1. About Cribl Edge 14
1.1. Basic Concepts 16
1.2. Log in to Cribl 19
1.3. QuickConnect 20
1.4. Onboard Faster With Packs 26
1.4.1. Get Pre-Built Pack Content 27
2. Explore Cribl Edge 32
2.1. Explore Cribl Edge Nodes 35
3. Cribl Edge on Linux 45
3.1. Install Cribl Edge on Linux 46
3.2. Enable Start on Boot on Linux 53
3.3. OS Tuning for Large Deployments 58
3.4. Run Edge as an Unprivileged Linux User 65
3.5. Install Edge on Linux via RPM 67
3.6. Install Edge on Linux via .deb 71
3.7. FIPS Mode for Cribl Edge (Linux) 74
3.8. Use ACLs to Allow Cribl Edge to Read Files 81
4. Cribl Edge on Windows 84
4.1. Install Cribl Edge on Windows 86
4.2. Windows User Permissions and Requirements 98
4.3. System Proxy Configuration on Windows 103
4.4. Windows Troubleshooting 107
4.5. FIPS Mode for Cribl Edge (Windows) 109
5. Cribl Edge on MacOS 115
5.1. Install Cribl Edge on MacOS 117
5.2. Deploy Cribl Edge on MacOS with JAMF 120
6. Cribl Edge in Containers 122
6.1. Run Cribl Edge in a Docker Container 123
6.2. Deploy Cribl Edge via Kubernetes 128
7. Set Up Cribl Edge 139
7.1. Get Started with Cribl Edge 140
7.2. Cribl.Cloud vs. Self-Hosted 144
7.3. Learn About Connected Environments 148
7.3.1. How to Connect On-Prem Leaders to Cribl.Cloud 150
7.3.2. Simplify Billing with Universal Subscription 154
7.3.3. Data Payloads for Connected Environments 156

7.3.4. Send Data from On-Prem to Cribl.Cloud 161
7.4. Tutorials 164
7.4.1. Route Collected Data 165
7.4.2. Forward Custom Data with Cribl Edge Tags 167
7.4.3. Monitor your Infrastructure with Cribl Edge 172
7.4.4. Monitor and Troubleshoot Cribl Edge 177
7.4.5. Migrate from Third-Party Agents to Cribl Edge 182
7.5. Deployment Planning 190
7.5.1. OS and System Requirements 194
7.5.2. Plan Large-Scale Deployments of Cribl Edge 197
7.6. Set Up Leader and Edge Nodes 200
7.7. Connect Nodes to Leader Through Cribl Outpost 206
7.7.1. Set Up Cribl Outpost 209
7.7.2. Manage Cribl Outpost 213
7.7.3. Configure Outpost Group Settings 216
7.8. Set Up Version Control 220
7.9. Manage Edge Node Config Bundles 221
7.10. Configurations and Restart 225
7.11. Leader High Availability/Failover 228
7.11.1. High Availability Requirements 231
7.11.2. Configure Standby Leader Nodes 235
7.11.3. Manage High Availability Deployment 238
7.12. Anti-Virus Exceptions 240
7.13. Ports 242
7.14. Configure Environment Variables 247
7.15. About Cribl.Cloud 250
7.15.1. Register Cribl.Cloud Organization 252
7.15.2. Manage Cribl.Cloud Organization 254
7.15.3. Cribl.Cloud Enterprise 256
8. Manage Fleets of Edge Nodes 259
8.1. Fleets 262
8.1.1. Design Fleet Hierarchy 267
8.1.2. Fleet Inheritance 271
8.1.3. Create and Manage Fleets and Subfleets 273
8.1.4. Configure Fleets and Deploy Changes 278
8.1.5. Recover a Deleted Fleet 282
8.2. Edge Nodes 283
8.2.1. Manage Edge Nodes 285

8.2.2. Add and Update Edge Nodes 289
8.2.3. Filter Edge Nodes 293
8.2.4. Map Edge Nodes to Fleets 302
9. Workspaces 307
9.1. Configure Workspaces 314
9.2. Enable Static Egress IPs for Cribl.Cloud 318
10. Administration 320
10.1. Upgrade Cribl Edge 321
10.1.1. Upgrade Leader Node 323
10.1.2. Upgrade Outpost 328
10.1.3. Edge Node Upgrades 329
10.1.3.1. Upgrade Edge Nodes in a Fleet 331
10.1.3.2. Upgrade Edge Nodes Manually 333
10.1.4. Upgrade Containers 336
10.1.5. Better Practices for Upgrading Cribl Edge 339
10.1.6. Monitor Node Upgrade Status 342
10.1.7. Fleet Upgrading Use Case 344
10.1.8. Roll Back Cribl Edge 345
10.1.9. Troubleshoot Edge Upgrades 347
10.2. Notifications 350
10.2.1. Email Notifications 357
10.2.2. Notification Targets 362
10.2.2.1. Webhook Notification Targets 364
10.2.2.2. PagerDuty Notification Targets 371
10.2.2.3. Slack Notification Targets 373
10.2.2.4. AWS SNS Notification Targets 375
10.2.2.5. Email Notification Targets 379
10.3. Configuration Management 382
10.3.1. Commit and Deploy Changes 383
10.3.2. Connect to External Git Repositories 389
10.3.3. Configure Fleet Settings 402
10.4. Uninstall Cribl Edge from Linux 415
10.5. Uninstall Cribl Edge from Windows 416
10.6. Uninstall Cribl Edge from MacOS 417
10.7. Customize the Interface 418
10.7.1. Custom Banners 419
10.7.2. Custom Login Page 420
10.8. Scripts 421

11. Secure Your Deployment 423
11.1. Secure Your Cribl.Cloud Deployment 424
11.2. Secure Your On-Prem/Hybrid Deployment 427
11.3. Secure Node Access 433
11.4. Create and Manage Authentication Tokens 434
11.5. Configure TLS 438
11.5.1. Add TLS Certificates and Keys 439
11.5.2. Secure Leader-Edge Node Communication with TLS 444
11.5.3. Secure Leader-Node Communication with mTLS (On-Prem) 448
11.5.4. Secure Sources and Destinations with TLS and mTLS 452
11.5.5. Configure TLS for API and UI Access 456
11.5.6. TLS Defaults and System-wide Settings 458
11.6. Custom HTTP Headers 464
11.7. Configure System Proxy 466
11.8. Configure SOCKS Proxy 471
11.9. Centralize and Reuse Global Secrets 477
11.9.1. Add, Use, and Deploy Global Secrets 480
11.9.2. Rotate Global Secrets 487
11.9.3. Back Up, Audit, and Troubleshoot Global Secrets 489
11.9.4. Connect External Secret Stores 496
11.9.4.1. Connect Azure Key Vault Secret Stores 497
11.9.4.2. Connect HashiCorp Vault Secret Stores 501
11.10. Create and Manage Legacy Secrets in Cribl Edge 505
11.11. Configure KMS Providers 512
11.12. Create and Manage Encryption Keys 520
11.13. Compliance 522
11.13.1. FIPS Mode for Cribl Edge (Linux) 523
11.13.2. