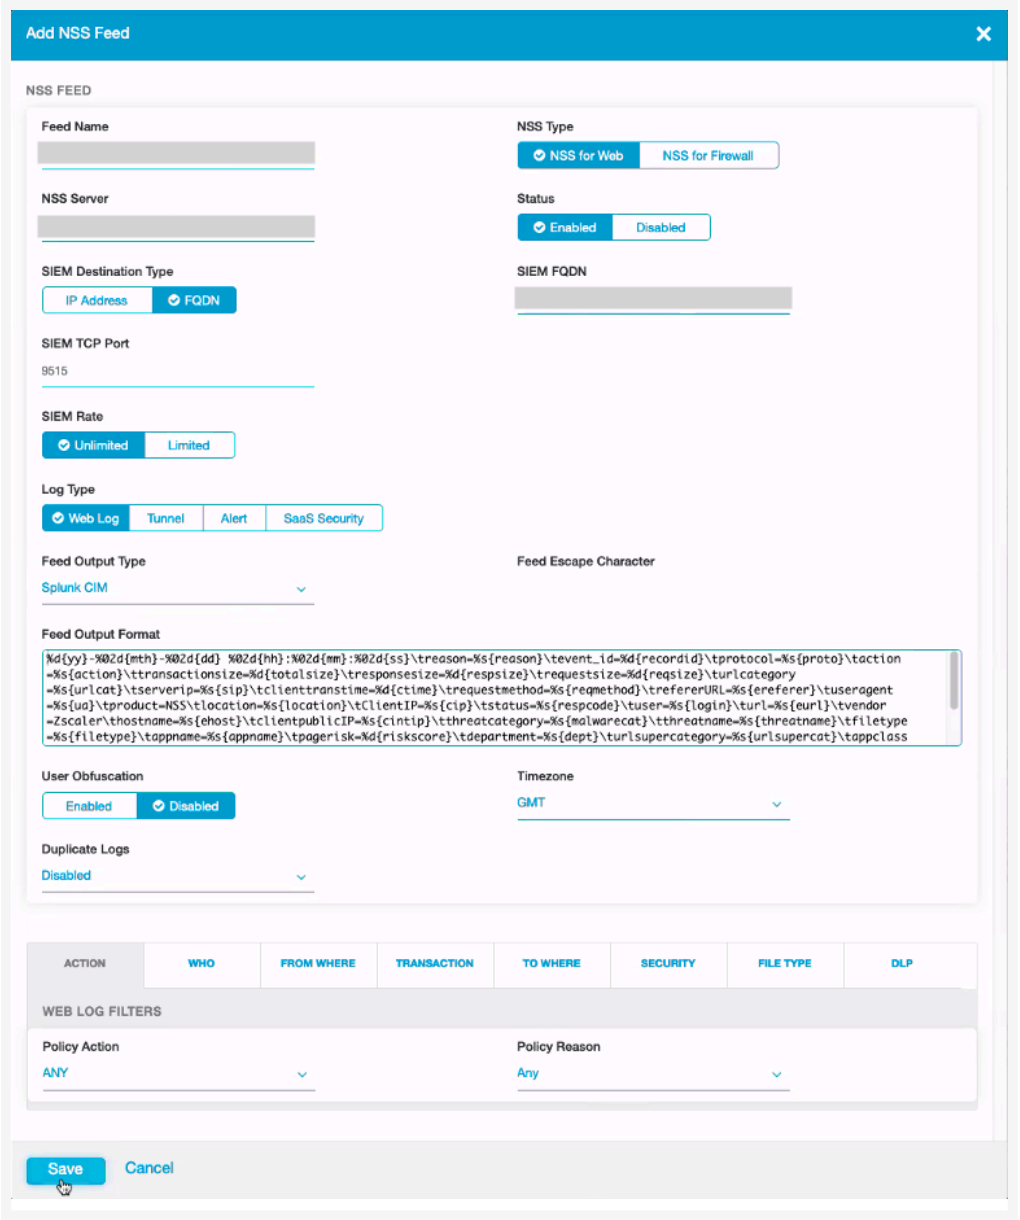
Configuring NSS to Send Data to Cribl Stream

Since Nanolog forwards data to a single IP address or FQDN, Cribl recommends that you use a load balancer to distribute data among Cribl Stream Workers.

Nanolog delivers data using a raw TCP connection.

In Zscaler:

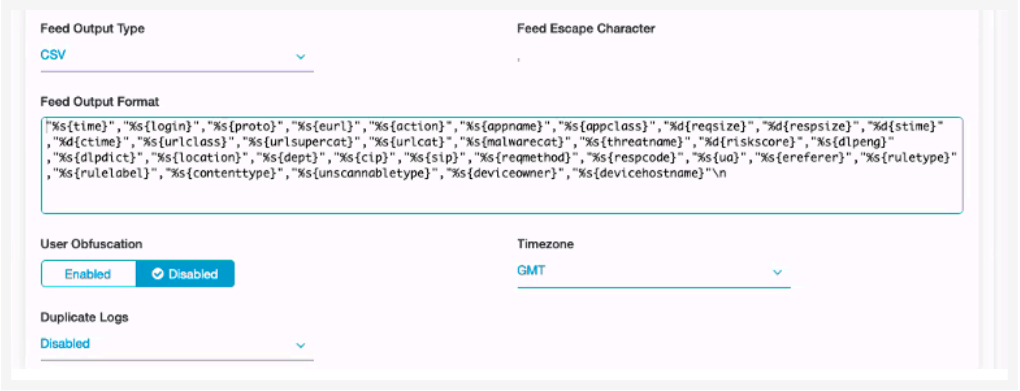
- Go to **Administration** > **Nanolog Streaming Service**.
- In the **NSS Feeds** tab, click **Add NSS Feed** to open the following configuration window:



Adding a Zscaler NSS feed

- Enter a **Feed Name** that identifies this feed as one that sends data to Cribl Stream.
- Enter the IP address or FQDN for either your Cribl Stream instance, or the load balancer you're using with your Cribl Stream instances.
- Select a **Feed Output Type**. `Splunk CIM`, a tab-delimited key/value format, is a typical choice.

Alternatively, you choose a different option, such as CSV:



Choosing a CSV output format

Example Pipeline

Cribl Stream can reduce Zscaler log size by (1) reformatting and reshaping the data, and (2) suppressing, sampling, and dropping appropriate fields.

The following code block shows how to correctly parse tab-delimited key-value pairs.

```
let temp = {};

// Substr drops the timestamp from _raw, otherwise the split does not work correctly
__e['_raw'].substr(20).split('\t').forEach((element) => {
    // Split K=V on the first equal sign
    let eq = element.indexOf('=')
    let name = element.substr(0, eq);
    let value = element.substr(eq + 1);

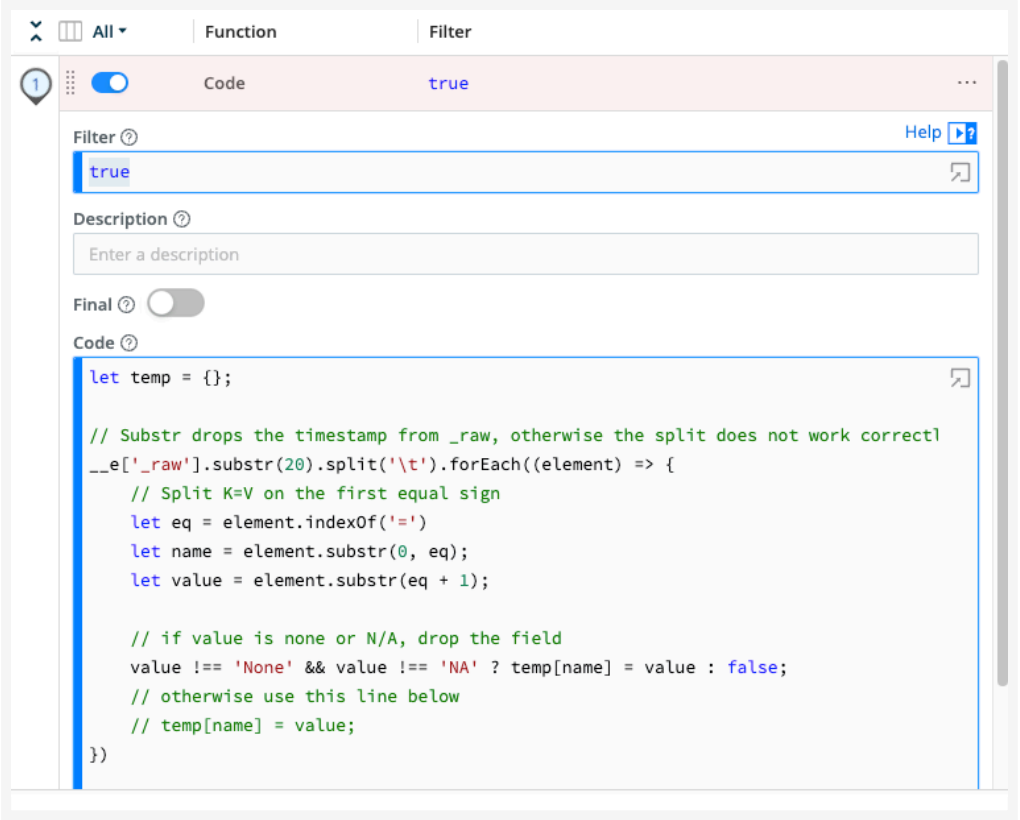
    // if value is none or N/A, drop the field
    value !== 'None' && value !== 'NA' ? temp[name] = value : false;
    // otherwise use this line below
    // temp[name] = value;
})

__e['_raw'] = temp;
```

Copy

Here's an example Pipeline that uses the parsing code above. (You can directly import this Pipeline in JSON form.)

A Code Function parses the data:

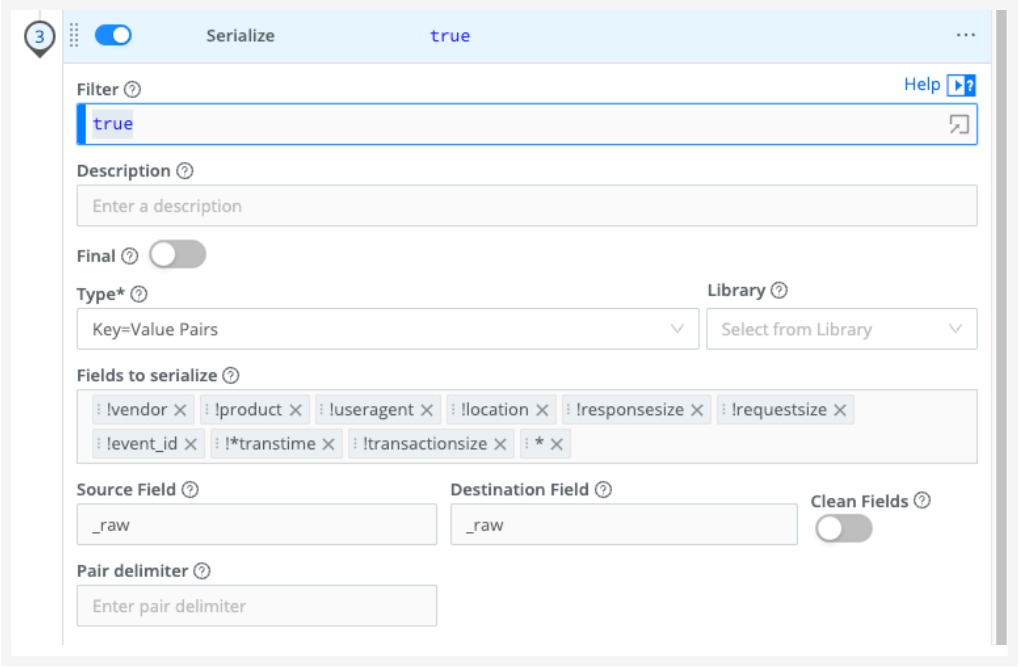


Parsing with a Code Function

An Eval Function reshapes the data:

Reshaping with Eval

And finally, a Serialize Function drops unwanted fields:



Dropping fields with Serialize

Example Pipeline JSON

To import the example Pipeline directly, copy and save the JSON below, then follow these instructions.

Zscaler Example Pipeline

```
{
  "id": "zscaler",
  "conf": {
    "output": "default",
    "groups": {},
    "asyncFuncTimeout": 1000,
    "functions": [
      {
        "id": "code",
        "filter": "true",
        "disabled": false,
        "conf": {
          "maxNumOfIterations": 5000,
          "code": "let temp = {};\n\n// Substr drops the timestamp from _raw, otherwi
        }
```

8.8.15. Tanium To Cribl Stream

Tanium is a security platform that provides rapid searches across multiple endpoints. Tanium integrates with a finite number of tools using its Tanium Connect module, but this can still leave gaps in conforming Tanium output to the specific data formats required by unsupported tools and destinations.

Cribl Stream can help collect, reduce, enrich, transform, and route data from Tanium to any destination. This includes SIEM (Security Information and Event Management) tools, logging tools, or other analytics platforms. In this guide, we'll explain how to configure Tanium Connect to send Tanium-captured data to Cribl Stream. For further details, see Tanium's Configuring SIEM Destinations topic.

Configure Tanium Connect

A Tanium Connection is essentially a scheduled search/collection of data linked to a destination. Tanium translates queries into **Questions**. It formats the Questions into the Tanium Search Language for a search, providing near real-time results.

The first step in configuring Tanium Connect is to set up a Question. A Question can be a Saved Search, Question Log, Client Status, or an Event.

To configure a new connection, go to the **Tanium Module** page and click **Tanium Connect**. On the **Connect Overview** page, scroll to the **Connections** section, and click **Create Connection**.

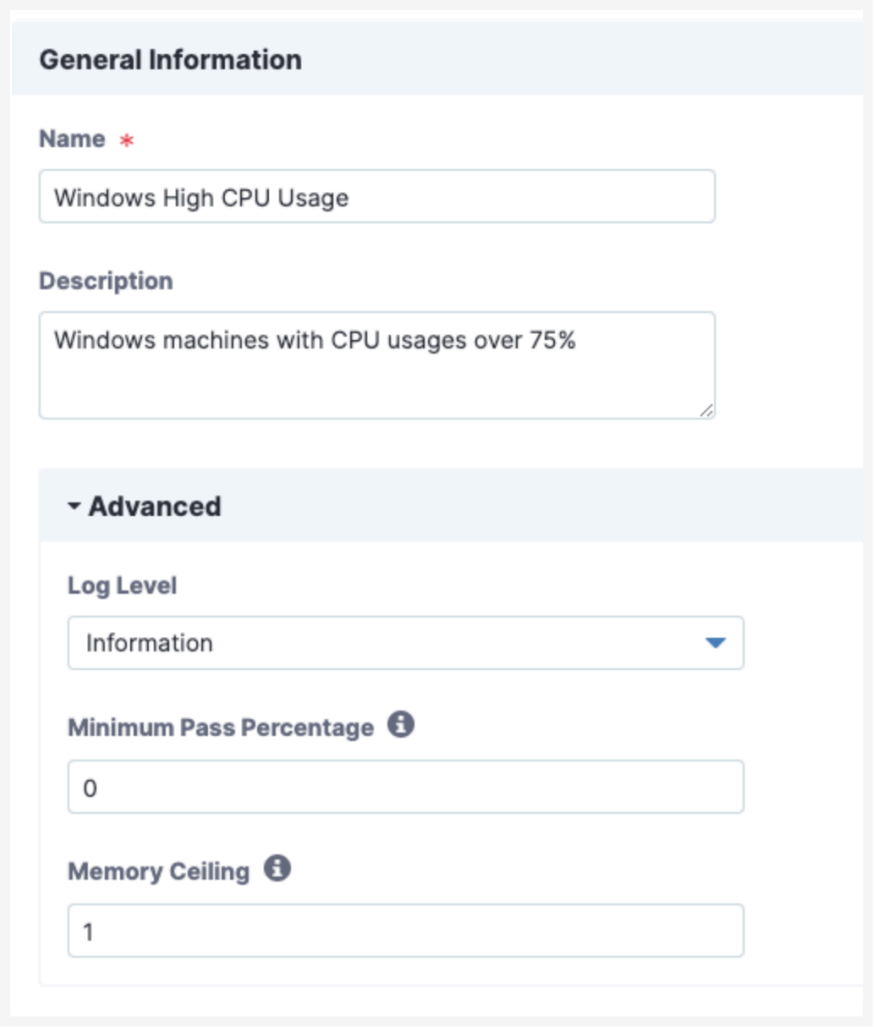
Specify General Connection Information

Name: A unique name for your connection.

Description: An optional description for this connection.

Advanced Settings: Optionally, configure the following fields:

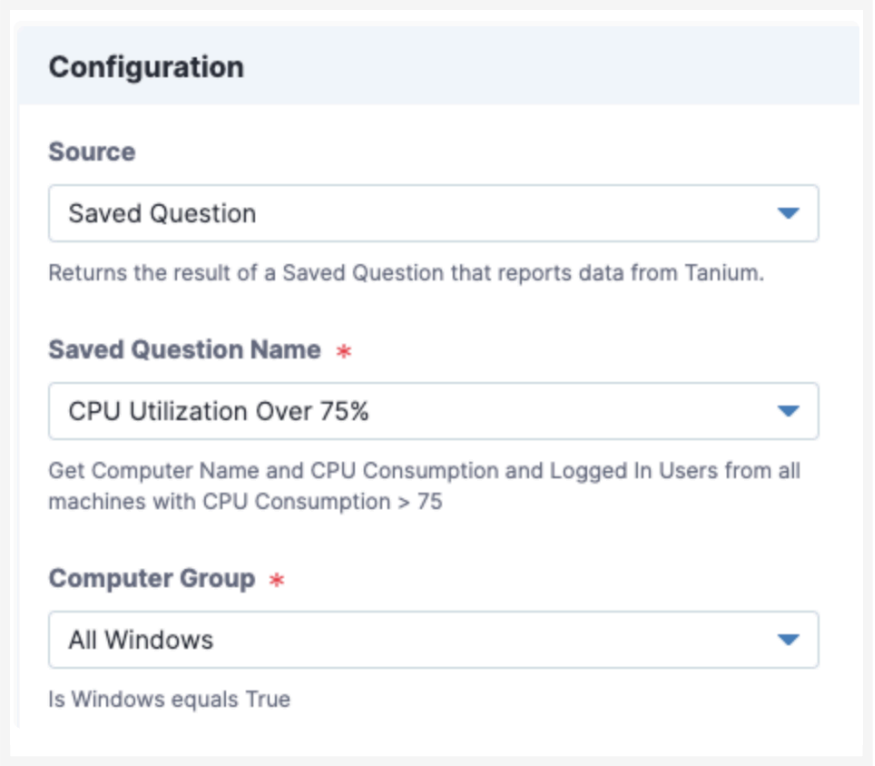
- **Log Level**: Defaults to **Information**. Change the **Log Level** to **Trace** or **Debug** if plan to debug the connection. Alternatively, set the **Log Level** to **Warning**, **Error**, or **Fatal** to reduce the amount of logging.
- **Minimum Pass Percentage**: Minimum percentage of the expected rows to process for the connection to succeed.
- **Memory Ceiling (GB)**: Maximum memory for the node process to run the connection.



General Connection Information tab

Configure the Connection Source

This section enables you to specify the type of data you are sending to your destination. The data is usually information from Tanium, such as a Saved Question, Question Log, Client Status, or Event. The settings vary depending on the Source.



Connection Source Configuration

When sending logs to Cribl Stream, you must create a network egress rule in Tanium for port 10060. See Tanium's Configure a new network egress rule topic.

Configure Your Destination

In this section, we'll configure Cribl Stream as the destination, using the following fields.

Destination: Select the destination type. For our example, we'll configure it as a `Socket Receiver`.

New: Configure a new destination.

Name: Specify a unique name for your new destination. (This field is displayed only when configuring a **new** destination.)

Existing: Update the settings on an existing destination. (Note that this will affect all the connections that use this destination.)

Destination Name: Drop-down list where you can specify a preconfigured destination. Displayed only when updating an **existing** destination.

Copy Settings: Copy settings from a preconfigured destination.

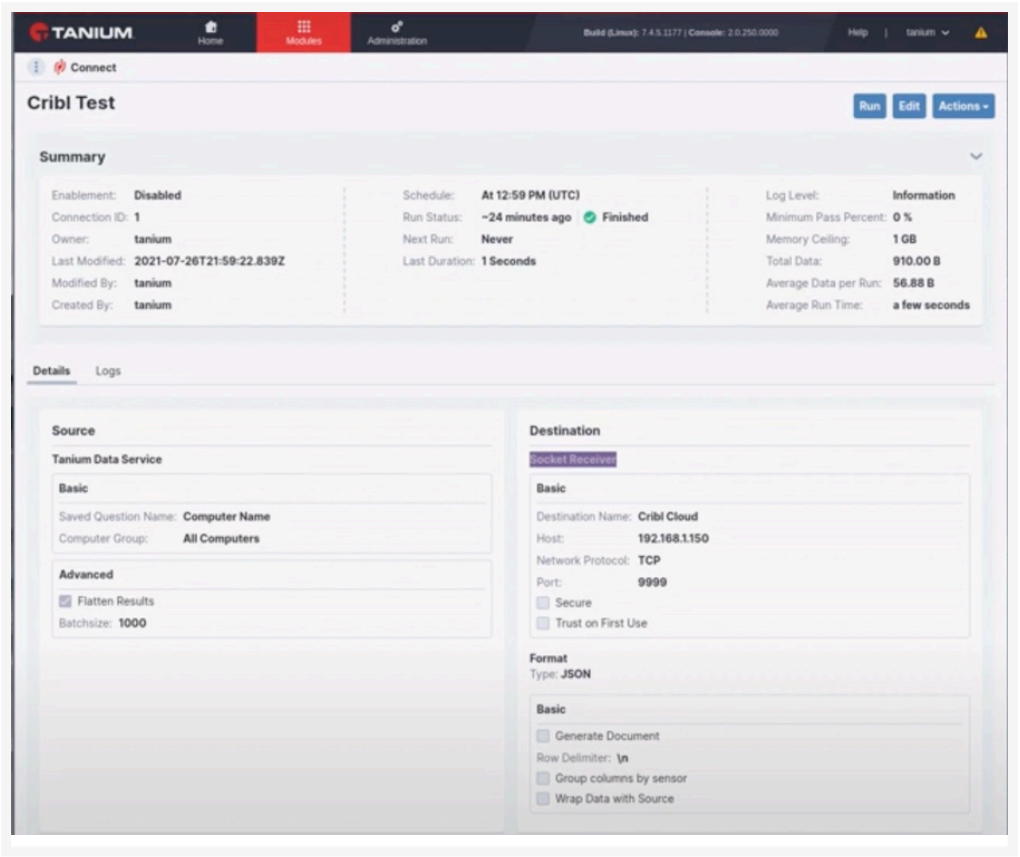
Host: Specify the destination'server host.

Network Protocol: Specify how to connect to the server (e.g., `TCP`).

Port: Enter the port number to listen on.

Secure: Select this option to use TLS encryption.

Trust on First Use: Select this option to accept the certificate presented from the server, and to trust **only** that certificate for future connection runs.



Sample Cribl Stream Configured Destination

Format the Data

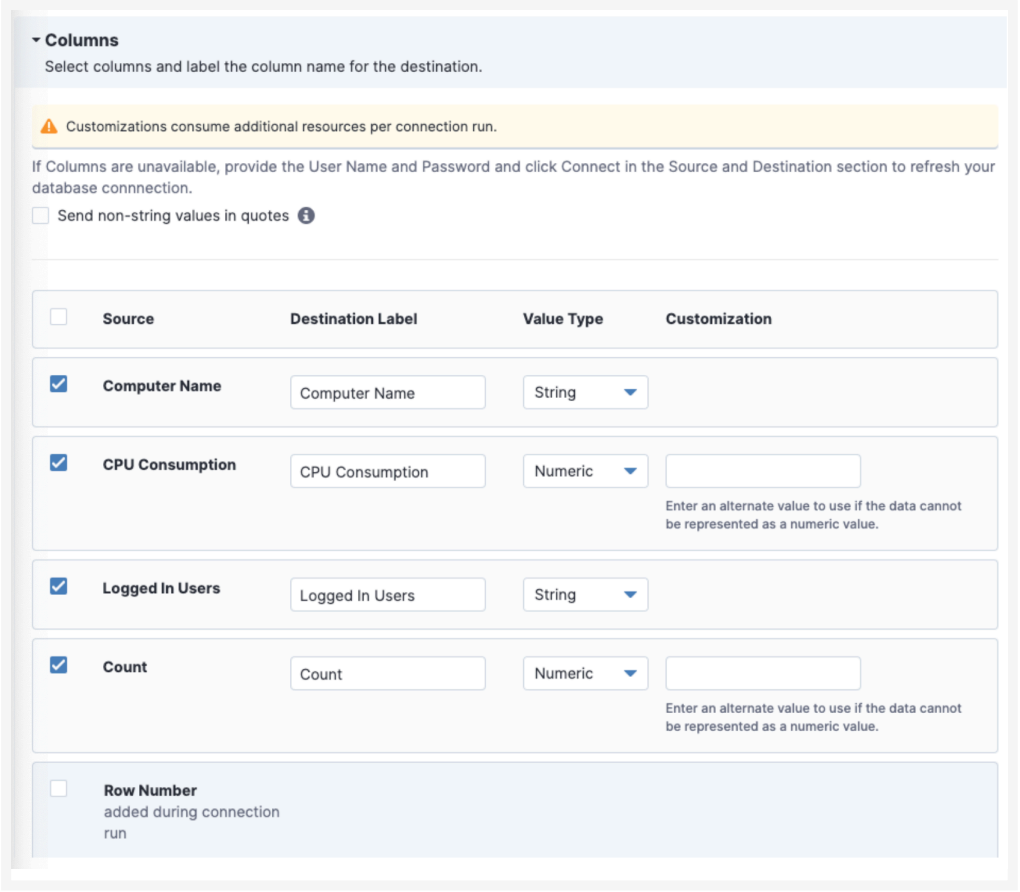
When you select a destination, the expected data format is displayed by default. For example, if you select Splunk, the `Syslog RFC 5424` automatically pre-populates the **Format Type** field. However, you can customize the format as needed. (For details, see Tanium's Format Types topic.)

Format Type: When sending to Cribl Stream, select the `JSON` data format for best results.

In the **Columns** section, configure the columns that you want to pass on to your Destination. (For details, see Tanium's Column Customizations topic.)

- **Source**: Check the box next to each **Source** to include the columns in your Destination.
- **Destination Labels**: You can optionally assign a new column heading. Defaults to the **Source** name.
- **Value Types**: You can change the data type to `String`, `Numeric`, or `Data/Time` value.
    - If you select a `Numeric` value, you must specify a default value. It can be any integer.

- If you select a `Data/Time` value, specify the format to apply for the column. R(For details, see Tanium's Time Stamp Variables topic.)



Configure your columns

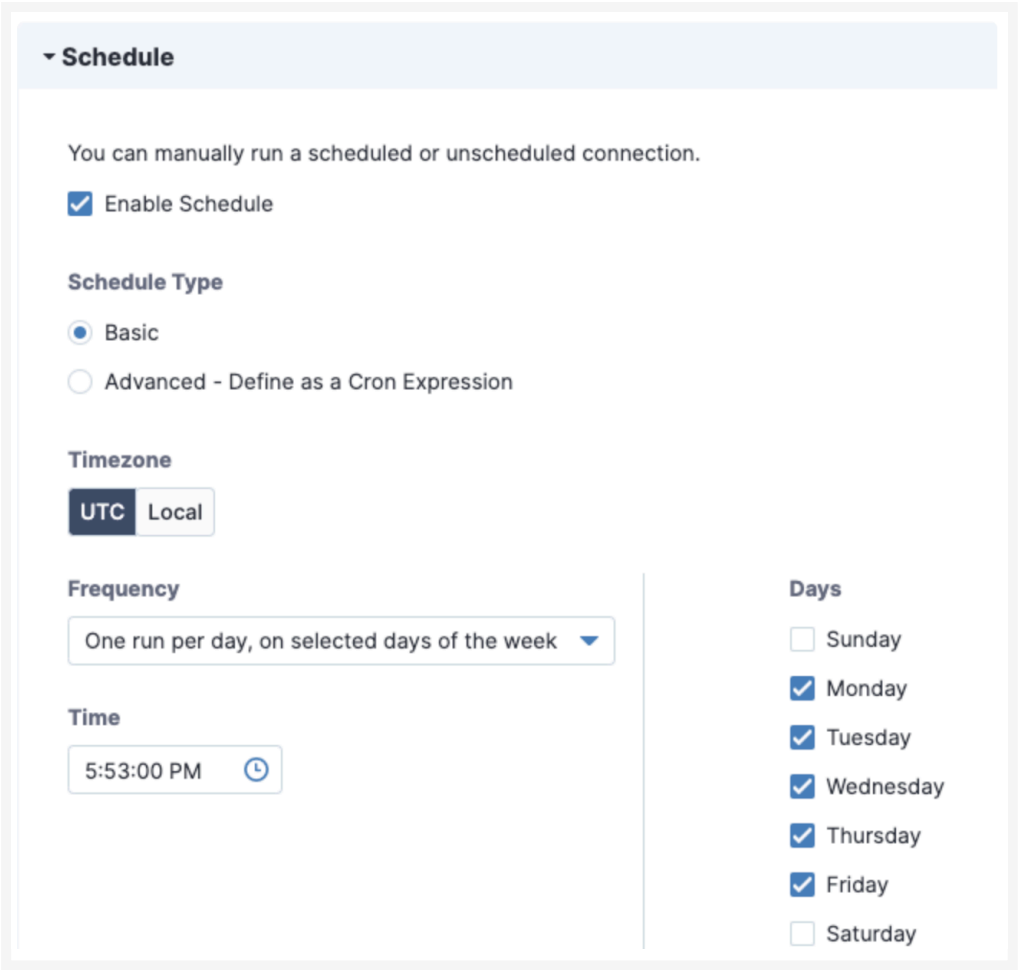
Schedule the Connection

Connections can run at a highly configurable time interval - anywhere from multiple times per hour, to daily, weekly, or monthly intervals. The **Schedule** section allows you to enable and configure the scheduler.

Enable Schedule: If you do not enable the scheduler here, the connection will run only when you explicitly run it.

Schedule Type: Select **Basic** to build a schedule with the provided controls.

Advanced - Define as a Cron Expression: Select this field to view or edit the cron expression directly.



Configure your columns

If the user who owns a connection is deactivated, future instances of a scheduled connection will not run. For details, see Tanium's Deleted User Troubleshooting topic.

9. Packs

Packs are self-contained bundles of Cribl Stream configurations. A Pack can include Routes, Pipelines, Sources, Destinations, and knowledge objects, grouped as a single portable unit that you can install, inspect, and reuse across Worker Groups and environments. You can create your own Packs or download pre-built configurations directly from the Cribl Packs Dispensary.

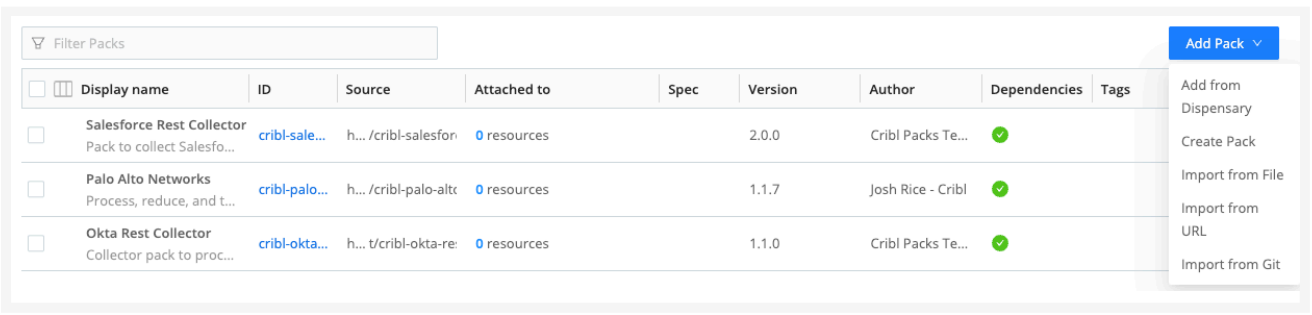
By providing end-to-end configurations for specific services, Packs enable you to:

- **Apply ready-made building blocks:** Install pre-built Packs from the Cribl Packs Dispensary to quickly integrate services and adapt them to your requirements. See Onboard Faster With Packs for information on using Dispensary Packs.
- **Maintain consistent configurations:** Capture organization-specific best practices and share standard workflows across your entire deployment. See Pack-Based Configuration Management to learn how to templatize your end-to-end deployment into a portable, reusable unit.
- **Learn from existing configurations:** Open and review Packs to see how configurations implement reduction, enrichment, normalization, and routing patterns. See Use Packs as Examples.
- **Share and contribute:** Package your own complex workflows to distribute to other teams, or publish them for the wider Cribl community. See the Packs Publication Standards for community guidelines on contributing to the Dispensary.

Get Packs

You can add Packs to your deployment by importing them from:

- Packs Dispensary
- File
- URL
- Git repo



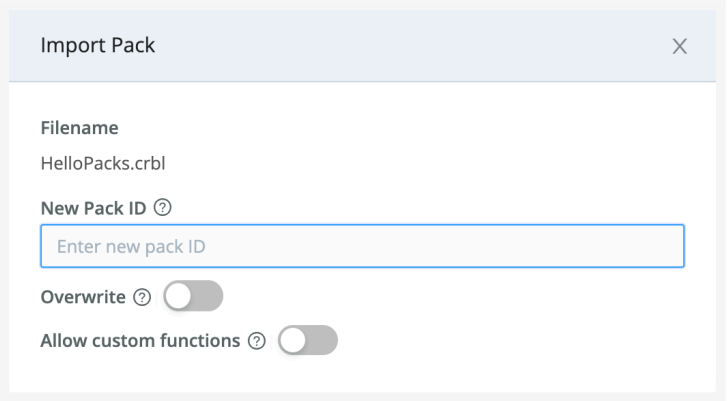
Importing a Pack

Pack Naming on Import

Each Pack that you install within a given Worker Group (or Single-instance deployment) must have a unique ID. The ID is based on the internal configuration of the Pack - not its container file name, nor on its **Display name**.

If you import a Pack whose internal ID matches an installed Pack - whether an update, or just a duplicate - you can choose one of two options:

- Assign a unique **New Pack ID**. This will import the Pack as a new, separate Pack with the new ID.
- Toggle **Overwrite** on to overwrite the installed Pack, reusing the same ID.



Renaming a Pack on import

Be careful about enabling the **Overwrite** option. Doing so will cause the imported Pack to completely overwrite your existing Pack configuration.

Each Pack within a Worker Group must have a unique **Pack ID**, so you cannot share an ID between two (or more) installed Packs.

Add From Dispensary

Browse and download Packs from the Cribl Packs Dispensary. See Onboard Faster With Packs for more information about using Packs from the Cribl Dispensary.

Import from a File

To import a Pack (`.crbl` file) from your local filesystem:

1. Navigate to the **Packs** page.
2. Select **Add Pack** at the upper right and select **Import from File**.
3. Select the file to import.

4. Optionally, give the Pack an explicit, unique **New Pack ID**. (For details about this option, see Upgrade an Existing Pack.)
5. Select **Import** to confirm the import.
6. If the Pack you are importing binds variables to any fields, you will see a **Configure Variables** button in the notification about successful import. Select it to go to the **Variables** page, where you can configure the values for the variables for your deployment.

Import from a URL

To import a Pack from a known, public or internal, URL:

1. Navigate to the **Packs** page.
2. Select **Add Pack** at the upper right and select **Import from URL**.
3. Enter a valid URL for the Pack's source. (This field's input is validated for URL format, but not for accuracy, before you submit the modal.)
4. Optionally, give the Pack an explicit, unique **New Pack ID**. (See Upgrade an Existing Pack.)
5. Select **Import** to confirm the import.
6. If the Pack you are importing binds variables to any fields, you will see a **Configure Variables** button in the notification about successful import. Select it to go to the **Variables** page, where you can configure the values for the variables for your deployment.

To import a Pack from a public URL, the Leader Node (or single instance) requires internet access. A Distributed deployment Leader can then deploy the Pack to Workers even if the Workers lack internet access.

Import from Git Repos

When you import a Pack from a private Git repository using a personal access token, you can also push changes back to the same branch or repository you imported from. If you don't provide an access token, Cribl Stream cannot write back to the repository. This means you won't be able to push changes to a repository without authenticating with a personal access token.

Some additional considerations:

- If you don't specify a branch during import, Cribl Stream assumes you want to use the repository's default branch.
- You cannot push changes to a Git tag. Importing from a tag is allowed, but writeback is only supported when importing from a branch.

- If you need to change the token used for Git operations, you'll need to re-import the Pack using the new token.

To import a Pack from a known public or private Git repo:

1. Navigate to the **Packs** page.
2. Select **Add Pack** at the upper right and select **Import from Git**.
3. Enter the source repo's valid URL.
   This field's input is validated for URL format, but not for completeness or accuracy, before you submit the modal. When targeting a private repo, use the format: `https://<username>:<token/password>@<repo-address>`. Public repos need only `https://<repo-address>`, as shown in the following example.
4. Optionally, give the Pack an explicit, unique **New Pack ID**. (See Upgrade an Existing Pack.)
5. Optionally, enter a **Branch or tag** to filter the import source using the repo's metadata. You can specify a branch (such as `master`) or a tag (such as a release number: `0.5.1`, and so forth).
6. Select **Import** to confirm the import.
7. If the Pack you are importing binds variables to any fields, you will see a **Configure Variables** button in the notification about successful import. Select it to go to the **Variables** page, where you can configure the values for the variables for your deployment.

To import a Pack from a public repo, the Leader Node (or single instance) requires internet access. A Leader in a Distributed deployment can then deploy the Pack to Workers even if the Workers lack internet access.

Prepare Pack for Use

After you have imported a Pack, take the following steps to ensure it is ready for use on your Worker Nodes:

- **Verify secrets:** If the Pack was exported in `merge` mode, any encrypted fields will have been removed for security. You must re-enter your secrets in the imported Pack to ensure it works as expected.
- **Configure variables:** If you did not configure values for a Pack variable during import, you can do it later by navigating to **Knowledge** > **Variables** in the imported Pack.
- **Commit and Deploy:** If your Pack includes Collectors and jobs, you must Commit and Deploy it after import. This step is critical because it ensures your Worker Nodes have the correct Pack context to successfully run jobs.

Use Packs

Version Compatibility

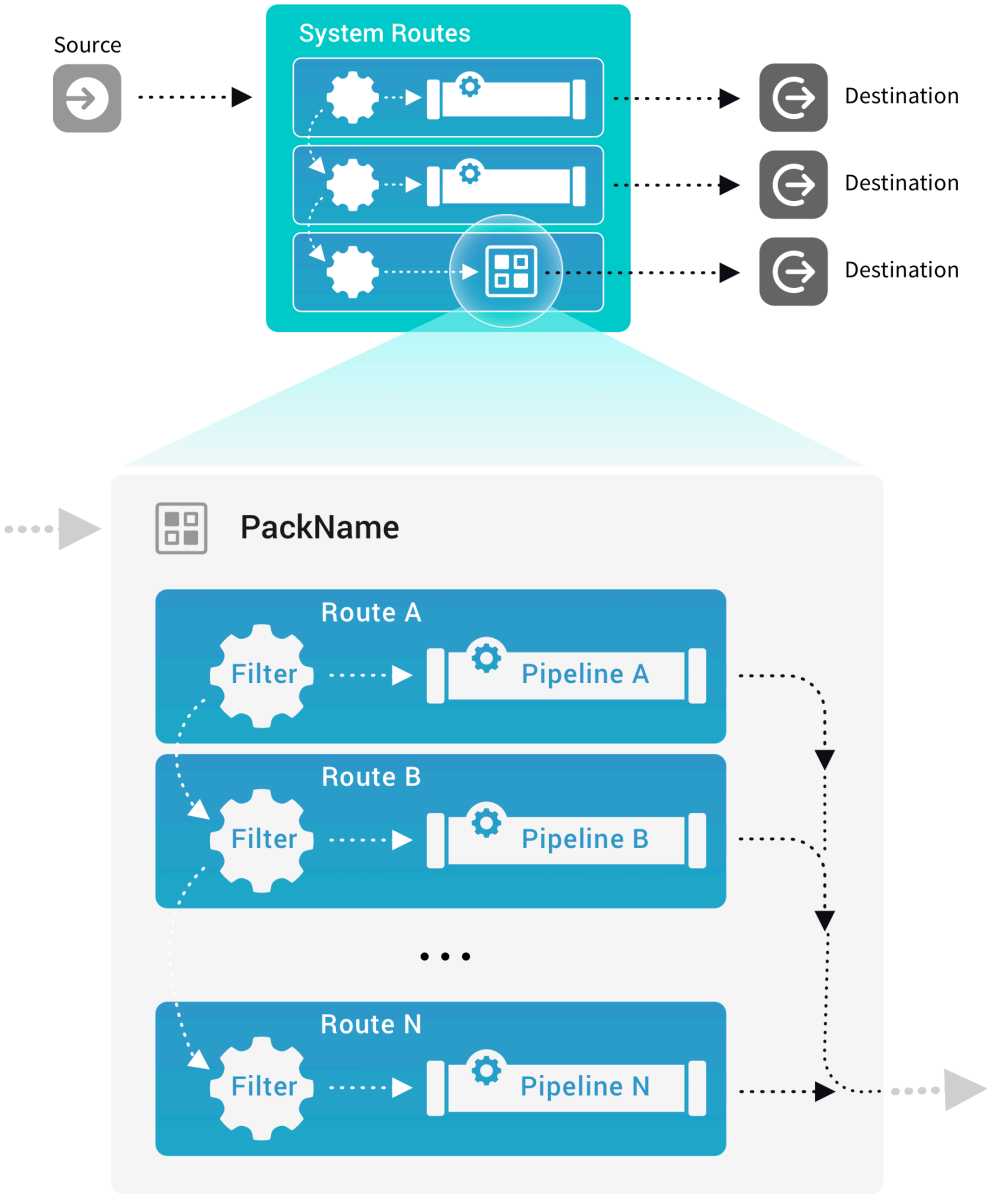
Packs created or modified in Cribl Stream 4.0.x cannot be used in any Cribl Stream version older than 4.0. (If you try, you'll see a `should NOT have additional properties` error.) To avoid this problem, Cribl recommends that you upgrade to Cribl Stream 4.0.x or newer.

For compatibility questions about any individual Packs, please contact us in the Cribl Community Slack `#packs` channel.

For Packs that do not contain Sources or Destinations, you can use them in all places where you can reference a Pipeline:

- In Sources, where you attach pre-processing Pipelines.
- In Destinations, where you attach post-processing Pipelines.
- In Routes, in the Routing table's **Pipeline** and **Destination** columns.

This expanded view shows how a Pack can replace a Pipeline in a Route:



A Pack can play the roles of an enhanced Pipeline

Packs are distinguished in the display with a **PACK** badge, as you can see here in the Routing table:

PACK badge in Routing table's Pipeline column

The **PACK** badge is also displayed when you click into a resource - shown here on one of the Routes from the above table:

PACK badge on a Pack connected to a Route

Cribl Stream's **Monitoring** page includes a **Packs** link where you can monitor the throughput of a Pack.

Access Packs

You access Packs differently, depending on your deployment type.

Single-Instance Deployment

In a Single-instance deployment, Packs are global. On the top bar, select **Processing** > **Packs**. On the filesystem, Packs (including those that you add) are stored at `$CRIBL_HOME/default/`.

Distributed Deployment

In a Distributed deployment, Packs are associated with (and installed within) Worker Groups. In the sidebar, select **Worker Groups**, and then select the Worker Group you want to manage. Next, from that Worker Group' submenu, select **Processing** > **Packs** (Stream) or **More** > **Packs** (Edge).

Each Group's Packs are stored at `$CRIBL_HOME/groups/<groupName>/default/`.

By design, you can readily share Packs **across** Worker Groups by copying them between Groups.

Use Packs as Examples

In addition to running Packs in production, you can open them to see complete, working configurations:

- How Routes, Pipelines, and knowledge objects are wired together for a specific data source or use case.
- How complex Function chains implement common patterns such as reduction, enrichment, or field normalization.
- How sample data and Data Preview are used inside a Pack to test changes safely.

This makes Packs a useful reference library when you are:

- Learning how to configure a new integration.
- Looking for a proven Pipeline pattern (for example, reducing noisy events or cleaning malformed data).
- Studying how a Pack models a particular vendor, technology, or log format so you can reuse or adapt the approach in your own configuration.

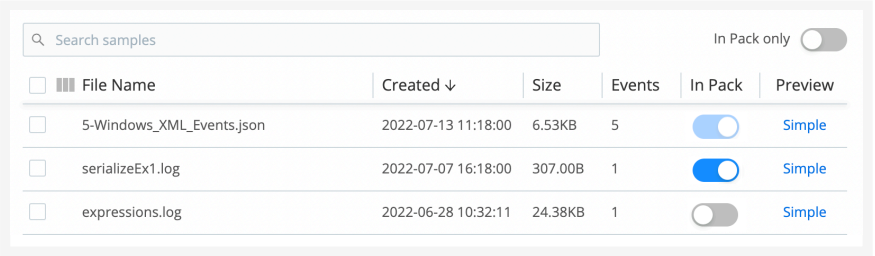
Use Sample Data

Within a Pack, the right pane defaults to displaying all sample data files available on your Cribl Stream instance. If you prefer to filter only sample files internal to the Pack, select the **In Pack only** option.

If you add sample data files via a Pack UI, they will be internal to that Pack. Each sample file here displays its own **In Pack** toggle on its row, which works as follows:

A light-blue toggle is locked, meaning that this sample file is internal to the Pack. It will export with the Pack. If you want to make this sample available across Cribl Stream, you'll need to also add it via the global right preview pane (accessed from **Routing** > **Data Routes** or **Processing** > **Pipelines**).

The toggle indicates whether the sample file is global to Cribl Stream and available to this Pack. Toggle on if you want the sample file to export along with the Pack.

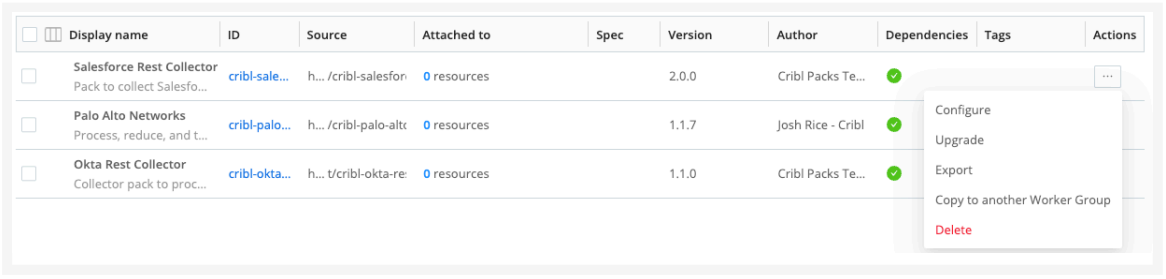


Sample file in Pack

Basically, you can manipulate all the options here as you would work with the equivalent options in the global navigation.

Upgrade an Existing Pack

To upgrade an **existing** Pack, open the Options ••• menu on its row, and then select **Upgrade**.



If you've modified an installed Pack, Cribl Stream will block the overwrite of the Pack, to prevent deletion of your locally created resources.

When upgrading a Pack, Cribl recommends that you:

- Import the updated Pack under a new name that includes the version number (for example, `cribl-syslog-input-120`). This allows you to review and adjust new functionality against currently-deployed configurations.
- Do a side-by-side comparison of the previous and new versions of the Pack - remember to review all comments in the new Pack. Doing this side-by-side comparison allows you to copy Function expressions and other settings from the current version into the same fields in the new version.
- Enable or disable any Functions in the new Pack as necessary.
- Update any Routes, Pipelines, Sources, or Destinations that use the previous Pack version to reference the new Pack.
- If the Pack includes any user-modified versions of default Cribl Stream Knowledge objects (for example, lookup files): Be sure to copy the modified files locally for safekeeping, before upgrading the Pack. After you install the upgrade, copy those files back to the upgraded Pack, overwriting the default versions in the Pack.
- Test, test, and test!
- Commit and Deploy.

Copy a Pack

You can share Packs in a Distributed deployment by copying the Packs between Worker Groups. You can copy one or more Packs from the **Packs** page as described here or using the Cribl API.

To copy a single Pack, your first step is to open its Options ••• menu, then select **Copy to another Worker Group**.

To copy multiple Packs in one operation:

1. Select the check boxes for all Packs you want to copy on the **Packs** page.
2. In the options ••• menu, select **Copy selected Packs to another Worker Group**.
3. Select the Worker Groups to which you want to copy the Pack.
4. Optionally, select the **Overwrite** option to replace existing Packs that have the same **Pack ID**.

Be careful about enabling the **Overwrite** option. Doing so will cause the imported Pack to completely overwrite your existing Pack configuration.

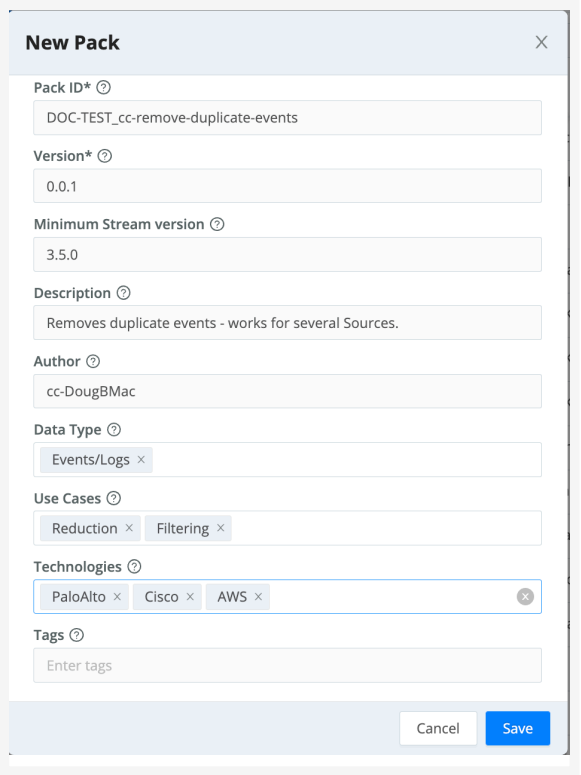
5. Select **Copy**.

A status modal will either display a success message, or list any Packs that failed to copy.

Create a Pack

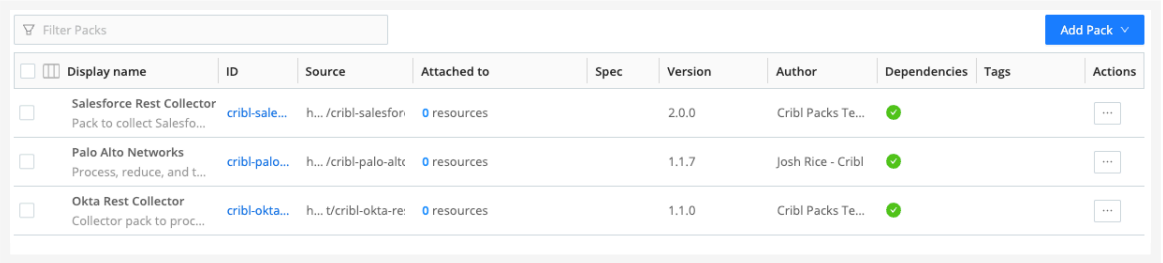
You can create a new Pack from scratch, to consolidate and export multiple Cribl Stream configuration objects:

1. Navigate to the **Packs** page and select **Add Pack**.
2. From the submenu, select **Create Pack**.
3. Enter a unique **Pack ID** and other details:
    - Each Pack within a Worker Group must have a separate **Pack ID**, but you can assign arbitrary **Display names**.
    - **Version** is a required field identifying the Pack's own versioning.
    - **Minimum Stream version** is an optional field specifying the lowest compatible version of Cribl Stream software.
    - **Description** and **Author** are optional identifiers.
    - **Data type**, **Use cases**, and **Technologies** are optional combo boxes. You can insert one or multiple keywords to help users filter Packs that you post publicly on the Cribl Packs Dispensary.
    - **Tags** are optional, arbitrary labels that you can use to filter/search and organize Packs.
4. Select **Save**.



Creating a Pack

1. On the **Packs** page, select the new Pack's row to open the Pack.



Manage Packs page

1. Use the standard Cribl Stream controls to configure and save the infrastructure you want to pack up. As you save changes in the UI, they're saved to the Pack.

Pack Variables

To make your Packs portable and reusable across different environments, replace fixed values in your configuration with variables and secrets. This practice, known as templatization, allows your Pack to adapt to different environments without you having to manually edit it each time.

For more information about Pack variables, see:

- Pack Variables
- Create a New Variable
- Use Variables in a Pack

- Update Variables After Import or Update
- Delete Variables

Use Named TLS Certificates

Cribl Stream allows you to optionally authenticate to Sources or Destinations using TLS (Transport Layer Security), which encrypts traffic and helps ensure secure communication with upstream or downstream services. TLS certificates help verify the identity of the remote service and can also support mutual authentication when required. See Secure Cribl Stream Sources and Destinations with Certificates for general information about authenticating with TLS certificates and specific instructions on adding and selecting a certificate to a Source or Destination.

For Sources or Destinations defined at the **global level** (outside of a Pack), Cribl Stream stores TLS certificates at the Worker Group level. Any Worker Nodes in the Worker Group can access those certificates when processing data.

For Sources or Destinations defined at the **Pack level** (inside a Pack), you can reference a TLS certificate by its name. This approach enables portable and secure configurations across environments:

- When you **export** that Pack, it does not include the TLS certificate itself, only the reference to the certificate name.
- When you **import** that Pack to a Worker Group, Cribl Stream checks the local certificate store for that Worker Group. If a certificate with the same name exists, Cribl Stream automatically binds it to the Worker Group.

This approach allows you to:

- Build TLS-secured Sources and Destinations directly within Packs.
- Reuse Pack configurations across environments without exporting certificate data.
- Maintain secure, environment-specific certificate management practices.

Packs do not include certificate files. Instead, they store the name of the certificate to reference. To ensure a successful deployment, make sure each environment contains a certificate with the expected name for the target Worker Group.

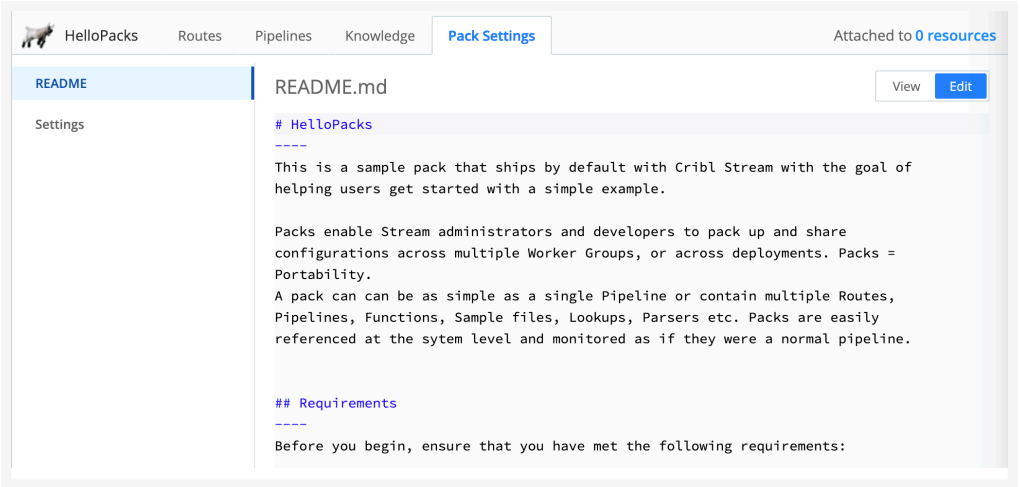
If you create the certificate after importing the Pack, commit and deploy the changes to restart the Worker Nodes. The Worker Nodes will pick up the new certificate after restart.

Modify Pack Settings

You can update Pack metadata (such as Version, Description, and Author) and the Pack's display settings. If you're developing a new Pack to share, you'll want to use this interface to populate the README and display

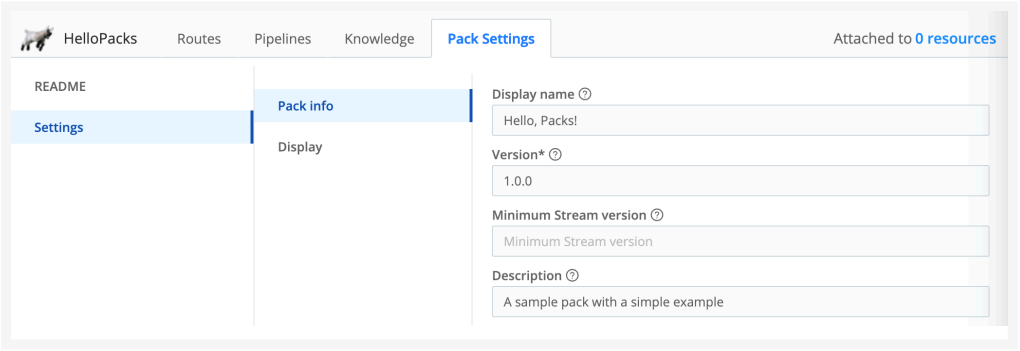
logo within the Pack:

1. Open a Pack and select **Pack Settings**. The left **README** tab will gain focus.
2. To populate the Pack README file, toggle **View** to **Edit**, replace the placeholder markdown content with your actual Pack description, and **Save**.



Editing a Pack's README

1. To update other metadata, select the left **Settings** tab.



Editing a Pack's metadata

1. You can add a Pack logo on the **Settings** tab.
   Cribl recommends adding a logo to each custom Pack, to visually distinguish the Pack UI from the surrounding Cribl Stream UI (as well as from other Packs). You can upload a `.png` or `.jpg`/`.jpeg` file, up to a maximum size of 2 MB and 350x350 px. Cribl recommends a transparent image, sized approximately 280x50 px.

Share and Publish Packs

To share your Pack with other users, you first need to export it from your deployment.

Then, if you wish, you can publish it to the Cribl Pack Dispensary to make it available for the whole Cribl ecosystem.

Export a Pack

You can also use the Cribl API to export a Pack.

To export a newly created or modified Pack from the **Packs** page, open its Options ••• menu and select **Export**.

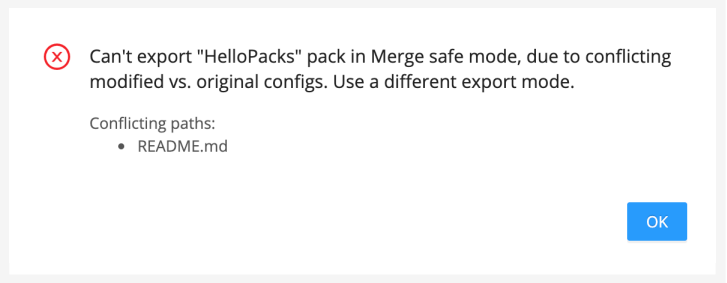
The **Export Pack** modal provides the following options.

Export Mode

Select one of these three buttons to determine the export mode:

- **Merge safe**: (Deprecated) Attempt to safely merge local modifications into the Pack's default layer (original configuration), then export.
- **Merge**: Force-merge local modifications into the Pack's original configuration, then export. When you export Packs in `merge` mode, Cribl Stream deletes all encrypted fields from Pipelines. Upon importing these packs, you will need to re-enter the secrets to make them functional again.
- **Default only**: Export only the Pack's original configuration, without local modifications.

The (deprecated) **Merge safe** option is conservative, and will block the export where Cribl Stream can't readily merge modified contents with the Pack's original contents, due to conflicts. If you encounter an error like the example shown below, use the **Merge** or **Default only** export mode instead.



Merge safe error

Exported Pack ID

Defaults to the Pack's current ID, with the version number appended. This field provides an opportunity to change the Pack's ID, if you're exporting a new version of the Pack.

Publish a Pack

If you'd like to share your Pack with the community of Cribl users, you can publish it on the Cribl Packs Dispensary.

The Cribl Packs Dispensary site is designed for sharing completed Packs. If you want to collaborate with others on iteratively developing a Pack, Cribl recommends relying on our Dispensary GitHub Repo for the development phase.

If you have a Cribl.Cloud account, you can also collaborate there by inviting team members to your Cribl.Cloud Organization. See Invite Members.

Once your Pack is ready to share, we encourage you to submit it to the Cribl Packs Dispensary site. If you already have completed Packs on our GitHub repo, bring them over here!

9.1. Pack-Based Configuration Management

As your Cribl deployment grows, maintaining consistency across multiple Worker Groups and environments becomes a significant operational challenge. To solve this challenge, use Pack-based configuration management to templatize your entire end-to-end Cribl data streams into reusable units that you can port to other Worker Groups in your deployment. This approach is helpful when you need standardized configuration management workflows to manage multiple Worker Groups, instances, or environments (such as development, testing, and production).

Pack-based configuration management has several advantages over the standard Leader-to-Worker Group configuration management workflow:

- **Composable management:** Define end-to-end data streams as a single unit. Package the configurations for a Source, its associated processing logic, and the final Destination into a reusable Pack that you can deploy across Cribl Stream to different Worker Groups and environments.
- **Git version-control:** You can version-control Packs in an external Git repository to make your Cribl configurations auditable and to flexibly adapt to your company's change management policies.
- **Environmental portability:** Move configurations easily between environments, such as from `dev` to `prod` or more. Packs allow you to bind configuration fields to variables, so that you can apply the same configuration components to multiple Worker Groups and then customize the configuration details that are specific to the local context of a given Worker Group.
- **Scalability:** Onboard new data streams or spin up additional Worker Groups quickly by deploying Packs that have been validated in one context to another.

When To Use Pack-Based Configuration Management

Pack-based configuration management is not required to manage deployments of Cribl Stream. For many deployments, the default Leader-to-Worker configuration management system is sufficient.

However, this workflow is particularly beneficial for organizations that require:

- **The ability for multiple configuration content developers or teams to collaborate on configurations.** Use this workflow if you need developers to work on configurations in parallel. Each content developer can work on isolated feature branches, merge changes systematically, and resolve conflicts before they impact production.
- **Two- or three-branch environment promotion and segregation workflows.** This workflow supports the classic development three-branch model where changes flow from `dev` to `test` to `prod` branches and environments in a controlled manner. You could also use a simpler two-branch model flow from `dev` to `prod` instead.

- **Formal configuration approval from a central Change Advisory Board (CAB).** Git workflows keep configuration changes visible so that stakeholders can review and approve them. An external Git repository can provide additional change traceability and a clear audit trail of who approved what and when.
- **The ability to roll back configurations quickly.** While this is already possible in Cribl Stream, the Pack-based configuration management workflow extends and complements the Leader-to-Worker Group control plane system by allowing you to track changes in an external Git repository. Git's version control capabilities make rollbacks straightforward so that you can easily revert to a previous, stable version. Connecting to an external repository provides additional visibility and auditability that integrates with your company's overall change management system.

Prior experience with Git is helpful for this workflow. For users familiar with Git, this workflow can streamline version control, change management, and CI/CD for your Cribl environments.

Key Components

The recommended Pack-based configuration management workflow for Cribl Stream uses these components:

- Packs: Packs contain the actual configuration content that you will track. This includes dependencies such as the Knowledge objects or (optionally) the sensitive resources (such as certificates or secrets) needed to run the Pack.
- Environments: A logical grouping of Cribl Stream resources that process data, depending on your Worker Group placement strategy. An environment is typically defined by a specific set of Worker Groups.
- Variables: Dynamic placeholders within a Pack configuration that map to a specific values defined at either the Pack or Worker Group level. Variables allow you to port the Pack to another environment, then make small adjustments to the logic to allow for specific differences that are unique to that Worker Group.
- External Git repository: A centralized Git repository serves as the single source of truth, tracking all changes to your Pack configuration. Each repository should track one individual Pack only.

Packs

The core building block of every Cribl Stream configuration management system is the Pack. A Pack contains a bundle of configurations that you want to develop, test, version control, and distribute to multiple Organizations or Worker Groups. Packs can contain configurations for many types of resources:

- Sources
- Destinations
- Event Breakers
- Pipelines

- Routes
- Knowledge Objects (such as lookup files)
- Sample data files

In other words, you can create Packs that contain a full, end-to-end Cribl Stream configuration. Think of a Pack as a configuration object that you can version control and export/import to other environments. It works well in workflows where multiple developers work in a sandbox development environment. Developers can review each other's work and merge their changes to a testing or production environment using Git workflows.

Environments

An Environment is a logical boundary that defines how data is processed, managed, and secured within your architecture. The logical boundary is defined by your Worker Group placement strategy, such as geographic regions or data proximity. It could also refer to content development environments that use the two- or three-branch development strategy, such as `dev`, `staging`, and `prod`.

While typically defined by a specific set of Worker Groups, an environment in the Pack-based workflow encompasses the unique variables and configurations required for that specific environment. This means a single Pack can be deployed across multiple environments while automatically adapting to the new context.

Variables

Variables allow you to copy or import that Pack to multiple Worker Groups, making small adjustments to the logic to adapt to the specific environment context for that Worker Group. For example, you could adjust the Worker Group-level variables that account for regional differences (such as different AWS regions), VPC endpoints, or local port assignments. This ensures that the core data processing business logic remains intact while adapting to the local requirements of its new Worker Group context. It also allows you to easily make updates to Packs and deploy those updates with minimal overhead.

External Git Repositories

Once you've built an end-to-end configuration of Cribl Stream inside a Pack, you can then integrate it with an external Git repository for version control, parallel development, and automated deployment with CI/CD.

Cribl Stream is compatible with all major Git platforms, including GitHub, GitLab, and Bitbucket.

Additional Configuration Management Components

This table explains how standard configuration management components map to Cribl Stream:

Element	Explanation	How it Applies in Cribl
Automation agent or runner	A process or tool that pulls from Git and applies the config to the target environment.	Handled inside Cribl Stream by committing and deploying imported Packs to Worker Groups. Can also be handled using a CI/CD pipeline tool in external repositories, including GitHub Actions, GitLab CI, and Jenkins.
Change workflow	Configuration changes go through a review and approval process.	Handled in an external Git repository linked to Cribl Stream in compliance with your internal change management policies.
Target system(s)	Where the configuration is ultimately applied.	Instances of Cribl Stream.
Secret management	Secrets or encrypted files.	Handled inside Cribl Stream and mapped to variables in external Git repositories.
Environment mapping	Directories or branches per environment.	Handled with variables inside Cribl Stream and mapped to variables in external Git repositories.

Considerations

When working with Packs, keep these considerations in mind:

- Packs cannot be cloned or imported from one Cribl product to another. For example, you cannot clone a Pack from Cribl Stream to Cribl Edge and vice versa.
- Sources and Destinations created in Packs add the Pack name to the `__inputId` and `__outputId` fields of their events. For example: `datagen:My_Pack.my_datagen_source`, or `cribl_http:My_Pack.my_http_destination`.

9.1.1. Plan A Pack-Based Strategy

To get started with Pack-based configuration management for Cribl Stream, your first objective is to create a Pack-based configuration management strategy that fits your team's workflows and operational needs. A thoughtful plan helps reduce duplication, simplify maintenance, and make your deployments more predictable and secure.

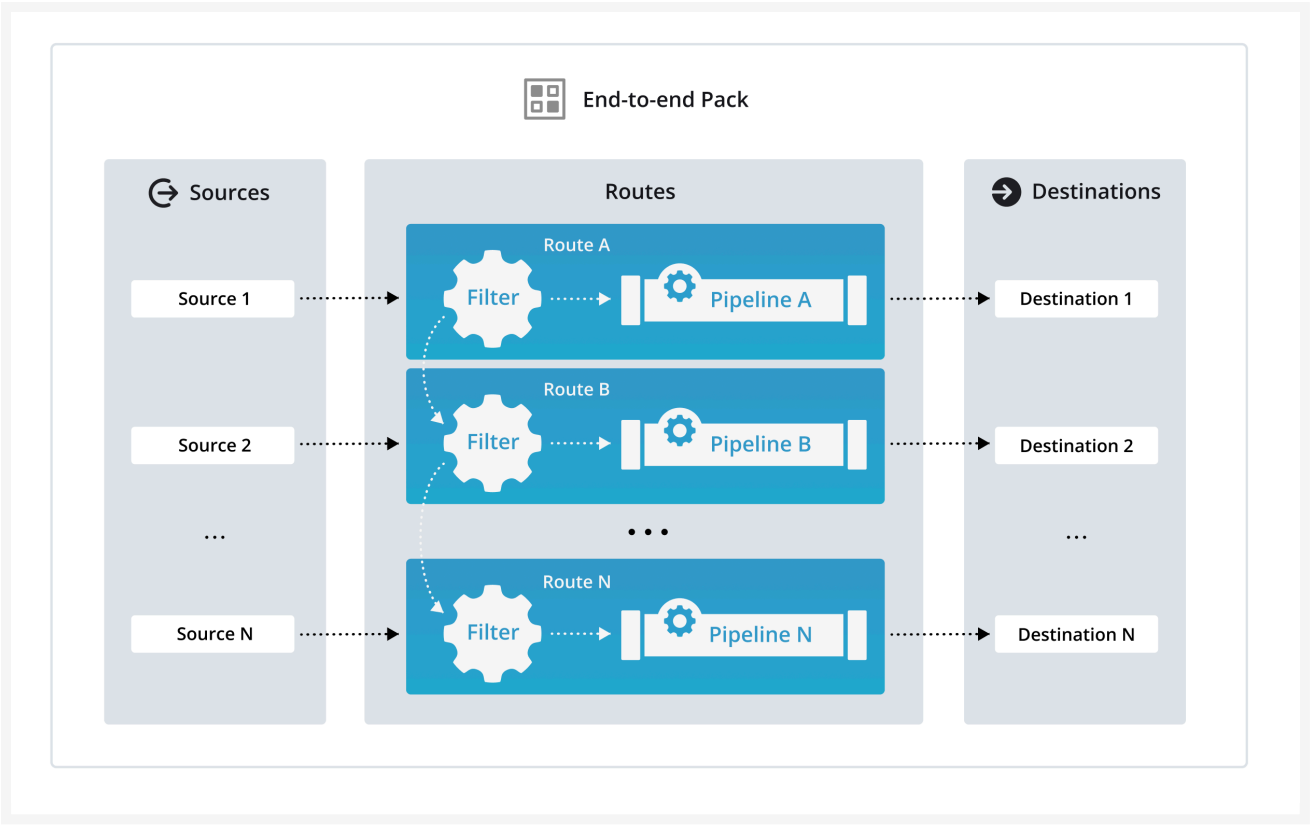
Your configuration plan should define:

- The Purpose and Scope of the Pack: The scope of the configurations in your Pack, which involves deciding whether to include Sources and Destinations. It also includes determining how data will flow in and out of Packs to other resources in Cribl Stream.
- Pack Variables: The variables you want to templatize in your Pack for easy transfer and adaptation across environments.
- Sensitive Data and Secrets: The sensitive data you need to store in Packs, including passwords, API keys, or security certificates, and authentication credentials.
- Pack Versioning System: Your Pack versioning and branch promotion strategies, which ensures your Packs remain consistent and synchronized across your Worker Groups.

Purpose and Scope of the Pack

The core building block of every configuration management system is the Pack. A Pack contains a bundle of configurations that you want to develop, test, version control, and distribute to multiple Organizations or Worker Groups.

If you're familiar with Packs from prior versions of Cribl Stream before 4.12, it's important to know that Packs have evolved. In previous versions, Packs were mainly used to package processing logic and included Pipelines, Routes, Functions, Knowledge objects, and sample data files. Packs can now contain complete, end-to-end data flow configurations for a single data stream.



Packs can contain end-to-end data flow components

For that reason, carefully plan the scope of the Pack you want to track with version control, which primarily means deciding whether to include Sources and Destinations in your Pack:

Scope	When to Use	Contains
End-to-end scope	When you want to configure your full end-to-end Cribl Stream deployment inside a Pack.	• A Source. • A Destination. • All the necessary components to process data from that Source to that Destination (Pipelines, Routes, and related Knowledge objects needed for that configuration to work).
Source-side scope	When you want to use a Pack similar to a pre-processing Pipeline.	• A Source. • Optionally, a Pipeline and all the necessary components to normalize, reduce, or process data from that Source, including Knowledge objects.
Destination-side scope	When you want to use a Pack similar to a post-processing Pipeline.	• A Destination.

Scope	When to Use	Contains
		• Optionally, a Pipeline and all the necessary components to prepare or optimize the incoming data for the requirements of the downstream receiver.
Data processing scope	When you only want the Pack to process data, meaning it will just contain a Route and Pipeline and related Knowledge objects.	• Only include Routes and Pipelines that process data. • Do not include Sources and Destinations in these Packs.

Keep each Pack scoped to a single purpose or use case where possible. Avoid mixing too many unrelated Sources or Destinations in one Pack. It increases complexity and makes version control more difficult. Consider these possible approaches for designing your Pack scope:

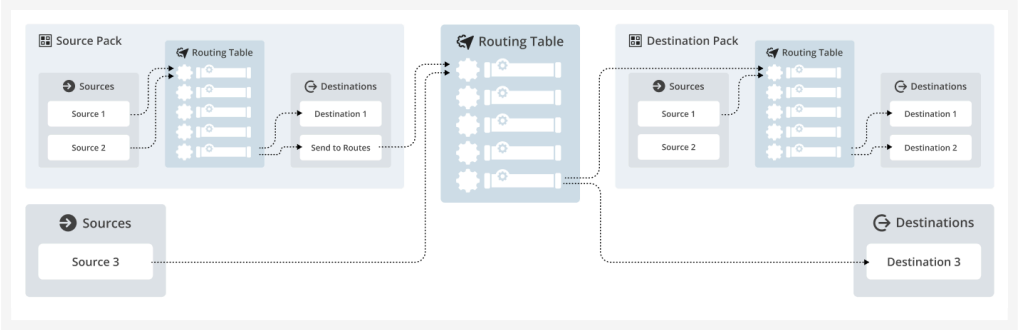
- **One Pack per vendor or technology:** Create a Pack for a specific technology (such as AWS CloudWatch or Syslog messages).
- **One Pack per data lifecycle stage:** Divide Packs by their function: one for normalization, one for enrichment, and one for redaction.
- **Packs for shared services:** Create a Pack that performs a universal task (such as redaction) that multiple other data streams can be routed through before reaching their next Pipeline or Destination.

Packs are fully self-contained, meaning that the objects inside the Pack are not aware of anything outside of the Pack context unless you use Routes to send data outside the Pack context. So, if you include a Source or Destination inside a Pack, **it won't be aware of data from an external Source or Destination** unless you integrate it into your data processing system by connecting it to a Source or Destination.

The rest of this guide assumes you plan to build Packs that include Sources and Destinations. However, you can adapt this guide to Packs with more limited scopes.

Design the Pack Data Flow

Packs allow you to break down repetitive configurations into modular, reusable components that can be chained together into a single data stream flow. Rather than a single, complex Pipeline at the Worker Group level, you can chain specialized Packs together by routing data through Routes at the Pack level.



Route data in and out of Packs

You can route data at two different scopes:

- **At the global Worker Group level:** You can route data to or from Packs using the global Routing table at the Worker Group level.
- **At the Pack level:** You have a self-contained Pack that contains a Source or a Destination (or both). Data can be processed in the Pack and then routed as it leaves the Pack as needed.

If you include a Source, Collector, or Destination in your Pack, that Pack will not be available when you select the **Pipeline** menu in Routes at the global Worker Group level. Only Packs scoped exclusively for data processing appear in the **Pipeline** dropdown. See Purpose and Scope of the Pack for a deeper explanation of how the content of Packs can be scoped.

You can design the scope of Packs using a few patterns that consider the overall flow of data:

- **Source-side Packs:** These Packs can contain one or more Sources and any specific Pipelines needed to normalize raw data into a standard internal schema. You could also use this Pack to drop or aggregate any unnecessary fields and events to optimize incoming data. From there, the data can flow out of the Pack to Routes at the Worker Group level for further processing.
- **Destination-side Packs:** These Packs can contain one or more Destinations and any specific Pipelines that prepare or optimize the incoming data for the requirements of the downstream receiver. The Pipelines in these Packs can refine, format, and batch data so that the Destination can ingest it as efficiently and cheaply as possible. Routes are the mechanism that sends data from the Worker Group level to these Packs.
- **Pass-through processing Packs:** Data originates from a Source that exists at the Worker Group level, then passes through Routes, which sends the data to a Pack for specific enrichment step before returning to Routes for further routing.

These workflows are ideal for organizations that require functional decoupling of their configuration logic. By segregating Source and Destination logic into independent Packs, individual contributors can iterate on specific data streams in isolation, eliminating the risk of cross-contamination or breaking global configurations.

Avoid processing data twice. When planning your flow, decide exactly where heavy data processing (like masking or Regex operations) should occur. Performing the same transformation in both a Source-side Pack and a Destination-side Pack wastes CPU cycles and increases latency.

See Connect Packs to Global Sources and Destinations for more specific information about how to route data in and out of Packs.

Pack Variables

If you plan to use the same Pack across multiple environments, take some time to identify which configuration values are environment-specific. These may include:

- Endpoint URLs or hostnames.
- Port numbers.
- Region-specific settings.
- Authentication details.

To reduce duplication and make your Packs reusable across environments, use Pack variables to templatize these values. In Cribl Stream, Pack variables let you define values that can be adapted to the local environment. This allows you to:

- Set environment-relative defaults (such as `api_base_url` or `destination_bucket`).
- Avoid hardcoding environment-specific information directly in your configuration.

Keep the following guidelines in mind about variables:

- **Field binding behavior:** Pack variables are bound to specific fields. If you update the variable's value, the corresponding field will reflect the change. However, if you delete the variable, the field retains its last set value rather than reverting or clearing it. See How Field Binding Works for more detailed information.
- **Field compatibility:** Variables are only supported in certain fields, which means you can't use variables universally in every field. Fields that can accept variables have a **Variable** icon ◈ next to them.
- **Exporting secrets:** Sensitive values, such as passwords or API keys, are bundled up with a Pack and exported along with the Pack.
- **Use variables and naming conventions consistently:** When Packs include Sources and Destinations, use clear, environment-aware naming (such as `src_aws_logs_dev`, `dst_s3_prod`). Consider using Pack-level variables to template environment-specific values.

See Configure Variables and Secrets for more specific information about how to use variables.

How Field Binding Works

When you bind a Pack variable to a configuration field, you create a dynamic link. Updating the variable's value automatically pushes that change to all bound fields. However, if you delete the variable, the binding is removed and the field retains its last resolved value as a static, hard-coded setting.

To see how Cribl Stream manages this binding, select **Manage as JSON** on a Source or Destination that uses a variable. Notice that any field bound to a variable generates two distinct entries that share related names:

Field type	Description	Examples

Static field	A hard-coded value that uses the last known value. This serves as the fallback value in case of deletion.	`"host": "localhost"`
		
		`"udpPort": 3000`

Variable template field	Prefixed by `__template_`, this lists the field name and the stored variable reference.	`"__template_host": "my-host-variable"`
		
		`"__template_udpPort": "my-port-variable"`

The `__template_` entry takes precedence over the static field. If you delete the variable, Cribl Stream removes the `__template_` entry from the JSON. Because the static field still exists, the configuration reverts to the last set value, ensuring the data stream remains functional even though it is no longer dynamic.

Never delete the static version of a configuration field from the JSON, even if a `__template_` field is present. The static field is a required component of the configuration file stored on the disk.

Sensitive Data and Secrets

Cribl Stream allows you to optionally authenticate to Sources or Destinations using TLS (Transport Layer Security), which encrypts traffic and helps ensure secure communication with upstream or downstream services. TLS certificates help verify the identity of the remote service and can also support mutual authentication when required.

When working with Packs, use the built-in secret store and named TLS certificates to manage all sensitive data. These methods are crucial for making your Packs portable and secure across different environments. You should plan to use the same process for all secrets, whether they are passwords, API keys, or security certificates.

Key considerations for your plan:

- **Secret isolation and referencing:** Unlike other configurations, sensitive values and secrets (such as TLS certificates and authentication credentials) are not bundled within Packs when you export them. Instead, a Pack only stores a reference to a secret by its name. This means:
    - You can build TLS-secured Sources and Destinations directly into your Packs.
    - The sensitive data (such as certificates) remains isolated in each Worker Group's local secret store.
- **Environment-specific secret management:** Plan to manage unique secrets for each environment (such as `dev` or `prod`) while using the same underlying Pack configuration across all environments.
- **Deployment prerequisites:** Cribl Stream stores secrets and certificates at the Worker Group level, so ensure that the secrets and certificates are properly deployed to the correct Worker Groups. For a Pack to deploy successfully with TLS-secured components, a certificate with the matching name must already exist in the target Worker Group's secret store.

Use the Cribl secret store whenever possible. This ensures different Cribl environments can hold their own distinct secret values, without needing you to redefine the setting multiple times within the Pack.

For Sources or Destinations defined at the **global level** (outside of a Pack), Cribl Stream stores TLS certificates at the Worker Group level. Any Worker Nodes in the Worker Group can access those certificates when processing data.

For Sources or Destinations defined at the **Pack level** (inside a Pack), you can reference a TLS certificate by its name. This approach enables portable and secure configurations across environments:

- When you **export** that Pack, you can choose whether to bundle sensitive resources along with the Pack. If you choose not to bundle the resources, it does not include the TLS certificate itself, only the reference to the certificate name.
- When you **import** that Pack to a Worker Group, you can choose whether to overwrite the local certificate store or not. If you choose not to overwrite it, Cribl Stream checks the local certificate store for that Worker Group. If a certificate with the same name exists, Cribl Stream automatically binds it to the Worker Group.

This approach allows you to:

- Build TLS-secured Sources and Destinations directly within Packs.
- Reuse Pack configurations across environments without exporting certificate data.
- Maintain secure, environment-specific certificate management practices.

Pack Versioning System

The last thing to consider as part of your configuration management plan is what your strategy for updating Packs will be.

Key considerations:

- Packs support semantic versioning structures (`0.0.0`), which correlates to `Major.Minor.Patch`.
- The core principle is that each increment of the Pack's semantic version number signifies a stable, tested state of the configuration suitable for promotion to the next environment.
- You can update Packs to new versions using the **Upgrade** option.
- When you upgrade a Pack, Cribl Stream compares the current Pack version against the Pack version in the external Git repository. If the version number has increased, Cribl Stream imports the latest changes from the Git repository to the Pack in the local environment.

IMPORTANT: Commit and Push Changes to Avoid Data Loss

When you upgrade a Pack with a higher version number, it overwrites any local changes to the Pack. To prevent loss, individual Pack developers should always ensure that they have saved, committed, and pushed changes from their local sandbox environment to their feature branch on the external Git repository before upgrading.

With these considerations in mind, the next section describes a recommended version increment strategy across environments.

Versioning Best Practices

Consider implementing these policies and strategies as part of your plan:

9.1.2. Create A Pack

Now that you have a clear plan for the Cribl Stream elements you want to version control, you can start building an initial Pack to test your basic configuration management workflow.

You can create a new Pack from scratch or you can create a Pack, then copy any configurations you developed in your Cribl Stream deployment into the Pack.

Best Practices for Working With Packs

When creating and working with Packs, keep these considerations in mind:

- **Keep the Pack simple at first.** For the purposes of setting up the initial Pack-based workflow, make your initial Pack simple to start and then test the version control workflow by adding more configurations in later steps.
- **Consider using Pack logos to help you remember the Pack context.** You might understandably lose track of whether you are creating Cribl Stream configurations in a local Pack context or a global context. To give yourself a visual cue that you are working in a local Pack, consider adding a logo to your Pack in the Pack settings. The logo will show up in the top breadcrumb bar so that you can clearly see when you are working in a local Pack context. When you don't see that logo, that will be your cue that you are working in a global context outside of the Pack.

Create a New Pack

Start by creating a new Pack based on the scope and goals you defined in your configuration plan:

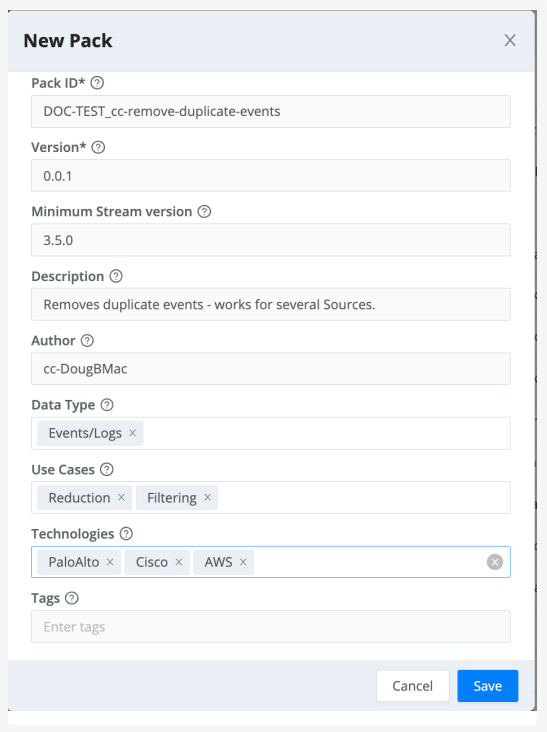
1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group.
2. Navigate to **Processing**, then **Packs** and select **Add Pack**. From the submenu, select **Create Pack**.
3. Enter a unique **Pack ID** and other details:
    - **Pack ID:** Required. Each Pack within a Worker Group must have a unique alphanumeric **Pack ID**. Some characters like hyphens or underscores are allowed, but spaces are not.

      Pack IDs must be all lowercase. If you enter uppercase letters when creating a Pack ID (such as `MyPack`), Cribl Stream automatically converts the ID to lowercase (`mypack`).

    - **Version:** Required. Set the initial Pack version. The default is `0.0.1`.

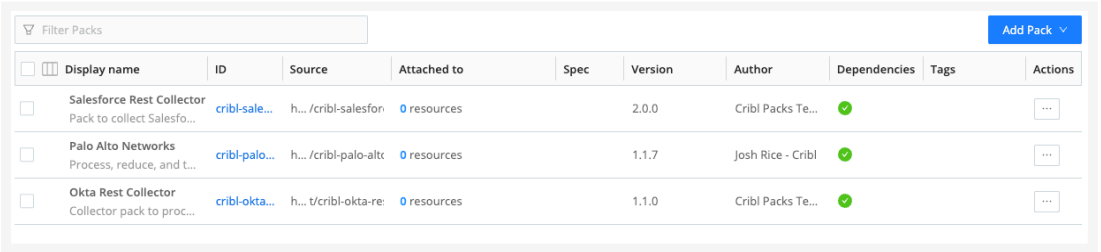
- **Minimum Stream version:** Specify the lowest compatible version of Cribl Stream software. For example, if the Pack uses a feature that was introduced in a specific release, set the version to that release number.
- **Description:** Add an optional description of the Pack's purpose or contents.
- **Author:** Optionally indicate the author of the Pack.
- **Data type**, **Use cases**, and **Technologies** are optional combo boxes. You can insert one or multiple keywords to help users filter Packs that you post publicly on the Cribl Packs Dispensary.
- **Tags** are optional labels that you can use to filter, search, and organize Packs.

4. Select **Save**.



Creating a Pack

5. On the **Packs** page, select the new Pack's row to open the Pack.



Manage Packs page

6. Use the standard Cribl Stream controls to configure the elements you want to include in the Pack. As you save changes in the UI, they're saved to the Pack.

Copy Resources Into the Pack (Optional)

If you developed configurations outside of a Pack context, you can manually copy configurations from one part of Cribl Stream into a Pack. This section provides steps for copying various resources into your newly created Pack. Select the tab for the type of resource you want to copy over:

Pipelines | Routes | Sources | Destinations

To copy a Pipeline into a Pack:

1. In the sidebar, select **Worker Groups**, then select a Worker Group.
2. On the **Worker Groups** submenu, select **Processing**, then **Pipelines**.
3. Locate the Pipeline you want to copy and open the Options ••• menu on its row
4. Select **Copy**.
5. Navigate to your new Pack and, in the Pack submenu, select **Pipelines**.
6. Select **Paste Pipeline** on the filter bar, confirm the Pipeline name and select **Save**.

Configure Variables and Secrets

To make your Packs portable and reusable across different environments, replace fixed values in your configuration with variables and secrets. This practice, known as templatization, allows your Pack to adapt to different environments without you having to manually edit it each time. See Pack Variables and Sensitive Data and Secrets for a reminder about how variables and secrets work.

As you build the Pack, design your variables with their ultimate scope in mind. The portability of Packs comes from the relationship between the Pack itself and the Worker Group context. This hierarchy allows a Pack to be environmentally aware, meaning it knows where it is and which local values it should use.

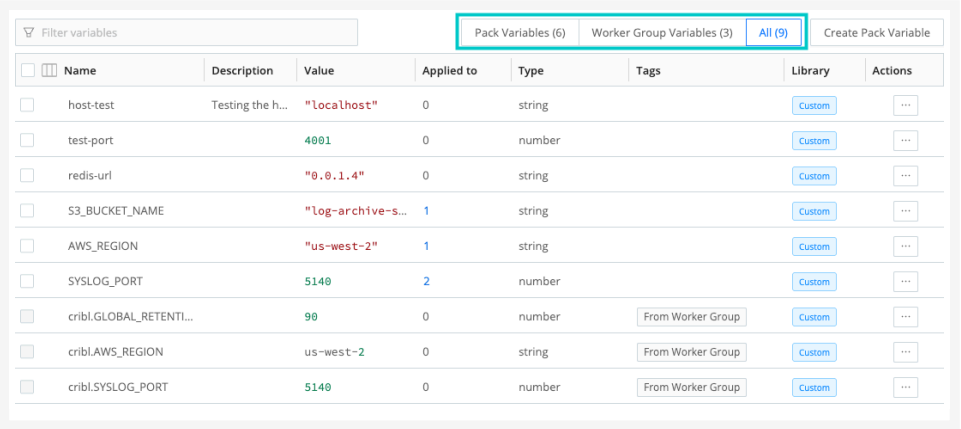
Variable	Description and Use Case	Behavior
Pack	Bundled directly within the Pack. These are best used for internal logic that should remain constant no matter where the Pack is deployed.	When you copy the Pack, these variables move with it automatically.
Worker Group	Allow you to define regional or environment-specific values that the Pack inherits once it is installed. For example, AWS regions (us-west-2 vs. us-east-1), VPC endpoints, or local port assignments.	When you port a Pack into a new Worker Group, the Pack's configuration fields use the Worker Group's context to populate these values.

When you reference a Worker Group variable in a Pack, Cribl adds a prefix to indicate that it is a Worker Group variable. In Stream, these variables are prefixed with `cribl.`. In Edge, they are prefixed with `edge.`.

Create a New Variable

To create a new variable:

1. From inside the Pack context, select **Knowledge**, then **Variables**. The **Variables** UI has tabs that allow you to select the correct scope for your variable. Select either **Pack Variables** or **Worker Group Variables** depending on the desired variable scope.



Select the correct tab

2. Select **Create Pack Variable** and configure the variable settings:
    - **Name:** Enter a unique name for the variable.
    - **Description**: Optionally, enter a description.
    - **Type:** Select the type of variable you want to create. See the Variables Library reference page for a detailed explanation of variable types.
    - **Value:** Enter the value, data structure, or JavaScript expression for this variable. This input must match the format required by the selected variable type. For example, Expressions should have JavaScript syntax. The system validates the input when you save.
    - **Tags:** Optionally, add tags that you can use for filtering and grouping in the variable list view. Use a tab or hard return between (arbitrary) tag names.
3. Save the variable. The system validates the **Value** field to ensure it matches the specified **Type** when it saves.

You can also add new variables directly in the field where you want to reference that variable.

Use Variables in a Pack

Fields that can accept variables have a **Variable** icon next to them. Select this icon to open the **Add Variable** modal. You can select an existing variable from this list or create a new one.

> Worker Group variables are designed specifically for configuration binding. They are not accessible using the C.vars expression in Pipeline Functions. You can only bind these variables to Source and Destination configuration fields that display the **Variable** icon .
>
> The only exception is the Redis Function, which can resolve Worker Group variables at runtime to manage external state or lookups.

Delete Variables

Before deleting a variable, identify where it is currently applied. When you delete a variable that is bound to a Source or Destination, the system performs the following actions:

- **Converts to static values:** The system replaces the variable reference with its last known value. For example, if a field was bound to an `AWS_REGION` variable with a value of `"us-west-2"`, the field will now contain the hard-coded string `"us-west-2"`.
- **Breaks environmental awareness:** Because the value is now hard-coded, the configuration will no longer adapt if you move the Pack to a different Worker Group or update the Pack or variable at the Worker Group context.
- **Prevents batch updates:** You can no longer update multiple Sources or Destinations by changing a single variable. You must manually edit each component to update its settings.

This action is permanent and cannot be undone. To restore variable binding, you must manually re-bind each field to a new variable.

Copy a Pack

After building and validating Packs, you can then copy or import that Pack to multiple Worker Groups, making small adjustments to the logic to allow for specific differences that are unique to that Worker Group. For example, you could adjust the Worker Group-level variables that account for regional differences (such as different AWS regions), VPC endpoints, or local port assignments.

When you move a Pack, it carries its entire data processing ecosystem with it, including Pipelines, Knowledge objects, and sensitive resources. This ensures that the core data processing business logic remains intact while adapting to the local requirements of its new Worker Group context. It also allows you to easily make updates to Packs and deploy those updates with minimal overhead.

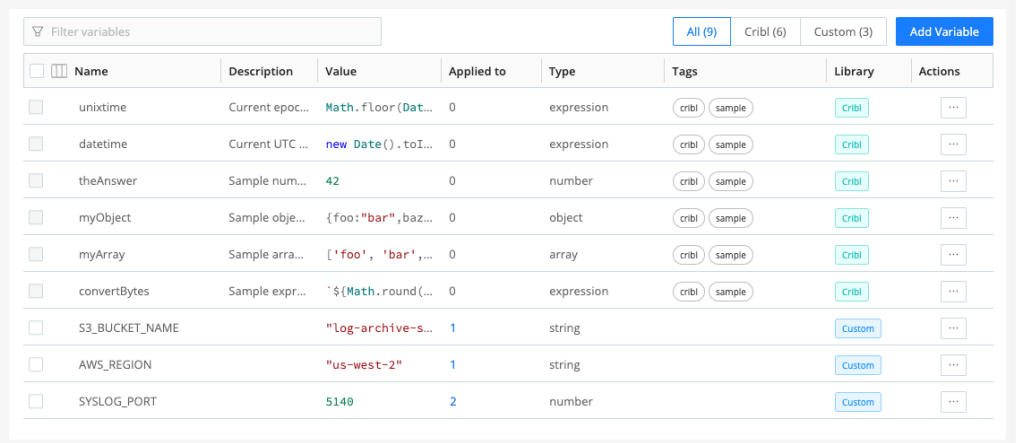
To copy a Pack:

1. In Cribl Stream, navigate to the **Packs** page and open the Options ••• menu on the row of your Pack.
2. Select **Copy to another Worker Group**.
3. In the modal, define the destination and content:
    - **Export mode:** Select one of the three available export modes. See Export Mode for more detailed information about each mode.
    - **Worker Group:** Type or select the target Worker Group.
    - **Overwrite:** Select this option if you want to replace all configurations, Pipelines, and variables in the target Worker Group with the versions from this Pack. Enabling this will permanently overwrite any local modifications made to the Pack in the target Worker Group.
    - **Include external dependencies (certificates, secrets, variables):** Bundle all certificates, secrets, and variables required for the Pack to function. This ensures the target Worker Group has the necessary credentials to run the Pack immediately. Existing resources in the target group are maintained, while only new or missing dependencies are added.
4. Select **Copy**.

Update Variables After Import or Update

When you import or copy a Pack into a new Worker Group, Cribl prompts you to configure the variables for that Worker Group context by displaying a message that indicates the import was successful. Select **Configure Variables** in this message to go to the **Variables** list. From here, you can see the list of variables available to the Pack, including its Pack variables. You can then update the variables to their custom value for that Worker Group.

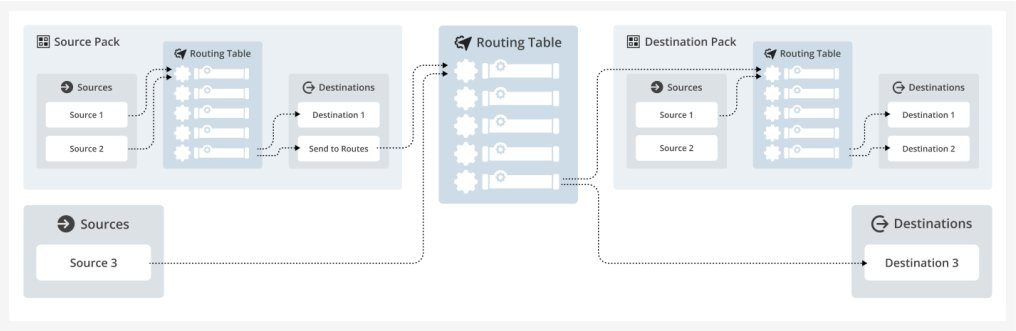
The **Applied to** column displays the number of active references for each variable. Select the value to open a modal listing all Sources and Destinations that reference this variable.



View all Pack variables

Connect Packs to Global Sources and Destinations

After you export a Pack to a new Worker Group, you can optionally set up the ability to transfer data in and out of Packs to other Sources and Destinations that are available at the Worker Group level. See Design the Pack Data Flow for an explanation of how to plan an effective data flow strategy.

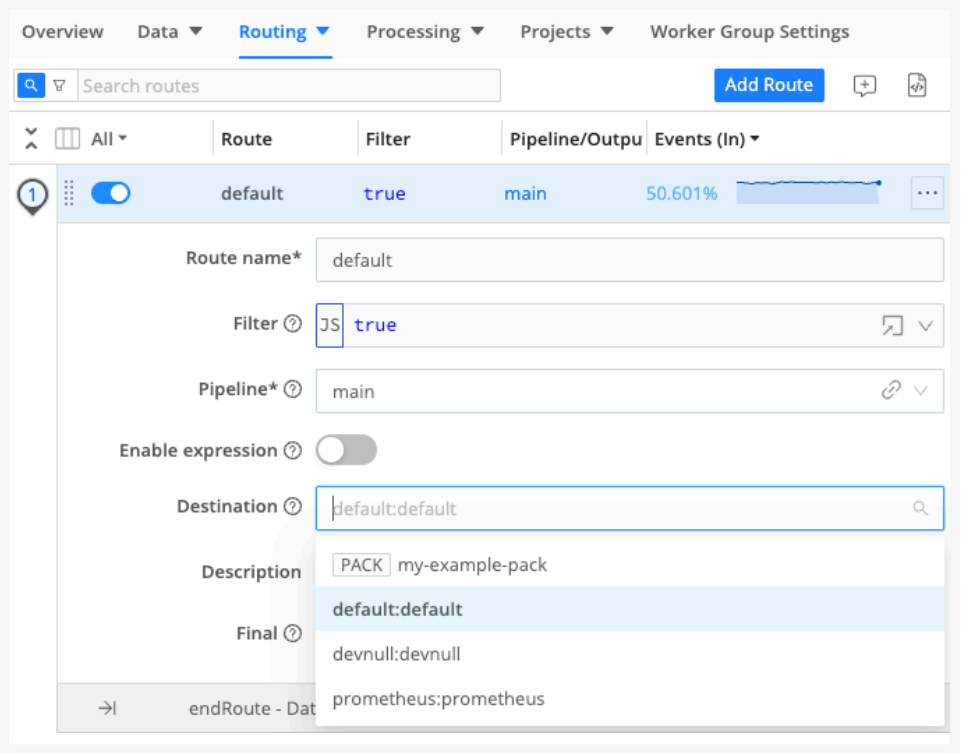


Route data in and out of Packs

Send Data From a Global Source to a Pack

To route data from a Source that exists at the Worker Group level to a Pack containing a Destination:

1. Ensure the target Pack contains a valid Destination.
2. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group.
3. Navigate to **Routing**, then **Data Routes**.
4. Add a new Route or expand an existing Route.
5. In the **Destination** field, select your Pack from the menu.



Box labels distinguish Packs from other objects in the Destination field

6. Verify that data is flowing as expected.

A Pack only appears as an available target in the **Destination** field if it contains at least one configured Destination. System-provided Destinations, such as Default or DevNull, do not fulfill this requirement and will not make the Pack visible in the selection menu.

Send Data From a Pack to a Global Destination

To route data originating in a Pack to a Destination that exists outside a Pack at the Worker Group level:

1. From inside the Pack context, select **Routes** from the top bar.
2. Add a new Route or expand an existing Route.
3. In the **Destination** field, select **Send to Worker Group Routes**. This sends any data matching the **Route** filter to the global Route table at the Worker Group level.
4. Verify that data is flowing as expected.

9.1.3. Version Control Packs In External Git Repos

You can track and version-control Packs in an external Git repository, such as GitHub, GitLab, and Bitbucket. Tracking a Pack using an external Git repository establishes Git as the single source of truth for Pack configurations. This allows you to track configuration changes in a central, company-owned repository. It also makes it easier to integrate your Cribl deployment into your company's existing change management workflows.

Best Practices for External Pack Repositories

When tracking Packs in an external Git repository, keep these considerations in mind:

- **Each Pack needs its own Git repository.** To easily import and export Packs to an external Git repository, set up a separate Git repository for each Pack you want to version control.
- **Use branches for two-way synchronization:** While you can import a Pack from either a Git branch or a tag, tags are immutable and do not support pushing changes back to the remote repository. To enable a bidirectional workflow (where you both pull updates and push your local changes), you must use a branch.
- **Always pay attention to the Pack version.** Whenever you develop or export a Pack, get in the habit of checking the Pack version number in the Pack settings. When you make a change, check that you increased the version of the Pack before exporting. Cribl Stream only updates Packs when the version number has increased.
- **Consider protecting branches to prevent accidental deletions.** Set appropriate merge rights on these branches as needed.
- **Document what the Pack does:** If storing the Pack in an external Git repository, include README files and comments within components that explain what kind of data the Pack handles, which environment is it intended for, and whether there are any Sources/Destinations shared across Packs.

Export a Pack to an External Git Repository

After you have built your initial Pack, you can export it to an external Git repository and begin tracking it with Git version control tools. To get started, set up the connection between the Pack in your local environment and the version-controlled Pack in a Git repository.

Export a Pack

The first step is to export your Pack:

1. In Cribl Stream, navigate to the **Packs** page and open the Options ••• menu on the row of your Pack.
2. Select **Export** and choose the **Merge** export mode.
3. Confirm with **Export** and save the file locally.

Add the Pack to an External Git Repository

Now that you exported your Pack, you can add it to a new Git repository. You can use a public or private repository in any common Git hosting service, such as GitHub, GitLab, or Bitbucket. Regardless of whether your repository is public or private, you need to set up a personal access token for this repository, as explained in a later step: Set up a Personal Access Token and Import the Pack.

To add the Pack to an external repository:

1. Create an empty private repository in any hosting platform.
2. Optionally, create branches for your development, testing, and production branches. For example, `dev`, `test`, `prod`.
3. Clone the new repository to your local computer.
4. Extract the `.crbl` file into the root repository directory.

Because they are gzipped, you can extract `.crbl` files using the `tar` utility. For example: `tar -xvzf WebdataStorage_0.0.1.crbl`.

5. Add, commit, and push the Pack content to your upstream Git repository.

Import and Update a Pack

In this step, you'll set up the connection between the Pack in your local Cribl Stream environment and the version-controlled Pack in a Git repository so that you can push and pull to branches from inside Cribl Stream.

You'll authenticate the connection by setting up a personal access token to connect Cribl Stream. Then, you'll make a change to the original Pack and push those changes to a development branch in your Git repository.

Set Up a Personal Access Token and Import the Pack

To import a Pack from Git into Cribl Stream, generate a personal access token for your Git hosting service:

1. Create a personal access token.
   Using GitHub as an example, create a personal access token with the `repo` scope.

For GitHub only: You must authorize your personal access token to access the organization identity if you:

- Enabled SSO (single sign-on) authentication for your personal access token, and
- Are using a classic personal access token (as opposed to fine-grained).

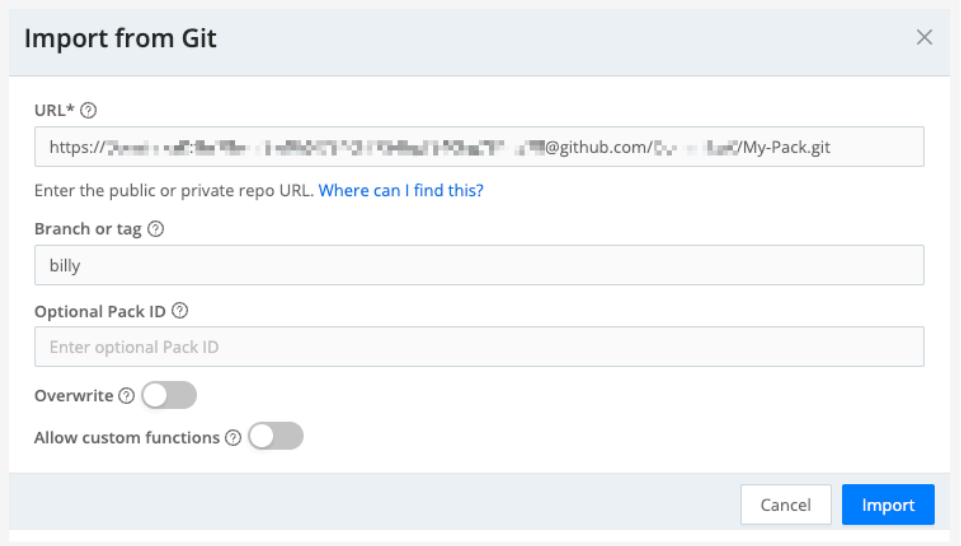
See the GitHub documentation about Authorizing a personal access token for use with single sign-on for specific instructions.

2. In Cribl Stream, select a Worker Group and navigate to the **Packs** page.
3. Select **Add Pack** at the upper right and select **Import from Git**.
4. Enter the repository's URL. Provide your username and the token in this format: `https://<username>:<token>@github.com/<username>/<repo_name>.git`.
5. In **Branch or tag**, provide the name of your branch in the remote repository.

Choose your import source carefully. While you can import from a tag or a branch, only branches support pushing changes back to the remote repository.

- **Branches:** Use these for two-way synchronization (pull and push).
- **Tags:** Use these for read-only snapshots.

To switch from a tag to a branch, or to target a different branch for exports, you must delete the Pack and re-import it with the correct branch.



Importing a Pack from a Git repository

6. Select **Import** to confirm.
7. If the Pack you are importing binds variables to any fields, you will see a **Configure Variables** button in the notification about successful import. Select it to go to the **Variables** page, where you can configure the values for the variables for your deployment.
8. Check that the Pack is working correctly with your current environment based on its scope:

- If the scope of your Pack contains Sources and Destinations, verify data flow between everything included in the Pack.
- If your Pack only contains Routes and Pipelines, verify data flow by connecting the Pack to a Worker Group that has the necessary Sources and Destinations.

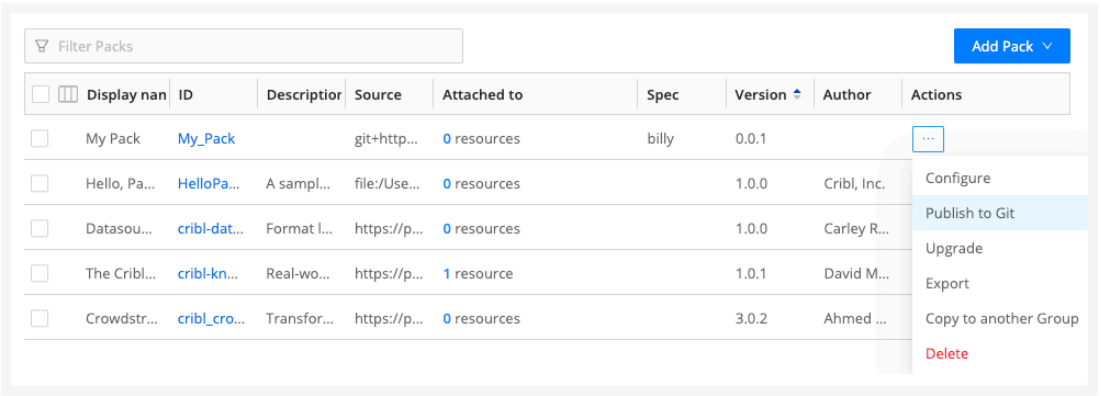
Verify data flow between Sources and Destinations both inside and outside the Pack.

For on-prem deployments, it is possible to authenticate using SSH rather than personal access tokens. See Authenticate With SSH for more information.

Modify the Pack and Push Changes to Git

Now you can customize the Pack. Modify the Pack in some way by editing the Pack's configuration objects. For example, try making an edit to a Source, Destination, Route, Pipeline, Event Breaker, or Knowledge Object. For your first time using an external Git repository, keep the changes small. Then, publish your changes to the remote Git repository:

1. Navigate to the **Packs** page and open the Options ••• menu on the row of your Pack.



Publishing a Pack to Git

2. Select **Publish to Git**, and in the modal window, confirm with **Publish to Git** again.
3. Your Pack's branch in the remote repository updates with your changes.

The repository maintainer can now synchronize the main branch with your branch in their preferred way (for example, by creating a pull request).

When you use **Publish to Git**, all files in the repository are overwritten except for hidden files and directories located at the repository root. This means that any non-hidden files not managed by Cribl (such as documentation, scripts, or CI/CD workflows) will be deleted.

To preserve important files, ensure they are stored as hidden files by prefixing their names with a `.` For example use `.github` for GitHub workflows.

Authenticate With SSH (On-Prem Only)

For on-prem deployments, you can connect Packs to external Git repositories using SSH instead of HTTPS. This approach allows you to avoid embedding personal access tokens in your import URLs.

To authenticate with SSH:

1. Add your private SSH key to the Leader Node. See Connect to a Remote with SSH for more information.

   This SSH key must also have the necessary permissions (Read/Write) on your Git host provider (GitHub, GitLab, Bitbucket).

2. Select **Add Pack** at the upper right and select **Import from Git**.
3. Enter the repository's URL.
   When using SSH, the URL format differs slightly from the standard SSH Clone string provided by Git UI buttons. Specifically, you must use a `/` (slash) instead of a `:` (colon) after the domain. For example:

Authentication Method	URL Syntax
Standard HTTPS URL (with personal access token)	`https://<username>:<token>@github.com/<org>/<repo>.git`
Optimized SSH URL	`ssh://git@github.com/<org>/<repo>.git`

4. In **Branch or tag**, provide the name of your branch in the remote repository.
5. Select **Import** to confirm.

The alternative SSH authentication is not supported in Docker-based sandbox or ephemeral environments. For containerized deployments, continue authenticating with a personal access token.

Time to GIT Serious - Automate Your Cribl Pack Deployments — Blog

9.2. Packs Publication Standards

This page outlines the process for Cribl Community members to publish Cribl Stream, Edge, and Search Packs to the Cribl Packs Dispensary. It also lists standards that apply to all publicly available Community Packs.

Publication Overview

Publishing your Pack is a five-stage process:

1. **Prepare**
    - Prior to starting development, read this topic's Pack Review Summary and Pack Review Checklist. These resources will help you create a Pack that can easily pass the review process. Decide on the problems you're trying to solve, and determine the dataset(s), data senders, and data receivers you're going to work with.
2. **Develop your Pack**
    - You'll generally develop Packs in your own Cribl environment, using saved sample data files to build out Stream/Edge Pipelines, or using Search Datasets to build Search Dashboards. During this stage, you might consider working collaboratively within Cribl's Community Slack `#packs` channel. When the Pack is ready for review, export it as a `.crbl` file, using the Cribl UI.
3. **Test your Pack**
    - Cribl strongly recommends that you test the Pack yourself, in your own environment. To verify that all content was exported correctly, import your Pack into a fresh Cribl environment. For Stream or Edge, this might be a newly created Docker instance, Worker Group, or Fleet. For Search, this might be a different Cribl Search Workspace. Upload the Pack, then use the Pack Review Checklist to verify that the Pack will pass review.
4. **Submit your Pack for review**
    - Sign into, or create an account on, the Cribl Packs Dispensary site. You can use your Cribl.Cloud account's email address to create the Cribl Packs Dispensary account.
    - If you don't have a Cribl.Cloud account, Cribl automatically creates a new one for you when you create your Cribl Packs Dispensary account.
    - Once you sign in, you'll see the Dispensary page with the **Publish Pack** button.

- Click **Publish Pack**, and then click **Upload Pack**.
- Select the `.crbl` Pack file you want to publish, and click **Submit**. You will be prompted to agree to the terms of Cribl's Pack Developer Agreement. As a Pack author, you must electronically acknowledge that you have read the Agreement, and that you intend to adhere to its requirements.

> Once you've uploaded the Pack, Cribl will review it. The review process typically takes a week or more. Once your Pack is reviewed, you'll receive an email from `packs@cribl.io` either informing you that it was accepted, or providing the reason(s) why it was rejected. (In the latter case, you can address the specified issues and resubmit.)

5. **Once your accepted Pack is published to the Cribl Packs Dispensary, it's time to celebrate!**

Pack Review Summary

To ensure consistency across published Packs, Cribl evaluates all submitted Packs against the Pack Review Checklist. Any Pack that fails to satisfy the checklist's requirements will be rejected. (As noted above, we will notify you of the basis for any rejection, so that you can remedy the issue and resubmit.)

Cribl recommends:

- Check your Pack against the checklist **before** trying to submit the Pack. This way, you can avoid having your Pack rejected for something easily fixed upfront.
- For Stream/Edge Packs, you can install the Syslog Pre-processing Pack as a reference - it includes clear examples of each item on the checklist.
- For Search Packs, you can install the Search Palo Alto Networks Traffic Pack as a reference.

Pack Review Checklist

This is a checklist for Packs you intend to submit to the Cribl Packs Dispensary. The following sections list setup requirements for product-specific Packs, and then for all Packs.

Stream/Edge Packs - Requirements

This section's requirements apply to Packs for Cribl Stream and Cribl Edge.

Sources and Destinations

If you include a Source (or Stream Collector) in your Pack, you must also include the intended Destination, so that the Routes table is wired up to receive and deliver data all within that Pack. If you include Sources (including Collectors) or Destinations inside a Pack, you must clearly state this in the README, and your README should warn users not to insert this Pack (as a Pipeline) into the global Routes table outside of the Pack.

The benefit of tying everything together in a Pack - Sources, Pipelines, Routes, Destinations - is enabling users to take advantage of an end-to-end telemetry stream configuration. This way, users need to update only selected values (for things like endpoints and authentication details) in order to run the Pack.

Routes

A submitted Stream or Edge Pack must include at least one Route in addition to the default Route.

- A Pack's Routes page must have a Route, with an appropriate filter, routing to a Pipeline.
- The filter should match **only** the set of data that the Pipeline is designed to process. The filter must **not** be set to `true`.
- If the Pack deals with multiple data types, each data type should have its own Route/Pipeline pair. (For a good example, look at the Palo Alto Networks Traffic Pack.)
- The Pack must not use the `default` Route to send events to a Pack-specific custom Pipeline. The `default` Route may have a Pipeline set to `main`, `devnull`, or `passthru` to handle events that do not match the Pack filter(s).
- Each Route must include a short description of the data sample being matched.
- Pairs of Routes and Pipelines should have matching names.

Pipelines

A Pack submitted must include at least one Pipeline in addition to the default Pipelines (which are `apache_sample_pipeline`, `devnull`, `main`, `passthru`, and `prometheus_metrics`.).

- If the Pack deals with multiple data types, there must be one Pipeline (and one Route) for each data type. (For a good example, look at the Palo Alto Networks Traffic Pack.)
- The Pack must not modify the default Pipelines. Leave these Pipelines unchanged.
- Every Pipeline must begin with a Comment Function that gives an overview of the Pipeline's operation as a whole. This Comment is a synopsis of what the entire Pipeline will be doing. For an example of the expected level of detail, refer to the Syslog Pre-processing Pack.
- If Function Groups are used within the Pipeline, each Function Group must begin with a Comment Function that gives an overview of what will happen within that Function Group.
- Every Function must have a Description that briefly explains exactly what is happening in that particular Function. During review, change the Pipeline view option to display the Description for each Function.

- Using the sample files provided with the Pack, validate that the Functions work as detailed in the Comment at the top of the Pipeline.

Sample Data Files

The Pack must include at least one sample data file for each of its Pipelines.

Sample data files:

- Must **not** have an expiration date.
- Must **never** include PII, customer data, or customer hostnames.
- Must be named to make it obvious which sample file(s) apply to each Pipeline.
- Must contain samples that are adequate for a customer to use to review the operation of a Pipeline. To allow performance analysis of the corresponding Pipeline, a sample should include 20 or more events, with 100 or more recommended.
- May be reused across Pipelines, but it is preferable to include multiple sample files, each specific to one Pipeline's Route and filter.
- Must work as expected on a clean installation of the Pack. This applies to all sample data files included in the Pack - Pack developers should test this before submitting the Pack.

Search Packs - Requirements

This section's requirements apply to Packs for Cribl Search.

Lookups

Ensure that lookup files contain no sensitive data. If Cribl review discovers any sensitive information in a submitted lookup file, Cribl will automatically reject the Pack.

When formatting references to the lookup table file, use this syntax:

```
pack(<pack_id>).<lookup_file_name>
```

Copy

When referencing the lookup table in queries, use this syntax:

```
dataset="cribl_search_sample" datatype="aws_vpcflow"
 | lookup pack(cribl-search-aws-vpc-flow-logs).protocol_codes on protocol=protocol_cc
 | summarize count=count() by protocol_name
 | order by count desc
```

Copy

Datatypes

Datatypes are important for Cribl Search Packs, because they provide the rules for how to process and search raw data. Adding Datatypes to Search Packs provides users with important parsing rules that enhance the overall search and Dashboard experience.

Essentially, Datatypes give structure to unstructured data, making it easier to query and explore vendor-specific datasets. Cribl strongly recommends that you implement Datatypes within Search Packs when needed. As a model, refer to the **Palo Alto Datatypes** ruleset that's built into Cribl Search.

All Products - Requirements

This section's naming and metadata requirements apply to all Packs.

Naming, Logo, and Tags

Every Pack must have both a unique **Pack ID** and a **Display name**.

When you view Packs in the Dispensary, the Display name appears above the Pack ID. The Pack ID must follow a specific format of sequenced tokens:

`<source>-<productArea>-<dataVendor>-<dataType>`.

Here:

- `<source>` identifies who contributed the Pack, not a data source. This is either `cribl` for Cribl-developed Packs, or `cc` for Community-contributed Packs. (Packs not satisfying this requirement will be immediately rejected.)
- `<productArea>` is one of `stream`, `edge`, or `search`.
- `<dataVendor>` and `<dataType>` identify (where applicable) the integration; and (where applicable) the focus of the transformations or configurations provided in the Pack. Examples for this pair of tokens might be `okta-rest`, or `palo-alto-networks-traffic`, or `exabeam-fortigate-firewall`.

Here are examples of complete Pack IDs from the Cribl Packs Dispensary (where you can find many additional examples):

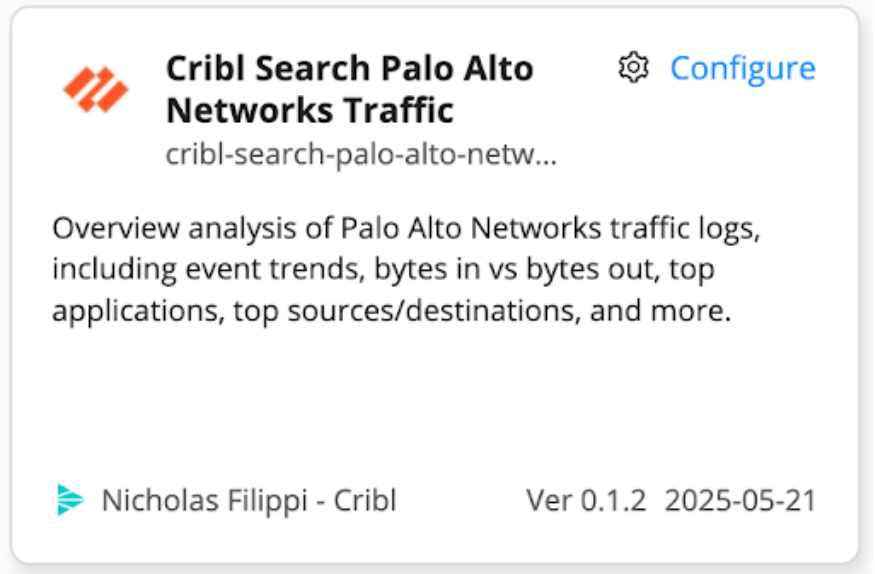
- `cribl-stream-sumologic`
- `cribl-search-cloudtrail-activity`

The Display name is a free-text summary of the purpose of the Pack. As examples:

- `Cribl Stream for Sumo Logic` is a Display name, while `cribl-stream-sumologic` is the corresponding Pack ID.
- `Cribl Search CloudTrail Activity` is a Display name, while `cribl-search-cloudtrail-activity` is the corresponding Pack ID:

Detailed requirements for both fields follow these graphical examples from Dispensary tiles.

Display Name and Pack ID - Stream or Edge example



Display Name and Pack ID - Search example

Pack ID Requirements

The Pack ID:

- Must start with either `cc-` (Community-contributed) or `cribl-` (Cribl-contributed). Packs not satisfying this requirement will be immediately rejected.
- Should (by convention) be all lowercase, using hyphens (`-`) as delimiters.
- Should **not** include the word "pack."

Display Name Requirements

The Display name is a friendly, human-readable version of the Pack name that:

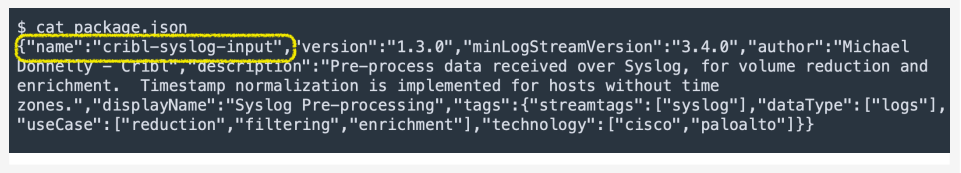
- Omits `cc-` and `cribl-`.
- Uses spaces where appropriate, and uses conventional capitalization.
- Matches the vendor's preferred spelling, spaces, and capitalization of any referenced company or product name.

Within a Pack, you can view or edit the Display name on the **Pack Settings** tab.

How to Review the Pack ID

This is the same procedure that the Cribl will perform when reviewing your Pack:

1. Extract the `.crbl` tarball that was submitted to the Dispensary:
   `tar zxvf <your_filename>.crbl`
2. View the `package.json` file:
   `cat package.json`
3. Check the value of the `name` field. This should be the Pack ID that you want.



Verifying the Pack ID

Pack Settings

You must review your **Pack Settings** to verify that the Pack satisfies all of the following criteria.

Display Name

A friendly, human-readable version of the Pack name, as defined above.

Version

The version number in the submitted Pack must have a corresponding entry in the README Release Notes. This number should be in SemVer (Semantic Versioning) format.

- The minimum version for initial publication is `0.1.0`. A Pack with a lower version **will be rejected**.
- A release that is considered "beta quality" should be designated as version `0.9.0`.

Description

Use this as a brief "hook" of one to two sentences. Example:

```
This pack for Syslog inputs will reduce volume, and address timestamp normalization for Syslog senders that omit timezones.
```

Author

Community-contributed Packs may include the author's name, a company name, or both.

All three of the following examples are valid:

1. `Jon Smith`
2. `Bazookatron`
3. `Jon Smith - Bazookatron`

Cribl-published Packs must use author's full name, plus `- Cribl`. Example: `Michael Donnelly - Cribl`.

Data Type, Use Cases, Technologies

Select all that apply.

Tags

Tags are optional but recommended, especially where multiple Packs are intended to work together. Tag examples include: `OCSF`, `AWS`.

Logo

The logo is optional, but recommended. You can include a logo associated with the technology addressed by the Pack. As examples: a Windows logo for Windows events, or an AWS Cloudwatch logo for AWS Cloudwatch data.

You can set the logo via **Pack Settings** > **Display**.

README

The `README` is the documentation others will use in selecting and deploying the Pack. The `README` requirements ensure that others will be able to successfully deploy the Pack.

The default sections for the README, as created when you click **Create Pack**, do not match the required and optional sections in the checklist. You will need to delete or replace certain sections.

On the Pack's **Pack Settings** > **README** tab, validate that the README text is correct. The following rules apply to all sections of the README:

- Proper grammar will help the users of your Pack. Use a grammar and spelling checker to make sure the README is clear and readable.
- If the README includes any text that looks like a placeholder, the Pack will be rejected.
- Trademark or product names must be spelled and capitalized exactly as the company that owns them would dictate. This requirement also applies to Pack settings, inline comments, and other uses. Examples: Amazon (not amazon), GCP (not Gcp), CrowdStrike (not Crowdstrike).

The README **must** include all of the sections enumerated here, as items **a** through **f**. The README may also include additional sections, as necessary to explain the resources you've included in the Pack.

a. About This Pack

Think of this initial section as the first paragraph of an essay, or as the only paragraph a person will read when deciding to use the Pack. It must clearly state what the Pack does. Start with the benefits of using the Pack. In sum, this section should answer the question, **Why should anyone use this Pack?**

If the Pack is tied to a specific data source, dataset, or destination, spell that out clearly here - even if that source or destination is in the Pack name.

b. Deployment

This **required** section must include all instructions necessary to get the Pack up and running. If the Pack requires any configuration after initial installation - but before it's put it into production - you must specify the configuration steps here.

Stream/Edge Pack Deployment

Filters: If applicable, say what filter must be used to route data to the Pack, or explain how to configure the filter. A filter based on `__inputId` is much more efficient than a match against `_raw`.

Sources: If the Pack requires a specific Source (or Stream Collector), include information on how to configure that Source. At a minimum, this needs to cover setting up the Source within Cribl. In some cases, this might include information on how to set up an external environment for collection by Cribl as well.

Destinations: If the Pack requires a specific Destination, include information on how to configure that Destination. Does it need a post-processing Pipeline tied to the Pack?

Pipelines: If the Pack includes Functions (within a Pipeline) that need to tailored, enabled, or disabled, include a full explanation and instructions.

Lookups: If the Pack includes Lookup files that need to be tailored, you must specify the configuration steps here.

Search Pack Deployment

Dataset Provider: If the Pack works with a Cribl Search built-in Dataset Provider, specify it. If the Pack requires adding a new Dataset Provider, provide specific instructions.

Dataset: Provide instructions on configuring compatible Datasets.

Datatype: Specify Datatypes to apply - whether built into Cribl Search or included in the Pack.

Macros: Provide instructions on using any custom Macros included in the Pack.

c. Upgrades

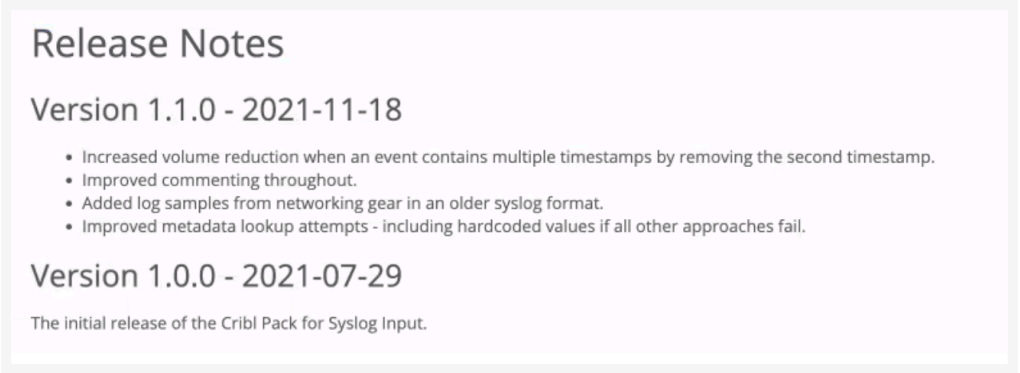
This **optional** section is strongly recommended if you expect others to customize their copy of the Pack and later upgrade the modified Pack.

- If included, this section should cover the usual set of problems with Pack upgrades as described in Upgrading an Existing Pack, and should explain the specifics of upgrading this particular Pack.

d. Release Notes

This **required** section is a list of release notes where each release note:

- Starts with the version number and date of release, separated by a space, a hyphen, and a space. For example: `Version 1.2.0 - 2022-07-11`.
- Continues with bullet points that describe what has changed and/or is new in the release.



Release notes

Release notes must adhere to the following rules:

- Designate the initial release version `Initial release.`
- The most current version listed must exactly match the Pack version in **Pack Settings** > **Pack Info**.
- Release notes versions must be listed starting with the most recent (in descending chronological order).

e. Contributing to the Pack

This **required** section explains how to contribute to the Pack.

- The information provided must be **actionable**. A section reading `[Contributor instructions go here.]` would be rejected.
- Cribl recommends that you refer potential contributors to Cribl's Community Slack. For example, Cribl-created Packs read as follows:

```
To contribute to the Pack, please connect with us on [Cribl Community Slack](htt
```

Copy

f. License

This **required** section must include text that designates **and links to** a legitimate license.

- Community-contributed Packs must include a license that allows for use by the general public, such as Apache 2.0, MIT, or GNU.
- Built-by-Cribl Packs must use the following snippet:

10. Reference

A reference for Cribl Stream, including:

- Cribl Expressions
- CLI
- Environment variables
- Config files

For reference documentation for the Cribl API, see the API Reference.

10.1. Knowledge Objects

Knowledge objects are reusable, customizable objects that help you scale and maintain your Cribl Stream more easily. You can reference these objects in multiple places, such as Functions or Pipelines. With these objects, you can change a single value in a central location and then populate that change everywhere you use that object. Access these objects in **Processing** > **Knowledge**.

Knowledge Object	Description
Lookups	Reference tables that you can apply to raw data events in your Pipeline for routing and enrichment.
Event Breakers	Event Breaker Rulesets are ordered collections of event-breaking rules that help you define the boundaries and structure of raw log data. Once you have converted unstructured raw data into structured events, you can then send them through Pipelines for further routing and data processing.
Parsers	Parsers for use in the Parser Function.
Global Variables	Store values you can reference elsewhere in Cribl Stream.
Sample Files	A data sample (often called a data capture) is a small, representative subset of live or stored data from a given data stream. When you creating samples as Knowledge objects, these files can be accessed by Routes, Pipelines, Event Breakers, and Datagens at the Worker Group or Pack level.
Regexes	Regular expressions for use in regex-related Functions.
Grok Patterns	Grok pattern files for use in the Grok Function.
Schemas (JSON)	JSON schemas for validating events.
Parquet Schemas	Schemas for writing out data in the Apache Parquet format.
Database Connections	(**Cribl Stream only**) Reusable configuration objects that enable Database Collectors to access and retrieve data from a MySQL, Oracle, Postgres, or SQL Server database.
HMAC Functions	(**Cribl Stream only**) Keyed hashing functions that you use with REST Collectors.

10.1.1. Variables Library

Variables store values you can reference elsewhere in Cribl Stream. These variables allow you to change a single value and then populate everywhere that variable is referenced.

Variables are an important component for scaling your Cribl deployment and improving ease of maintenance. Typical use cases for variables include:

- Storing a constant that you can reference from any Function in any Pipeline.
- Storing a relatively long value expression, or one that uses one or more arguments.
- Converting abstract, complex logical expressions into a reusable variable that has a human-readable name for easier maintenance.

Cribl Stream supports a variety of variable types:

- **Number, String, Boolean:** Store simple, static configuration values for reuse and ease of updating (such as threshold limits or names).
- **Encrypted String:** Store sensitive strings (like API keys or passwords). The value is encrypted at rest but retrieved as plain text when referenced, including when you are logged into the Cribl interface.
- **Object:** Store complex, structured data or key-value dictionaries, often used as an alternative to small lookup files.
- **Array:** Store a list of items (such as IP ranges or required field names).
- **Expression:** Define complex, repeatable logic that requires calculated output, especially when the logic needs to accept arguments.

You access all variables using the standard syntax `C.vars.<variableName>`. See Cribl Expressions for more information about `C.vars` and other Cribl Expressions.

This page explains the general use case for variables. For more information about using variables in Packs, see:

- Pack Variables
- Configure Variables and Secrets

Limitations

When multiple variables share the same name, Cribl Stream resolves the value based on scope, moving from the most specific (inner) scope to the most general (outer) scope. In other words: local scope values win over

broader scopes.

For example, a variable defined inside a Pack (which has a local scope) will always override a variable with the same name defined in the Worker Group settings.

Create a Variable

Creating a new variable has three main phases:

1. Define the variable scope.
2. Configure the variable.
3. Reference the variable in a Function or Pipeline.

Define the Variable Scope

Variables are scoped to different levels of the application. You can only use a variable in the scope in which it is defined.

When creating a new variable, you determine its scope based on where you access and create the variable:

Worker Group | Pack | Single-Instance Deployment

To access and create variables specific to a given Worker Group:

1. Select **Worker Groups** from the sidebar, and choose a Worker Group.
2. On the **Worker Groups** submenu, select **Processing**, then **Knowledge**.
3. In the sidebar, select **Variables**.

You cannot access variables from a Pack in a Worker Group.

Configure the Variable

After ensuring you have accessed the variable from the correct scope, create a new variable:

1. Select **Add Variable**.
2. Configure the variable settings:
    - **Name:** Enter a unique name for the variable.
    - **Description**: Optionally, enter a description.

- **Type:** Select the type of variable you want to create. Options include:

Type	Explanation	Use Cases
String	A sequence of characters (text).	Can centralize environment identifiers, file paths, URL prefixes, or standard naming conventions. If a string or name changes depending on its context (such as a different environment), you only have to update it in the variable and it populates to configurations in that environment.
Number	For numeric values, including integers (whole numbers) and floating-point numbers (decimals).	Ideal for defining thresholds or limits that might need tuning later.
Encrypted string	Stores a string value that is automatically encrypted when saved to the configuration file on disk (YAML). However, within the application at runtime, it is decrypted and treated as a standard string.	Use for storing sensitive credentials like API tokens, secret keys, or passwords. This ensures that if someone inspects your configuration files or git commits, they only see the encrypted hash, not the plaintext secret.
Boolean	Represents a binary logical value that resolves to `true` or `false`.	Use as a switch to enable or disable specific logic paths, detailed logging, or experimental features across your entire deployment without editing individual Pipelines.
Array	An ordered list of values (strings, numbers) stored in a single variable.	Can help maintain long lists of items, such as IP ranges, required field names, known good or bad hostnames, and more.
Object	A structured collection of key-value pairs (dictionaries).	Functions as a lightweight, in-memory lookup table.
Expression	A snippet of JavaScript code that is evaluated only when called. Expressions can accept arguments, allowing them to act like reusable custom logical functions.	Allows you to encapsulate complex, multi-condition logic (like regex matching) into a single function with a human-readable name.
Any	A flexible container that accepts a value of any variable data type (string, number, expression) without enforcing strict validation rules.	While this variable type is flexible, it removes the safety net of UI validation. Use specific types (like number or boolean) whenever possible for better reliability.

- **Value:** Enter the value, data structure, or JavaScript expression for this variable. This input must match the format required by the selected variable type. For example, Expressions should have JavaScript syntax. The system validates the input when you save.
- **Tags:** Optionally, add tags that you can use for filtering and grouping in the variable list view. Use a tab or hard return between (arbitrary) tag names.

3. Save the variable. The system validates the **Value** field to ensure it matches the specified **Type** when it saves.

Reference the Variable

After creating the variable, you can start calling it in Functions, Pipelines, and Packs. You can reference a variable in fields that let you use custom JavaScript code. See the introduction of Build Custom Logic to Route and Process Your Data for examples and images of JavaScript-enabled fields.

Some variable types require additional inputs or arguments:

Variable Type	How to Reference	Examples
Number, String, Boolean	Use `C.vars.variable_name` in any field that lets you use custom JavaScript code.	`C.vars.my_variable`
Encrypted String	Use `C.vars.variable_name` in any field that lets you use custom JavaScript code.	`C.vars.api_key`
Object	Reference these as you would any other object or array using standard JavaScript object notation.	`C.vars.lookup_map.key` `C.vars.my_config.region`

Array	Reference these as you would any other object or array using standard JavaScript object notation.	`C.vars.varname[0]`
		`C.vars.varname.nested`
		`C.vars.host_list[0]`

Expression	Call it with the arguments in parentheses.	`C.vars.varname(arg1,arg2)`

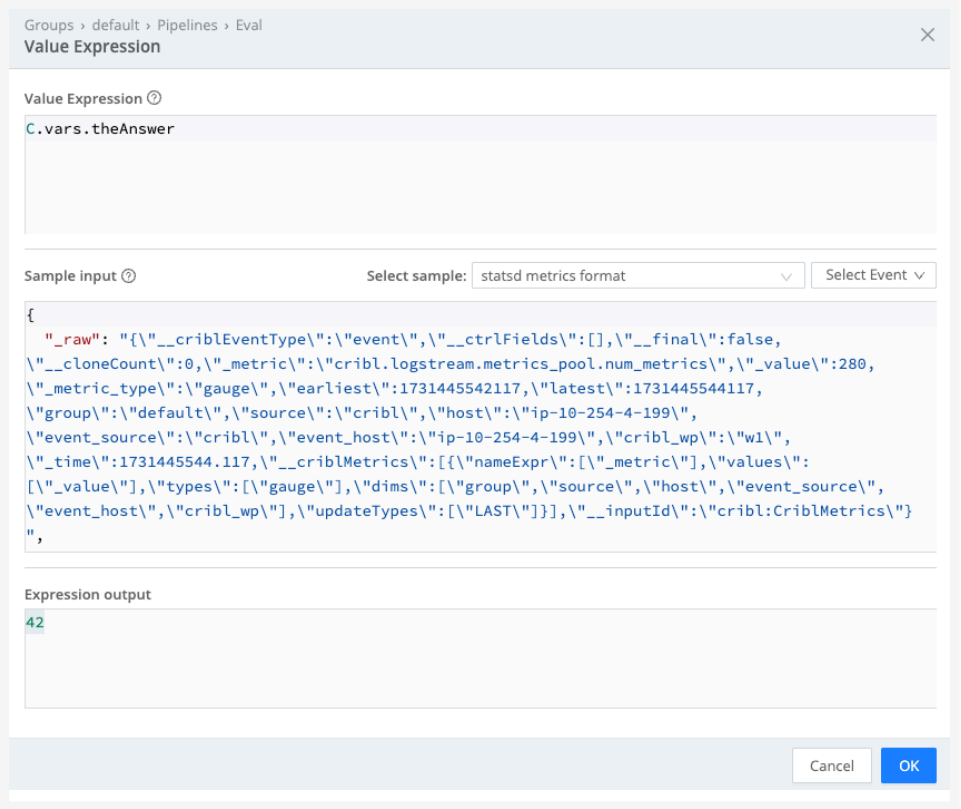
To illustrate the workflow for referencing a variable, imagine a scenario in which you want to add a field named `myField` to all incoming events. This field value will get referenced in multiple Pipelines and may possibly change, which is why you decided to make it a variable named `theAnswer`. For now, you want to set it to a static number value of `42`.

After creating the number variable named `theAnswer` with a value of `42`, you could then reference it in a Pipeline:

1. Add the Eval Function. (The Eval Function adds, modifies, or removes event fields.)
2. Select **Add Field** to add a new field.
3. Configure the new field to reference the `theAnswer` variable:

- **Name:** myField
- **Value Expression:** `C.vars.theAnswer`

4. To validate the value, select **Advanced Mode** in the **Value Expression**.
5. Confirm that the **Expression output** is `42` as expected.



Value Expression Advanced Mode

You can then reference this variable in multiple Functions or Pipelines as needed. When you change the variable value, it will update anywhere the variable is referenced.

> Worker Group variables are designed specifically for configuration binding. They are not accessible using the C.vars expression in Pipeline Functions. You can only bind these variables to Source and Destination configuration fields that display the **Variable** icon .
>
> The only exception is the Redis Function, which can resolve Worker Group variables at runtime to manage external state or lookups.

Use Case Examples

You can personally test these examples within your own Cribl Stream deployment to understand how Cribl evaluates variables.

Expression Example

This example shows an expression variable that executes JavaScript logic to get the current time and assign it to a field named `nowEpoch`. This expression does not require any input arguments, so it gets left blank.

Variable settings:

- **Name:** `epochTime`
- **Type:** Expression
- **Value:** `Date.now()/1000`

You could then add an Eval Function to a Pipeline:

- **Field Name:** nowEpoch
- **Value Expression:** `C.vars.epochTime()`

Object Example

This example demonstrates how to use an Object variable as a central configuration store (dictionary). You can reference specific keys within the object using dot notation. In this scenario, the goal is to assign the field `contact_email` a value that is stored in the `admin_email` key of a global configuration object.

Variable settings:

- **Name:** `my_app_config`
- **Type:** Object
- **Value:**

```
{
  "env": "production",
  "retry_count": 3,
  "admin_email": "ops@example.com"
}
```

Copy

You could then add an Eval Function to a Pipeline:

- **Field Name:** contact_email
- **Value Expression:** `C.vars.my_app_config.admin_email`

Array Example

This example shows how to use an Array variable to store a list of values (like hostnames) and check if a specific event field exists within that list. In this scenario, the goal is to drop the event if the host field matches any entry in the `blocked_hosts` list. This will be accomplished with logic that returns `false` in a filter.

Variable settings:

- **Name:** `blocked_hosts`
- **Type:** Array
- **Value:** `["bad-host-1", "test-server-99", "retired-asset"]`

You could then add a Drop Function to a Pipeline with a **Filter** value set to: `C.vars.blocked_hosts.includes(host)`.

Additional Examples

There are endless possibilities for how to use variables in Cribl Stream. See more examples in the Goat-to Resources and continue sharing use cases with the rest of the Cribl Community on Slack.

Goat-to Resources

Using Global Variables to Simplify, Automate, and Save — Blog

10.1.2. Regexes

Regexes offer predefined regular expressions that you can use in regex-related Functions.

Cribl ships with a collection of commonly-used regexes and gives you the possibility of adding your own custom ones.

Regexes let you quickly identify and filter data that conforms to specific patterns, including commonly-used patterns like credit card numbers, IP addresses, or personal identification numbers. You can use expressions from the regex collection in several Functions, such as Regex Filter, Regex Extract, or Mask, in configuration for certain Sources and Destinations, as well as in other settings.

Prerequisites

You configure regexes per Worker Group, or within a Pack. You can only use the regex within its scope, that is, in the Worker Group or Pack you defined it in.

Regexes defined in an Edge Fleet are subject to Fleet inheritance.

Regex Priority

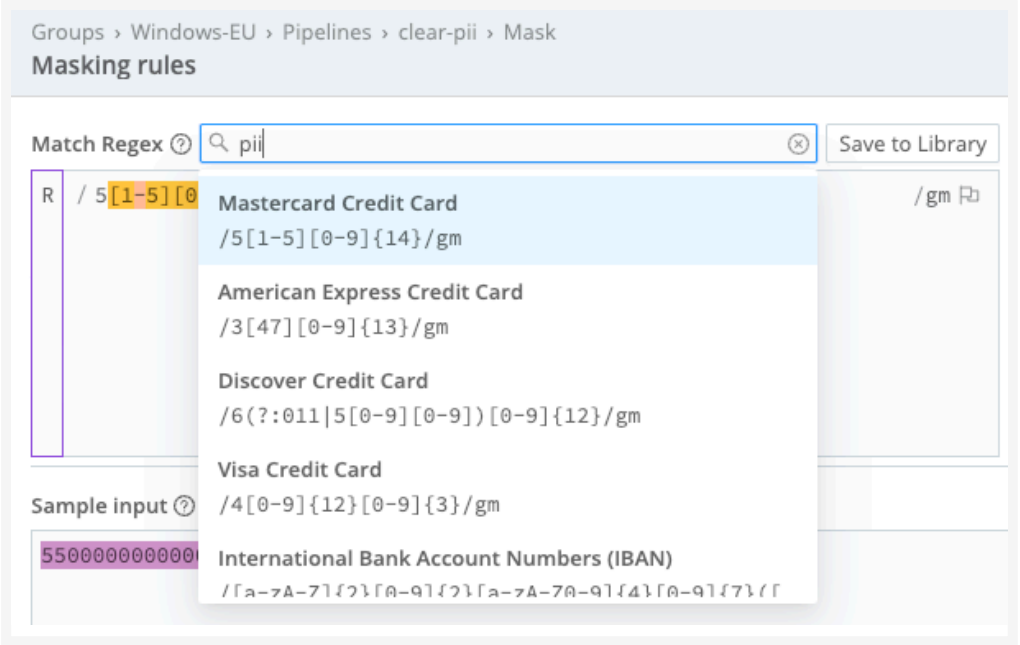
Built-in Regexes are listed with the **Cribl** tag, while those you add are tagged with **Custom**. When you edit any built-in regex, it changes to a **Custom** one as well.

If two regexes with the same ID exist, the custom pattern takes priority in listings and search. For example, if a Cribl-provided pattern and a Custom one are both named `ipv4`, the one from Cribl will not be displayed or delivered as a search result.

Use a Regex

To insert a regex into a field that supports it, for example in a Function, select the Advanced mode or Edit icon beside that field.

In the resulting modal, regexes will appear as typeahead options. Select a pattern to paste it in. You can then use the pattern as-is, or modify it as necessary.



Using a built-in regex

Create a Regex

To create a new regex:

1. In the sidebar, select **Worker Groups** and choose a Worker Group.
2. In the **Worker Groups** submenu, select **Processing**.
3. If you are adding regex to a Pack, select **Packs** and choose your Pack.
4. Select **Knowledge**, then **Regexes**. You will see a list of prebuilt and custom regexes.
5. Select **Add Regex**.
6. Enter an **ID** for the regex and an optional **Description**.
7. In **Regex pattern**, enter the pattern, using the JavaScript (ECMAScript) regex flavor. Use the flag icon to select options for regex matching.
8. In **Sample data**, you can enter a sample text to check the expression against. Matches will be indicated visually.

Adding a custom regex

9. Optionally, add one or more **Tags** that will help you search for this regex.
10. Select **Save**.

Examples

Mask SSN Numbers

If you need to mask personal identification numbers, you can use a build-in regex in conjunction with the Mask Function.

Add a Mask Function to your Pipeline. In the Function's **Masking Rules** modal, search and select the **US Social Security Numbers** regex in the **Match Regex** box. In **Replace Expression**, select the string or expression you want to mask the number with.

Mask Other Personal Identity Numbers

10.1.3. JSON Schemas

Cribl Stream uses JSON schemas for validating JSON events.

You can use the built-in Cribl Schema or create custom ones and use them to validate any fields by using the `C.Schema` expression.

JSON schemas are based on the popular JSON Schema standard, and Cribl Stream supports schemas matching that standard's Drafts 0 through 7.

You can refer to a single JSON schema in multiple expressions. When editing them, be aware that any change will affect all places it is used in.

Cribl Stream supports two kinds of schemas:

- JSON schemas for validating JSON events, described on this page.
- Parquet schemas for writing data from a Cribl Stream Destination to Parquet files.

These schemas serve different purposes. Operations that work for one kind of schema can't be used with the other. For example, the validation method for JSON schemas can't be used to validate Parquet schemas.

Validate an Object Against the Schema

To validate an object against a schema, use the `C.Schema` expression: `C.Schema('<schema_name>').validate(<object_field>)`.

You can call this method anywhere in Cribl Stream that supports JavaScript expressions. Typical use cases for schema validation include:

- Making a decision before sending an event down to a Destination.
- Making a decision before accepting an event (for example, dropping an event if invalid).
- Making a decision to route an event based on the result of validation.

Add New Schema

To add a new JSON schema:

1. In the sidebar, select **Worker Groups** and choose a Worker Group.

2. In the **Worker Groups** submenu, select **Processing**.
3. If you are adding the schema to a Pack, select **Packs** and choose your Pack.
4. Select **Knowledge**, then **Schemas**.
5. Select **Add Schema**.
6. Enter an **ID** for the regex and an optional **Description**.
7. In **Schema**, paste the JSON schema content.
8. Select **Save**.

JSON Schema Example

To add this example JSON Schema, enter the following into **New Schema** fields:

- ID: `schema1`.
- Description: (Enter your own description here.)
- Schema: Paste the following schema.

JSON Schema - Sample

```
{
  "$id": "https://example.com/person.schema.json",
  "$schema": "http://json-schema.org/draft-07/schema#",
  "title": "Person",
  "type": "object",
  "required": ["firstName", "lastName", "age"],
  "properties": {
    "firstName": {
      "type": "string",
      "description": "The person's first name."
    },
    "lastName": {
      "type": "string",
      "description": "The person's last name."
    },
    "age": {
      "description": "Age in years which must be equal to or greater than zero.",
      "type": "integer",
      "minimum": 0,
      "maximum": 42
    }
  }
}
```

Copy

Assume that events look like this:

Events

```
{"employee":{"firstName": "John", "lastName": "Doe", "age": 21}}
{"employee":{"firstName": "John", "lastName": "Doe", "age": 43}}
{"employee":{"firstName": "John", "lastName": "Doe"}}
```

Copy

To validate whether the `employee` field is valid per `schema1`, we can use the following:

`C.Schema('schema1').validate(employee)`

10.1.4. Parquet Schemas

Selected Cribl Stream Destinations support writing out data as files in the Apache Parquet columnar storage format.

The following Destinations support the Parquet format:

- Azure Blob Storage
- Azure Data Explorer
- Cloudflare R2
- Databricks
- Filesystem/NFS
- Google Cloud Storage
- MinIO
- Amazon S3 Compatible Stores
- Amazon Security Lake

You can select the Parquet format from the Destination's **General** > **Data format** drop-down. (An exception is the Amazon Security Lake Destination, which does not have the drop-down, because it uses the Parquet format exclusively). When the `Parquet` format is selected, you can configure the Parquet settings for the Destination, including selecting the Parquet schema to use.

You can automatically generate a Parquet schema based on the events of each Parquet file the Destination writes, by toggling on **Parquet Settings** > **Automatic schema** for the Destination. The automatically-generated schema preserves the exact structure of the ingested events, with no data lost. Every field in the generated schema will have a data type of `JSON`, `STRING`, `INT_64`, `UNSIGNED_INT_64`, or `DOUBLE`.

You can refer to a single Parquet schema in multiple Destinations. When editing them, be aware that any change will affect all places it is used in.

When logging is set to `debug`, you will see what schema is associated with the Parquet files that Cribl Stream writes out. On Linux, you can use the Cribl Stream CLI's `parquet` command to view a Parquet file, its metadata, or its schema.

Cribl Stream supports two kinds of schemas:

- Parquet schemas for writing data from a Cribl Stream Destination to Parquet files, described on this page.
- JSON schemas for validating JSON events.

> These schemas serve different purposes. Operations that work for one kind of schema can't be used with the other. For example, the validation method for JSON schemas can't be used to validate Parquet schemas.

Automatic Parquet Schema Generation

When you decide whether or not to generate Parquet schemas automatically, consider these pros and cons.

Advantages:

- Configuration is minimal.
- There's no need to know how events you want to ingest are structured.
- There's no need to change Parquet schema when event structure changes.

Disadvantages:

- Writing Parquet files takes longer than with predefined schemas. Note that schema complexity increases linearly with the number of events used to generate the schema.
- Automatically-generated Parquet schemas cannot be as fine-tuned as predefined ones, to capture certain nuances. For example, encoding will always be `PLAIN`, compression will always be `SNAPPY`.
- Some aspects of event structure (such as maps and sets) cannot be captured in the schema.
- Some aspects of time-related fields cannot be captured in the schema.
- Because the system produces a new Parquet schema for each file written, there may be differences between successive schemas. This can limit your ability to concatenate a collection of Parquet files.

Add Parquet Schema

If you are not using automatic schema generation, or if there's no pre-existing schema that suits your data, before configuring a Destination for Parquet output, you should add an existing Parquet schema, or create a new Parquet schema that suits the data you're working with.

You do not need to start from scratch: Cribl provides sample Parquet schemas for you to clone and then customize as needed.

To add a new Parquet schema:

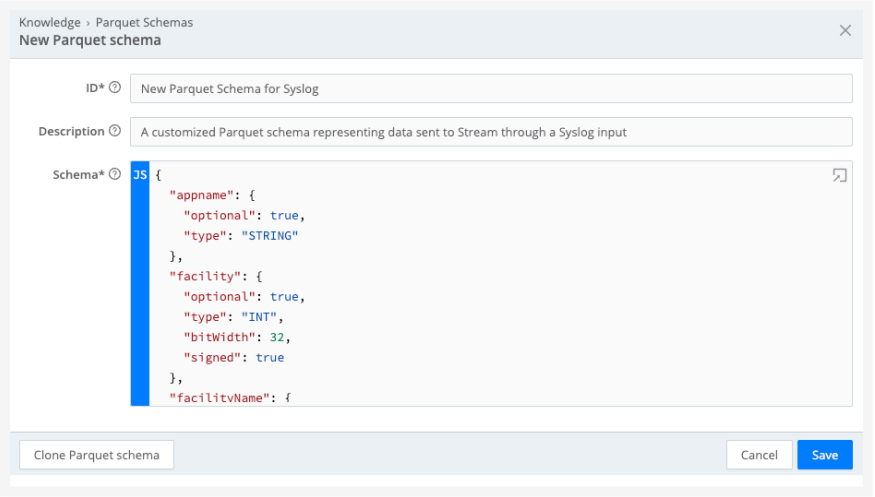
1. In the sidebar, select **Worker Groups** and choose a Worker Group.
2. In the **Worker Groups** submenu, select **Processing**.
3. If you are adding the schema to a Pack, select **Packs** and choose your Pack.
4. Select **Knowledge**, then **Parquet Schemas**.

5. Select **Add Parquet schema**.
6. Enter an **ID** for the regex and an optional **Description**.
7. In **Schema**, paste the Parquet schema content.
8. Select **Save**.

Modify Parquet Schema

You can modify existing Parquet schemas, but Cribl strongly recommends that you first clone the schema, and give the clone its own distinct name.

1. Select the schema you want to start with, to open it in a modal.
2. Select **Clone Parquet Schema** to open the **New Parquet schema** modal.
3. Give the new schema a name and description.



Creating a Parquet schema

Cloning vs Modifying Schemas

Modifying an existing schema does **not** propagate your modifications to its clones. Cloning and renaming schemas is the safest approach, because it ensures that your Destination will use the newly modified version of the schema.

If you do not clone and rename the schema (that is, you leave the schema name unchanged), you still must re-select the schema in the Destination's **Parquet schema** drop-down to bring the modified version into the Destination.

Parquet Format Used by Cribl Stream

Different Parquet readers and writers behave differently. Keep the following guidelines in mind when working with Parquet in Cribl Stream.

In the Parquet Schema editor, you express your Parquet schema in JSON. This does not look like the examples in the Parquet spec, which have their own syntax (like the repetition/name/type triple), but they are functionally equivalent. See the examples below.

The editor provides autocompletion and validation to guide you. (However, Cribl Stream currently does not fully support autocompletion on deeply nested schemas.)

File Extensions

Cribl Stream can read Parquet files only if they have the extension `.parquet`, `.parq`, or `.pqt`.

Field Content

When Cribl Stream writes to a Parquet file:

- If the data contains a field that **is not** present in the schema - i.e, an extra field - Cribl Stream writes out the parent rows, but omits the extra field.
- If the data contains a field that **is** present in the Parquet schema, but whose properties violate the schema, Cribl Stream treats this as a data mismatch. Cribl Stream drops the rows containing that field - it does not write those rows to the output Parquet file at all.
- If the data contains JSON, the JSON must be stringified. Otherwise, Cribl Stream treats this as a data mismatch, and does not write out the row. For example, this valid (but not stringified) JSON will trigger a data mismatch: `{ "name": "test"}`.
  The same JSON in stringified form will work fine: `"{\"name\": \"test\"}"`.

Data Types

Cribl Stream supports:

- All primitive types.
- All logical types.
- All converted types.

Converted types have been superseded by logical types, as described in the Apache Parquet docs. Cribl Stream can read Parquet files that use converted types, but will write out the same data using corresponding logical types.

Repetition Type

You have three alternatives when defining a field's Repetition type:

- Set `optional` to `true`.
- Set `repeated` to `true`.
- Set neither `optional` nor `repeated`. This **implicitly** sets the Repetition type to `required`, and it is the default.

Usage guidelines:

- Do not set both `optional` **and** `repeated` to `true`.
- Do not use the `required` key at all.
- Instead of omitting `optional`, you have the option to include it, but set it to `false`.
- Instead of omitting `repeated`, you have the option to include it, but set it to `false`.
- If any field's Repetition type is `repeated`, Cribl Stream represents this field as a single key whose value is an array - not as separate key-value pairs with identical keys.

Encodings

- Among the `*DICTIONARY` encodings, Cribl Stream supports only `DICTIONARY`. Trying to assign the unsupported encodings `PLAIN_DICTIONARY` or `RLE_DICTIONARY` will produce an error.
- `BYTE_STREAM_SPLIT` encoding can be used only with `DOUBLE` or `FLOAT` types, and otherwise produces errors.
- The `RLE` and all `DELTA*` encodings also produce errors.

Parquet Limitations

Cribl Stream does not support writing Parquet files which employ any of the following:

- Parquet Modular Encryption.
- The Parquet Bloom Filter.
- Separation of metadata and/or column data into multiple files.

Cribl Stream does not support reading or writing Parquet files which employ the deprecated `INT96` data type.

Examples of Parquet Schema as JSON

These examples should give you a hint of how to express Parquet schema in JSON. For a full explanation of the Parquet syntax, see the Parquet spec.

List Example

In this example, the whole schema is named `the_list`, and its structure consists of a container named `list` whose zero or more elements are each named `element`. Note that in Parquet schema, to specify that a field is nested (that is, contains other fields), you just give it the type `group`.

Parquet Schema Example 1

```
message schema {
  REQUIRED group the_list (LIST) {
    REPEATED group list {
      REQUIRED BYTE_ARRAY element (STRING);
    }
  }
}
```

Copy

Expressed as JSON, the same schema is more spread-out, because to specify that a field is nested, you give it a sub-field named `fields`. (This is equivalent to declaring the nested field's type as `group`.)

Parquet Schema Example 1 Expressed as JSON

```
{
  "the_list": {
    "type": "LIST",
    "fields": {
      "list": {
        "repeated": true,
        "fields": {
          "element": {
            "type": "STRING"
          }
        }
      }
    }
  }
}
```

Copy

Map Example

In this example, the whole schema is named `the_map`, and its structure consists of a container named `key_value` whose zero or more pairs of elements each contain a `key` and a `value` element. Both the `key` and the `value` are strings in this case, but they could be other data types.

Parquet Schema Example 2

```
message schema {
  REQUIRED group the_map (MAP) {
    REPEATED group key_value {
      REQUIRED BYTE_ARRAY key (STRING);
      REQUIRED BYTE_ARRAY value (STRING);
    }
  }
}
```

Copy

Parquet Schema Example 2 Expressed as JSON

```
{
  "the_map": {
    "type": "MAP",
    "fields": {
      "key_value": {
        "repeated": true,
        "fields": {
          "key": {
            "type": "STRING"
          },
          "value": {
            "type": "STRING"
          }
        }
      }
    }
  }
}
```

Copy

Array of Arrays Example

In this example, the whole schema is named `array_of_arrays`, and its structure consists of a container named `list` whose zero or more elements - which are themselves lists - are each named `element`. Within each of those `element` lists are one or more additional `list/element` structures.

Parquet Schema Example 3

```
message schema {
  REQUIRED group array_of_arrays (LIST) {
    REPEATED group list {
      REQUIRED group element (LIST) {
        REPEATED group list {
          REQUIRED INT64 element;
        }
      }
    }
  }
}
```

Copy

Expressed as JSON, the same schema is cumbersome to read compared to Parquet, which was designed to express nested structures concisely.

Parquet Schema Example 3 Expressed as JSON

```
{
  "array_of_arrays": {
    "type": "LIST",
    "fields": {
      "list": {
        "repeated": true,
        "fields": {
          "element": {
            "type": "LIST",
```

10.1.5. AppScope Configs

AppScope is deprecated and will be removed in a future release. Don't use AppScope in production and ensure it is not part of your data flow configuration. For details, please read the announcement in Cribl Community Slack.

10.2. Cribl Expressions

Native Cribl Stream methods can be found under `C.*`, and can be invoked from any Function that allows for expression evaluations. For example, to create a field that is the SHA1 of a another field's value, you can use the Eval Function with this **Evaluate Fields** pair:

Name	Value Expression
myNewField	`C.Mask.sha1(myOtherField)`

> Where fields' names contain special characters, you can reference them using the `__e['<field-name-here>']` convention. For details, see Build Custom Logic to Route and Process Your Data: Fields with Non-Alphanumeric Characters.

Cribl expressions offer methods and properties in the following classes:

- C.Crypto - data encryption and decryption
- C.Encode and C.Decode - encoding and decoding data
- C.Lookup - running lookups
- C.Mask - masking sensitive data
- C.Net - network methods
- C.Text - text manipulation
- C.Time - time and date manipulation
- C.Schema - schema validation
- C.Secret - secret management
- C.env - environment properties
- C.os - system methods
- C.vars - global variables
- C.version - Cribl Stream versions
- C.Misc - various other methods

10.2.1. C.Crypto - Data Encryption And Decryption

C.Crypto.decrypt()

```
C.Crypto.decrypt(value: string, escape: boolean = false, escapeSeq = '"'): string
```

Copy

Decrypts all occurrences of ciphers in the given value. Instances that cannot be decrypted (for any reason) are left intact.

Returns `value` with ciphers decrypted.

Parameter	Type	Description
`value`	string	String in which to look for ciphers.
`escape`	boolean	Set to `true` to escape double quotes in output after decryption (for example, for data encrypted in Splunk.) Defaults to `false`.
`escapeSeq`	string	String used to escape double quotes. The default `'"'` escapes CSV output.

Examples

To decrypt the contents of the `encrypted` field, use:

```
C.Crypto.decrypt(encrypted)
```

Copy

C.Crypto.encrypt()

```
C.Crypto.encrypt(value: Buffer | string, keyclass: number, keyId?: string, defaultVal
```

Copy

Encrypts the given value with the `keyId`, or with a `keyId` picked up automatically based on `keyclass`.

Returns the encrypted value. If encryption does not succeed, returns `defaultVal` if specified; otherwise, `value`.

Parameter	Type	Description
`value`	string | Buffer	The value to encrypt.
`keyclass`	number	Key Class to pick a key from, if `keyId` isn't specified.
`keyId`	string	Encryption `keyId`, takes precedence over `keyclass`.
`defaultVal`	string	Value to return if encryption fails; if unspecified, the original value is returned.

You can decrypt the encrypted data in Cribl Search, using the `encrypt` and `decrypt` functions in your queries.

Examples

To encrypt the `customer` field using key with `keyId` 2, use:

```
C.Crypto.encrypt(customer, -1, 2)
```

Copy

To encrypt the same field with a key selected from the Key Class 3, without specifying a `keyId`:

```
C.Crypto.encrypt(customer, 3)
```

Copy

C.Crypto.createHmac()

```
C.Crypto.createHmac(value: string | Buffer, secret: string, algorithm: string = 'sha2
```

Copy

Generates an HMAC that can be added to events, or can be used to validate events that contain an HMAC.

Returns the calculated HMAC digest on success; otherwise, `value`.

Parameter	Type	Description
`value`	string | Buffer	The data to encrypt. When the `outputFormat` is invalid or undefined, this parameter is returned as the digest, via a Buffer.
`secret`	string	The secret key used to generate the MAC.
`algorithm`	string	The hash algorithm used to generate the MAC. Defaults to `'sha256'`. Run `openssl list -digest-algorithms` to see the list of available algorithms.
`outputFormat`	`'base64'` | `'hex'` | `'latin1'`	Output format for the MAC. Defaults to `'hex'`.

Examples

To generate HMAC from the `customer` field, provide the secret as the second argument:

```
C.Crypto.createHmac(customer, 'kETvYtLKZkgIzBvfRdVcZULBITANjOMd')
```

Copy

To additionally specify that you want to use the SHA512 hash algorithm and to output the HMAC in `latin1` format, run:

```
C.Crypto.createHmac(customer, 'kETvYtLKZkgIzBvfRdVcZULBITANjOMd', 'sha512', 'latin1')
```

Copy

10.2.2. C.Decode And C.Encode - Encoding And Decoding

C.Decode - Data Decoding Methods

C.Decode.base64()

```
C.Decode.base64(val: string, resultEnc: string = 'utf8'): string | Buffer | undefinec
```

Copy

Performs Base64 decoding of the given string.

Returns a string or Buffer, depending on the `resultEnc` value.

Parameter	Type	Description
`val`	string	Value to decode.
`resultEnc`	`'utf8' | 'utf8-valid' | 'buffer'`	Encoding to use to convert the binary data to a string. Use `'utf8-valid'` to validate that result is valid UTF8; use `'buffer'` if you need the binary data in a Buffer. Defaults to `'utf8'`.

Examples

To decode an `encoded` field and return the decoded value as a Buffer, use:

```
C.Decode.base64(encoded, 'buffer')
```

Copy

C.Decode.gzip()

```
C.Decode.gzip(value: Buffer | string, encoding?: BufferEncoding) : string
```

Copy

Gunzips the supplied value.

Parameter	Type	Description
`value`	any	Value to gunzip.
`encoding`	string	Encoding of `value`, for example: `'base64'`, `'hex'`, `'utf-8'`, `'binary'`. Default is `'base64'`. If data is received as Buffer (from gzip with encoding: `'none'`), decoding is skipped.

Example

To decode a `hostname` field which had been encoded using `hex`, run:

```
C.Decode.gzip(hostname, 'hex')
```

Copy

C.Decode.hex()

```
C.Decode.hex(val: string): number
```

Copy

Performs hex to number conversion. Returns `NaN` if value cannot be converted to a number.

Parameter	Type	Description
`val`	string	Hex string to parse to a number (for example, `0xcafe`).

C.Decode.inflate()

```
C.Decode.inflate(value: Buffer | string, encoding: BufferEncoding = 'base64', isRaw =
```

Copy

Inflates the supplied value.

Parameter	Type	Description
`value`	string | Buffer	The value to inflate. May be a Buffer or a string.
`encoding`	string	If a string `value` is provided, this specifies how it has been encoded. If no `encoding` is provided, `base64` is used. This parameter is ignored if `value` is already a Buffer.
`isRaw`	boolean	Indicates whether the data is in raw deflate format (without zlib headers). Default value is `false`.

Examples

To Base64-decode and inflate the value contained in a `_raw` field, you can use:

```
C.Decode.inflate(_raw)
```

Copy

To additionally specify a different encoding to use, run:

```
C.Decode.inflate(_raw, 'hex')
```

Copy

`C.Decode.mime()`

```
C.Decode.mime(val: string): string
```

Copy

Decode string that has been encoded with MIME RFC 2047 standard. This standard is frequently used in email subject lines within logs to handle non-ASCII characters.

Parameter	Type	Description
`val`	string	The input string to decode. This string must be formatted according to RFC 2047, typically starting and ending with `=?<charset>?<encodingType>?...?=`.

Examples

To decode a MIME-encoded string using the Quoted-Printable format, typically seen when the non-ASCII content is mostly readable text, use:

```
C.Decode.mime('=?UTF-8?Q?R=C3=A9sum=C3=A9?=') // Returns: 'Résumé'
```

Copy

To decode a MIME-encoded string using the Base64 format, often used when the non-ASCII content is complex or binary data, use:

```
C.Decode.mime('=?UTF-8?B?Q2Fmw6k=?=') // Returns: 'Café'.

### `C.Decode.uri()`

```js
C.Decode.uri(val: string): string
```

Copy

Performs URI-decoding of the given string.

Parameter	Type	Description
`val`	string	Value to decode.

C.Encode - Data Encoding Methods

`C.Encode.base64()`

```
C.Encode.base64(val: string | Buffer, trimTrailEq: boolean = false, encoding?: Buffer
```

Copy

Returns a Base64 representation of the given string or Buffer.
```

Parameter	Type	Description
`val`	any	Value to encode.
`trimTrailEq`	boolean	Whether to trim any trailing `=`.
`encoding`	string	Optional parameter that specifies the encoding of the value. Options include `base64`, `hex`, `utf-8`, and `binary`. The default is `utf-8`.

Examples

To Base64-encode the `username` field, and remove the trailing `=`, use:

```
C.Encode.base64(username, true)
```

Copy

To Base64-encode the `hexValue` field, where the value of the field is a hex string:

```
C.Encode.base64('4672616e6b7575757575', undefined, 'hex')
```

Copy

`C.Encode.deflate()`

```
C.Encode.deflate(value: Buffer | string, encoding: BufferEncoding | 'none' = 'base64'
```

Copy

Deflates and optionally Base64-encodes the supplied value.

Parameter	Type	Description
`value`	string or Buffer	Value to deflate.
`encoding`	string	Encoding to apply to the deflated result, for example: `base64`, `hex`, `utf-8`, `binary`, `none`. Default is `base64`. If `none` is specified, data will be returned as a Buffer.
`toRaw`	boolean	Indicates whether to return the raw deflated data, without zlib headers. Default is `false`, which will prepend normal zlib header bytes to the returned

Parameter	Type	Description
		value.

Examples

To deflate and hex-decode the value provided in an `inflated` field, run:

```
C.Encode.deflate(inflated, 'hex')
```

Copy

C.Encode.gzip()

```
C.Encode.gzip(value: Buffer | string, encoding?: string) : string | Buffer
```

Copy

Gzips, and optionally Base64-encodes, the supplied value.

Parameter	Type	Description
`value`	string	Value to gzip.
`encoding`	string	Encoding of `value`, for example: `'base64'`, `'hex'`, `'utf-8'`, `'binary'`, `'none'`. Default is `'base64'`. If `'none'` is specified, data will be returned as a Buffer.

Examples

To encode the `hostname` field, for example using `hex` encoding, run:

```
C.Encode.gzip(hostname, 'hex')
```

Copy

C.Encode.hex()

```
C.Encode.hex(val: string | number): string
```

Copy

Rounds the number to an integer and returns its hex representation (lowercase). If a string is provided, it will be parsed into a number or `NaN`.

Parameter	Type	Description
`val`	string | number	Value to convert to hex.

`C.Encode.mime()`

```
C.Encode.mime(val: string, encoding: string = 'Q', maxLineLength: number = 0, charset
```

Copy

Encode a string with MIME RFC 2047 standard. This method is used to prepare header values that contain non-ASCII characters for transport, such as email subject lines.

Parameter	Type	Description
`val`	string	The raw string to be encoded, including any non-ASCII characters.
`encoding`	MIME Encoding	Defines the encoding type. Use `Q` for Quoted-Printable, which is the default and can be omitted. Use `B` for Base64.
`maxLineLength`	number	Used for folding long lines, which is required by the RFC for headers. If greater than zero, inserts a newline delimiter after this defined number characters to ensure line wrapping. If `0`, no folding is performed.
`charset`	string	The character set of the input string, if it is not UTF-8.

Examples

To encode a MIME-encoded string using the Quoted-Printable format, use:

```
C.Encode.mime(_raw)
```

Copy

To encode a MIME-encoded string using the Base64 format, use:

```
C.Encode.mime(_raw, `B`)
```

Copy

To encode a string using Quoted-Printable and apply line folding to ensure no encoded line exceeds 20 characters:

```
C.Encode.mime('A much longer subject line with a non-ascii character: Español', 'Q',
// Returns `=?UTF-8?Q?A_much_longer_subject_line_with_a_non-ascii_characte?= \n =?UTF
```

Copy

C.Encode.uri()

```
C.Encode.uri(val: string): string
```

Copy

Returns the URI-encoded representation of the given string.

Parameter	Type	Description
val	string	Value to encode.

10.2.3. C.Lookup - Inline Lookup Methods

C.Lookup - Exact Lookup

```
C.Lookup: (file: string, primaryKey?: string, otherFields: string[]=[],ignoreCase: bo
```

Copy

Returns an instance of a lookup to use inline.

Examples

In this example, `host` is the name of the primary key field:

```
C.Lookup('lookup_name.csv', 'IP_field_name_in_lookup_file').match(host)
```

Copy

Here, the quoted `'event_field_or_string_to_match'` could be a string to match in the primary key field:

```
C.Lookup('name_of_lookup_file.csv', 'field_in_csv_to_match').match('event_field_or_st
```

Copy

This example checks whether `someValue` is present or not and returns the answer as a boolean.

```
C.Lookup('file', 'primaryKeyCol', additionalCols).match('someValue')
```

Copy

This expression returns a string - the `fieldToReturn` column from the matched lookup row:

```
C.Lookup('file', 'primaryKeyCol', additionalCols).match('someValue','fieldToReturn')
```

Copy

This expression returns an array - the specified `fieldToReturn1` and `fieldToReturn2` columns from the matched lookup row:

```
C.Lookup('file', 'primaryKeyCol').match('someValue', ['fieldToReturn1', 'fieldToRetu
```

Copy

To return an array with all columns from the matched lookup row, you can use:

```
C.Lookup('file', 'primaryKeyCol').match('someValue', [])
```

Copy

> `C.Lookup` can load lookup files of up to 10 MB.
>
> All inputs to Lookup methods' `match()` method must be strings. If your lookup file contains numeric fields, convert them to strings, e.g.: `.match(String(<fieldname>))`.
>
> You can use the optional `otherFields[]` argument, shown in the above `C.Lookup()` signatures and examples, to limit which columns of the lookup table will be available in a subsequent `.match()` call. If omitted, or set to `undefined`, all columns will be available.
>
> Cribl Stream 4.1 and newer support returning all columns from a matched row. Use the empty-array convention shown in the above examples: `.match('someValue',[])`.

`C.LookupCIDR` - CIDR Lookup

```
C.LookupCIDR: (file: string, primaryKey?: string, otherFields: string[]=[]) => Inline
```

Copy

Returns an instance of a CIDR lookup to use inline.

`C.LookupIgnoreCase` - Case-insensitive Lookup

```
C.LookupIgnoreCase: (file: string, primaryKey?: string, otherFields: string[]=[]) =>
```

Copy

Returns an instance of a lookup (ignoring case) to use inline. Works identically to `C.Lookup`, except ignores the case of lookup values. (Equivalent to calling `C.Lookup` with its fourth `ignoreCase?` parameter set to `true`).

C.LookupRegex - Regex Lookup

```
C.LookupRegex: (file: string, primaryKey?: string, otherFields: string[]=[]) => Inlir
```

Copy

Returns an instance of a Regex lookup to use inline.

C.Lookup.match()

```
InlineLookup.match(value: string): boolean

InlineLookup.match(value: string, fieldToReturn?: string): any
InlineLookup.match(value: string, fieldToReturn: string[]): {[key: string]: any}
```

Copy

Parameter	Type	Description
`value`	string	the value to look up.
`fieldToReturn`	string | string []	name of the lookup file > field to return.

Examples

To find the last row where the value from column `foo` matches the string `abc`, you can use the following expression. If a matching row is found, the expression returns the row's value for column `bar`.

```
C.Lookup('lookup-exact.csv', 'foo').match('abc', 'bar')
```

Copy

To find the last row where the value from column `transport` matches the string `tcp`, you can use the following expression. If a matching row is found, the expression returns the row's value for column `port_number`.

```
C.Lookup('service_names_port_numbers.csv', 'transport').match('tcp', 'port_number')
```

Copy

You can find the last row where the CIDR range in `cidr` includes `192.168.1.1` with the following expression. If a matching row is found, the expression returns the row's value for column `bar`.

```
C.LookupCIDR('lookup-cidr.csv', 'cidr').match('192.168.1.1', 'bar')
```

Copy

The following expression finds the last row where the value from column `cidr` matches `hostIP`. If a matching row is found, it returns the row's value for column `location`.

```
C.LookupCIDR('lookup-cidr.csv', 'cidr').match(hostIP, 'location')
```

Copy

To find the last row where the regex in column `foo` matches the string `manchester`, use the following expression. If a matching row is found, the expression returns the row's value for column `bar`.

```
C.LookupRegex('lookup-regex.csv', 'foo').match('manchester', 'bar')
```

Copy

With `C.LookupRegex`, ensure that your lookup file contains no empty lines - not even at the bottom. Any empty rows will cause `C.LookupRegex().match()` to always return `true`.

10.2.4. C.Mask - Data Masking Methods

The `C.Mask` expression provides a suite of methods for data masking, which is the process of obscuring sensitive information in your data. This ensures data privacy and maintains compliance with regulations like GDPR and HIPAA. It can protect personally identifiable information (PII) before sending it to a downstream Destination.

Use the methods in this expression to:

- **Redact sensitive information:** Replace data with a literal value like `REDACTED`. For example, replacing a credit card number like `1234-5678-9101-1121` to `REDACTED`.
- **Obfuscate data:** Replace values with a random or repeating character set. For example, obfuscating a username like `jdoe@example.com` by replacing it with a string of repeating characters, such as `XXXXXXXXXXXXXXX`.
- **Pseudonymize data:** Transform values into a non-identifiable, consistent value using a cryptographic hash. This technique allows you to perform analytics on the masked data without risking a privacy breach. For example, psudonymize a user ID like `user:1234567` into a consistent hash, such as `4b4f5d21c9a63c`. This makes it possible to analyze the data without revealing the original value.

By using `C.Mask` expressions, you can ensure that you handle sensitive data securely and that your Pipelines meet the necessary privacy and compliance standards.

For easier navigation, this page organizes the `C.Mask` methods by their purpose:

- Identity Validation and Masking: Methods for masking common identifiers like credit card and IMEI numbers, which also perform a basic validation check.
- Checksums and Validation: Methods that generate checksums and perform validation, which are the building blocks for more complex validation rules.
- Hashing: A collection of cryptographic hashing functions for pseudonymizing data while preserving its uniqueness for analytics.
- String Manipulation: General-purpose functions for creating random or repeating strings.

Identity Validation and Masking

`C.Mask.CC()`

Checks whether a value could be a valid credit card number. If the value matches the respective format, it masks a subset of the value. By default, all digits except the last 4 will be replaced with `X`.

Usage:

```
C.Mask.CC(value: string, unmasked: number = -4, maskChar: string='X'): string
```

Copy

Parameters:

Parameter	Type	Description
`value`	string	The string to mask, **if and only if** it could be a valid credit card number.
`unmasked`	number	Number of digits to leave unmasked: positive for left, negative for right, `0` for none.
`maskChar`	string	String to replace each digit with.

Examples:

Assuming your parsed data contains a `creditCard` field, you can mask this number by using a Mask Function. Apply it to the `cardNumber` field and create the following masking rule:

Match Regex	Replace Expression	Example result
`(.*)` (catches the whole field contents)	`${C.Mask.CC(g1)}`	`cardNumber: XXXXXXXXXX4860`

To control how the masking is performed, you can specify how many digit should be unmasked and what masking character to use:

Match Regex	Replace Expression	Example result
`(.*)` (catches the whole field contents)	`${C.Mask.CC(g1, 4, "Z")}`	`cardNumber: 6011ZZZZZZZZZZZZ`

C.Mask.IMEI()

Checks whether a value could be a valid IMEI number. If the value matches the respective format, it masks a subset of the value. By default, all digits except the last 4 will be replaced with `X`.

Usage:

```
C.Mask.IMEI(value: string, unmasked: number = -4, maskChar: string='X'): string
```

Copy

Parameters:

Parameter	Type	Description
`value`	string	The string to mask, **if and only if** it could be a valid IMEI number.
`unmasked`	number	Number of digits to leave unmasked: positive for left, negative for right, `0` for none.
`maskChar`	string	String to replace each digit with.

Examples:

Assuming your parsed data contains an `imei` field, you can mask this number by using a Mask Function. Apply it to the `imei` field and create the following masking rule:

Match Regex	Replace Expression	Example result
`(.*)` (catches the whole field contents)	`${C.Mask.IMEI(g1)}`	`imei: XXXXXXXXXXX7011`

To control how the masking is performed, you can specify how many digit should be unmasked and what masking character to use:

Match Regex	Replace Expression	Example result
`(.*)` (catches the whole field contents)	`${C.Mask.IMEI(g1, 4, "M")}`	`cardNumber: 5356MMMMMMMMMM`

`C.Mask.isCC()`

Checks whether the given value could be a valid credit card number, by computing the string's Luhn's checksum modulo 10 == `0`.

Usage:

```
C.Mask.isCC(value: string): boolean
```

Copy

Parameters:

Parameter	Type	Description
`value`	string	String to check for being a valid credit card number.

Examples:

The following example expression uses `isCC()` to check whether the `cardNumber` field actually contains a credit card number. If it does, the card number is replaced with the `REDACTED` string, otherwise, en empty string is returned.

```
C.Mask.isCC(cardNumber) ? C.Mask.REDACTED : ""
```

Copy

`C.Mask.isIMEI()`

Checks whether the given value could be a valid IMEI number, by computing the string's Luhn's checksum modulo 10 == `0`.

Usage:

```
C.Mask.isIMEI(value: string): boolean
```

Copy

Parameters:

Parameter	Type	Description
`value`	string	String to check for being a valid IMEI number.

Examples:

The following example expression uses `isIMEI()` to check whether the `imei` field actually contains an IMEI number number. If it does, the IMEI number is replaced with the `REDACTED` string, otherwise, en empty string is returned.

```
C.Mask.isIMEI(imei) ? C.Mask.REDACTED : ""
```

Copy

C.Mask.REDACTED

`C.Mask.REDACTED` is a literal string (not a function) that evaluates to `REDACTED`. It's used to completely remove sensitive data by replacing it with a clear, non-identifiable placeholder.

Usage:

```
C.Mask.REDACTED: string
```

Copy

Examples:

This example demonstrates using `C.Mask.REDACTED` within a conditional expression. It checks if the `cardNumber` field is a valid credit card number. If it is, the value is replaced with `REDACTED`. Otherwise, it keeps the original value.

```
C.Mask.isCC(cardNumber) ? C.Mask.REDACTED : cardNumber
```

Copy

Checksums and Validation

C.Mask.luhn()

Masks a value only if its checksum is valid. This is useful for sanitizing data and ensuring that only correctly formatted numbers are sent downstream.

It checks that value's Luhn checksum mod 10 is `0`, and masks a subset of the value. By default, all digits except the last 4 will be replaced with `X`. If the value's Luhn's checksum mod 10 is not `0`, then the value is returned unmodified.

Usage:

```
C.Mask.luhn(value: string, unmasked: number = -4, maskChar: string='X'): string
```

Copy

Parameters:

Parameter	Type	Description
`value`	string	The string to mask, **if and only if** the value's Luhn checksum mod 10 is `0`.
`unmasked`	number	Number of digits to leave unmasked: positive for left, negative for right, `0` for none.
`maskChar`	string	String to replace each digit with.

Examples:

Expression	Input Value	Output
`C.Mask.luhn(value)`	`49927398716` (a valid Luhn number)	`XXXXXXX8716`
`C.Mask.luhn(value)`	`49927398717` (an invalid Luhn number)	`49927398717`
`C.Mask.luhn(value, 4, "Y")`	`49927398716` (a valid Luhn number)	`4992YYYYYYY`

`C.Mask.luhnChecksum()`

Generates a checksum that can be used to validate a number. This is useful for building your own custom validation rules or for debugging.

Generates the Luhn checksum (used to validate certain credit card numbers, IMEIs, and more). By default, the mod 10 of the checksum is returned. Pass mod = `0` to get the actual checksum.

Usage:

```
C.Mask.luhnChecksum(value: string, mod: number=10): number
```

Copy

Parameters:

Parameter	Type	Description
`value`	string	String whose digits you want to perform the Luhn checksum on.
`mod`	number	Return checksum modulo for this number. If `0`, skip modulo. Default is `10`.

Examples:

This example demonstrates how to get the default `mod 10` checksum. This expression returns the last digit of the checksum, which is commonly used to validate a number. A valid Luhn number will return `0`.

```
// This will return the number 0
C.Mask.luhnChecksum("49927398716")
```

Copy

This example demonstrates how to get the full checksum. You can get the full checksum by setting `mod` to `0`.

```
// This will return the number 70, which is the full checksum
C.Mask.luhnChecksum("49927398716", 0)
```

Copy

Hashing

`C.Mask.crc32()`

Generates a CRC32 hash of given value.

Usage:

```
C.Mask.crc32(value: string): string
```

Copy

Parameter:

Parameter	Type	Description
`value`	string	The string to hash.

Examples:

Expression	Input Value	Output
`C.Mask.crc32(value)`	`example_log_123`	`cf0e3d3a`
`C.Mask.crc32(host + file_path)`	`webserver01/var/log/app.log`	`b9b661b6`

C.Mask.md5()

Generates an MD5 hash of a given value.

`C.Mask.md5()` doesn't work when Cribl Stream is running in FIPS mode.

Usage:

```
C.Mask.md5(value: string, len?: string | number, encoding?: BufferEncoding): string
```

Copy

Parameters:

Parameter	Type	Description
`value`	string	The string to hash.
`len`	string or number	Length of hash to return: `0` for full hash, a +number for left or a -number for right substring. If a string is passed, its length will be used.
`encoding`	string	Optional parameter that specifies the encoding of the value. Options include `base64`, `hex`, `utf-8`, and `binary`. The default is `utf-8`.

Examples:

To hash the contents of a `username` field with the MD5 algorithm, run:

```
C.Mask.md5(username)
```

Copy

To hash the contents of an `authToken` field, where the value of the field is a base64-encoded string, with the MD5 algorithm, run:

```
C.Mask.md5(authToken, undefined, 'base64')
```

Copy

C.Mask.sha1(), C.Mask.sha256(), C.Mask.sha512(), C.Mask.sha3_256(), C.Mask.sha3_512()

Generates a hash of a given value. Supported algorithms:

- SHA1
- SHA256
- SHA512
- SHA3-256
- SHA3-512

Usage:

```
C.Mask.sha1(value: string, len?: string | number, encoding?: BufferEncoding): string
C.Mask.sha256(value: string, len?: string | number, encoding?: BufferEncoding): strir
C.Mask.sha512(value: string, len?: string | number, encoding?: BufferEncoding): strir
C.Mask.sha3_256(value: string, len?: string | number, encoding?: BufferEncoding): str
C.Mask.sha3_512(value: string, len?: string | number, encoding?: BufferEncoding): str
```

Copy

Parameters:

Parameter	Type	Description
`value`	string	The string to hash.
`len`	string or number	Length of hash to return: `0` for full hash, a +number for left, or a -number for right substring. If a string is passed, its length will be used.
`encoding`	string	Optional parameter that specifies the encoding of the value. Options include `base64`, `hex`, `utf-8`, and `binary`. The default is `utf-8`.

Examples:

To hash the contents of a `secret` field with the SHA256 algorithm, run:

```
C.Mask.sha256(secret)
```

Copy

To hash the contents of an `authToken` field, where the value of the field is a base64-encoded string, with the SHA256 algorithm, run:

```
C.Mask.sha256(authToken, undefined, 'base64')
```

Copy

String Manipulation

`C.Mask.random`

Generates a random alphanumeric string.

Usage:

```
C.Mask.random(len?: string | number): string
```

Copy

Parameters:

Parameter	Type	Description
`len`	string or number	Length of the result; or, if a string, use its length.

Examples:

Assuming you have some identifying user information in a `username` field, you can replace it with a random string of the same length with:

```
C.Mask.random(username)
```

Copy

Input	Output
`McGoatFace`	`xY2KLHkyTg`

`C.Mask.repeat()`

Generates a repeating character or string pattern, such as `XXXX`.

Usage:

```
C.Mask.repeat(len?: number | string, char: string = 'X'): string
```

Copy

Parameters:

Parameter	Type	Description
`len`	string or number	Length of the result; or, if a string, use its length.
`char`	string	Pattern to repeat `len` times.

Examples:

The following example will repeat the `GOAT` string as many time as there are characters in the first parameter, `goat`, so four times:

```
C.Mask.repeat("goat", "GOAT")
```

10.2.5. C.Net - Network Methods

C.Net.cidrMatch()

```
C.Net.cidrMatch(cidrIpRange: string, ipAddress: string): boolean
```

Copy

Determines whether the supplied IPv4 or IPv6 `ipAddress` is inside the range of addresses identified by `cidrIpRange`.

Parameter	Type	Description
`cidrIpRange`	string	IP address range in CIDR format. E.g., `10.0.0.0/24`.
`ipAddress`	string	The IP address to test for inclusion in `cidrIpRange`.

Examples

(IPv4): `C.Net.cidrMatch('10.0.0.0/24', '10.0.0.100')` returns `true`.

(IPv6): `C.Net.cidrMatch('2001:db8::/32', '2001:db8:0:0:0:ffff:0:0')` returns `true`.

C.Net.communityIDv1()

```
C.Net.communityIDv1(sourceIP: string, destIP: string, sourcePort: number | undefined,
```

Copy

Calculates the Community ID for a given network flow. A Community ID is a unique identifier that is reversible - it is the same for both sides of a connection. It is calculated based on source and destination IP addresses, ports, a protocol, and (optionally) a seed (explained below). When the protocol is ICMP, the Community ID will be reversible provided that the network flow uses types with a clear request/response relationship (for example, Echo and Echo Reply).

Usage

This method returns a Base64-encoded string.

Provide IP addresses - whether IPv4 or IPv6 - as strings.

When the protocol is ICMP (v4 or v6), `sourcePort` corresponds to message type and `destPort` corresponds to message code. For other Layer 3 protocols, `sourcePort` and `destPort` should be `undefined`.

You can specify `proto` either as a number (recommended, to avoid ambiguity) or a string.

- If a string, `proto` must be the desired protocol's keyword as specified in the IANA protocol registry.
- For network flows coming from the Cribl Stream NetFlow & IPFIX Source, use the protocol name as-is - the Source will provide it in correct form.

The optional `seed` parameter defaults to `0`. If you want to generate different Community IDs for different use cases within the same flow, change `seed` to a different value for each use case.

Parameter	Type	Description
sourceIP	string	Source IPv4 or IPv6 address
destIP	string	Destination IPv4 or IPv6 address
sourcePort	number or undefined	Source port. For ICMP, use the ICMP type. For other portless protocols, use `undefined`.
destPort	number or undefined	Destination port. For ICMP, use the ICMP code. For other portless protocols, use `undefined`.
proto	number or string	IP protocol number, such as `6`, `17`, or `1`. May also be the protocol name, such as `'tcp'`, `'udp'`, or `'icmp'`.
seed	number	Optional seed value; defaults to `0`

Examples

Bidirectional TCP flow using the protocol number.

```
// Protocol number 6 is TCP

C.Net.communityIDv1('1.2.3.4','5.6.7.8',1122,3344,6)
// '1:wCb3OG7yAFWelaUydu0D+125CLM='

C.Net.communityIDv1('5.6.7.8','1.2.3.4',3344,1122,6)
// '1:wCb3OG7yAFWelaUydu0D+125CLM='
```

Copy

Bidirectional UDP flow using the protocol name.

```
C.Net.communityIDv1('1.2.3.4','5.6.7.8',1122,3344,'udp')
// '1:0Mu9InQx6z4ZiCZM/7HXi2WMhOg='

C.Net.communityIDv1('5.6.7.8','1.2.3.4',3344,1122,'udp')
// '1:0Mu9InQx6z4ZiCZM/7HXi2WMhOg='
```

Copy

ICMP Echo/Echo Reply flow.

```
// Protocol number 1 is ICMP
// Echo is Type=8, Code=0
// Echo Reply is Type=0, Code=0

// Echo (equivalent of request)
C.Net.communityIDv1('1.2.3.4','5.6.7.8',8,0,1)
// '1:crodRHL2FEsHjbv3UkRrfbs4bZ0='

// Echo Reply (equivalent of response)
C.Net.communityIDv1('5.6.7.8','1.2.3.4',0,0,1)
// '1:crodRHL2FEsHjbv3UkRrfbs4bZ0='
```

Copy

C.Net.isIp()

```
C.Net.isIp(value: string): boolean
```

Copy

Determines whether the value supplied is an IP address (either IPv4 or IPv6).

Parameter	Type	Description
value	string	The IP address to test.

C.Net.isIpV4()

```
C.Net.isIpV4(value: string): boolean
```

Copy

Determines whether the value supplied is an IPv4 address.

Parameter	Type	Description
value	string	The IP address to test.

C.Net.isIpV6()

```
C.Net.isIpV6(value: string): boolean
```

Copy

Determines whether the value supplied is an IPv6 address.

Parameter	Type	Description
value	string	The IP address to test.

C.Net.isIPV4Cidr()

```
C.Net.isIPV4Cidr(value: string): boolean
```

Copy

Determines whether a value supplied is an IPv4 CIDR range.

Returns `true` if the value is a valid IPv4 CIDR range; otherwise, `false`.

Parameter	Type	Description
`value`	string	String value that may be an IPv4 CIDR range.

C.Net.isIPV6Cidr()

```
C.Net.isIPV6Cidr(value: string): boolean
```

Copy

Determine whether a value supplied is an IPv6 CIDR range.

Returns `true` if the value is a valid IPv6 CIDR range; otherwise, `false`.

Parameter	Type	Description
`value`	string	String value that may be an IPv6 CIDR range.

C.Net.isIpV4AllInterfaces()

```
C.Net.isIpV4AllInterfaces(value): boolean
```

Copy

Determines whether the value supplied is the IPv4 all-interfaces address, typically used to bind to all IPv4 interfaces - i.e., '0.0.0.0'.

Parameter	Type	Description
`value`	any	The IP address to test.

C.Net.isIpV6AllInterfaces()

```
C.Net.isIpV6AllInterfaces(value): boolean
```

Copy

Determines whether the value supplied is an IPv6 all-interfaces address, typically used to bind to all IPv6 interfaces - one of: '::', '0:0:0:0:0:0:0:0', or '0000:0000:0000:0000:0000:0000:0000:0000'.

Parameter	Type	Description
`value`	any	the IP address to test.

C.Net.ipv6Normalize()

```
C.Net.ipv6Normalize(address: string): string
```

Copy

Normalizes an IPV6 address based on RFC draft-ietf-6man-text-addr-representation-04.

Parameter	Type	Description
`address`	string	The IPV6 address to normalize.

C.Net.isPrivate()

```
C.Net.isPrivate(address: string): boolean
```

Copy

Determines whether the supplied IPv4 address is in the range of private addresses per RFC1918.

Parameter	Type	Description
`address`	string	The IP address to test.

C.Net.parseAddressOrRangeString()

```
C.Net.parseAddressOrRangeString(source: string, mask?: string | number)
```

Copy

Parses a string representation of an IP or IP range.

Returns an `IPv4` or `IPv6` object. When the `source` argument is an IP range, this method returns the first IP in the range.

Parameter	Type	Description
`source`	string	The string to parse.
`mask`	string | number	Optional parameter containing the CIDR mask. Used only when `source` is a valid IP string.

C.Net.IPv4_CIDR_REGEX

10.2.6. C.Text - Text Methods

C.Text.entropy()

```
C.Text.entropy(bytes: Buffer | string): number
```

Copy

Computes the Shannon entropy of the given Buffer or string.

Returns the entropy value; or `-1` in case of an error.

Parameter	Type	Description
`bytes`	Buffer | string	value to undergo Shannon entropy computation.

C.Text.hashCode()

```
C.Text.hashCode(val: string | Buffer | number): number
```

Copy

Computes hashcode (djb2) of the given value.

Returns hashcode value.

Parameter	Type	Description
`val`	string | Buffer | number	value to be hashed.

C.Text.isASCII()

```
C.Text.isASCII(bytes: Buffer | string): boolean
```

Copy

Checks whether all bytes or chars are in the ASCII printable range.

Returns `true` if all chars/bytes are within ASCII printable range; otherwise, `false`.

Parameter	Type	Description
`bytes`	string | Buffer	value to check for character range.

`C.Text.isUTF8()`

```
C.Text.isUTF8(bytes: Buffer | string): boolean
```

Copy

Checks whether the given Buffer contains valid UTF8.

Returns `true` if bytes are UTF8; otherwise, `false`.

Parameter	Type	Description
`bytes`	Buffer | string	bytes to check.

`C.Text.parseWinEvent()`

```
C.Text.parseWinEvent(xml: string, nonValues: string[] = C.Text._WIN_EVENT_NON_VALUES)
```

Copy

Parses an XML string representing a Windows event into a compact, prettified JSON object. Works like `C.Text.parseXml`, but with Windows events, produces more-compact output. For a usage example, see Reducing Windows XML Events.

Returns an object representing the parsed Windows Event; or `undefined` if the input could not be parsed.

Parameter	Type	Description
`xml`	string	an XML string; or an event field containing the XML.

Parameter	Type	Description
`nonValues`	string[]	array of string values. Elements whose value equals any of the values in this array will be omitted from the returned object. Defaults to `['-']`, meaning that elements whose value equals `-` will be discarded.

C.Text.parseXml()

```
C.Text.parseXml(xml: string, keepAttr: boolean = true, keepMetadata: boolean = false,
```

Copy

Parses an XML string and returns a JSON object. Can be used with Eval Function to parse XML fields contained in an event, or with ad hoc XML.

Returns an object representing the parsed XML; or `undefined` if the input could not be parsed. An input collection of elements will be parsed into an array of objects.

Parameter	Type	Description
`xml`	string	XML string, or an event field containing the XML.
`keepAttr`	boolean	whether or not to include attributes in the returned object. Defaults to `true`.
`keepMetadata`	boolean	whether or not to include metadata found in the XML. The `keepAttr` parameter must be set to `true` for this to work. Defaults to `false`. (Eligible metadata includes namespace definitions and prefixes, and XML declaration attributes such as encoding, version, etc.)
`nonValues`	string[]	array of string values. Elements whose value equals any of the values in this array will be omitted from the returned object. Defaults to `[]` (empty array), meaning discard no elements.

C.Text.relativeEntropy()

```
C.Text.relativeEntropy(bytes: Buffer | string, modelName: string = 'top_domains'): nu
```

Copy

Computes the relative entropy of the given Buffer or string.

Returns the relative entropy value, or `-1` in case of an error.

Parameter	Type	Description
`bytes`	Buffer | string	Value whose relative entropy to compute.
`modelName`	string	Optionally, override the default `$CRIBL_HOME/data/lookups/model_relative_entropy_top_domains.csv` model used to test the input. Create a custom lookup file with the same column and value structure as the default, and store it in the same path, as `model_relative_entropy_<custom-name>.csv`. To reference it, pass your `<custom-name>` substring as the `modelName` parameter.

When using `modelName` in a distributed deployment, the corresponding paths are `$CRIBL_HOME/groups/<worker-group-name>/data/lookups/`. Creating your custom lookup file via Cribl Stream's UI will automatically set the appropriate paths.

10.2.7. C.Time - Time Methods

C.Time.adjustTZ()

```
C.Time.adjustTZ(epochTime: number, tzTo: string, tzFrom: string = 'UTC'): number | ur
```

Copy

Adjusts a timestamp from one timezone to another.

Returns the adjusted timestamp, in Unix time (ms).

Parameter	Type	Description
`epochTime`	number	Timestamp to adjust, in Unix time.
`tzTo`	string	Timezone to adjust to (full name).
`tzFrom` (optional)	string	Timezone of the timestamp.

Cribl relies on this list of TZ Database Time Zones.

Note that these are timezone identifiers (full names), not abbreviations such as "CET", "PST", "EST", and so on.

Examples

To adjust a timestamp found in the `_time` field to a selected timezone (here, Australia/Melbourne), use:

```
C.Time.adjustTZ(_time, "Australia/Melbourne")
```

Copy

The method returns the timestamp in milliseconds. If you want to further operate on it using methods such as `strftime()`, which takes as parameter Unix time in seconds, you can divide it by 1000:

```
C.Time.strftime(C.Time.adjustTZ(_time, "Australia/Melbourne") / 1000, "%d %B %Y %H %M
```

Copy

C.Time.clamp()

```
C.Time.clamp(date: T, earliest: T, latest: T, defaultDate?: T ): T  | undefined
```

Copy

Constrains a parsed timestamp to realistic earliest and latest boundaries.

Returns a JavaScript Date object or timestamp, depending on the format of the `date` parameter.

Parameter	Type	Description
`date`	Date | number	Timestamp to constrain, in Unix time (ms) or JavaScript Date format.
`earliest`	Date | number	Earliest allowable timestamp, in Unix time (ms) or JavaScript Date format.
`latest`	Date | number	Latest allowable timestamp, in Unix time (ms) or JavaScript Date format.
`defaultDate` (optional)	Date | number	Default date, in Unix time (ms) or JavaScript Date format. This date is used for values that fall outside the `earliest` or `latest` boundaries.

Examples

Suppose you have a date in a `"YYYY-MM-DD"` format in a `time` field. To make sure this date does not exceed the range of 1 Jan 2020 - 1 Jan 2025, you can use:

```
C.Time.clamp(time, "2020-01-01", "2025-01-01")
```

Copy

Input	Output
`"2016-02-11"`	`"2020-01-01"` (set to the earliest value)

Input	Output
`"2026-01-01"`	`"2025-01-01"` (set to the latest value)
`"2023-12-24"`	`"2023-12-24"` (unchanged, because it fits inside the defined range)

To make sure that all dates that fall outside the bounds are changed to a specific value, add the third parameter:

```
C.Time.clamp(time, "2020-01-01", "2025-01-01", "2022-02-22")
```

Copy

Input	Output
`"2016-02-11"`	`"2022-02-22"` (set to the default value)
`"2026-01-01"`	`"2022-02-22"` (set to the default value)
`"2023-12-24"`	`"2023-12-24"` (unchanged, because it fits inside the defined range)

C.Time.strftime()

```
C.Time.strftime(date: number | Date | string, format: string, utc: boolean = true): s
```

Copy

Formats a Date object or timestamp number as a time string, using d3js time format.

Returns representation of the given date in the specified format.

Parameter	Type	Description
`date`	number | Date | string	Date to format, in Unix time (in seconds) or JavaScript Date format.
`format`	string	New format for the date.
`utc` (optional)	boolean	Whether to output the time in UTC (`true`), rather than in local timezone.

Examples

To transform a `_time` field containing a timestamp (in Unix time) to a string with time formatted, for example: `15 November 2023, 08:03`, you can use:

```
C.Time.strftime(_time, "%d %B %Y, %H:%M")
```

Copy

Some common formats (assuming timestamp in Unix time of 1702460134) are:

Format	Output
`"%Y-%m-%d"` (ISO date)	`"2023-12-13"`
`"%d %B %Y %H:%M:%S"`	`"13 December 2023 09:35:34"`
`"%x %X"` (the locale's date and time format)	`"12/13/2023 9:35:34 AM"`

For detailed reference of the date and time tokens, see d3js reference or Auto Timestamp.

C.Time.strptime()

```
C.Time.strptime(str: string, format: string, utc: boolean = true, strict: boolean = f
```

Copy

Extracts time from a string using d3js time format that defines the format of the incoming string.

Returns a parsed JavaScript Date object, or `null` if the specified `format` did not match.

Parameter	Type	Description
`str`	string	Timestamp to parse.
`format`	string	Format to parse.
`utc` (optional)	boolean	Whether to interpret times as UTC (`true`), rather than as local time.

Parameter	Type	Description
`strict` (optional)	boolean	Whether to return `null` if there are any extra characters after timestamp.

Examples

To convert a string in the `"YYYY-MM-DD"` format, for example `"2023-12-12"`, to a Date object, use:

```
C.Time.strptime(F, "%Y-%m-%d")
```

Copy

Additionally, to interpret the time in UTC, and make sure null is returned if the timestamp contains any trailing characters, use:

```
C.Time.strptime(F, "%Y-%m-%d", true, true)
```

Copy

For detailed reference of the date and time tokens, see d3js reference or Auto Timestamp.

C.Time.timestampFinder()

```
C.Time.timestampFinder(utc?: boolean).find(str: string): IAutoTimeParser
```

Copy

Extracts time from the specified field, using the same algorithm as the Auto Timestamp Function and Event Breakers.

Returns representation of the extracted time; truncates timestamps to three-digit (milliseconds) resolution, omitting trailing zeros.

Parameter	Type	Description
`utc`	boolean	Whether to output the time in UTC (`true`), rather than in local timezone.
`str`	string	The field in which to search for the time.

Examples

To find timestamps in the `_raw` field and output them in UTC, you can use:

```
C.Time.timestampFinder(true).find(_raw)
```

Copy

You can then format the string output with `strftime()`:

```
C.Time.strftime(C.Time.timestampFinder(true).find(_raw), "%d.%m.%Y, %H.%M")
```

Copy

C.Time.timePartition()

```
C.Time.timePartition(date: number | Date | string, level: 'd' | 'h'): string | undefi
```

Copy

Provides the part of the file path prefix that contains the date.

Returns a string in the format `YYYY/MM/DD` for `d` and `YYYY/MM/DD/HH` for `h`.

Parameter	Type	Description
`date`	number | Date | string	Datetime to extract the file path prefix for.
`level`	string	Granularity of the partitioning, `d` for daily, and `h` for hourly.

Examples

To get the file path prefix from the `_time` field:

```
C.Time.timePartition(_time)
```

Copy

This will return the prefix in the form of, for example: `2024/04/23`.

C.Time.s3TimePartition()

```
C.Time.s3TimePartition(date: number | Date | string, level: 'd' | 'h'): string | unde
```

Copy

Provides the full S3 file path prefix for a given datetime.

Returns the file path prefix as a string.

Parameter	Type	Description
`date`	number | Date | string	Datetime to extract the file path prefix for.
`level`	string	Granularity of the partitioning, `d` for daily, and `h` for hourly.

Examples

To get the S3 file path prefix from the `_time` field:

```
C.Time.s3TimePartition(_time)
```

Copy

10.2.8. Miscellaneous Expression Methods

C.Schema - Schema Methods

`C.Schema`

```
C.Schema: (id: string) => SchemaValidator
```

Copy

`C.Schema.validate()`

```
C.SchemaValidator.validate(data: any): boolean
```

Copy

Validates the given object against the schema.

Returns `true` when schema is valid; otherwise, `false`.

Parameter	Type	Description
`data`	any	Object to be validated.

Examples

To validate whether a `myField` conforms to `schema1`, you can use:

```
C.Schema('schema1').validate(myField)
```

Copy

See Schema Library for more details.

C.Secret - Secrets-Management Methods

`C.Secret()`

```
C.Secret: (id: string, type?: string): ISecret
C.Secret(id: string, type: 'keypair') => IPairSecret
C.Secret(id: string, type: 'text') => ITextSecret
C.Secret(id: string, type: 'credentials') => ICredentialsSecret
```

Copy

Returns a secret matching the specified ID.

Parameter	Type	Description
`id`	string	ID of the secret.
`type` (optional)	'text' | 'keypair' | 'credentials'	Type of the secret.

Examples

To return a text secret with ID `victorias` (or with undefined, if no such secret exists), use:

```
C.Secret('victorias', 'text')
```

Copy

You can also get attributes of secrets with the following expressions:

```
C.Secret('api_key', 'keypair').secretKey
C.Secret('secret_hash', 'text').value
C.Secret('user_pass', 'credentials').password
```

Copy

Common returned attributes for `ISecret` objects:

- `secretType` - one of `keypair`, `text`, or `credentials`.

- `description` (optional) - the secret description.
- `tags` (optional) - a comma separated list of tags.

Additional returned attributes for `IPairSecret` objects:

- `apiKey` - the API key value
- `secretKey` - the Secret key value

Additional returned attributes for `ITextSecret` objects:

- `value` - the text value

Additional returned attributes for `ICredentialsSecret` objects:

- `username` - the username value
- `password` - the password value

See Securing Cribl Stream > Secrets for more details.

C.env - Environment

`C.env`

```
C.env: {[key: string]: string;}
```

Copy

Returns an object containing Cribl Stream's environment variables. All internal variables, that is, those starting with `CRIBL_`, are accessible in this method.

Examples

To return the parent of Cribl's `bin` directory (generally `/opt/cribl`), use:

```
C.env.CRIBL_HOME
```

Copy

To return the hostname of the machine where Cribl Stream is running, use:

```
C.env.HOSTNAME
```

Copy

C.os - System Methods

`C.os.hostname()`

Returns hostname of the system running this Cribl Stream instance.

C.vars - Global Variables

See Global Variables Library for more details.

> Worker Group variables are designed specifically for configuration binding. They are not accessible using the `C.vars` expression in Pipeline Functions. You can only bind these variables to Source and Destination configuration fields that display the **Variable** icon ◈.
>
> The only exception is the Redis Function, which can resolve Worker Group variables at runtime to manage external state or lookups.

C.version - Cribl Stream Versions

`C.version`

Returns the Cribl Stream version currently running.

`C.confVersion`

Returns the commit hash of the Worker Node's current config version. (Evaluates only against live data sent through Worker Nodes. Values will be undefined in the Leader's Preview pane.)

C.Misc - Miscellaneous Utility Methods

`C.Misc.zip()`

```
C.Misc.zip(keys: string[], values: any[], dest?: any): any
```

Copy

Sets the given keys to the corresponding values on the given `dest` object. If `dest` is not provided, a new object will be constructed.

Returns object on which the fields were set.

Parameter	Type	Description
`keys`	string[]	Field names corresponding to keys.
`values`	any[]	Values corresponding to values.
`dest`	any	Object on which to set field values.

Examples

Let's take the following expression:

```
people = C.Misc.zip(titles, names)
```

Copy

If sample data contains: `titles=['ceo', 'svp', 'vp']`, `names=['foo', 'bar', 'baz']`, this expression create an object called `people`, with key names from elements in `titles`, and with corresponding values from elements in `names`.

Result: `"people": {"ceo": "foo", "svp": "bar", "vp": "baz"}`

`C.Misc.uuidv4()`

```
C.Misc.uuidv4(): string
```

Copy

Returns a version 4 (random) UUID in accordance with RFC-4122.

Examples

To create a UUIDv4, use:

```
C.Misc.uuidv4()
```

Copy

Result: a conforming UUIDv4, such as `58d8be36-4db0-4b1c-ac80-28bb03c45e0d`. It is highly improbable that two version 4 UUIDs will ever have the same value.

`C.Misc.uuidv5()`

```
C.Misc.uuidv5(name: string, namespace: string): string
```

Copy

Returns a version 5 (namespaced) UUID in accordance with RFC-4122 for the given `name` and `namespace`. If `namespace` is not a valid UUID, this function will fail.

Parameter	Type	Description
`name`	string	Any arbitrary name to use in UUID generation.
`namespace`	string	One of `DNS`, `URL`, `OID`, or `X500` to use a predefined namespace, or else a valid UUID.

Examples

To create a UUIDv5 with the predefined DNS namespace, use:

```
C.Misc.uuidv5('example', 'DNS')
```

Copy

Result: a UUID that is highly likely to be the same for the same name and namespace. In this case, the result would be `7cb48787-6d91-5b9f-bc60-f30298ea5736`.

C.Misc.validateUUID()

```
C.Misc.validateUUID(maybeUUID: string): boolean
```

Copy

Returns `true` if `maybeUUID` is a valid UUID of any version, and false otherwise.

Parameter	Type	Description
`maybeUUID`	string	A string to test for a valid UUID.

Examples

```
C.Misc.validateUUID(C.Misc.uuidv4())
```

Copy

Result: returns `true`

```
C.Misc.validateUUID('clearly not a UUID')
```

Copy

Result: returns `false`

C.Misc.getUUIDVersion()

```
C.Misc.getUUIDVersion(uuid: string): number
```

Copy

Returns a `number` of the UUID version given by `uuid` if it is a valid UUID, otherwise `undefined`.

Parameter	Type	Description
`uuid`	string	A UUID for which to determine the version.

Examples

```
C.Misc.getUUIDVersion(C.Misc.uuidv4())
```

Copy

Result: `4`

```
C.Misc.getUUIDVersion(C.Misc.uuidv5('example', 'X500'))
```

Copy

Result: `5`

`C.WorkerGroupId`

```
C.WorkerGroupId: string
```

Copy

Returns the name of the current Worker Group. Use this expression to enrich logs or metrics with the Worker Group identity, enabling filtering and grouping in dashboards and analytics tools. This method always returns a string, even in single-node deployments.

Prefer `C.WorkerGroupId` over `C.env.CRIBL_GROUP_ID` where possible. The environment variable may be unset or stale, whereas `C.WorkerGroupId` always reflects the current Worker Group assignment from your configuration.

Example

To add the current Worker Group name to an event field:

10.3. CLI Reference

Command line interface basics and reference

In addition to starting and stopping the Cribl Stream server, the Cribl Stream command line interface enables you to initiate many configuration and administrative tasks directly from your terminal.

The command-line interface is only available to on-prem or hybrid customers.

To use the CLI:

1. First check that you have read/write access to the directory where Cribl Stream is installed. Contact your Cribl administrator to request access if needed.
2. Navigate to the directory where Cribl Stream is installed:

```
cd $CRIBL_HOME/bin
```

Copy

3. Execute a command. CLI commands have this basic syntax:

```
./cribl <command> <sub-command> <options> <arguments>
```

Copy

Not all commands have sub-commands.

4. To see the documentation for any command, append the `--help` option. For example:

```
./cribl vars --help

./cribl vars get --help

./cribl vars get -i myArray --help
```

Copy

Prevent and Troubleshoot CLI Problems

Immediate Execution

As indicated in the command reference and sample output, some commands take effect immediately.

Commands that require additional input will echo the sub-commands, options, and arguments they expect.

Persistent Volumes

If you start Cribl Stream with the `CRIBL_VOLUME_DIR` variable, all subsequent CLI commands should have this variable defined. Otherwise, those commands will apply the Cribl Stream default directories, yielding misleading results.

You can set `CRIBL_VOLUME_DIR` as an environment variable, or you can explicitly include it in each command, as in this example:

```
CRIBL_VOLUME_DIR=<writable-path-name> /opt/cribl/bin/cribl status
```

When set, `$CRIBL_VOLUME_DIR` overrides `$CRIBL_HOME`.

Avoid setting `$CRIBL_VOLUME_DIR` to an existing folder because it creates predefined folders in the specified directory. If that directory already contains folders with those names, Cribl Stream will overwrite those directories.

Failover Mode

In failover mode, set the `CRIBL_CONF_DIR` variable to your failover directory, ensuring your CLI commands access the correct configuration directory. For example, `CRIBL_CONF_DIR=/<path_to_failover_volume> cribl diag create`.

Your failover directory is either defined by the environment variable `CRIBL_DIST_LEADER_FAILOVER_VOLUME` (alternatively `CRIBL_DIST_MASTER_FAILOVER_VOLUME`), or defined in the instance.yml configuration file.

Commands Available

To see a list of available commands, enter `./cribl` alone (or the equivalent `./cribl help`). To execute a command, or to see its required parameters, enter `./cribl <command>`.

Command	Description
auth	Command to log into or out of the product
boot-start	Command to enable or disable product boot-start
cloud-workspace	Command to update a Leader with new config that allows it to connect to the Cribl.Cloud Leader and send it usage metrics
decrypt	Command to decrypt data with a secret key
diag	Command to manage diagnostic bundles
encrypt	Command to encrypt data with a secret key
git	Command to manage Worker Group or Fleet configuration
help	Displays a list of commands and their help
keys	Command to manage encryption keys
limits	Command to control the availability of Cribl features
mode-master	Command to configure an instance as a Leader
mode-single	Command to configure an instance as a Single-instance deployment
mode-edge	Command to configure Cribl Edge as a Single-instance deployment
mode-worker	Command to configure Cribl Stream as a Worker instance
mode-managed-edge	Command to configure Cribl Edge as an Edge Node
mode-outpost	Command to configure an instance as a Cribl Outpost
nc	Command to listen a port for traffic and output stats and data
node	Command to execute a JavaScript file
pack	Command to mange Cribl packs
parquet	Command to view a Parquet file, its metadata, or its schema
pipe	Command to feed stdin to a Pipeline
pq	Command for persistent queue performance benchmarking
reload	Command to reload the product

Command	Description
restart	Command to restart the product
start	Command to start the product
status	Command to display the product status
stop	Command to stop the product
vars	Command to manage global variables

10.3.1. Auth

Log into or out of Cribl Stream.

Sub-commands:

- `auth login`
- `auth logout`
- `auth mf`

Sub-commands and Options

`auth login`

Login with a username and password or use a file with credentials.

Usage:

```
./cribl auth login -H http://localhost:9000 -u example-username -p example-password
./cribl auth login -H http://localhost:9000 -f example-credentials-file.txt
```

Copy

See additional `auth login` Examples.

Arguments:

Option	Definition
`-H <host>`	Host URL. Example: `http://localhost:9000`.
`-u <username>`	Username.
`-p <password>`	Password.
`-f <file>`	File with credentials.

Arguments of the `login` subcommand correspond to the following environment variables:

Argument	Variable
`<username>`	`CRIBL_USERNAME`
`<password>`	`CRIBL_PASSWORD`
`<host>`	`CRIBL_HOST`

`auth login` Examples

Launch interactive login:

```
$CRIBL_HOME/bin/cribl auth login
```

Append credentials as command arguments:

```
$CRIBL_HOME/bin/cribl auth login -h <url> -u <username> -p <password>
```

All `-h` and `host` arguments are optional, provided that the `cribl.yml` file's `api:` section lists the API host and port.

Provide credentials in environment variables:

```
CRIBL_HOST=<url> CRIBL_USERNAME=<username> CRIBL_PASSWORD=<password>
$CRIBL_HOME/bin/cribl auth login
```

Provide credentials in a file:

```
$CRIBL_HOME/bin/cribl auth login -f <path/to/file>
```

Corresponding file contents:

```
host=<url>
username=<username>
password=<password>
```

Copy

`auth logout`

Logout from the current session.

Usage:

```
./cribl auth logout
```

Copy

auth mf

Control multi-factor authentication (PIV).

Usage:

```
./cribl auth mf -e true
```

Copy

See additional auth mf Examples.

Arguments:

Option	Definition
-e <enable>	Disable or enable multi-factor authentication using PIV. Accepts: [“true”, “false”].
-u <usernameRegex>	Username regex pattern (defaults to ‘/CN=(?:\w+.)+(\d+)/’).
-f <usernameField>	Field from which username is to be extracted (defaults to ‘subject’). Accepts: [subject,san]
-o <accessControlAllowOrigin>	Access control allow origin header. Example: “https://127.0.0.1:9000” or “https://fqdn”
-a <apiServerUrl>	API server internal FQDN or IP:PORT combo. Make sure this is also part of server TLS certificate SAN->IP or SAN->DNS (such as “https://[IP]:[PORT]” or “https://internal-fqdn”).

auth mf Examples

Check the status of multi-factor authentication using Personal Identity Verification (PIV):

```
$CRIBL_HOME/bin/cribl auth mf
```

The response includes the status (disabled or enabled) and the current configuration, along with notifications for unconfigured values and issues like failure to restart or enable TLS. For example:

```
PIV multi-factor authentication is disabled.
Username field not defined. Please make sure to configure it.
Username regex pattern: /(?:UPN:)([^,]+)(?:,|$)/
Access control allow origin header: https://127.0.0.1:9000
Api server url: https://127.0.0.1:9000
You will need to restart instance before your changes take full effect.
Warning: TLS is not enabled. PIV will not function until TLS is successfully configur
```

Copy

Enable multi-factor authentication login using PIV:

```
$CRIBL_HOME/bin/cribl auth mf -e true
```

The response confirms that PIV authentication is enabled and lists the current configuration. For example:

```
PIV multi-factor authentication is enabled.
Username field: san
Username regex pattern: /(?:UPN:)([^,]+)(?:,|$)/
Access control allow origin header: https://127.0.0.1:9000
Api server url: https://127.0.0.1:9000
```

Copy

Disable multi-factor authentication login using PIV:

```
$CRIBL_HOME/bin/cribl auth mf -e false
```

The response confirms that PIV authentication is disabled and lists the current configuration. For example:

```
PIV multi-factor authentication is disabled.
Username field: san
Username regex pattern: /(?:UPN:)([^,]+)(?:,|$)/
Access control allow origin header: https://127.0.0.1:9000
Api server url: https://127.0.0.1:9000
```

Copy

For a detailed example that uses the mf sub-command to configure and enable PIV authentication, see Personal Identity Verification (PIV) Authentication.

10.3.2. Boot-Start

Enables or disables Cribl Stream boot-start.

Sub-commands:

- `boot-start disable`
- `boot-start enable`

Sub-commands and Options

`boot-start disable`

Disable boot-start.

Usage:

```
./cribl boot-start disable -m initd
```

Copy

Arguments:

Option	Definition
`-m <manager>`	Init manager. Accepts: `systemd` or `initd`.
`-c <configDir>`	Config directory for the init manager.

`boot-start enable`

Enable boot-start.

Usage:

```
./cribl boot-start enable -m initd
```

Copy

Sample response:

```
Enabling Cribl to be managed by initd...
boot-start enable command needs root privileges...
Enabled Cribl to be managed by initd as user=root.
```

Copy

Arguments:

Option	Definition
`-m <manager>`	Init manager. Accepts: `systemd` or `initd`.
`-u <user>`	User to run the instance as.
`-c <configDir>`	Config directory for the init manager.

10.3.3. Cloud-Workspace

Updates an on-prem Leader Node with a new config in the `instance.yml` file called `cloudWorkspace`. With this config, the local Leader will connect to the Cribl.Cloud Leader and send it usage metrics.

Usage:

```
./cribl cloud-workspace -H <host> -p <port> # etc: flags
```

Copy

Arguments:

Option	Definition
`-d <deploymentId>`	Deployment ID used to report telemetry on multiple deployments.
`-H <host>`	Hostname/IP. Defaults to `0.0.0.0`.
`-p <port>`	Port. Defaults to `4200`.
`-n <certName>`	Name of the saved certificate to use. Mutually exclusive with `-k` or `-c`.
`-k <privKeyPath>`	Path on server to the private key to use. PEM format. Can reference `$ENV_VARS`.
`-c <certPath>`	Path on server to the certificate to use. PEM format. Can reference `$ENV_VARS`.
`-u <authToken>`	Authentication token to include as part of the connection header.
`-S <tls>`	Sets, or disables, secure communication between Leader and Worker/Edge Nodes via TLS. Accepts: ["true", "false"].
`-i <ipWhitelistRegex>`	Regex matching IP addresses that are allowed to establish a connection.
`-r <resiliency>`	Resiliency mode on the Leader. Accepts: ["none", "failover"].
`-v <failoverVolume>`	For resiliency=failover, the volume to use as shared storage.

10.3.4. Decrypt

Decrypts data with a secret key. See the related encrypt command.

Usage:

```
./cribl decrypt -v 12345 -s my-path-name
```

Copy

Arguments:

Option	Definition
`-v <value>`	Value to decrypt.
`-s <criblSecretPath>`	The cribl.secret decrypt key path. If you do not specify a cribl.secret file with -s options, the default cribl.secret is used.

10.3.5. Diag

Manages diagnostic bundles. For failover mode, see how to prevent and troubleshoot CLI problems.

Sub-commands:

- `diag create`
- `diag cpuprofile`
- `diag heapsnapshot`
- `diag list`
- `diag perf`
- `diag send`

Sub-commands and Options

`diag create`

Create a diagnostic bundle for this instance.

Usage:

```
./cribl diag create
```

Copy

Arguments:

Option	Definition
`-d`	Run create in debug mode.
`-j`	Do not append '.txt' to js files.
`-k`	Include metrics for the top 10 Sources, Destinations, Pipelines, Routes, and Packs from the last 24 hours. This matches the **Include top talkers** option in the UI and is separate from the main metrics store controlled by -M.
`-t <maxIncludeJobs>`	Maximum number of jobs (and all associated tasks) to include in the bundle.

Option	Definition
`-M`	Exclude the persistent internal metrics store from the bundle. This reduces bundle size, especially on Leaders and single-instance deployments, but does not remove other metric-related data (such as logs or data added with -k).
`-g`	Exclude git from bundle.
`-i`	Include install logs.

Windows PowerShell usage:

```
PS > $env:CRIBL_VOLUME_DIR='c:\ProgramData\Cribl'; & 'c:\Program
Files\Cribl\bin\cribl.exe' diag create
```

The Windows command requires the `CRIBL_VOLUME_DIR` environment variable. If your deployment doesn't use the default path (`c:\ProgramData\Cribl`), verify that `CRIBL_VOLUME_DIR` points to the correct directory. Otherwise, you might get empty diag files.

Sample response:

```
Created diagnostic bundle at c:\ProgramData\Cribl\diag\edge-DESKTOP-C9BEMQ2-202409251
```

Copy

Windows CMD usage:

```
> set "CRIBL_VOLUME_DIR=c:\ProgramData\Cribl" && "c:\Program
Files\Cribl\bin\cribl.exe" diag create
```

Sample response:

```
Created diagnostic bundle at c:\ProgramData\Cribl\diag\edge-DESKTOP-C9BEMQ2-202409251
```

Copy

Diagnostic Bundles and Failover

If Cribl is configured for failover, the Leader stores its runtime state (including jobs, job history, and similar data) in a special failover volume instead of the default install `/state` directory. The running Leader process sets the `CRIBL_STATE_DIR` environment variable to the failover volume, such as `<failover-`

volume>/state. However, the CLI is a separate process and does not inherit the CRIBL_STATE_DIR environment variable from the Leader.

To collect a complete diagnostic bundle, set CRIBL_STATE_DIR when you run the diag create subcommand as shown in the following example. Replace <failover-volume> with the root path of the failover volume in your environment (such as /mnt/cribl-failover) so that CRIBL_STATE_DIR resolves to the same path that the Leader uses.

```
CRIBL_STATE_DIR=<failover-volume>/state ./cribl diag create -g
```

Copy

Align the environment variables CRIBL_CONF_DIR and CRIBL_VOLUME_DIR with your deployment as for other CLI commands.

If you do not set the CRIBL_STATE_DIR environment variable in the shell, the CLI may default to <configuration-root>/state and the bundle may omit the failover state (for example, it may have empty or incomplete job data).

diag cpuprofile

Collect a 30-second CPU profile and place in the diag directory.

Usage:

```
./cribl diag cpuprofile -p 12345
```

Copy

Sample response:

```
Created a Cribl diagnostic bundle at /opt/cribl/diag/<product>-zedborcdb72f-20210820T
```

Copy

Arguments:

Option	Definition
-p <pid>	The pid of the process to dump the CPU profile.

`diag heapsnapshot`

Generate heap snapshot of a Cribl process and place in the `diag` directory.

Usage:

```
./cribl diag heapsnapshot -p 12345
```

Copy

Sample response:

```
Heap-1672574400000-12345.heapsnapshot
```

Copy

The response format is `Heap-<epoch-timestamp>-<pid>.heapsnapshot`.

Arguments:

Option	Definition
`-p <pid>`	The pid of the process to dump the heap snapshot.

`diag list`

List existing diagnostic bundles.

`diag perf`

Collect a 30-second CPU profile and a heapsnapshot and place both in the `diag` directory.

Option	Definition
`-p <pid>`	The pid of the process to dump both the CPU profile and heap snapshot.

`diag send`

Send diagnostics bundle to Cribl Support.

```
./cribl diag send -c 00001234
```

Copy

Arguments:

Option	Definition
`-c <caseNumber>`	Cribl Support Case Number.
`-p <path>`	Diagnostic bundle path. If empty, it creates a new bundle.

10.3.6. Encrypt

Encrypts data with a secret key. See the related decrypt command.

Usage:

```
./cribl encrypt -v my_token -s my-path-name
```

Copy

Sample response:

```
LzmJ3uqA6WXtXjaLPwuM++WX84o3fPxBaubA6Q0look=
```

Copy

Arguments:

Option	Definition
`-v <value>`	Value to encrypt.
`-s <criblSecretPath>`	The cribl.secret encrypt key path. If you do not specify a cribl.secret file with -s options, the default cribl.secret is used.

10.3.7. Git

Manages Worker Group configuration.

Sub-commands:

- `git commit`
- `git commit-deploy`
- `git deploy`
- `git list-groups`

Sub-commands and Options

`git commit`

Commit Worker Group or Fleet configuration changes.

Usage:

```
./cribl git commit -g production_logs -m "Add syslog pipeline"
./cribl git commit -g webserver_data -m "Remove Parser function from webhook pipeline
```

Copy

Arguments:

Option	Definition
`-g <group>`	Group ID.
`-m <message>`	Commit message.

`git commit-deploy`

Commit and also deploy Worker Group or Fleet configuration changes.

Usage:

```
./cribl git commit-deploy -g production_logs -m "Add syslog pipeline"
./cribl git commit-deploy -g webserver_data -m "Remove Parser function from webhook p
```

Copy

Option	Definition
`-g <group>`	Group ID.
`-m <message>`	Commit message.

`git deploy`

Deploy Worker Group or Fleet configuration changes.

Usage:

```
./cribl git commit-deploy -g production_logs -v 7c04de1
```

Copy

Sample response:

```
Successfully committed version 7c04de1
```

Copy

Arguments:

Option	Definition
`-g <group>`	Group ID.
`-v <version>`	Deploy version.

`git list-groups`

List Worker Groups or Fleets.

10.3.8. Help

Displays a list of commands with a description (help) for each. Defaults to a selection of generally useful commands.

Usage:

```
./cribl help [-a]
```

Copy

Sample response:

```
Software version: 4.4.2
Usage: [sub-command] [options] [args]

Commands:
help              - Display help
mode-edge         - Configure instance in Edge mode
mode-managed-edge - Configure instance in Managed-Edge mode
mode-master       - Configure instance in Leader mode
mode-single       - Configure instance in Single-Instance mode
mode-worker       - Configure instance in Worker mode
reload            - Reload instance
restart           - Restart instance
start             - Start instance
status            - Display status
stop              - Stop instance
version           - Print version
```

Copy

Arguments:

Option	Definition
`-a`	Display the list of all commands, except for `scope`.

10.3.9. Keys

Manages encryption keys.

You must append the `-g <group>` argument to specify a Worker Group/Fleet. As a fallback, append the argument `-g default`. For example: `./cribl keys list -g default`.

Sub-commands:

- `keys add`
- `keys list`

Sub-commands and Options

`keys add`

Add encryption keys.

Usage:

```
./cribl keys add -g default
./cribl keys add -g production_logs
```

Copy

Sample response:

```
Adding key succeeded. Key count=1
```

Copy

Arguments:

Option	Definition
`-a <algorithm>`	Encryption algorithm. Supported values: aes-256-cbc (default), aes-256-gcm.

Option	Definition
`-c <keyclass>`	Key class to set for the key.
`-k <kms>`	KMS to use. Must be configured; see cribl.yml.
`-e <expires>`	Expiration time, in Unix time.
`-i`	Use an initialization vector. (IV size configurable for algorithm aes-256-gcm & fixed to 16 for algorithm aes-256-cbc)
`-s <ivSize>`	(For algo 'aes-256-gcm' only) Initialization vector size (bytes). Supported values: 12 (default), 13, 14, 15, 16
`-g <group>`	Worker Group ID.

`keys list`

List encryption keys.

Usage:

```
./cribl keys add -g default
./cribl keys add -g production_logs
```

Copy

Arguments:

Option	Definition
`-g <group>`	Worker Group ID.

10.3.10. Limits

Controls the availability of Cribl features. See Scripts for more information.

Usage:

```
./cribl limits -s true
./cribl limits -s false
```

Copy

Arguments:

Option	Definition
`-s <enable>`	Enable custom scripts API. Accepts: [“true”, “false”].

10.3.11. Mode-Master

Configures instance as a Leader.

For more information, see:

- Leader High Availability/Failover
- Set Up Leader and Worker Nodes

Usage:

```
./cribl mode-master -r failover -v /tmp/shared
```

Copy

Arguments:

Option	Definition
`-d <deploymentId>`	Deployment ID for reporting telemetry on multiple deployments.
`-H <host>`	Hostname/IP. Defaults to `0.0.0.0`.
`-p <port>`	Port. Defaults to `4200`.
`-f <uiAccess>`	Controls whether the distributed port responds to requests on behalf of the API process. The default port is `4200`. When disabled, `4200` only responds to Worker/Edge Node queries for config bundles and distributed upgrades. Accepts: ["true", "false"]. Defaults to `true` for backward compatibility.
`-n <certName>`	Name of the saved certificate to use. Mutually exclusive with -k or -c.
`-k <privKeyPath>`	Path on server to the private key to use. Accepts PEM format. Can reference `$ENV_VARS`.
`-c <certPath>`	Path on server to the certificate to use. Accepts PEM format. Can reference `$ENV_VARS`.
`-u <authToken>`	Authentication token to include as part of the connection header.
`-S <tls>`	Sets, or disables, secure communication between Leader and Worker/Edge Nodes via TLS. Accepts: ["true", "false"].

Option	Definition
`-i <ipWhitelistRegex>`	Regex matching IP addresses that are allowed to establish a connection.
`-r <resiliency>`	Resiliency mode for the Leader. Accepts: [“none”, “failover”].
`-v <failoverVolume>`	For resiliency=failover, the volume to use as shared storage.

10.3.12. Mode-Single

Configures node as a Single-instance Cribl Stream deployment.

Usage:

```
./cribl mode-single -d d0e301e4-f961-4f50-956a-5153224b34e3
```

Copy

Arguments:

Option	Definition
`-d <deploymentId>`	Deployment ID for reporting telemetry on multiple deployments.

10.3.13. Mode-Edge

Configures node as a Single-instance Cribl Edge deployment.

Usage:

```
./cribl mode-edge -d d0e301e4-f961-4f50-956a-5153224b34e3
```

Copy

Arguments:

Option	Definition
`-d <deploymentId>`	Deployment ID for reporting telemetry on multiple deployments.
`-H <host>`	Hostname/IP. Defaults to `127.0.0.1`.
`-p <port>`	Port. Defaults to `9420`.

10.3.14. Mode-Worker

Configures instance as a Cribl Stream Worker Node.

Running this command resets all the related options. This means that even if you want to change only one option, you also need to provide values for all the other arguments.

When you generate bootstrap scripts through the UI to add or update Workers, these scripts automatically set the `-S` option according to the Leader TLS configuration.

For more information, see Set Up Leader and Worker Nodes.

Usage:

```
./cribl mode-worker -H 127.0.0.1 -p 9420 -u myToken
```

Copy

The `-H <host> -p <port> -u <authToken>` parameters are required for successful connection to the Leader.

Arguments:

Option	Definition
`-d <deploymentId>`	Deployment ID for reporting telemetry on multiple deployments.
`-H <host>`	Leader's hostname or IP address. Required.
`-p <port>`	Leader's cluster communications port. Example: `4200`. Required.
`-n <certName>`	Name of the saved certificate to use. Mutually exclusive with `-k` or `-c`.
`-k <privKeyPath>`	Path on server to the private key to use. Accepts PEM format. Can reference `$ENV_VARS`.
`-c <certPath>`	Path on server to the certificate to use. Accepts PEM format. Can reference `$ENV_VARS`.
`-u <authToken>`	Authentication token to include as part of the connection header. Required.

Option	Definition
`-S <tls>`	Sets, or disables, secure communication between Leader and Worker/Edge Nodes via TLS. Accepts: [“true”, “false”].
`-e <envRegex>`	Regex to select environment variables to report to Leader. For example: `"/test/"`.
`-t <tags>`	Tag values to report to Leader.
`-g <group>`	Worker Group to report to Leader.

In Cribl.Cloud, get the token for your Workspace from the Worker Node modal (**Add/Update Worker Node**) from the **Auth token** field.

In an on-prem deployment, get the token from **Settings** > **Global** > **System** > **Distributed Settings** > **Leader Settings** > **Auth token**.

10.3.15. Mode-Managed-Edge

Configures instance as a Cribl Edge Node.

Running this command resets all the related options. This means that even if you want to change only one option, you also need to provide values for all the other arguments.

When you generate bootstrap scripts via the UI to add or update Workers, these scripts automatically set the `-S` option according to the Leader TLS configuration.

Usage:

```
./cribl mode-managed-edge 127.0.0.1 -p 9420 -u myToken && ./cribl restart
```

Copy

The `-H <host> -p <port> -u <authToken>` parameters are required for successful connection to the Leader.

Arguments:

Option	Definition
`-d <deploymentId>`	Deployment ID for reporting telemetry on multiple deployments.
`-H <host>`	Leader's hostname or IP address. Required.
`-p <port>`	Leader's cluster communications port Example: `4200`. Required.
`-n <certName>`	Name of the saved certificate to use. Mutually exclusive with `-k` or `-c`.
`-k <privKeyPath>`	Path on server to the private key to use. Accepts PEM format. Can reference `$ENV_VARS`.
`-c <certPath>`	Path on server to the certificate to use. Accepts PEM format. Can reference `$ENV_VARS`.
`-u <authToken>`	Authentication token to include as part of the connection header. Required.
`-S <tls>`	Sets, or disables, secure communication between Leader and Worker/Edge Nodes via TLS. Accepts: ["true", "false"].

Option	Definition
`-e <envRegex>`	Regex to select environment variables to report to Leader. Example: `"/test/"`.
`-t <tags>`	Tag values to report to Leader.
`-g <group>`	Fleet to report to Leader.

In Cribl.Cloud, get the token for your Workspace from the Worker Node modal (**Add/Update Worker Node**) from the **Auth token** field.

In an on-prem deployment, get the token from **Settings** > **Global** > **System** > **Distributed Settings** > **Leader Settings** > **Auth token**.

10.3.16. Mode-Outpost

Configures instance as a Cribl Outpost.

For more information, see:

- Cribl Outpost
- Set up Outpost

Usage:

```
./cribl mode-outpost \
  -H leader.example.com \
  -p 4200 \
  -u myToken \
  -S 1
```

Copy

The `-H <host> -p <port> -u <authToken>` parameters are required for successful connection to the Leader.

Arguments:

Option	Definition
`-d <deploymentId>`	Deployment ID for reporting telemetry on multiple deployments.
`-H <host>`	Leader's hostname or IP address.
`-p <port>`	Leader's cluster communications port.
`-n <certName>`	Name of the saved certificate to use. Mutually exclusive with -k or -c.
`-k <privKeyPath>`	Path on server to the private key to use. Accepts PEM format. Can reference `$ENV_VARS`.
`-c <certPath>`	Path on server to the certificate to use. Accepts PEM format. Can reference `$ENV_VARS`.
`-u <authToken>`	Authentication token to include as part of the connection header. Required.

Option	Definition
`-S <tls>`	Sets, or disables, secure communication between Leader and the Outpost via TLS. Accepts: [“true”, “false”].
`-e <envRegex>`	Regex to select environment variables to report to Leader. Example: `"/test/"`.
`-t <tags>`	Tag values to report to Leader.

In Cribl.Cloud, get the token for your Workspace from the Worker Node modal (**Add/Update Worker Node**) from the **Auth token** field.

In an on-prem deployment, get the token from **Settings** > **Global** > **System** > **Distributed Settings** > **Leader Settings** > **Auth token**.

10.3.17. Nc

Listens on a port for traffic, and outputs stats and data. (Netcat-like utility.)

Usage:

```
./cribl nc -p 4200
```

Copy

Sample response:

```
2021-08-20T22:44:30.457Z - starting server on 0.0.0.0:9999
2021-08-20T22:44:30.462Z - server listening 0.0.0.0:9999
2021-08-20T22:44:31.461Z - messages: 0, socks: 0, thruput: 0MBps
2021-08-20T22:44:32.466Z - messages: 0, socks: 0, thruput: 0MBps
...
2021-08-20T22:44:39.212Z - got connection: 127.0.0.1:37190
2021-08-20T22:44:39.213Z - got connection: 127.0.0.1:37192
```

Copy

Arguments:

Option	Definition
`-p <port>`	Port to listen on.
`-f <family>`	If this is `6` then nc will listen on `::1`. Otherwise, it listens on `0.0.0.0`.
`-s <statsInterval>`	Stats output interval (ms), use `0` to disable.
`-u`	Listen on UDP port instead.
`-o`	Output received data to stdout.
`-t <throttle>`	Throttle rate in (unit)/sec, where units can be KB, MB, GB, and TB.

10.3.18. Node

When you run `node` with no options, it displays a command prompt, as shown here:

```
>
```

Copy

To execute a JavaScript file, you can enter path/file name at the prompt.

With the `-v` option, prints the version of NodeJS that is running.

With `-e`, evaluates a string. Write to console to see the output. For example:

Usage:

```
./cribl node -e 'console.log(Date.now())'
./cribl node -v
```

Copy

Sample response:

```
./cribl node -e 'console.log(Date.now())'
1629740667695
```

Copy

```
v14.15.1
```

Copy

Arguments:

Option	Definition
`-e <eval>`	String to evaluate.
`-v`	Prints NodeJS version.

10.3.19. Pack

Manages Cribl Packs.

Sub-commands:

- `pack export`
- `pack install`
- `pack list`
- `pack uninstall`
- `pack upgrade`

Sub-commands and Options

`pack export`

Exports Cribl packs.

Usage:

```
./cribl pack export -m merge
```

Copy

Arguments:

Option	Definition
`-m <mode>`	Mode to export. Accepts: merge_safe, merge, default_only.
`-o <filename>`	Where to export the Pack on disk.
`-n <name>`	Name to override the installed Pack's name on export.
`-g <group>`	The Worker Group/Fleet to execute within.

`pack install`

Install a Cribl Pack.

Usage:

```
./cribl pack install -g default https://packs.cribl.io/dl/cribl-sysdig-events/1.0.3/c
```

Copy

In this command, `default` Worker Group ID.

Sample response:

```
{"time":"2025-11-13T08:14:05.599Z","cid":"api","channel":"ConfFeatureFlagsMgr","level
{"time":"2025-11-13T08:14:05.600Z","cid":"api","channel":"ConfFeatureFlagsMgr","level

{"time":"2025-11-13T08:14:06.993Z","cid":"api","channel":"PackMgr","level":"info","me
```

Copy

Arguments:

Option	Definition
`-d`	Run install in debug.
`-f`	Force install.
`-c`	Disallow installation of Packs with custom functions.
`-n <name>`	Name of the Pack to install, defaults to source.
`-g <group>`	The Worker Group/Fleet to execute within. Required for distributed deployments.

pack list

Lists Cribl Packs.

Usage:

```
./cribl pack list
```

Copy

Arguments:

Option	Definition
`-v`	Display all Pack information in verbose mode.
`-g <group>`	The Worker Group/Fleet to execute within.

pack uninstall

Uninstall a Cribl Pack.

Usage:

```
./cribl pack uninstall
```

Copy

Arguments:

Option	Definition
`-d`	Run uninstall in debug.
`-g <group>`	The Worker Group/Fleet to execute within.

pack upgrade

Upgrade a Cribl Pack.

Usage:

```
./cribl pack upgrade -s https://packs.cribl.io/packs/cribl-sysdig-events
```

Copy

Arguments:

Option	Definition
`-d`	Run upgrade in debug.
`-s <source>`	Provide the Pack source.
`-m <minor>`	Only upgrade to minor version.
`-g <group>`	The Worker Group/Fleet to execute within.

10.3.20. Parquet

For any Parquet file: view (`cat`) the file, its metadata (`details`), or its `schema`.

This command is available only on Linux.

Sub-commands:

- `parquet cat`
- `parquet details`
- `parquet schema`

Sub-commands and Options

`parquet cat`

Cat Parquet events to console.

Usage:

To view a Parquet file:

```
./cribl parquet cat -f /some_parquet_file
```

Copy

Sample response:

```
{"__bytes":274,"Unnamed: 0":0,"name":"apples","quantity":10,"price":2.6,"date":"2018-
...
```

Copy

Arguments:

Option	Definition
`-f <file>`	Path to Parquet file.
`-m <max>`	Maximum events to print.

`parquet details`

View all Parquet details (schema and statistics) and metadata, including encoding and compression.

Usage:

```
./cribl parquet details -f /some_parquet_file
```

Copy

Sample response:

```
{
  "schema": {
    "Unnamed: 0": {
      "optional": true,
      "type": "INT64"
    },
    ...
  },
  "path": "../../../src/sluice/js/util/__tests__/data/parquet/single/small_fruits.par
  "num_rows": 40000,
  "num_cols": 11,
  "num_real_cols": 11,
  "num_row_groups": 1,
  "created_by": "parquet-cpp-arrow version 11.0.0",
  "schema_root_name": "schema",
  "metadata": {
    "pandas": "{\"index_columns\": [{\"kind\": \"range\", \"name\": null, \"start\":
    ...
  },
  "version": "PARQUET_2_6",
  "metadataSize": 6072,
  ...
    }
  ]
}
```

Copy

Arguments:

Option	Definition
`-f <file>`	Path to Parquet file.

`parquet schema`

View a Parquet file's schema (not including encoding or compression), expressed as JSON like in the Parquet Schema editor.

Usage:

```
./cribl parquet schema -f /some_parquet_file
```

Copy

Sample response:

```
{
  "Unnamed: 0": {
    "optional": true,
```

10.3.21. Pipe

Feeds standard input (stdin) to a Pipeline.

Usage:

```
cat sample.log |  ./cribl pipe -p pipelineName
cat sample.log |  ./cribl pipe -p pipelineName 2>/dev/null
```

Copy

Sample response:

```
...
{"time":"2021-08-20T20:37:00.017Z","cid":"api","channel":"commands","level":"info","m
{"time":"2021-08-20T20:37:00.019Z","cid":"api","channel":"pipe:main","level":"info","
{"time":"2021-08-20T20:37:00.021Z","cid":"api","channel":"pipe:main","level":"info","
{"time":"2021-08-20T20:37:00.022Z","cid":"api","channel":"commands","level":"info","m
{"time":"2021-08-20T20:37:00.028Z","cid":"api","channel":"GrokMgr","level":"info","me
...
```

Copy

Arguments:

Option	Definition
`-p <pipeline>`	Pipeline to feed data through.
`-d`	Include dropped events.
`-c <cpuProfile>`	Perform CPU profiling.
`-t`	Perform pipeline tracing.
`-a <pack>`	Optional Cribl Pack context. Mutually exclusive with -b.
`-b <project>`	Optional Cribl Project context.
`-i`	Runs the pipe command without sandboxing javascript expressions from potential attackers.

10.3.22. Pq

Benchmark persistent queue (PQ) performance. Use `pq write` to simulate high-throughput event ingestion and `pq read` to simulate PQ consumption. This command is useful for internal benchmarking and evaluating disk performance in customer environments.

Sub-commands:

- `pq read`
- `pq write`

Sub-commands and Options

`pq-read`

Read data from a persistent queue and discard it. Use this command to test PQ deserialization and consumer performance.

Usage:

```
./cribl pq read -o /tmp/pq
```

Copy

Sample response:

This response prints every second during operation:

```
{"time":"2025-07-15T22:38:37.978Z","cid":"api","channel":"IPersistentQueue","level":'
{"time":"2025-07-15T22:38:37.982Z","cid":"api","channel":"IPersistentQueue","level":'

{"time":"2025-07-15T22:38:47.148Z","cid":"api","channel":"commands:pq","level":"info'
```

Copy

Arguments:

Option	Definition
`-o <path>`	**(Required)** Directory path to read persistent queue files from.

This command does not commit or remove files from the persistent queue. It's intended for read-only performance testing.

`pq-write`

Read data from `stdin` and write to a persistent queue. Use this command to test PQ serialization and disk write performance.

Usage:

```
cat ~/work/syslog_large.log | ./cribl pq write -o /tmp/pq -b 1000 -s 10485760 -c gzip
```

Copy

Sample response:

This response prints every second during operation:

```

```

Copy

Output includes the number of events and bytes processed every second, and a final summary on completion.

Arguments:

Option	Definition
`-o <path>`	**(Required)** Directory path to store persistent queue files.

10.3.23. Reload

Reloads Cribl Stream. Executes immediately.

Usage:

```
`./cribl reload`
```

Copy

Sample response:

```
Reload request submitted to Cribl
```

Copy

10.3.24. Restart

Restarts Cribl Stream. Executes immediately.

Executing this command cancels any running collection jobs.

Usage:

```
./cribl restart
```

Copy

Sample response:

```
Stopping Cribl, process 17
..............
Cribl is not running
Starting...
....
Cribl started
```

Copy

10.3.25. Start

Starts Cribl Stream. Executes immediately. Upon first run, echoes the Cribl Stream default login credentials.

Usage:

```
./cribl start
```

Sample response:

```
Starting...
...
Cribl started
```

Copy

Arguments:

Option	Definition
`-d <dir>`	Configuration directory.
`-r <role>`	Process role.

10.3.26. Status

Displays status of Cribl Stream, including the API Server address, instance's mode (Leader or Worker), process ID, and GUID. Executes immediately.

Usage:

```
./cribl status
```

Copy

Sample response:

```
Address: http://172.17.0.3:9000
Mode: master
Status: Up
Software Version: 3.1.0-f765e418
Config Version: 347079c
Master: 0.0.0.0:4200
PID: 4100
GUID: e706052a-ace9-4511-a7c7-b58a414a07d3
```

Copy

10.3.27. Stop

Stops Cribl Stream. Executes immediately.

Executing this command cancels any running collection jobs.

Usage:

```
./cribl stop
```

Copy

Sample response:

```
Stopping Cribl, process 3951
.............
Cribl is not running
```

Copy

10.3.28. Vars

Manages Cribl Stream global variables.

See Global Variables for more information.

Sub-commands:

- `vars add`
- `vars get`
- `vars remove`
- `vars update`

Sub-commands and Options

`vars add`

Add a global variable.

Usage:

```
./cribl vars add -i exampleVariable -v 42 -t number -d "Sample number variable" -c cr
```

Copy

Sample response:

```
[
  {
    "type": "number",
    "lib": "cribl",
    "description": "Sample number variable",
    "value": "42",
    "tags": "cribl,sample",
    "id": "exampleVariable"
  }
]
```

Copy

Arguments:

Option	Definition
`-i <id>`	Global variable ID.
`-t <type>`	Type.
`-v <value>`	Value.
`-a <args>`	Arguments.
`-d <description>`	Description.
`-c <tags>`	Custom Tags (comma separated list).
`-g <group>`	Group ID.

`vars get`

List global variables.

Usage:

```
./cribl vars get
```

Copy

Arguments:

Option	Definition
`-i <id>`	Global variable ID.
`-g <group>`	Group ID.

`vars remove`

Remove global variable.

Usage:

```
./cribl vars remove -i exampleVariable
```

Copy

Arguments:

Option	Definition
`-i <id>`	Global variable ID.
`-g <group>`	Group ID.

`vars update`

Update global variable.

Usage:

```
./cribl vars update -i exampleVariable -v 2001
```

Copy

Arguments:

Option	Definition
`-i <id>`	Global variable ID.
`-t <type>`	Type.
`v <value>`	Value.
`-a <args>`	Arguments.
`-d <description>`	Description.
`-c <tags>`	Custom Tags (comma separated list).
`-g <group>`	Group ID.

10.3.29. Version

Displays Cribl Stream version. Executes immediately.

Usage:

```
./cribl version
```

Copy

Sample response:

```
Software Version: 4.7.3-6f48361f
```

Copy

10.4. Environment Variables

You can use the following environment variables to configure your Cribl Stream installation.

Name	Purpose
`CRIBL_TMP_DIR`	Defines the root of a temporary directory. See Usage Notes below.
`CRIBL_VOLUME_DIR`	Sets a directory that persists modified data between different containers or ephemeral instances. When set, this environment variable overrides `CRIBL_HOME`. It also creates predefined subdirectories in the specified directory. If that directory already contains subdirectories with those names, they will be overwritten.
`CRIBL_BOOTSTRAP`	Quickstart a Cribl instance by configuring this variable.
`CRIBL_BOOTSTRAP_HOST`	Host name for connecting to the Leader Node when setting up a new Worker Node.
`CRIBL_API_HOST`	Overrides the **Host** setting.
`CRIBL_API_PORT`	Overrides the **Port** setting.
`CRIBL_EDGE`	(Cribl Edge only) When set to any value, runs this command at container start: `cribl mode-edge -H 0.0.0.0`. This launches the instance as an Edge Node, listening on a host at `0.0.0.0`.
`CRIBL_EDGE_FS_ROOT`	(Cribl Edge running in a container only) Location of the host OS filesystem when mounting in a container. Defaults to `/hostfs`.
`CRIBL_K8S_POD`	(Cribl Edge on Kubernetes only) Sets the name of the Kubernetes Pod in which Cribl Edge is deployed.
`CRIBL_K8S_TLS_REJECT_UNAUTHORIZED`	(Cribl Edge on Kubernetes only) Set to `0` to disable certificates validation when connecting to the Kubernetes APIs. When you disable this environment variable, all Kubernetes features (including Metadata, Metrics, Logs, and workload instrumentation metadata) will tolerate invalid TLS certificates (such as, expired, self-signed, and so forth) when connecting to the Kubernetes APIs.
`CRIBL_SERVICEACCOUNT_PATH`	(Cribl Edge on Kubernetes only) Path to the `ServiceAccount` to use to query the Kubernetes API.

Name	Purpose
	Defaults to `/var/run/secrets/kubernetes.io/serviceaccount`.
`CRIBL_K8S_CPU_LIMIT`	(Cribl Stream on Kubernetes only) Automatically sets CPU shares for Cribl Stream based on the `resources.limits.cpu` value, configured by default in the Helm chart.
`CRIBL_MAX_WORKERS`	(Cribl Stream on Kubernetes only) Setting a maximum amount of Worker Processes on a Kubernetes node helps to prevent overloading the node with more CPUs than it can handle.
`CRIBL_NOEXEC`	When set to `1`, prevents the Exec Source from processing any data, effectively putting it into a "disabled" state. To re-enable, remove or unset the `CRIBL_NOEXEC` variable.
`CRIBL_ENABLE_CORE_DUMP`	When set to `1` in a container, enables core dumps. This requires setting `core_pattern` at the host level. Otherwise, core dumps from a container are disabled.

Distributed Deployment Variables

You can use the following environment variables to configure your distributed Cribl Stream instance.

Name	Purpose
`CRIBL_DEPLOYMENT`	Use this variable to set a human-readable name for your on-prem Leader. Example: `linux_production`. The value you set using this variable will appear on the Connected Environments page.
`CRIBL_CLOUD_WORKSPACE_URL`	URL of the Leader Node in a Cribl.Cloud deployment. Example: `CRIBL_DIST_LEADER_URL=tls://<authToken>@leader:4200`. See Usage Notes.
`CRIBL_DIST_LEADER_URL`	URL of the Leader Node. Example: `CRIBL_DIST_LEADER_URL=tls://<authToken>@leader:4200`. See Usage Notes.
`CRIBL_DIST_MODE`	`worker` or `leader`. Defaults to `worker`, if (and only if) `CRIBL_DIST_LEADER_URL` is present.
`CRIBL_DIST_WORKER_PROXY`	Communicate to the Leader Node via a SOCKS proxy. See Usage Notes below.
`CRIBL_DIST_LEADER_BUNDLE_URL`	Specifies the location of configuration bundles. When set, Worker Nodes will attempt to retrieve their configuration bundles from the

Name	Purpose
	URL specified by this variable, rather than directly from the Leader Node.

Usage Notes

This section explains how to use certain environment variables.

`CRIBL_DIST_LEADER_URL`

Use this format:

`<tls|tcp>://<authToken>@<host>:<port>?group=defaultGroup&tag=tag1&tag=tag2&tls.<tls_settings>`

> To generate a random authentication token, leave `<authToken>` unchanged. You can define it to add your own token instead, but make sure it's secure enough.
>
> The auth token can include only alphanumeric characters or the underscore (`_`). Do not include `<`, `>`, `"`, `` ` ``, `\r`, `\n`, `\t`, `{`, `}`, `|`, `\`, `^`, or `'`.

When configuring the node as a Leader, use `0.0.0.0` (or another suitable binding address) for `host`. Then, set `CRIBL_DIST_MODE` to `leader`.

Here are the components:

- `group` - The preferred Worker Group assignment.
- `resiliency` - The preferred Leader failover mode.
- `volume` - The location of the NFS directory to support Leader failover.
- `tag` - A list of tags that you can use to map (Stream, Edge) the Worker to a Worker Group.
- `disableSNIRouting` - Whether Server Name Indicator (SNI) routing is enabled on the Worker Node. Boolean; defaults to `false`.

  > Do not edit this advanced setting without supervision by Cribl Support. Changing this setting can affect the scalability of your system because it determines how Cribl Stream routes connections between Leader Nodes and Worker Nodes. See the Known Issue that resulted in this setting for more details.

- `tls.privKeyPath` - Private Key Path.

- `tls.passphrase` - Key Passphrase.
- `tls.caPath` - CA Certificate Path.
- `tls.certPath` - Certificate Path.
- `tls.rejectUnauthorized` - Validate Client Certs. Boolean; defaults to `false`.
- `tls.requestCert` - Authenticate Client (mutual auth). Boolean; defaults to `false`.
- `tls.commonNameRegex` - Regex matching peer certificate > subject > common names allowed to connect. Used only if `tls.requestCert` is set to `true`.
- `compression` - Codec used for compressing the data before sending. One of: `gzip` or `none`.

`CRIBL_DIST_LEADER_URL` was previously called `CRIBL_DIST_MASTER_URL`. This name is still in use in certain contexts, for example in Helm charts.

CRIBL_TMP_DIR

Sources use this variable to construct temporary directories in which to stage downloaded Parquet data. If `CRIBL_TMP_DIR` is not set (the default), Cribl applications create subdirectories within your operating system's default temporary directory:

- For Cribl Stream: `<OS_default_temporary_directory>/stream/`.
- For Cribl Edge: `<OS_default_temporary_directory>/edge/`.

For example, on Linux, Stream's default staging directory would be `/tmp/stream/`.

If you explicitly set this `CRIBL_TMP_DIR` environment variable, its value replaces this OS-specific default parent directory.

CRIBL_DIST_WORKER_PROXY

`CRIBL_DIST_WORKER_PROXY` lets you configure a SOCKS proxy for communication between the Leader Node and Worker Nodes.

The default protocol is SOCKS5, which uses the format: `socks5://<username>:<password>@<host>:<port>`. Only `<host>:<port>` are required.

You can alternatively specify SOCKS4 as the protocol with the format: `socks4://<proxyhost>:<port>`. To authenticate on a SOCKS4 proxy with username and password, use this format: `socks4://<username>:<password>@<proxyhost>:<port>`. The `<proxyhost>` can be a hostname, IPv4, or IPv6.

To configure a SOCKS proxy via the UI, see Configure SOCKS Proxy. To configure an HTTP(S) proxy to use for your Sources and Destinations, refer to System Proxy Configuration.

CRIBL_BOOTSTRAP_HOST

`CRIBL_BOOTSTRAP_HOST` overrides the Add/Bootstrap New Worker script generator's default hostname.

For example, if you set `CRIBL_BOOTSTRAP=myhost`, then `myhost` will appear in the script modal's **Leader or Outpost hostname/IP** field, instead of the URL used in the browser.

CRIBL_BOOTSTRAP

`CRIBL_BOOTSTRAP` enables specifying a URL, an absolute disk file path, or a YAML string, in order to bootstrap a configuration to the `$CRIBL_HOME/local` directory. Cribl Stream applies this configuration only upon its first startup.

For any method, Cribl Stream expects each targeted config file to be YAML-formatted. Each file's top-level keys should be the paths to config files inside the `$CRIBL_HOME/local/...` subdirectory.

Below is an example of a bootstrap file. Its output, when Cribl Stream starts, would be to create three files inside the `$CRIBL_HOME/local/cribl` path: `inputs.yml`, `outputs.yml`, and `pipelines/route.yml`.

```
cribl/inputs.yml:
  inputs:
    <id>:
      <config>
cribl/outputs.yml:
  outputs:
    <id>:
      <config>
cribl/pipelines/route.yml:
  id: default
  groups: {}
  comments: []
  routes:
    ...
```

Copy

For details about each file's syntax, see Config Files and its child topics.

`CRIBL_GIT_REMOTE` and `CRIBL_GIT_REMOTE_URL`

These two GitOps bootstrap variables are closely related but behave very differently. Use them with the following in mind.

`CRIBL_GIT_REMOTE` (Bootstrap/Force Sync)

When `CRIBL_GIT_REMOTE` is set on a Leader at startup, it triggers a one-time forced synchronization from the Git repo, rather than simply setting the remote URL.

On Leader startup with `CRIBL_GIT_REMOTE` set:

- Treats the remote Git repo as the source of truth for configuration.
- Replaces any uncommitted local configuration in the Leader's Git working copy with the contents of the configured remote and branch. Effectively a `git reset --hard`.
- Restarts the Leader after the sync is complete.
- Removes `CRIBL_GIT_REMOTE` from the running process so that this forced sync does not recur on subsequent restarts.

This bootstrap process runs based solely on the presence of `CRIBL_GIT_REMOTE`, even if `CRIBL_GIT_OPS` is set to `none`. If the remote repo is unreachable or misconfigured, the Leader can fail to start until the environment variable is removed or corrected.

Recommended use: For one-time bootstrap or recovery scenarios, where you explicitly want to discard uncommitted local configuration in favor of a remote branch, and you have a backup of `$CRIBL_HOME` before enabling this variable.

`CRIBL_GIT_REMOTE_URL` (Remote URL Configuration)

`CRIBL_GIT_REMOTE_URL` exists to configure the Git remote in a way that matches the Git Settings UI without triggering a forced synchronization or restart.

- It sets the Git remote URL used by the Leader.
- It does not wipe uncommitted local configuration.
- When both variables are set, `CRIBL_GIT_REMOTE_URL` takes precedence for the URL value, while `CRIBL_GIT_REMOTE` acts as the switch to enable the forced bootstrap behavior.

Recommended use: For standard Git integration where you want to maintain local changes until you explicitly commit and push them. This is best for keeping the UI's remote URL in sync via environment variables without risking data loss.

Adding Fallback Leaders

You can configure fallback Leader Nodes to support high availability and failover. Use the following environment variables.

Name	Purpose
`CRIBL_DIST_MASTER_RESILIENCY=failover`	Sets the Leader's `Resiliency` to `Failover` mo
`CRIBL_DIST_MASTER_FAILOVER_VOLUME=/tmp/shared`	Sets the location of the NFS directory to support failover. For example: `/mnt/cribl`.
`CRIBL_DIST_MASTER_FAILOVER_MISSED_HB_LIMIT`	Determines how many Lease refresh periods ca before the standby Leader Nodes attempt to pro themselves to primary. Cribl recommends settin
`CRIBL_DIST_MASTER_FAILOVER_PERIOD`	Determines how often the primary Leader refres on the Lease file. Cribl recommends setting this
`CRIBL_INSTANCE_HOME`	In `Failover` mode, this variable points to the L `root` directory, as opposed to the shared volum to access `$CRIBL_INSTANCE_HOME/local/_system/in` (`C:\ProgramData\Cribl\local\_system.ym` Edge on Windows).

GitOps Variables

Cribl Stream provides the following environment variables to facilitate using GitOps in Cribl Stream.

You can use these variables to override the defaults in the UI if you are not using systemd to manage the `cribl` service.

Bootstrap Variables

Name	Purpose
`CRIBL_GIT_REMOTE`	Location of the remote repo to track. Can contain username and password for HTTPS auth. See Usage Notes.
`CRIBL_GIT_REMOTE_URL`	Configure simple Git remote URL. Takes precedence over `CRIBL_GIT_REMOTE` for URL setting. See Usage Notes.

Name	Purpose
`GIT_SSH` / `GIT_SSH_COMMAND`	See Git's documentation.
`CRIBL_GIT_BRANCH`	Git ref (branch, tag, commit) to track/check out.
`CRIBL_GIT_AUTH`	One of: `none`, `basic`, or `ssh`.
`CRIBL_GIT_USER`	Used for `basic` auth.
`CRIBL_GIT_PASSWORD`	Used for `basic` auth.
`CRIBL_GIT_OPS`	Controls which GitOps workflow to use. One of: `push` to enable the GitOps push workflow, or `none` to disable GitOps.
`CRIBL_INTERACTIVE`	Controls whether git commands called by Cribl CLI at startup are interactive.
`CRIBL_GIT_SSH_KEY`	Content of the SSH key used to access git remote.
`CRIBL_GIT_STRICT_HOST_KEY_CHECKING`	Controls whether to check the host key strictly.

Additional Environment Variables

Cribl Stream uses the following variables for multiple purposes.

Name	Purpose
`CRIBL_SPOOL_DIR`	Specifies the base path where events from various Sources and Destinations are spooled. Defaults to `$CRIBL_HOME/state/spool` or `$CRIBL_VOLUME_DIR/state/spool`.

Cribl.Cloud Certificate Variables

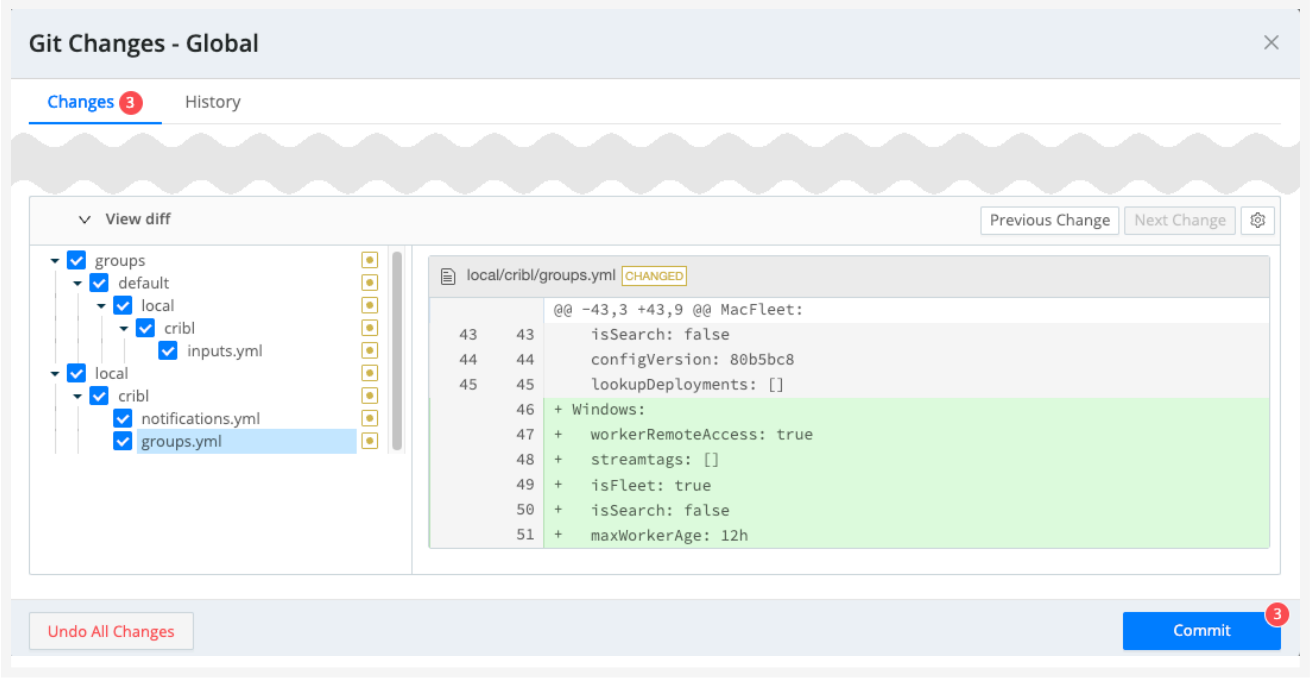
The following variables point to the location of default certificate files on Cribl.Cloud:

Name	Purpose
`CRIBL_CLOUD_KEY`	Path to the default private key on Cribl.Cloud.
`CRIBL_CLOUD_CRT`	Path to the default certificate on Cribl.Cloud.

10.5. Configuration Files

Configuration files store the configuration changes locally on your system. They reflect the changes you make to configuration settings in the UI.

You can preview how settings are translated into configuration changes in the Git Changes modal whenever you commit your changes via the Version Control option.



Git Changes screen showing Git diff with changes to configuration files.

Typically, you do not modify configuration files manually. If you need to edit the configuration outside the UI, Cribl recommends using the API. However, if your particular use case requires it, in an on-prem deployment the files are open for editing.

Configuration File Locations

In an on-prem deployment, configuration files are stored in the `$CRIBL_HOME/local/cribl` directory (where `$CRIBL_HOME` is your installation directory, for example, `/opt/cribl/`). Configuration for specific Worker Groups or Fleets is located `$CRIBL_HOME/groups/<group-or-fleet-name>/local/cribl`.

You can view the default configurations by taking a look in the `default` directory, instead of `local`.

Pack configuration resides within a separate subdirectory for each Pack: `$CRIBL_HOME/default/<pack_name>`.

Configuration file/folder	Description
`ai.yml`	Cribl AI settings.
`app-limits.yml`	Internal limit configuration.
`appscope.yml`	Deprecated legacy instrumentation configuration file.
`breakers-search.yml`	Cribl Search Event Breaker settings.
`breakers.yml`	Event Breakers configuration.
`certificates.yml`	TLS/SSL certificates.
`collectors`	Directory storing individual Collector configurations.
`conditions`	Directory storing configurations for Notification conditions.
`cribl.yml`	General system configuration.
`dataset-providers.yml`	Cribl Search Dataset Providers.
`datasets.yml`	Cribl Search Datasets.
`email-templates.yml`	Templates for Email Notifications.
`executors`	Executor job configurations.
`fleet-mappings.yml`	Mapping rulesets for Edge Nodes.
`functions`	Directory storing individual Function configurations.
`grok-patterns`	Directory storing individual Grok Pattern configurations.
`groups.yml`	Worker Group and Edge Fleet settings.
`inputs.yml`	Sources configuration.
`instance.yml`	Configuration for the current instance.
`iometrics.yml`	Metrics levels for individual Sources and Destinations in Cribl Stream.
`ipfix-information-elements.yml`	Predefined IPFIX fields for handling and decoding IPFIX fields from the Cribl Stream NetFlow & IPFIX Source.
`jobs.yml`	Collector configuration.
`job-limits.yml`	Parameters for Collection jobs and system tasks.

Configuration file/folder	Description
`kms.yml`	KMS provider configuration.
`lake-config.yml`	Configuration for Cribl Lake.
`lakes.yml`	Configuration for individual Cribl Lake datasets.
`leader.yml`	Secondary Leader configuration.
`licenses.yml`	Licenses.
`limits.yml`	Limit configuration.
`logger.yml`	Logging levels and redactions.
`mappings.yml`	Mapping rulesets for Stream Workers.
`messages.yml`	Messages displayed in the UI's `Messages` fly-out.
`mdt-devices.yml`	Configuration for MDT (Model Driven Telemetry) devices.
`notifications.yml`	Notifications and Notification targets.
`notification-templates.yml`	Templates for email Notifications.
`outpost.yml`	Configuration for Cribl Outpost.
`outputs.yml`	Destinations configuration.
`parquet-schemas.yml`	Parquet Schemas.
`parquet-schemas`	Directory storing individual Parquet Schema configurations.
`parsers.yml`	Parsers Library.
`perms.yml`	Permission configuration.
`persistent-queue.yml`	Persistent queue configuration.
`pipelines`	Directory storing individual Pipeline configurations.
`policies.yml`	RBAC Policies.
`protobuf-libraries.yml`	Configuration for Protobuf libraries.
`redis-cache-limits.yml`	Redis cache settings.

Configuration file/folder	Description
`redis-limits.yml`	Redis connection settings.
`regexes.yml`	Regex Library.
`roles.yml`	RBAC Roles.
`route.yml`	Route configuration. Located in `local/cribl/pipelines/routes.yml`.
`samples.yml`	Metadata about about stored sample data files.
`saved-queries.yml`	Saved searches in Cribl Search.
`schemas.yml`	Schema Library.
`schemas`	Directory storing individual schema configurations.
`scripts.yml`	Scripts configured at **Settings** > **Global** > **Scripts**.
`sds-rules.yml`	Cribl Guard rules.
`sds-rulesets.yml`	Cribl Guard rulesets.
`search-limits.yml`	Limit configuration for Cribl Search.
`search-usage-groups`	Cribl Search Usage Group configuration.
`secrets.yml`	Secrets.
`scope_protocol.yml`	Deprecated legacy instrumentation configuration for protocol detection.
`scope.yml`	Deprecated legacy instrumentation configuration.
`search-limits.yml`	Cribl Search limits.
`search-usage-groups.yml`	Cribl Search Usage Groups.
`service.yml`	Service processes.
`vars.yml`	Variables Library.

Configurations and Restart

You can **Restart** and **Reload** via the UI. In the sidebar, select **Settings**, then **Global**. Under **System** >

> **Controls** select **Reload** or **Restart**.

In a distributed environment, Worker Nodes poll the Leader for configuration changes. Many of these changes require a quick reload to read the new configuration, while others require a restart of the Cribl processes on the Worker Node.

Upon restarts, be aware of the following:

- Syslog data still being received over UDP might be dropped.
- Worker Nodes will temporarily disappear from the Leader's **Workers** or **Edge Nodes** page.
- Aggregation and suppression operations will start over.
- Worker Nodes' local copies of Monitoring metrics will be dropped.
- Cribl Stream will drop any events still in RAM that were bound for persistent queues. (However, PQ data already written to disk will persist through the restart.)

Changes that require reloads include configuration changes to:

- Functions
- Pipelines
- Packs
- Routes
- Lookups
- Parquet schemas
- Global variables
- Group Settings > Limits
- Group Settings > Logging > Levels

Changes that require restarts include configuration changes to:

- Distributed mode (Leader versus Managed Worker Node or Single instance)
- Worker Group assignment
- Event Breakers
- QuickConnect configs
- Sources
- Destinations
- Group Settings > General Settings > TLS
- Group Settings > General Settings > Advanced

- Group Settings > Worker Processes > Process count and Memory

Some general guidelines to keep in mind:

- Configuration changes generated by most UI interactions - for instance, changing the order of Functions in a Pipeline, or changing the order of Routes - **do not require restarts**.
- Some configuration changes in the **Settings** UI **do require restarts**. These will prompt you for confirmation before restarting.
- All direct edits of configuration files in `$CRIBL_HOME/local/` **will require restarts**.
- Worker Nodes might temporarily disappear from the Leader's **Workers** or **Edge Nodes** tab while restarting.
- A `git commit` command on the Leader Node's host (using a freestanding `git` client not embedded in Cribl's CLI or UI) **will require either a reload or restart**.
- When using the Cribl App for Splunk, changes to Splunk configuration files might or might not require

10.5.1. Breakers.Yml

Event Breaker configuration is stored in `breakers.yml`.

breakers.yml

```
# ID - ID can contain only letters (A-Z, a-z), numbers (0-9), dashes, underscores, ar
# [string; required]
id:
# Library - Library classification for the ruleset
# One of: custom | cribl-custom
# [string; default: custom]

10.5.3. Cribl.Yml

`cribl.yml` contains settings for configuring API and other system properties.

cribl.yml

```
# API Server Settings
api:
  # Host - Hostname or address to bind API server to. Defaults to 0.0.0.0. Using $CRI
  # overrides this setting.
  # [string; default: 0.0.0.0; required]
  host:
  # Port - API port to listen to. Defaults to 9000. Using $CRIBL_API_PORT overrides t
  # [number; max: 65535; default: 9000; required]
  port:
  # Protocol - Protocol that API server speaks, defaults to http1.1
  # [string; default: http1.1]
  protocol:
  # Retry count - Number of times to retry binding to API port
  # [number; min: 0; default: 120]
  retryCount:
  # Retry period - Period, in seconds, between consecutive port binding retries
  # [number; min: 0; default: 5]
  retrySleepSecs:
  # URL base path - URL base path from which to serve all assets (useful when behind
  # [string; default: '']
  baseUrl:
  # Local UI access - Enable to allow direct browser access to the Cribl Stream Worke
  # [boolean; default: false]
  disabled:
  # Listen on port - Expose the API service to the network on the configured port.
  # [boolean; default: true]
  listenOnPort:
  # Enable teleporting to Worker Nodes - Enables authenticated access to each Worker
  # Leader
  # [boolean; default: false]
  workerRemoteAccess:
  # Log out on roles change - Log users out when their roles change
  # [boolean; default: true]
  revokeOnRoleChange:
  # Auth token TTL - How long (in seconds) authentication tokens remain valid. Defaul
  # minimum is 1 sec.
  # [number; min: 1; default: 3600]
  authTokenTTL:
  # Session idle time limit - How long (in seconds) Cribl Stream will observe no user
  # before invalidating user's session tokens. Default is 1 hr.; minimum is 60 sec.
  # [number; min: 60; default: 3600]
  idleSessionTTL:

10.5.7. IOMETRICS.YML

`iometrics.yml` is a configuration file that defines the metrics levels for individual Sources and Destinations in Cribl Stream. It allows you to control the granularity of metrics emitted by each integration. These correspond to the **Metrics Levels** settings of a Worker Group.

iometrics.yml

```
# Default metrics level - Default level for I/O metrics collection if not otherwise s
# One of: minimal | basic | detailed | comprehensive
# [string]
DEFAULT:
# Input/Output specific metrics levels - Maps specific input/output IDs to their metr
# One of: minimal | basic | detailed | comprehensive
<metric>:
```

Copy

Example `iometrics.yml` configuration:

Example iometrics.yml configuration

```
DEFAULT:
  level: detailed
input:in_splunk_tcp:
  level: minimal
input:in_syslog:
  level: detailed
output:syslog_loopback_dest_udp:
  level: detailed
input:eh_in:
  level: basic
input:in_cribl_http:
  level: minimal
```

Copy

10.5.8. JOBS.YML

`jobs.yml` maintains parameters for configured Collectors, corresponding to those listed on the **Collectors** page. Each collection job is listed according to the pattern shown below.

jobs.yml

```
collection_job: # [object]
  workerAffinity: # [boolean] Worker affinity - If enabled, tasks are created and run
  collector: # [object]
    type: # [string] Collector type - The type of collector to run

    # -------------- if type is azure_blob ---------------

    conf: # [object] [required]
      type: # [string]
      outputName: # [string] Auto-populate from - An optional predefined Destination
      authType: # [string] Authentication method - Enter authentication data directly

      # -------------- if authType is manual ---------------

      connectionString: # [string] Connection string - Enter your Azure storage accou

      # -----------------------------------------------------

      # -------------- if authType is secret ---------------

      textSecret: # [string] Connection string (text secret) - Text secret

      # -----------------------------------------------------

      # -------------- if authType is clientSecret ---------------

      storageAccountName: # [string] Storage account name - The name of your Azure st
      tenantId: # [string] Tenant ID - The service principal's tenant ID
      clientId: # [string] Client ID - The service principal's client ID
      clientTextSecret: # [string] Client secret (text secret) - Text secret containi
      endpointSuffix: # [string] Endpoint suffix - The endpoint suffix for the servic
      azureCloud: # [string] Azure Cloud - The Azure cloud to use. Defaults to Azure

      # -----------------------------------------------------

      # -------------- if authType is clientCert ---------------

```

10.5.9. Job-Limits.Yml

`job-limits.yml` maintains parameters for Collection jobs and system tasks. In the UI, you can configure these per Worker Group at **Group Settings** > **General Settings** > **Limits** > **Jobs**.

Where we do not specify or validate a minimum or maximum value, Cribl provides a prudent default. Adjust this initial value to match your architecture and needs.

job-limits.yml

```
# Disable jobs/tasks - When jobs/tasks are disabled, Worker and Edge Nodes on versior
# poll the Leader for tasks. Nodes running 4.4.4 and older will honor the Jobs settir
# are disabled.
# [boolean; default: false]
disableTasks:
# Concurrent job limit - The total number of jobs that may run concurrently
# [number; min: 1; default: 10]
concurrentJobLimit:
# Concurrent system job limit - The total number of system jobs that may run concurre
# [number; min: 1; default: 10]
concurrentSystemJobLimit:
# Concurrent scheduled job limit - The total number of scheduled jobs that can run cc
# relative to concurrent job limit.
# [number; default: -2]
concurrentScheduledJobLimit:
# Concurrent task limit - The total number of tasks that a Worker Process can run cor
# [number; min: 0; default: 2]
concurrentTaskLimit:
# Concurrent system task limit - The number of system tasks that a Worker Process car
# [number; min: 0; default: 1]
concurrentSystemTaskLimit:
# Task usage percentage limit - Value from 0 to 1 representing the percentage of tota
# system a job may consume
# [number; min: 0; max: 1; default: 0.5]
maxTaskPerc:
# Task poll timeout - The number of milliseconds the Worker's task handler will wait
# before retrying the request for a task
# [number; min: 10000; default: 60000]
taskPollTimeoutMs:
# Artifact reaper period - Time period at which the system attempts to reap stale dis
# to the jobs
# [string; default: 30m]
jobArtifactsReaperPeriod:
# Finished job artifacts limit - Maximum number of finished job artifacts to keep on
# [number; min: 0; default: 100]
finishedJobArtifactsLimit:
```

10.5.10. Leader.Yml

`leader.yml` contains configuration for a secondary Leader and is located under `$CRIBL_HOME/local/cribl` in the volume of that Leader.

This configuration file is created when you have configured a Leader for failover and the new Leader becomes active in case of failover.

leader.yml

```
# Host/IP address to bind to - The host address for the instance
# [string; default: 0.0.0.0; required]
host:
# Port number to bind to - The port number for the instance
# [number; default: 4200; required]
port:
# Protocol - Communication protocol
# [string]
protocol:
# Auth Token - Authentication token for secure communication
# [string]
authToken:
# IP allowlist regex - Regex matching IP addresses that are allowed to establish a cc
# [string; default: /.*/]
ipWhitelistRegex:
# Proxy settings - SOCKS proxy configuration
proxy:
# Compression - Data compression method
# [string]
compression:
# Connection timeout - Timeout for establishing connections
# [number]
connectionTimeout:
# Write timeout - Timeout for write operations
# [number]
writeTimeout:
# Max buffer bytes - Maximum buffer size in bytes
# [number]
maxBufferBytes:
# Forward to Leader API - Controls whether distributed traffic gets proxied to Leader
# [boolean; default: true]
forwardToLeaderApi:
# TLS configuration - TLS/SSL settings
tls:
  # Disabled - Whether TLS is disabled
  # [boolean]
  disabled:
  # Certificate Name - Name of the certificate to use
  # [string]
  certificateName:
  # Private Key Path - Path to private key file
  # [string]
```

```
privKeyPath:
# Passphrase - Passphrase for private key
# [string]
passphrase:
# Certificate Path - Path to certificate file
# [string]
certPath:
# CA Path - Path to certificate authority file
# [string]
caPath:
# Request Certificate - Whether to request client certificates
# [boolean]
requestCert:
# Reject Unauthorized - Whether to reject unauthorized certificates
```

10.5.11. LIMITS.YML

`limits.yml` maintains parameters for the system. In a distributed deployment, these parameters are configured on both the Leader and the Workers.

In the UI, you can configure them:

- On the Leader at **Settings** > **Global** > **General Settings > Limits**.
- On a single instance at **Settings** > **General Settings > Limits**.
- On Worker Groups at `<Group/Fleet-name>` > **Group Settings** > **General Settings > Limits**.

Where we do not specify or validate a minimum or maximum value, Cribl provides a prudent default. Adjust this initial value to match your architecture and needs.

limits.yml

```
# Default managed node heartbeat period - How many seconds a managed node will wait t
# the Cribl control plane
# [number; min: 1]
defaultHeartbeatSeconds:
# Samples
samples:
  # Sample size limit - Maximum file size for the sample, in binary units (KB, MB). (
  # [string]
  maxSize:
# Min free disk space - The minimum amount of disk space in the system before various
# measures to prevent disk usage (KB, MB, etc.)
# [string; default: 5 GB]
minFreeSpace:
# Worker Process PQ size limit - Highest accepted value for individual integrations'
# queue size' parameters. Consult Cribl Support before increasing the default 1 TB.
# [string; default: 1TB]
maxPQSize:
# Metrics GC period - The interval at which the system attempts to free memory by pru
# the Stream system metrics store
# [string; default: 60s]
metricsGCPeriod:
# Number of metrics allowed - The system's total allowed number of metric series. Cor
# before updating this value.
# [number; default: 1000000]
maxMetrics:
# Worker metrics limit - The maximum number of metric series allowed per worker. Cons
# before updating this value.
# [number; default: 100000]
workerMaxMetrics:
# Metrics cardinality limit - The system's allowed number of permutations of a given
# [number; default: 1000]
metricsMaxCardinality:
# Metrics disk space limit - Maximum allowed disk space for persisting metrics to dis
# [string; default: 64GB]
metricsMaxDiskSpace:
# Metrics worker tracking - List of metric names for which to disable tracking of Wor
# Supports wildcards.
# [array; default: host.*, source.*, sourcetype.*, index.*]
metricsWorkerIdBlacklist:
# Metrics never-drop list - List metric names for which to ensure delivery. Supports
# [array; default: total.*]
metricsNeverDropList:
```

```
# Disable field metrics - List of event fields for which to disable metric collectior
# [array; default: source, host, index, sourcetype]
metricsFieldsBlacklist:
# Metrics directory - Directory to store metrics on disk
# [string; default: $CRIBL_STATE_DIR/metrics]
metricsDirectory:
# CPU profile TTL - The time to live for collected CPU profiles
# [string; default: 30m]
cpuProfileTTL:
# Event metadata sources - List of event metadata sources to enable
eventsMetadataSources:
# Metrics to send from Edge Nodes - Choose a set of metrics for Edge Nodes to send to
# a custom set. Details about pre-defined sets are in [the docs](https://docs.cribl.i
# One of: basic | detailed | none | custom
# [string; default: basic]
edgeMetricsMode:
# Metrics expression - JavaScript expression to filter metrics
# [string; required]
edgeMetricsCustomExpression:
# Persist metrics - Disable to stop writing metrics to disk
# [boolean; default: true]
enableMetricsPersistence:
# Edge Nodes estimated count - Used to pre-allocate connection handlers. Changing thi
# currently running connection handlers, causing all Edge Nodes to reconnect. A blank
# default, which starts a handler on demand when an Edge Node attempts to connect.
# [number; min: 0; max: 250000; default: 0]
edgeNodesCount:
# Disable Node persistence - Do not persist connection data across restarts. Caution:
# [boolean; default: false]
enableWorkerInMemory:
# Enable KVStore WAL - Enable the write-ahead log for the KVStore
# [boolean; default: false]
kvStoreEnableWAL:
# KVStore persist period - How often the KVStore syncs itself to disk. When WAL mode
# the KVStore are synced to disk immediately as they happen; however, the WAL is merg
# KVStore on this interval.
# [number; min: 10000]
kvStoreServicePeriod:
# KVStore WAL file bytes limit - The amount of bytes to allow a WAL file to get to be
# back into the KVStore. This may result in performance degradation if adjusted.
# [number; min: 1024; default: 5242880]
kvStoreWALMaxBytes:
# Config bundle download timeout (secs) - The maximum time a Worker will wait for a s
```

```
# connection before canceling a download of a new configuration bundle. A 0 value mea
# which could cause Workers to hang.
# [number; min: 0; default: 0]
bundleDownloadTimeoutSeconds:
# Minimum reconnect interval - The minimum time to wait before attempting to reconnec
# being disconnected. The interval is doubled with each failed reconnect attempt unti
# reached.
# [string; default: 2s]
minReconnectInterval:
# Maximum reconnect interval - The maximum time to wait before attempting to reconnec
# being disconnected.
# [string; default: 1m]
maxReconnectInterval:
# Random reconnect interval - Upper limit on the random time added to each reconnect
# non-zero interval to randomly spread out reconnection attempts. Useful for Leaders
# Worker or Edge nodes.
# [string; default: 0s]
randomReconnectInterval:
# Consult Cribl Support before adjusting this advanced setting. The maximum number of
# a worker node is allowed to ingest. If 0 or not configured, no rate limiting is app
# means automatic determination based on configurations.
# [string; default: '']
rateLimitBytesPerSecond:
# Use Windows tools to collect process info - Enable PowerShell to collect process in
# using the native API
# [boolean; default: false]
enableProcessInfoUsingWindowsTools:
# Lookup file max size - Maximum allowed disk space for persisting single lookup data
# [string; default: 500MB]
lookupMaxSize:
# Lookup files disk limit - Maximum allowed disk space for persisting lookup data and
# [string; default: 2GB]
lookupMaxTotalSize:
```

10.5.12. Logger.Yml

`logger.yml` maintains logging levels and redactions, per channel. In the UI, you can configure these at **Settings** > **Global** > **System** > **Logging**.

logger.yml

```
# Logger Configuration ID
# [string]
id:
# Default redact fields - List of default field names to redact in internal logs
defaultRedactFields:
# Additional redact fields - List of additional field names to redact in internal log
redactFields:
# Custom redact string - Literal redaction string to apply on selected field values.
# [string]
redactLabel:
# Log channels - Configuration for individual log channels
channels:
# TTL configuration - Time-to-live configuration for log levels
ttlConfig:
  # Log level - Level at which to log messages
  # One of: error | warn | info | http | verbose | debug | silly
  # [string; required]
  level:
  # Time to live - Duration in seconds after which log level will revert to default
  # [number; required]
  ttl:
# Max log file size - Maximum log file size in bytes
# [number]
maxSizeBytes:
# Rate limit - Rate limit for log messages (0 to disable)
# [number]
limitRate:
```

Copy

10.5.13. Mappings.Yml And Fleet-Mappings.Yml

Mapping ruleset configurations for Stream Workers and Edge Node are stored in `$CRIBL_HOME/local/cribl/mappings.yml` and `$CRIBL_HOME/local/cribl/fleet-mappings.yml`, respectively.

mappings.yml or fleet-mappings.yml

```
# Mapping ID - Unique identifier for the mapping ruleset
# [string; required]
id:
# Configuration - Mapping ruleset configuration
conf:
  # Functions - List of functions to pass data through
  functions:
# Active - Whether this mapping ruleset is active
# [boolean]
active:
```

Copy

10.5.14. Messages.Yml

`messages.yml` stores messages displayed in the UI's `Messages` fly-out.

logger.yml

```
# Message ID - Unique identifier for the message
# [string]
id:
# Message Type - Type of the bulletin message
# [string]
type:
# Message Text - Content of the message
# [string]
message:
# Severity - Severity level of the message
# [string]
severity:
# Created - Timestamp when the message was created
# [number]
created:
# TTL - Time to live for the message
# [number]
ttl:
```

Copy

10.5.15. Notifications.Yml

`notifications.yml` contains settings for Notifications.

notifications.yml

```
# Notification Targets - Configuration for notification targets
targets:
  # Output ID - Unique identifier for this notification target
  # [string; required]
  id:
  # Output Type - Type of notification target
  # [string; required]
  type:
  # System fields - Fields to automatically add to events, such as cribl_pipe. Suppor
  # [array; default: cribl_host]
  systemFields:
  # Webhook configuration (webhook type only)
  # URL - Webhook endpoint URL
  # [string; required for webhook]
  url:
  # Format - Data format for webhook payload
  # [string; default: ndjson for webhook]
  format:
  # Method - HTTP method for webhook requests
  # [string; default: POST for webhook]
  method:
  # Authentication type - Authentication method for webhook requests
  # [string; default: none for webhook]
  authType:
  # Token - Authentication token (when authType is token)
  # [string]
  token:
  # Username - Username for basic authentication (when authType is basic)
  # [string]
  username:
  # Password - Password for basic authentication (when authType is basic)
  # [string]
  password:
  # Source expression - Expression to evaluate on events to generate output notificat
  # [string]
  srcExpression:
  # Slack configuration (slack type only)
  # Slack webhook URL - Slack incoming webhook URL
  # [string; required for slack]
  slackUrl:
  # PagerDuty configuration (pager_duty type only)
  # Routing key - PagerDuty integration key
```

```
# [string; required for pager_duty]
routingKey:
# Severity - Alert severity level
# [string; required for pager_duty]
severity:
# Group - Alert group identifier
# [string]
group:
# Class - Alert class identifier
# [string]
class:
# Component - Alert component identifier
# [string]
component:
# SNS configuration (sns type only)
# Topic ARN - AWS SNS topic ARN
# [string; required for sns]
topicArn:
# Region - AWS region

  # [boolean; default: false]
  disabled:
```

```
# Condıtıon - When to trıgger thıs notıfıcatıon
# [string; required]
condition:
# Notification targets - Targets to send any Notifications to
targets:
# Target configuration - Configuration for specific targets
```

10.5.16. Outpost.Yml

`outpost.yml` contains configuration for a Cribl Outpost instance.

outpost.yml

```
# Settings for the internal distributed-management interface
listener:
  # Host - Host/IP address to bind to
  # [string; required]
  host:
  # Port - Port number to bind to
  # [number; required]
  port:
```

10.5.17. Outputs.Yml

`outputs.yml` contains configuration settings for Cribl Stream Destinations.

outputs.yml

```
outputs: # [object]
  default_output: # [object]
    type: # [string] Output Type
    defaultId: # [string,null] Default Output ID - ID of the default output. This wil
    pipeline: # [string] Pipeline - Pipeline to process data before sending out to th
    systemFields: # [array of strings] System fields - Fields to automatically add to
    environment: # [string] Environment - Optionally, enable this config only on a sp
    streamtags: # [array of strings] Tags - Tags for filtering and grouping in Cribl
  webhook_output: # [object]
    type: # [string] Output Type
    method: # [string] Method - The method to use when sending events
    format: # [string] Format - How to format events before sending out

10.5.19. Persistent-Queue.Yml

`persistent-queue.yml` contains settings for configuring persistent queues.

persistent-queue.yml

```
# Buffer size limit - The maximum number of events to hold in memory before writing t
# [number; default: 1000]
maxBufferSize:
# File size limit - The maximum size to store in each queue file before closing and c
# Enter a numeral with units of KB, MB, etc.
# [string; default: 10MB]
maxFileSize:
# Queue size limit - The maximum disk space that the queue can consume before queueir
# [string; default: 1GB]
maxSize:
# Mode - Queue operation mode
# One of: always | never | smart
# [string; default: always]
mode:
# Queue file path - The location for the persistent queue files
# [string]
path:
# Compression - Codec to use to compress the persisted data
# One of: gzip | none
# [string]
compress:
# Commit frequency - The number of events to send downstream before committing that S
# [number]
commitFrequency:
```

Copy

10.5.20. Regexes.Yml

`regexes.yml` maintains a list of regexes. Cribl's Regex Library ships under `default`. Each regex is listed according to the following pattern:

regexes.yml

```
# Regex ID - Unique identifier for the regex pattern
# [string; required]
id:
# Library - Library classification for the regex
# One of: cribl | cribl-custom | custom
# [string]
lib:
# Description - Description of the regex pattern
# [string]
description:
# Regex pattern - The regular expression pattern
# [string; required]
regex:
# Sample data - Optionally, paste in sample data to match against this regex
# [string]
sampleData:
# Tags - Tags associated with the regex
# [string]
tags:
```

Copy

10.5.21. SAMPLES.YML

`samples.yml` contains metadata about about stored sample data files (size, number of events, date created, name, and so on).

samples.yml

```
# ID - Unique identifier for the sample
# [string; required]
id:
# Sample Name - Name of the sample file
# [string; required]
sampleName:
# Pipeline ID - Associate with Pipeline - Select a pipeline to associate with sample
# sure. Deprecated.
# [string]
pipelineId:
# Pack ID - ID of the pack this sample belongs to
# [string]
packId:
# Is Pack Only - Whether this sample only exists within this pack and cannot be turne
# [boolean]
isPackOnly:
# Description - Brief description of this sample file. Optional.
# [string]
description:
# Tags - One or more tags related to this sample file. Optional.
# [string]
tags:
# Library - Library classification for the sample
# [string]
lib:
# Created - Timestamp when the sample was created
# [number]
created:
# Modified - Timestamp when the sample was last modified
# [number]
```

10.5.22. Schemas.Yml

`schemas.yml` stores configuration data for the Knowledge > Schema Library.

schemas.yml

```
# Schema ID - Unique identifier for the schema
# [string; required]
id:
# Description - Description of the schema
# [string]
description:
# Schema - JSON schema matching standards of draft version 2019-09
# [string; required]
schema:
# Tags - Tags associated with the schema
# [string]
tags:
```

Copy

10.5.23. Scripts.Yml

`scripts.yml` stores configuration data for scripts configured at **Settings** > **Global** > **Scripts**:

scripts.yml

```
# Script ID - Unique identifier for the script (cannot contain forward slashes)
# [string; required]
id:
# Command - Command to execute for this script
# [string; required]
command:
# Description - Description of the script
# [string]
description:
# Arguments - Arguments to pass when executing this script
args:
# Env variables - Extra environment variables to set when executing script
env:
```

Copy

10.5.24. Service.Yml

`service.yml` maintains configuration for Cribl Stream service processes.

In the UI, you can configure some of these settings on the Leader at **Settings** > **Global** > **System** > **Service Processes** > **Services**.

Be careful about reducing the predefined `memoryLimit` values. Extremely low values can prevent some Cribl Stream components from functioning.

service.yml

```
# Service configuration - Configuration for various Cribl services
# Available service types: connections, metrics, notifications, stream_connections, e
connections:
  # Connections listener number of processes - Negative values are offsets from the r
  # on the host.
  # [number; default: 1]
  procs:
  # Connections listener heap memory limit - Heap memory limit for the connection lis
  # [string; default: 2GB]
  memoryLimit:
metrics:
  # Metrics number of processes - Single process; values above 1 will be treated as 1
  # offsets from the number of available cores on the host.
  # [number; default: 1]
  procs:
  # Metrics heap memory limit - Heap memory limit for the metrics process
  # [string; default: 2GB]
  memoryLimit:
notifications:
  # Notifications number of processes - Single process; values above 1 will be treate
  # are offsets from the number of available cores on the host.
  # [number; default: 1]
  procs:
  # Notifications heap memory limit - Heap memory limit for the notifications process
  # [string; default: 2GB]
  memoryLimit:
stream_connections:
  # Stream connection processes - Negative values are offsets from the number of avai
  # [number; default: 1]
  procs:
  # Auto scale - Do not modify this setting. Defines whether Leader can start the ser
  # Worker node connects to it.
  # [boolean]
  autoScale:
  # Stream connection memory limit - Heap memory limit for the Stream connection proc
  # [string; default: 2GB]
  memoryLimit:
edge_connections:
  # Edge connection processes - Negative values are offsets from the number of availa
  # [number; default: 1]
  procs:
  # Edge auto scale - Do not modify this setting. Defines whether Leader can start th
```

```
  # qualifying Edge node connects to it.
  # [boolean]
  autoScale:
  # Edge connection memory limit - Heap memory limit for the Edge connection processe
  # [string; default: 2GB]
  memoryLimit:
# Connection proxy service - Proxy service that runs on a standby Leader node to forw
# from port 4200 to the primary Leader.
connection_proxy:
  # Connection proxy processes - Number of processes to spawn for connection proxy se
  # Set to 0 to disable the service. Negative values are offsets from the number of a
  # [number; default: 0]
```

10.5.25. VARS.YML

`vars.yml` stores configuration data for the Knowledge > Global Variables Library.

As of Cribl Stream 4.16.0, new Worker Groups do not have sample variables by default.

vars.yml

```
# Name - Global variable name
# [string; required]
id:
# Library - Library classification for the variable
# One of: cribl | cribl-custom | custom
# [string]
lib:
# Description - Description of the global variable
# [string]
description:
# Type - Data type of the variable
# One of: string | number | encryptedString | boolean | array | object | expression |
# [string; default: any; required]
type:
# Value - Value or expression for the variable
# [string; required]
value:
# Tags - Tags associated with the variable
# [string]
tags:
# Arguments - For expression type variables, define function arguments
args:
```

Copy

11. Troubleshoot Cribl Stream

Use the resources in this section to diagnose and resolve issues in Cribl Stream:

- Known Issues: Get information about issues that affect Cribl Stream, along with temporary workarounds and fix versions when applicable.
- Diagnosing Issues: Create and export diagnostic bundles to share with Cribl Support.
- Common Errors and Warnings: Learn how to resolve common errors and warning messages in Cribl Stream.
- Git Push Errors: Learn how to resolve common errors when pushing a `git` commit.
- Git Remote Repos & Trusted CAs: Learn how to resolve errors related to self-signed certificates when pushing or pulling a `git` commit.
- Sample Logs for Login Scenarios: Get examples of the event series that Cribl Stream records in common login scenarios.

11.1. Diagnose Issues

To help diagnose Cribl Stream problems, you can share a diagnostic bundle with Cribl Support. The bundle contains a snapshot of configuration files and logs at the time the bundle was created, and gives troubleshooters insights into how Cribl Stream was configured and operating at that time.

What's in the Diagnostic Bundle

The bundle includes the following subdirectories (and their contents) of `$CRIBL_HOME`:

- `.../default/*`
- `.../local/*` - except for `/local/cribl/auth/`, to exclude sensitive files.
- `.../log/*`
- `.../groups/*`
- `.../state/jobs/*` - will return all jobs if left empty.

As a security measure to protect sensitive information, the bundle excludes sample files, lookup files, and all certificate files (`.crt`, `.pem`, `.cer`, and `.key`) from all `$CRIBL_HOME` subdirectories.

Create and Export a Diagnostic Bundle

If you're managing your own Cribl Stream deployment (single-instance Stream/Edge or distributed Stream/Edge), you can create and securely share bundles with Cribl Support, either from the UI or via the CLI.

With a Cribl.Cloud deployment, create bundles and securely share them with Cribl Support directly from the UI. In the Using the UI instructions below, **Send to Cribl Support** will always be enabled, and the **Export**/download option will be unavailable.

Requirements

Using either medium, you'll need outbound internet access to `https://diag-upload.cribl.io` and a valid support case number. The above URL works only when using the `cribl diag` command or uploading using the Cribl Stream UI. (So connecting directly to it with your web browser will fail.)

If your organization doesn't permit outbound access to `https://diag-upload.cribl.io` to upload from within Cribl, you can also submit diags directly via the Support Portal (login required). If none of

> these options work with your organization's policies, please work directly with your Support engineer to find a solution.

Open your support case before sending a diagnostic bundle to Cribl Support. Then, when creating the bundle, be sure to use the case number provided. Case numbers are 8 digits in length, and you must include any leading zeros. For example, `00001234`.

Use the UI

Depending on the issue you're debugging, you can create a bundle either from the Leader or from an individual Worker Node.

UI Options

The **Create & Export Diag Bundle** modal provides these additional options:

- **Rename .js files**: When enabled, appends `.txt` to JavaScript files in the bundle. Defaults to toggled on.
- **Include metrics**: When enabled, includes the persistent internal metrics store used by Leaders and single-instance deployments in the bundle. This metrics store can grow to many gigabytes over time. Individual Worker Node do not maintain this metrics store, their metric-related information still appears in logs, diag artifacts, and other files regardless of this setting. Defaults to toggled on.
- **Include git**: Includes the last 14 days of git log in the bundle, identifying each commit's message, author, timestamp, and files changed. Defaults to toggled on. Unavailable on Leader-managed Stream Workers and Edge Nodes, as well as on Outpost Nodes.
- **Include top talkers**: Adds detailed metrics for the top 10 Sources, Destinations, Pipelines, Routes, and Packs (based on the last 24 hours) to the diagnostic bundle. These JSON files (such as, `top_sources.json`) contain in/out events and bytes, aiding in troubleshooting and performance analysis. Disabled by default to minimize bundle size, this requires Leader Node access to the `/system/metrics/query` API.
- **Latest number of jobs**: The number of jobs (and all tasks) the bundle will include. Defaults to empty, which means unlimited jobs.
- **Include installation logs**: Includes Windows MSI logs, only available on Windows deployments of Cribl Edge. Default is toggled off.
    - This option is not available for Linux deployments.
    - If MSI logs are available, the diag bundle will contain them. If no MSI logs are present, the bundle will not contain them even with this option toggled on.

Cribl Support will advise you on changing the defaults here. Because the Leader metrics store can be large, they often recommend disabling **Include metrics** unless they specifically request metrics store contents for your case.

From the Leader Node

To create a bundle from the Leader Node, go to **Settings** > **Global** > **Diagnostics** and select **Create Diagnostic Bundle**.

- To share the bundle with Cribl Support, toggle **Send to Cribl Support** on. Enter your case number, and then select **Export**.
- To download the bundle locally to your machine (on-prem only), select **Export**.

From Worker Nodes

To create a bundle from individual Worker Nodes, you must be able to access the Worker Node's UI. You can easily use the Leader to get authenticated access to each Worker Node, if you first enable the parent Worker Group's **Teleport** setting:

1. In the Cribl Stream sidebar, select **Worker Groups**.
2. Make sure the relevant Worker Group's **Teleport** toggle is on.
3. Select the displayed number of Worker Nodes to access the **Worker Nodes** page.
4. In the **GUID** column, select the link for the Worker Node you're debugging.
5. Look for the purple border to confirm that you've teleported to that Worker Node.
6. Select **Worker Node Settings** (top right) > **Diagnostics** (lower left) > **Diagnostic Bundle**, and select **Create Diagnostic Bundle**.
7. Use the appropriate **Export** options listed above for the Leader.

On on-prem deployments, new and previously created bundles are stored in `$CRIBL_HOME/diag`. They're also listed in the UI, where you can re-download them or share them with Cribl Support.

Use the CLI

To create a bundle using the CLI, use the `diag` command. (This option is on-prem only.) Depending on the issue you're debugging, you can create a bundle either from the Leader host or from an individual Worker Node host.

diag command CLI

```
# $CRIBL_HOME/bin/cribl diag
Usage: [sub-command] [options] [args]

Commands:
create       - Creates diagnostic bundle for this instance, args:
  [-d]                  - Run create in debug mode.
  [-j]                  - Do not append '.txt' to js files.
  [-k]                  - Include metrics for the top 10 Sources, Destinations, Pipel
  [-t <maxIncludeJobs>] - Maximum number of jobs (and all associated tasks) to includ
  [-M]                  - Exclude the persistent internal metrics store from the bund
  [-g]                  - Exclude git log from bundle.
  [-i]                  - Include install logs.
heapsnapshot - Generate heap snapshot of a Cribl process, args:
  [-p <pid>] - The pid of the process to dump the heap snapshot
list         - List existing diagnostic bundles
send         - Send diagnostics bundle to Cribl Support, args:
   -c <caseNumber> - Cribl Support Case Number
  [-p <path>]      - Diagnostic bundle path (if empty then new bundle will be created

## Creating a diagnostic bundle
# $CRIBL_HOME/bin/cribl diag create
Created Cribl Stream/Edge diagnostic bundle at /opt/cribl/diag/ <product>-<hostname>-

## Creating and sending a diagnostic bundle
# $CRIBL_HOME/bin/cribl diag send -c <caseNumber>
Sent Cribl diagnostic bundle to Cribl Support

## Sending a previously created diagnostic bundle
# $CRIBL_HOME/bin/cribl diag send -p /opt/cribl/diag/ <product>-<hostname>-<datetime>
Sent Cribl diagnostic bundle to Cribl Support
```

Copy

For complete command syntax, see diag.

Taking a diag from a Cribl Edge Node running on Windows requires setting the `CRIBL_VOLUME_DIR` environment variable. See `diag` for more information.

Include CPU Profiles

This section is applicable only to Cribl Stream.

If Cribl Support asks you to grab CPU profiles of Worker Processes, follow these steps:

1. Use `top` or `htop` on the Worker Node to identify Worker Node PIDs consuming a lot of CPU.
2. See Measuring CPU or API Load for instructions on accessing the UI's **Profile** options (for your deployment type), and generating and saving profiles.
3. Find the Worker Processes matching the PIDs you identified above.
4. Select **Profile** on each. Start with the default 10-second **Duration**.
5. Once the profile is displayed, save it to a `.json` file. (See details at the above link.)
6. Repeat steps 3-5 for other CPU-intensive Worker Processes.
7. Upload the profile `.json` files to Cribl Support.

On an already CPU-starved Worker Node, profiling might fail with an error message, or just hang. In this case, you might need a few retries to get a successful profile.

Include Memory Snapshots

Cribl.Cloud does not support taking memory snapshots. This feature is for on-prem deployments only.

If you encounter a memory leak, Cribl Support might request a memory snapshot of a `cribl` process to better understand where the leak is occurring.

There are two ways to generate a memory snapshot:

- Automatically
- Manually

Automatically Capture a Memory Snapshot

To automatically capture memory snapshots when Worker Processes approach or exceed memory limits, turn on the **Enable heap snapshots setting** in the Worker Group's **General Settings**. Navigate to **Worker Group Settings** > **System** > **Worker Processes** and toggle on. Only the two most recent heap snapshots are retained. Older snapshots are automatically deleted. This behavior cannot be modified.

This setting should only be enabled if recommended by support or if you are experiencing out-of-memory issues. Be aware that enabling this setting may impact system performance and storage usage.

For details, see Worker Processes.

Manually Capture a Memory Snapshot Prerequisites

To manually generate a reliable memory snapshot for Cribl Stream diagnostics, ensure two key conditions are met:

1. **Correct `CRIBL_HOME` Environment Variable**: This variable points to the Cribl Stream installation directory. Open a new terminal session and verify its value using `echo $CRIBL_HOME`. If empty, set it appropriately for your operating system (for example, `export CRIBL_HOME=/path/to/cribl` on Linux, `setex cribl C:\Program Files\Cribl /m` on Windows).
2. **Run as the `cribl` User**: The `diag heapsnapshot` command requires permissions to create the snapshot file within the run Cribl Stream directory. Use `sudo su - cribl` to switch to the cribl user before running the command. Remember to exercise caution with `sudo`. On Windows, if Cribl is set to run under a specific user account, log in as that user before running Cribl. Alternatively, you can run Cribl Stream as an `Administrator`.

Capture the Memory Snapshot

To capture the memory snapshot:

1. Note the PID of the process of interest.
2. In a terminal, `cd` to the directory where Cribl Stream is installed.

```
cd $CRIBL_HOME/bin
```

Copy

3. Run the `diag heapsnapshot` command with the PID you noted in step 1.

- For Linux:

```
./cribl diag heapsnapshot -p <pid>
```

Copy

Locate the PID on Windows

There are three methods to identify the Process ID (PID) for `cribl.exe`:

1. **Task Manager**: Open the Task Manager application. Locate the **Processes** tab and search for `cribl.exe` in the list. The PID will be displayed in the corresponding column.
2. **Command Line Interface (CLI)**: Open a Command Prompt window. Run the following command:

```
tasklist /FI "IMAGENAME eq cribl.exe"
```

Copy

This command will list all running processes. The line containing `cribl.exe` will also display the PID in the corresponding column (usually the second column).

3. **PowerShell**: Open a PowerShell window. Run the following command:

```
PowerShell
Get-Process -Name cribl
```

Copy

This command will list details about running processes. The output will include the PID for any process named `cribl`.

Once you locate the PID, run the `diag heapsnapshot` command:

1. Navigate to the Cribl Stream installation directory: For example, `C:\Program Files\Cribl\bin` or `$CRIBL_HOME\bin`.
2. Run the `diag heapsnapshot` command with the PID.

```
./cribl diag heapsnapshot -p <pid>
```

Copy

Cribl will capture the memory snapshot in `$CRIBL_HOME/diag/`.

Example output:

```
Heap-1690906031148-2458958.heapsnapshot
```

11.2. Common Errors And Warnings

This page lists common error and warning messages that you might find in Cribl Stream's internal logs and/or UI. It includes recommendations for resolving the errors/warnings. Messages are grouped by component (Sources, Destinations, and so on).

Whole message texts are not listed in every case. They may have different capitalization than the messages you may encounter in the product.

Where events are written to log files, they might reside in different logs variously devoted to data processing, cluster communication, or the REST API. (For details, see Types of Logs.) We note the log type where necessary.

NodeJS serves as the Cribl Stream backend and has a large collection of well documented errors of its own. Some of system-level are listed on this page with the appropriate action to take. The remainder are documented at https://nodejs.org/api/errors.html, specifically in the `Common system errors` section of that page.

Web UI

Duplicate GUID

When you deploy and first run Cribl Stream software, it generates a GUID (globally unique identifier) and stores it in a `.dat` file located in `CRIBL_HOME/local/cribl/auth/`. For example:

```
# cat CRIBL_HOME/local/cribl/auth/676f6174733432.dat

{"it":1570724418,"phf":0,"guid":"48f7b21a-0c03-45e0-a699-01e0b7a1e061"}
```

Copy

When deploying Cribl Stream as part of a host image or VM, be sure to remove this file, so that you don't end up with duplicate GUIDs. The file will regenerate on the next run.

"Failed to fetch"

Occurs only when accessing **Data** > **Collectors**. It can occur with ad blockers, or in the Brave browser (because the newly loaded page's URL includes the string `collector`).

Recommendation

If you have an ad blocker, allowlist the `https://<hostname>:9000/jobs/collectors` (single-instance) URL or the `https://<leadernode>:9000/m/<group_name>/jobs/collectors` (Leader) URL.

"No workers registered"

Occurs during a live data capture, when there are no Workers available to fulfill the capture request. This error can be triggered if you attempt to capture events too quickly following a commit & deploy.

Recommendation

- If you recently committed and deployed changes, wait 30 seconds and retry the live capture.
- Navigate to the **Workers** page and confirm there are Workers currently registered with the Leader. Note that the error appears on a per-Group basis, which means that even if you have Workers registered, they may not be in the Group you're capturing live data from.

"The Config Helper service is not available..."

Full Text: "The Config Helper service is not available because a configuration file doesn't exist or the settings are invalid. Please fix it and restart Cribl server."

Occurs only on Leader Nodes. Each Worker Group relies on a config helper process that runs on its behalf on a Leader Node, and that process is not currently running. This error is usually triggered by restarting Cribl Stream on the Leader Node, and then trying to access one of these features before the Cribl Stream server is fully up:

- **Groups** or **Configure** link (3.x).
- **Worker Groups** menu (2.x).
- **Manage** > **Groups** or **Manage** > **Workers** tabs (4.x).

Recommendation

Try again in a few seconds. If you've made changes to the backend or filesystem permissions, stop Cribl Stream, and make sure the `cribl` user owns all relevant assets, before restarting: `sudo chown -R cribl.cribl /opt/cribl`

"KMS saved, but secret exists in destination location. No data was migrated."

This will appear when you attempt to save KMS Settings with a **Secret Path** entry that references a secret that already exists in HashiCorp Vault. It can also occur with OpenID Connect remote authentication. Cribl Stream has aborted the remote write to avoid overwriting an external shared secret.

Recommendation

Edit the Leader Node's `kms.yml` file to use `provider: local`. Then restart Cribl Stream to correct the path conflict.

"The number of Worker Processes has been limited by the license."

Workers use their local license until they connect to the Leader and download their current license data, which is why the message appears in Logs.

Recommendation

Ignore the message. Once the Worker checks in with the Leader and receives the production license, the rest of the Workers will start.

Sources

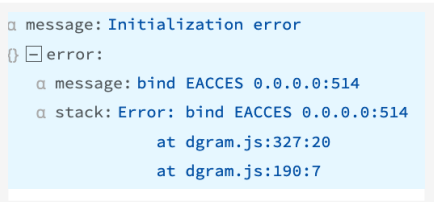
Here are some general errors that can occur with many Sources. When you encounter a problem with a specific Source, check the "Troubleshooting" section in its documentation as well for potential solutions.

"bind EACCES 0.0.0.0:514"

Cribl Stream doesn't have proper privileges to bind to the specified IP and port. Usually, this simply indicates that Cribl Stream is running as a non-root user, but a Source was accidentally configured to use a privileged port below 1024.

Recommendation

Check your Cribl Stream Sources' configuration. The error's `channel` field will indicate which input is affected. If you choose to enable access to the port range below 1024, see our configuration instructions for systemd and initd.



EACCES error

“bind EADDRINUSE 0.0.0.0:9514”

The interface and port combination is already in use by another process, which might or might not be Cribl Stream.

Recommendation

Check your Cribl Stream Sources’ configuration. The error’s `channel` field will indicate which Source is affected, but this error means that one or more other inputs are also using the same IP/port combination.

EADDRINUSE error

Destinations

Here are some general errors that can occur with many Destinations. When you encounter a problem with a specific Destination, check the “Troubleshooting” section in its documentation as well for potential solutions.

“Sending is blocked”

The Destination is blocking. This can occur with any TCP-based Destination, and is logged only after 1 second of blocking. This can also occur between Worker and Leader when the Worker can’t connect to the Leader Node to send metrics data. When triggered by cluster communication, the warning will be in the Worker’s API log.

“Begin backpressure” and “end backpressure”

The Destination is blocking. Like the “sending is blocked” message, “begin backpressure” is logged only after 1 second of blocking. It is logged only once while backpressure is occurring (at the start), and it will always be followed by the “end backpressure” message.

“Unable to write to the filesystem, disk space low”

Full Text: “Unable to write to the filesystem, disk space low, see destination status and logs for more information”

This error can occur if the available disk space on the host is below the specified minimum storage limit.

Recommendation

To check this limit, in **Worker Group Settings**, select **General Settings** > **Limits**, and then select **Storage**. Make sure the available disk space in the location you're writing to is above the **Min free disk space** listed. See Storage in Worker Group Settings for more information on storage limits.

To prevent Cribl service disruptions due to a full data partition, we recommend setting your staging and PQ directories to a partition other than `/opt/cribl` (or `$CRIBL_HOME` installation).

TLS

"Certificate has expired"

Validate server certs or **Validate client certs** is enabled, and the peer's certificate has expired.

Recommendation

Disable **Validate server certs** or **Validate client certs** (depending on whether Cribl Stream is serving as the client or server), so that encryption can still occur without authentication. Or renew the expired certificate.

"Client network socket disconnected..."

Full Text: "Client network socket disconnected before secure TLS connection was established"

Typically caused by a TLS protocol version mismatch between the client and server.

Recommendation

Verify that client's and server's TLS settings use the same minimum/maximum TLS version.

"Unable to get local issuer certificate"

Client can't validate the server certificate's CA (that is, the issuer) because it doesn't trust the CA certificate. Or vice versa (server can't validate client's certificate CA) if mutual auth is enabled.

Recommendation

The CA certificates used by the server's leaf certificate must be trusted by the client. See Configuring CA certs.

“Self signed certificate”

The client or server was presented with a self-signed cert from the peer, but that cert is not trusted.

Recommendation

The self-signed certificate must be trusted by the peer to which it’s presented. See Configuring CA certs.

“Hostname/IP does not match certificate’s altnames”

Full Text: “Hostname/IP does not match certificate’s altnames: host: <server hostname> is not in the cert’s list” or: “Hostname/IP does not match certificate’s altnames: IP: <server IP> is not in the cert’s list”

The server’s hostname/FQDN used on the client is not found in the CN or SAN attribute of the server’s certificate.

Recommendation

Examine the CN and/or SAN attribute, to see which names are listed that can be used as the server hostname/FQDN on the client. **CN values with spaces are not supported as hostnames/FQDNS.** If there isn’t a SAN attribute, then a new cert will need to be issued.

“No protocols available”

Full Text: “140244944713600:error:141E70BF:SSL routines:tls_construct_client_hello:no protocols available:”

The highest TLS protocol available by the client is still too low for the server to support.

Recommendation

Review the minimum/maximum TLS version settings on the client and server, to ensure that they overlap.

“Wrong version number”

Full Text: “140251374995328:error:1408F10B:SSL routines:ssl3_get_record:wrong version number”

The client is using TLS but the server is probably not configured for TLS.

Recommendation

Review the TLS settings on the server.

Pipelines/Functions

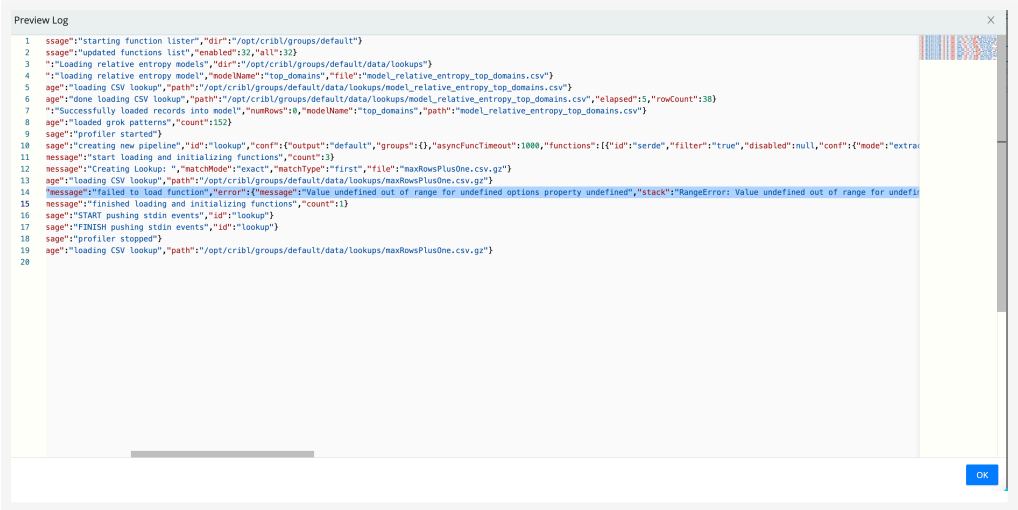
These events will be in the Worker Process logs.

“Failed to load function…Value undefined out of range…”

A Lookup Function attempted to load a Lookup table that exceeded Node.js’ hard size limit of 16,777,216 (that is, 2^{24}) rows.

Recommendation

Split the Lookup table to smaller tables, or use the Redis Function.



Oversized Lookup table error

Diag Command

“You are running Cribl Stream CLI as user=root…”

Full Text: “WARNING: You are running Cribl Stream CLI as user=root, while the binary is owned by the user=cribl. This may change the ownership of some files under CRIBL_HOME=/opt/cribl. Please make sure all files under CRIBL_HOME=/opt/cribl are owned by the user=cribl.”

This is caused by improper ownership on `$CRIBL_HOME`, and will cause some files to be missing from the diag.

Recommendation

Execute the `chown` command on the entire `$CRIBL_HOME` directory, so that everything can be owned by the proper user. Afterward, run the `./cribl diag create` command again.

Distributed Deployment

“Access denied”

The Worker’s authtoken (located in `$CRIBL_HOME/local/_system/instance.yml`) is missing or doesn’t match the Leader’s.

11.3. Git Push Errors

This page anticipates common errors you might see in Cribl Stream's UI, or in the `git` CLI, when pushing a commit.

Failed to Push Some Refs

Your first push to a remote repo might fail with one of several `failed to push some refs` errors.

As a first step in debugging these errors, edit the `$CRIBL_HOME/.git/config` file to make sure that its `name` and `email` key values match the credentials you've set on your repo provider or git server.

Also make sure that the `remote "origin"` key value matches the remote you set when you connected to the remote repo. This example shows all three keys, with placeholder values:

```
[user]
        name = <your-login-name>
        email = <email@example.com>
[remote "origin"]
        url = https://<user-name>:<token>@github.com/<username>/<repo-name>
```

Copy

Next, verify the remote repo from the command line, as follows:

```
cd $CRIBL_HOME/.git
git remote -v
```

Copy

In response, `git` should echo your configured remote twice - once for `fetch` and once for `push` operations.

If all of the above settings are correct, the `push` is very likely blocking because the remote repo has some commit history, or was simply created with a `readme.md` file. For command-line instructions to remedy this - by syncing your local repo to its remote - see GitHub's Dealing with Non-Fast-Forward Errors topic.

Large Files Detected

A push command might also trigger “large file” warnings or, more seriously, errors of this form (CLI/GitHub example):

```
remote: warning: File data/lookups/geo.mmdb is 60.12 MB; this is larger than GitHub's
remote: error: GH001: Large files detected. You may want to try Git Large File Storag
remote: error: Trace: [############################################################
remote: error: See http://git.io/iEPt8g for more information.
remote: error: File groups/default/data/lookups/largelookup.csv is 313.91 MB; this ex
```

Copy

Cribl recommends adding such large files to `.gitignore`, to exclude them from subsequent `push` commands. As the above examples show, typical culprits are large `.csv` or `.mmdb` lookup files. A simple option is to place these files in a `$CRIBL_HOME` subdirectory that’s already listed in `.gitignore` - for details, see About Lookups.

Other available workarounds include staging such files **outside** `$CRIBL_HOME`, or using plugins to accommodate the large files. For GitHub-specific options, see Working with Large Files.

See Also

- Git Remote Repos with Trusted CAs

11.4. Git Remote Repos & Trusted CAs

If you are using an internal Git server, a self-signed certificate might prevent Cribl Stream from successfully pushing commits to the origin. You might see errors like these when pushing (or pulling) via the CLI:

```
SSL certificate problem: self signed certificate in certificate chain
SSL certificate problem: unable to get local issuer certificate
```

Copy

Resolving the Errors

To ensure that Git trusts your self-signed certificate, follow these steps:

1. Obtain the certificate chain (root, intermediates, and leaf) for the Git server.
2. As the `cribl` user, run this command: `git config http.sslCAInfo /path/to/certs.pem`
3. Test with this command: `git push origin` Verify that this throws no errors.

Obtain the Certificate Chain (TLS/SSL)

Use these steps to enable Worker-to-Leader mutual authentication:

A. Validate the Client Certs

If you are using an internal certificate authority, obtain a copy of the CA public certificate, then add it to `/etc/systemd/system/cribl.service`:

```
...
[Service]
Environment="NODE_EXTRA_CA_CERTS=/opt/cribl/local/cribl/auth/certs/ca.pem"
...
```

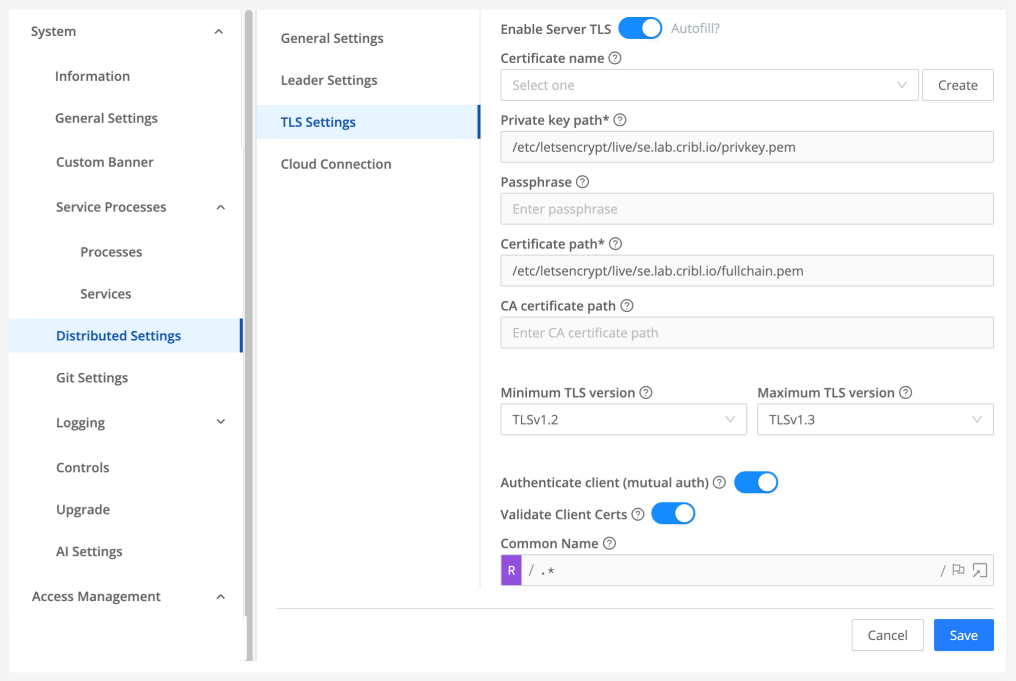
Copy

For details, see CA Certificates and Environment Variables.

B. Simplify the Common-Name Regex

The common-name regex (if required) should omit the `CN=` at the beginning of the **Common Name** field. The following example will match all immediate subdomains of `se.lab.cribl.io`, like `madsci.se.lab.cribl.io`.

If you disable **Validate Client Certs**, Cribl Stream will match only on common names.



Common Name example

C. Extract SSL Certificate Info

As in this example:

```
openssl x509 -in certificate.pem -text -noout
```

Copy

D. Dump the Certificate Chain from the Server

As in this example:

```
echo "" | openssl s_client -host www.google.com -port 443 -showcerts 2>&1 | sed -n '/
```

Copy

11.5. Sample Logs For Login Scenarios

This page lists sample event series that Cribl Stream records in common login scenarios. Cribl Stream captures event series for both successful and failed login attempts. Note that these samples omit the following repeating fields that are captured in each log:

- `cid:api`
- `channel:cribl`
- `level:info`

Successful Authentication Using the `memberOf` Attribute

12. CrowdStream

CrowdStrike announced end-of-life for CrowdStream in March 2026. If you are a current CrowdStream user, see our blog post for more information.

CrowdStream is a special Cloud-hosted version of Cribl Stream, available through CrowdStrike Falcon LogScale. This collaboration is tailored to forward data from a wide range of sources into LogScale for XDR analysis and log management.

En route, you can process events using all of Cribl Stream's options for aggregating, sampling, redacting, cloning, and otherwise shaping and directing your data. CrowdStream provides parallel options to route data to cost-effective Amazon S3 storage, and to S3 data lakes, for later replay and analysis.

Getting Started

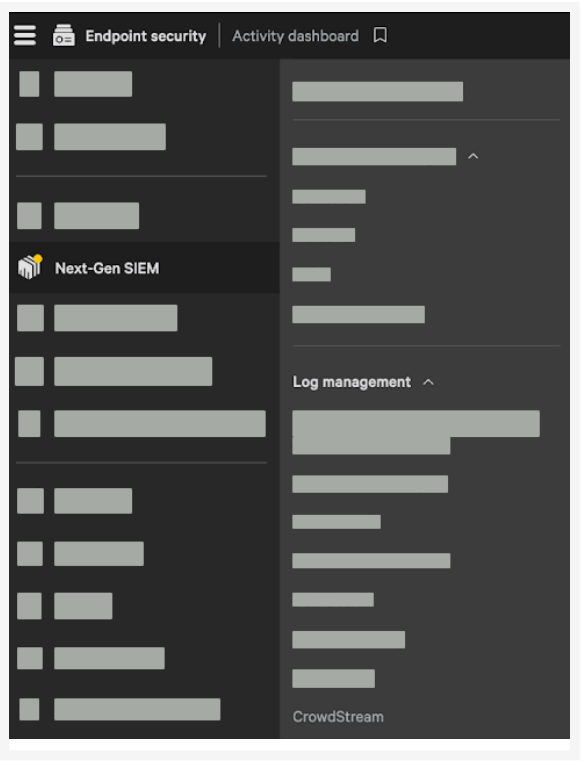
These steps assume that you've set up your CrowdStrike Falcon LogScale account, obtained your corresponding API token.

You can get access to CrowdStream in two ways:

- Through Falcon Next-Gen SIEM interface
- Through Falcon LogScale interface

To log into CrowdStream from Next-Gen SIEM interface:

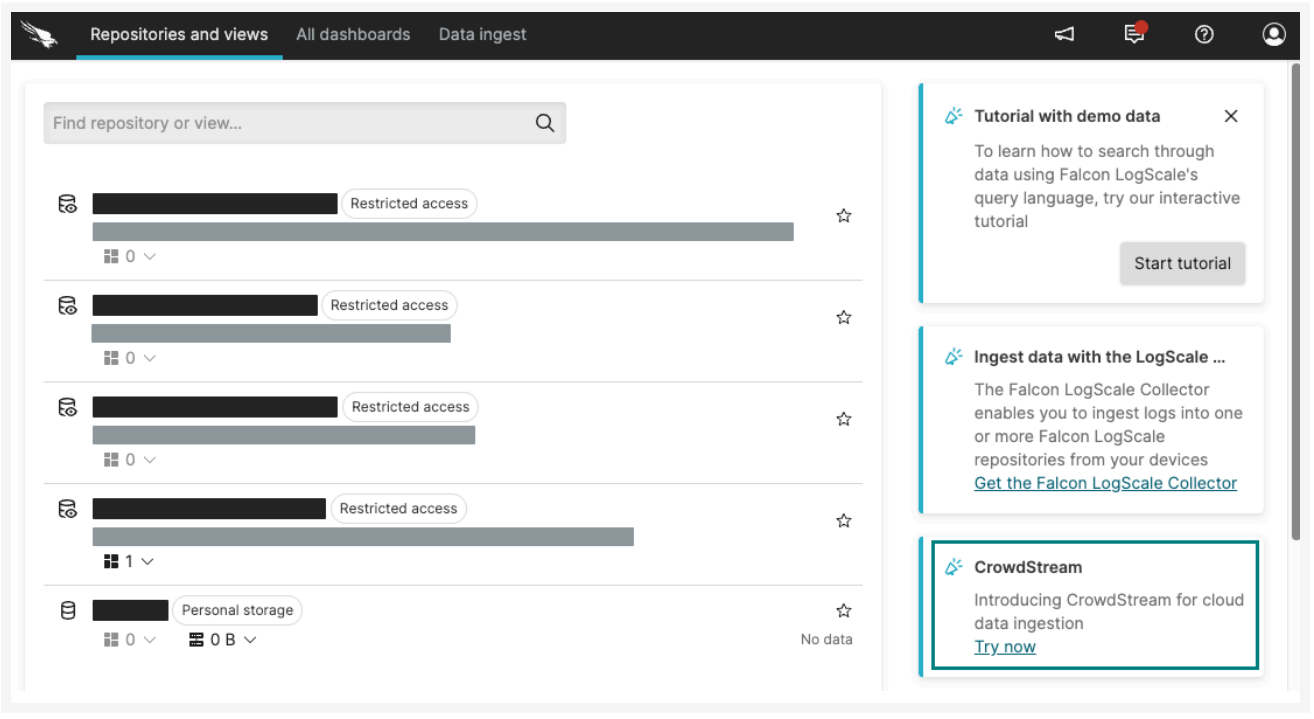
1. In the left menu, select **Next-Gen SIEM**
2. Then, under **Log management** select **CrowdStream**.



Navigating from Next-Gen SIEM to CrowdStream

To log into CrowdStream from LogScale interface:

1. Log into LogScale.
2. On the **CrowdStream** tile at right, select **Try now**.

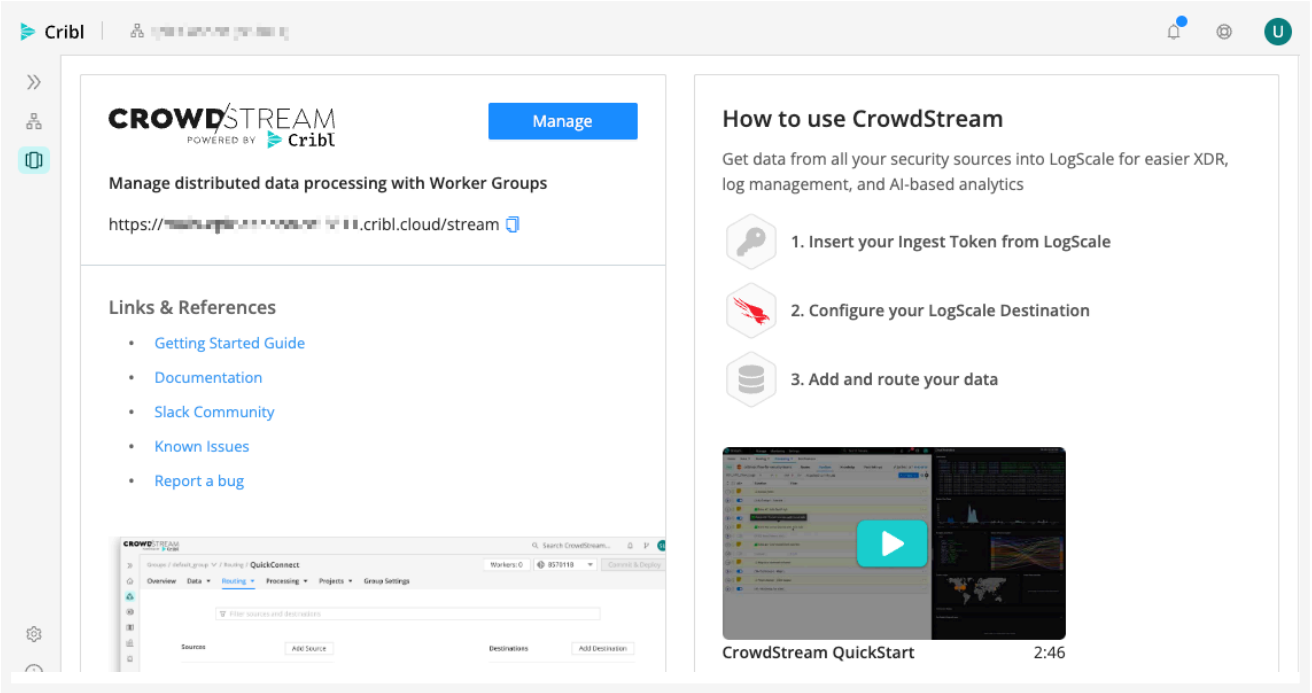


Navigating from LogScale to CrowdStream

3. On the resulting page, select **Log in**.

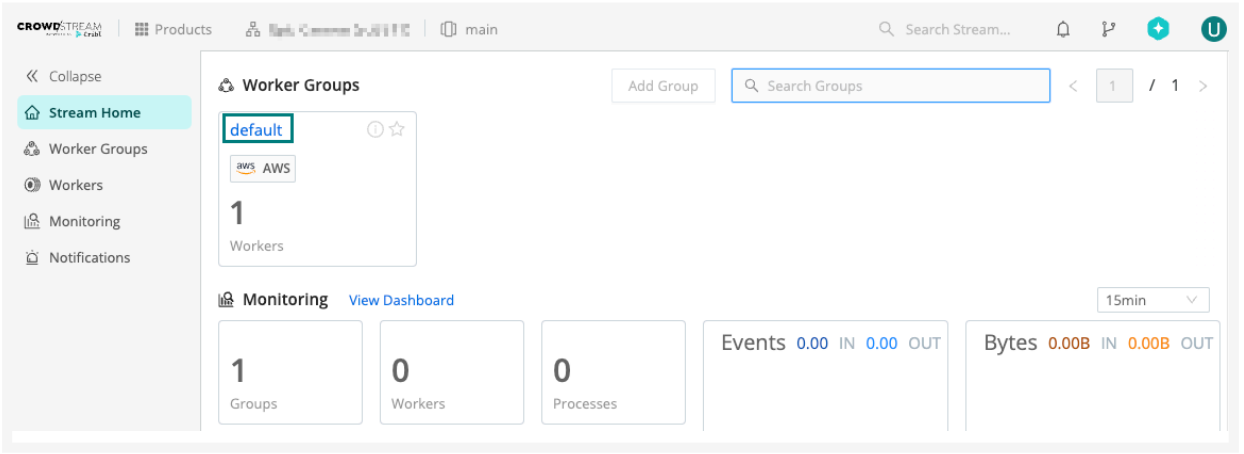
Regardless of your login method, you should now see the CrowdStream home page.

4. Select **Manage** on the **CrowdStream** tile.



Selecting the CrowdStream app

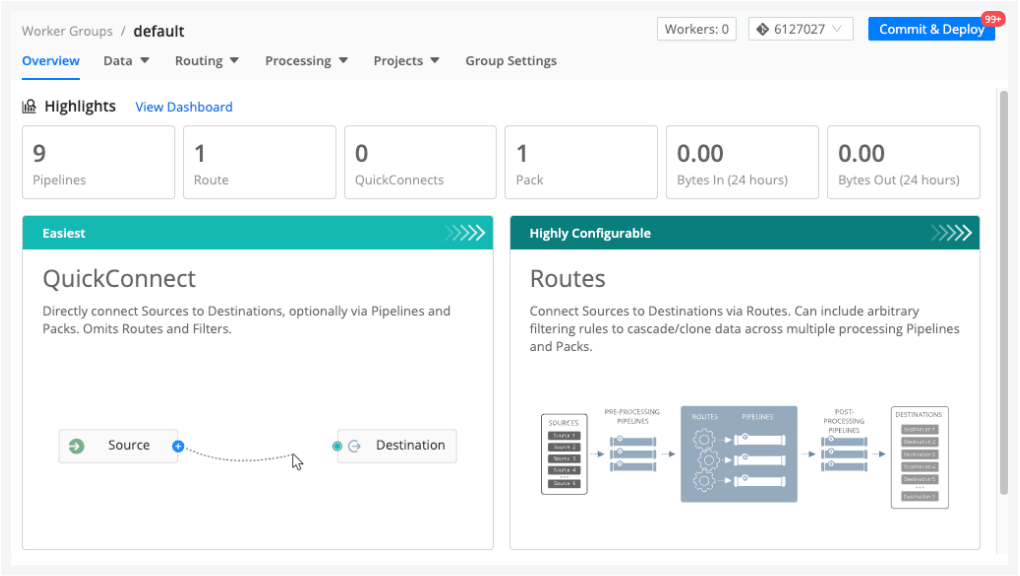
5. On CrowdStream's home page, under **Worker Groups**, select the **default** Group.
(A Worker Group is a collection of processing instances that share the same configuration. For details, see Cribl Stream's Distributed Deployment topic.)



Selecting the **default** Group

If you see a **Worker Group is not provisioned** warning, select the **Provision Now** button to create Workers before proceeding.

6. To configure this Group, you can choose between the **QuickConnect** or **Routes** tiles. How to choose? See the next section.



Group **Overview** page

For More Information

- Cribl.Cloud Launch Guide

Simple or Complex Routing?

Your first choice is how simply or intricately you want to configure data flow from the first data Source you set up. CrowdStream offers two user interfaces:

- QuickConnect (the left tile shown above) provides a simple visual UI. You drag and drop connections from Sources on the left to Destinations on the right. Each connection can include as much or as little intermediate processing as you like. To remove a connection, just drag it off the Destination (you'll get a confirmation modal). The only practical limitation here is that data flow through every Source -> Destination connection must be parallel and independent.
- Data Routing (the right tile shown above) provides fine-grained control, via a more traditional UI that you configure across separate modals and pages. You build a Routing table with conditional processing. This can cascade and clone data across multiple processing Routs, according to the arbitrary filtering rules and sequence that you define.

So the trade-off between these two options is ease of use versus flexibility. These two options are separate, but not mutually exclusive: You can set up simultaneous data flows through QuickConnect and Data Routes.

You can also move Sources, and their connections to Destinations, between the two UIs. So one obvious option is to configure your first data flow in QuickConnect, and then move to the Routing UI as your familiarity and

needs expand.

Here is a lightning-fast (one-minute) preview of **all** the configuration steps below, in QuickConnect:

Navigate Between User Interfaces

To work in QuickConnect, select the left tile shown above, or open the **Worker Groups** and select **Routing** > **QuickConnect**.

To work in the Routing UI, select the right tile shown above, or open the **Worker Groups** submenu and select **Routing** > **Data Routes** .

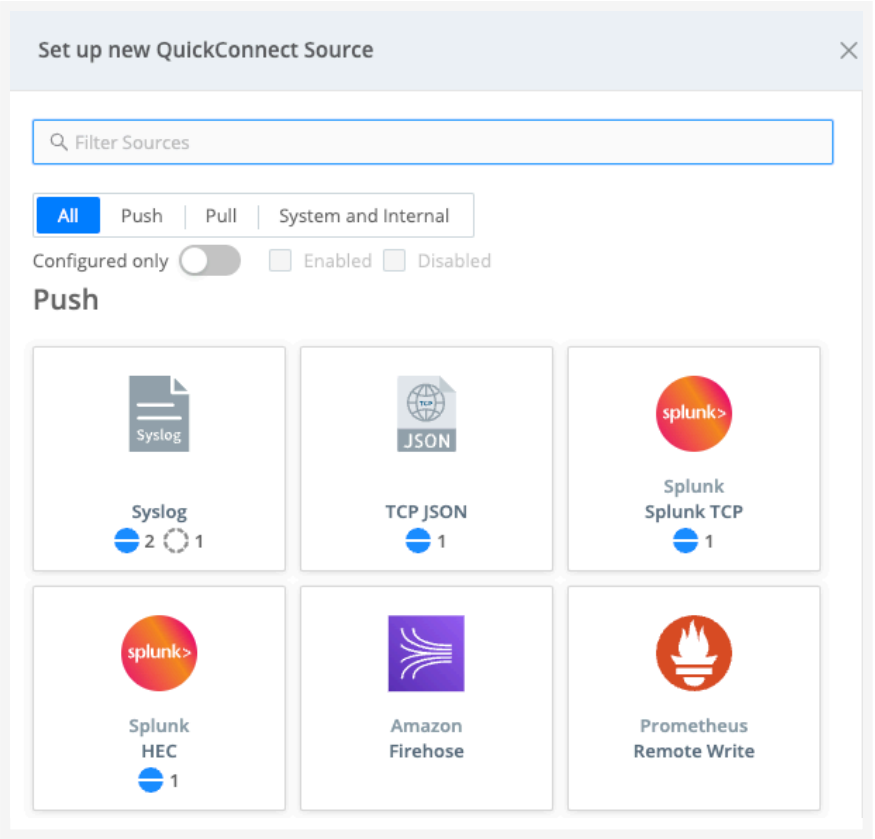
Configure a Source

A CrowdStream Source is a model of an upstream service sending data into the system. In this model, you configure authentication and/or other needed parameters.

You can configure multiple instances of a given Source type, each with different parameters. You can also attach processing that's specific to each instance. CrowdStream provides the Datagen Source type to generate sample inbound events for development and testing.

Using QuickConnect

In QuickConnect, select **Add Source** on the left (Sources) side. In the resulting left drawer, search for and select your desired Source type to begin configuring a new instance of that Source.



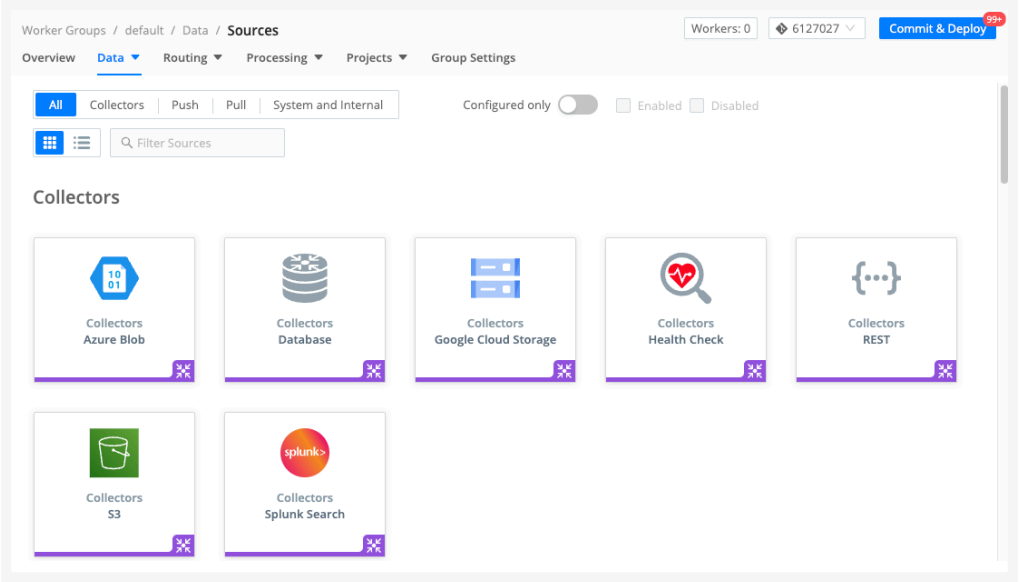
Selecting a Source through the QuickConnect UI

To configure (or reconfigure) a Source that's already present in QuickConnect, hover over its tile and select **Configure**. Note that for multiple Sources of the same type, tiles will display stacked until you hover over the stack.

Using Data Routes

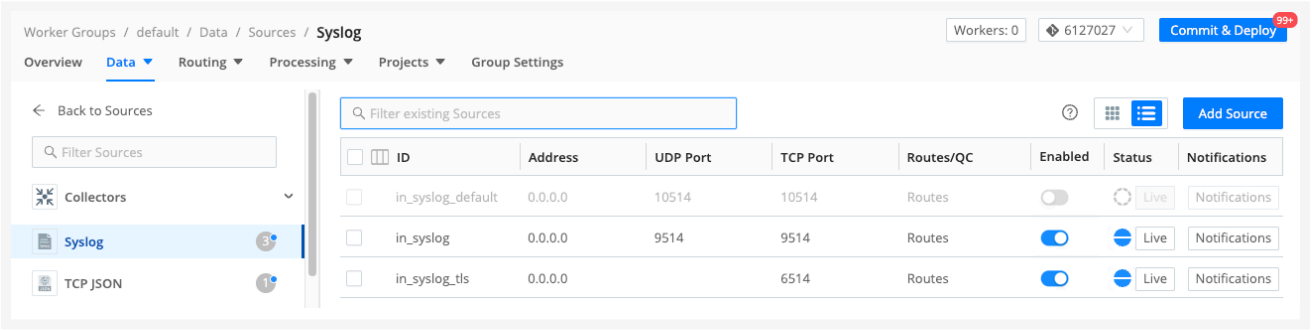
To use the Routing UI, on the **Worker Groups** submenu select **Data**, then **Sources**. On the resulting **Sources** page, search for your desired Source type, then select its tile to begin configuring a new instance of that Source.

(After you click through to a Source, the same set of peer Sources will be available in the left nav.)



Sources page

Select an existing Source's row here to access its configuration, or select **Add Source** to configure a new instance of that Source.



Manage Syslog Sources UI

To get data flowing, jump ahead to commit and deploy your new configuration.

For More Information

- Sources
- Using Datagens
- QuickConnect
- Routes

Configure a Destination

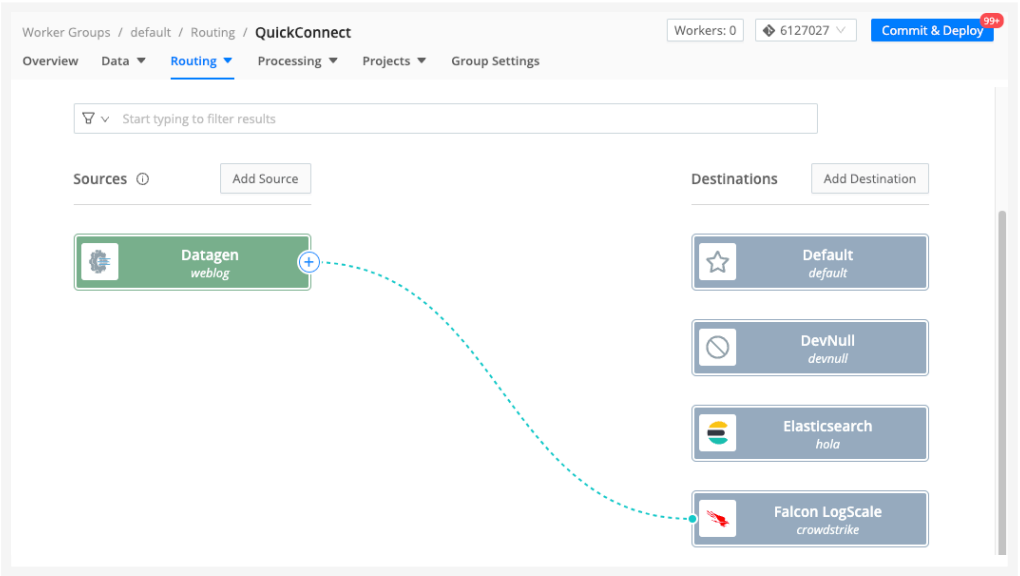
A CrowdStream Destination is a model of a downstream receiver of events, enabling you to configure authentication and/or other needed parameters.

As with Sources, you can configure multiple instances of a given Destination type, each with different parameters. You can attach processing that's specific to each instance. CrowdStream provides the following Destinations:

- CrowdStrike Falcon LogScale - Set up your LogScale endpoint, token, and other parameters here.
- Amazon S3 Compatible Stores - Route full-fidelity data to cost-effective storage for later replay and analysis.
- Data Lakes > Amazon S3 - Store full-fidelity data for later retrieval or analysis. Compatible with Cribl Search (a separate product).
- DevNull - This output simply consumes and discards events, to facilitate development and testing.

Using QuickConnect

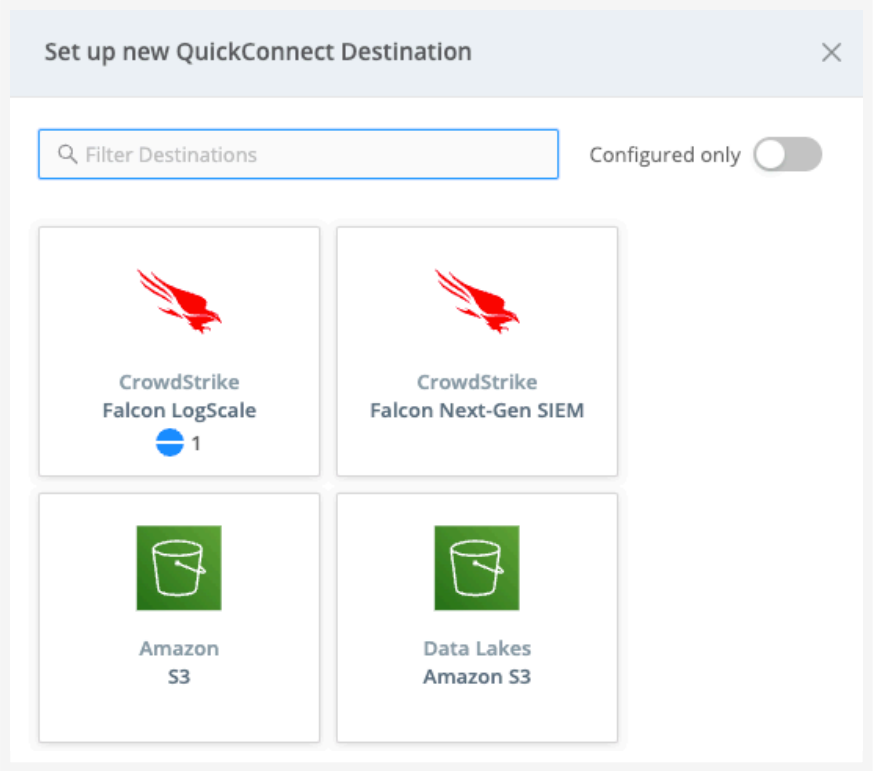
To connect a configured Source to a Destination tile already present on the right, just drag from the Source and drop the connector onto the Destination. A pop-up will prompt you to configure the connection via a Passthru, Pipeline or Pack (explained below).



Multiple Destinations added to QuickConnect

To configure (or reconfigure) the Destination, hover over its tile and select **Configure**. For multiple Destinations of the same type, tiles will display stacked until you hover over the stack.

To add a new Destination, select **Add Destination** on the right (Destinations) side. In the resulting right drawer, search for and select your desired Destination type to begin configuring a new instance of that Destination.

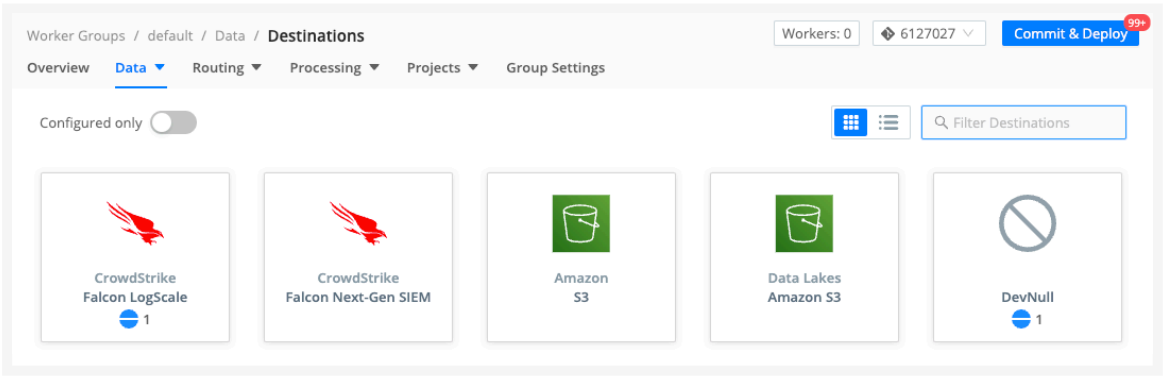


Selecting additional Destinations in QuickConnect

Using Data Routes

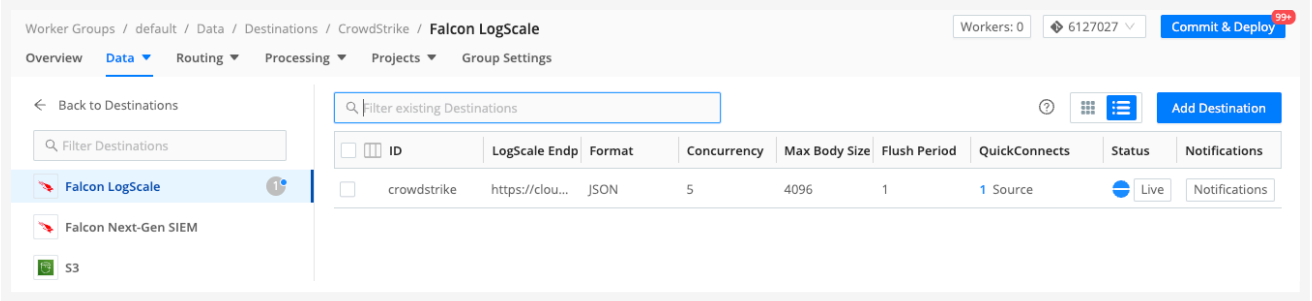
To use the Routing UI, on the **Worker Groups** submenu select **Data**, then **Destinations**. On the resulting **Destinations** page, search for your desired Destination type, then select its tile to begin configuring it.

(After you click through to a Destination, the same set of peer Destinations will be available in the left nav.)



Destinations page

Select an existing Destination's row here to access its configuration, or slect **Add Destination** to configure a new instance of that Destination.



Manage LogScale Destinations UI

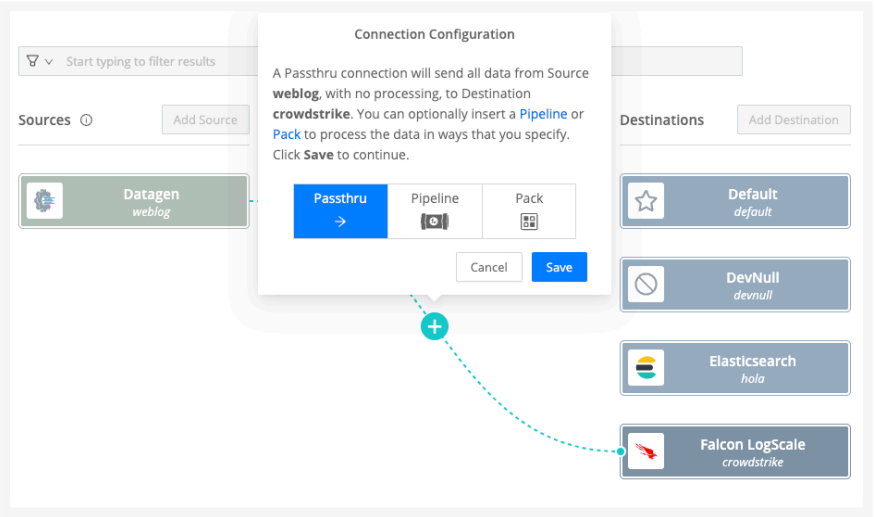
To get data flowing, jump ahead to commit and deploy your new configuration.

For More Information

- See the individual Destination topics linked at the head of this section.

Connect: Passthru, Pipeline, or Pack

In QuickConnect, as soon as you drag and drop a Source -> Destination connection, a pop-up dialog will prompt you to select a connection type: **Passthru**, **Pipeline**, or **Pack**. (In Data Routes, you'll make the same choices elsewhere.)



Connection-type selector in QuickConnect

What are these options?

- A **Passthru** establishes a simple direct connection between a Source -> Destination pair.
- A Pipeline hosts a stack of Functions to process your data, in the order you arrange them.

- A Pack is a microcosm of a whole CrowdStream configuration, designed to share configs between Worker Groups or deployments. A Pack can encapsulate its own Pipelines, Routes, Knowledge libraries, and sample data (but not data Sources or Destinations). A Pack can snap in wherever you can use a Pipeline.

So let's unpack Pipelines, where you'll define most of your event processing.

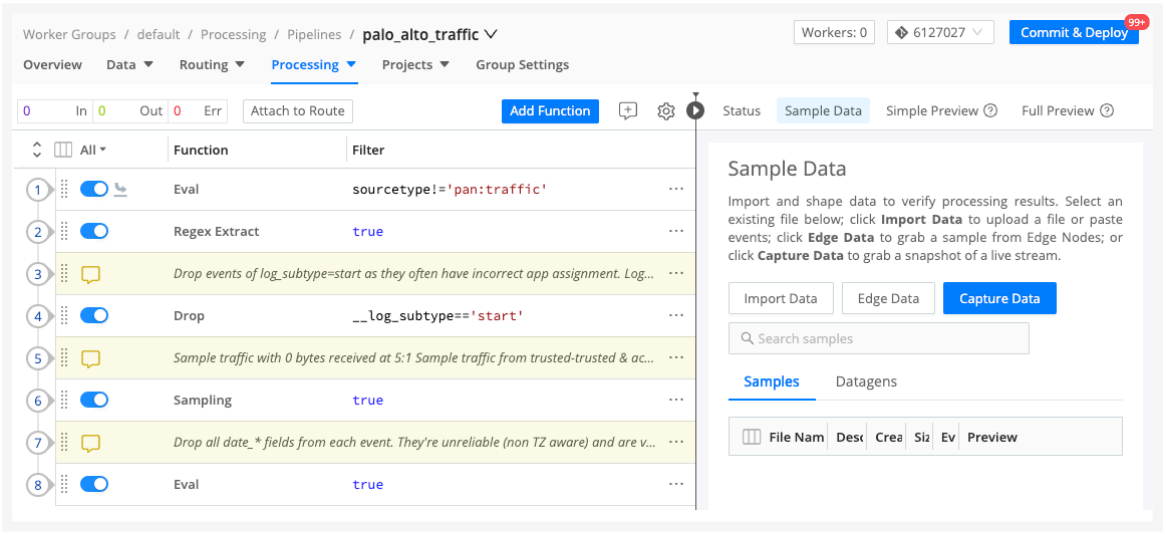
Pipeline Options

When you first create a new Pipeline, it's empty, making it equivalent to **Passthru**. CrowdStream provides a set of out-of-the-box Pipelines for specific purposes. As you can see below, one of these is a **Passthru** Pipeline. This similarly contains no Functions - making it the Data Routes UI's equivalent of QuickConnect's **Passthru** button.

For these reasons, it's easy to start with an empty Pipeline, and then add Functions as you need them.

A Pipeline, as you populate it, is a stack of processing Functions and optional comments. Use the accordions on the left to expand or collapse each Function. Use the toggles on the left to enable/disable each Function - preserving structure as you develop and debug.

Use the right **Sample Data** pane to preview how the Pipeline's current state transforms a set of events. (Controls here enable you to capture live data, save it to sample or datagen files, and reload those files.)



A Pipeline's Functions stack

Although you'll configure most data shaping in processing Pipelines between Sources and Destinations, you can also attach a pre-processing Pipeline to any Source instance, and a post-processing Pipeline to any Destination instance. Use these options when you need to "condition" the specific data type handled by a particular inbound or outbound integration.

Connect via QuickConnect

To select a connection type in QuickConnect, select the appropriate button in the pop-up dialog shown above. To accept the default **Passthru** option, select **Save**. Your Source and Destination will now be connected.

If you select **Pipeline**, you'll see an **Add Pipeline to Connection** modal. Here, you can choose an existing Pipeline, or select **Add Pipeline** to define a new one. Then select **Save** here to establish the connection.

Selecting **Pack** opens an **Add Pack to Connection** modal that works exactly the same way.

Whichever option you choose here, your connection between this Source and Destination is now complete.

To get data flowing, jump ahead to commit and deploy your new configuration.

Connect via Data Routes

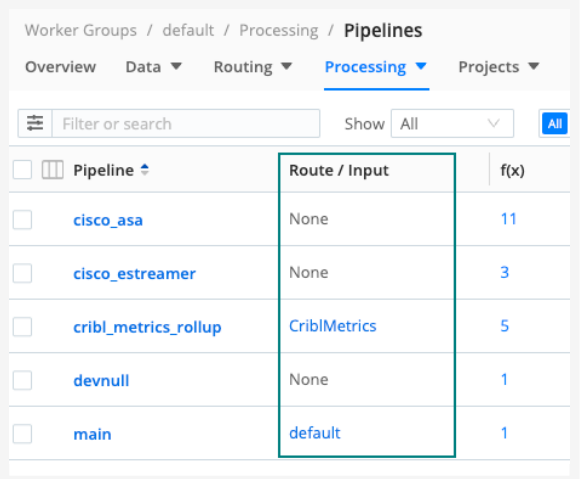
The Data Routes UI enables you to finely configure multiple, interdependent connections between Sources and Destinations. Events clone and cascade across a Routing table, based on the filtering rules and sequence you define.

In exchange for this flexibility, you sacrifice QuickConnect's one-stop, snap-together UI metaphor. After configuring your Sources and Destinations - which you've already done above - you need to connect them by separately setting up at least one Pipeline and one Route.

Pipelines Access

On the **Worker Groups** submenu, select **Processing**, then **Pipelines**. In addition to the minimal **Passthru** Pipeline identified above, other simple building blocks here include **main** (which initially contains only a simple Eval Function) and **devnull** (which contains a single Function that just drops events).

Out-of-the-box Pipelines are already connected to Routes. On the **Pipelines** page, the **Route/Input** columns displays the connected Route, as shown here. But as our final connection step, let's next look at how to connect up everything (Source, Pipeline, Destination) in a Route.



Checking Pipelines Route connections

For More Information

- Refine Data with Functions walks you through configuring CrowdStream's built-in Pipeline Functions to perform common processing tasks like parsing, masking, adding, deleting, and renaming event fields.

Configure a Route

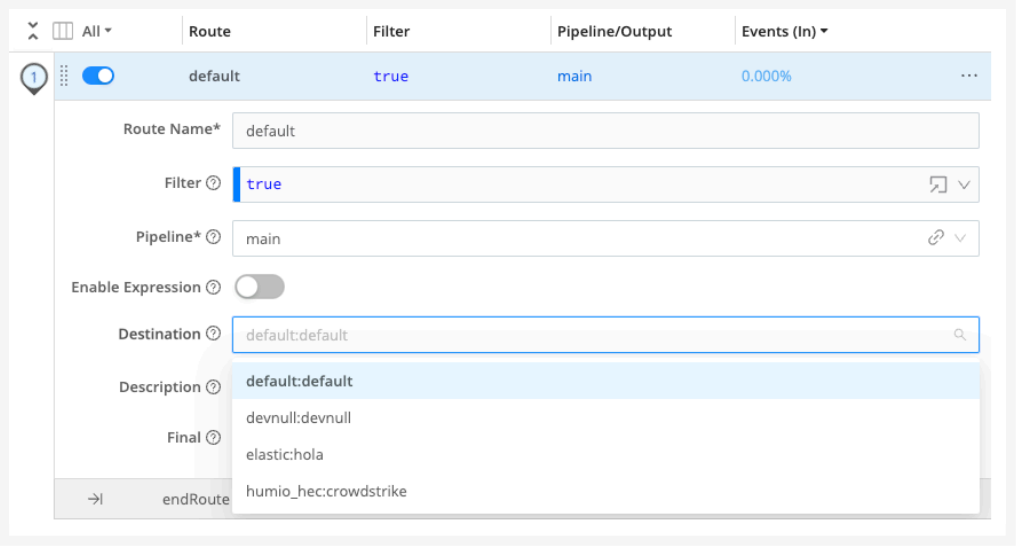
In the Data Routes UI, a Route is where you complete a data-flow connection. Each Route connects exactly one Pipeline with exactly one Destination.

This combination can consume data from one, multiple, or all the Sources you've configured on the Data Routes side. (QuickConnect Sources are separate, but you can open those Sources' configs to move them to the Data Routes UI.) This is governed by the filtering we'll see below.

To open the Routing table, on the **Worker Groups** submenu, select **Routing**, then **Data Routes**.

CrowdStream ships with one starter Route named **default**. It's configured as follows:

- The **Filter** expression is set to **true**. This simple, default expression makes data from **all** active Sources available to this Route. (See finer filtering options below.)
- The **Pipeline** drop-down is where you set the 1:1 Pipeline:Route connection. This starter Route's Pipeline defaults to **main**, but you can select any one other configured Pipeline.
- The **Destination** drop-down defines the single Destination for this Pipeline:Route connection. If this isn't already set to your LogScale Destination, you'll most likely want to select that here. (Note that each option displayed on this list corresponds to the unique, arbitrary **Output ID** set on one **instance** of a Destination type. So some names might initially be unfamiliar.)



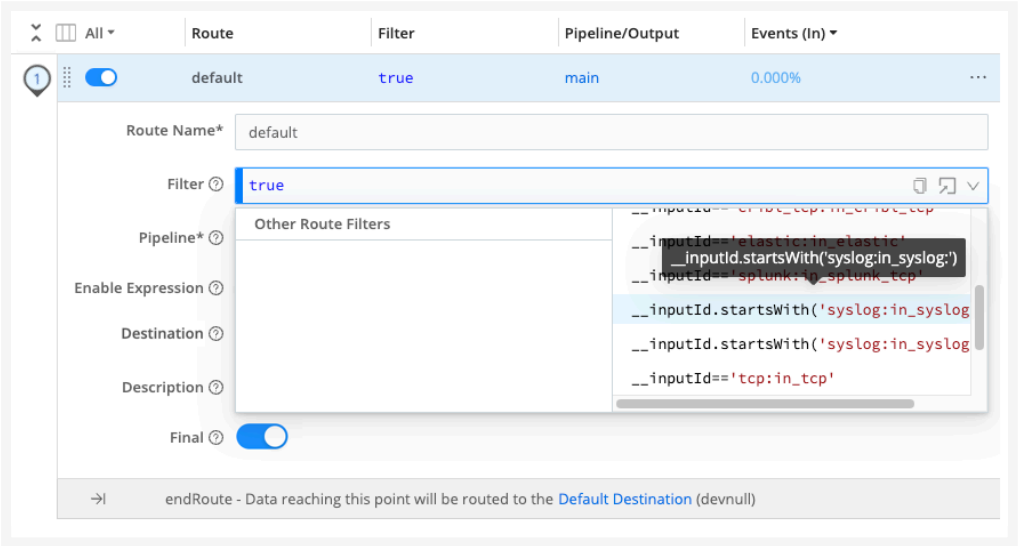
Changing a Route's Destination

To get data flowing, jump ahead to commit and deploy your new configuration.

Filter a Route's Input Data

When you want a Route to ingest data from only one Source, or a subset of Sources, you expand its **Filter** expression beyond the default **true** catch-all.

Filter is itself a drop-down. Open it to select among typeahead suggestions for several common inbound data types.



Tuning a Route's Filter expression

You can select one of these expressions and then modify it, using the same `__inputId` syntax. In the example expression below, note that the identifier after the `:` is - as with the **Destination** options we saw above - the arbitrary name of one Syslog Source instance:

```
__inputId.startsWith('syslog:in_syslog:')
```

For More Information

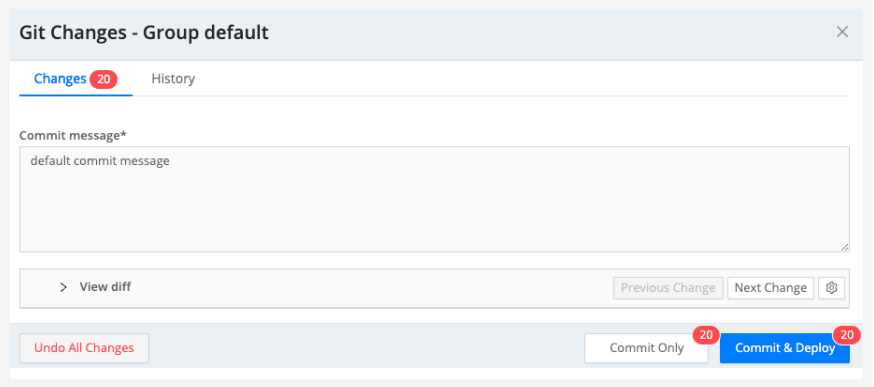
- Build Custom Logic to Route and Process Your Data: Filter Expressions

Commit/Deploy Config Changes

To get data flowing as you expect, you'll always need to use CrowdStream's built-in Git version-control integration to commit your configuration changes and deploy them to your event-processing Worker instances. After any significant configuration change, you'll be prompted with Group-level **Commit & Deploy** button at the upper right

Depending on your version control settings, **Commit** and **Deploy** might appear as separate buttons.

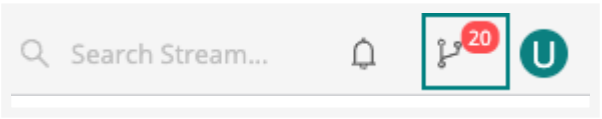
Selecting either flavor of the **Commit** button will display a confirmation modal like this. You can either accept the default commit message, or enter a specific message. Then be sure to select the appropriate buttons to both commit **and** deploy your changes.



Confirming a commit

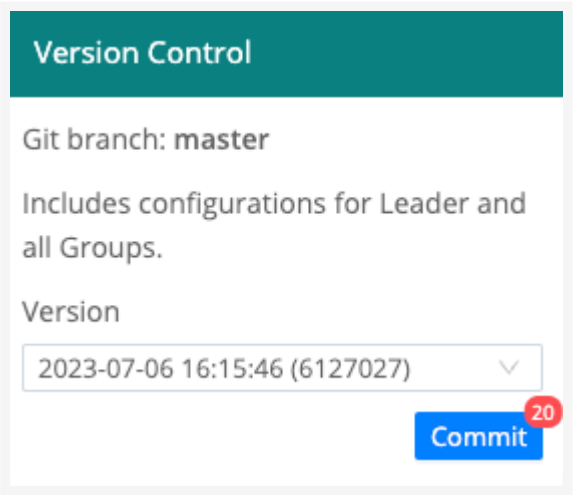
Data should now start flowing through the Workers. (You can check this by selecting the top nav's **Monitoring** link. This takes you to read-only dashboards, so remember to select **Manage** when you want to return to configuration options.)

In return for clearing all the red-dot prompts, your reward will be one more red dot, on the top nav's CrowdStream-wide Version Control button. This is because CrowdStream sees the preceding deploy to Workers as a change to record (commit) on the **Leader's** configuration.



Leader commit prompt

This top-level commit isn't necessary to enable data flow, but it backs up and safeguards your overall configuration. Select the button to display one final confirmation prompt:



Confirming a commit on the Leader

Select **Commit** here, and your configuration is complete!
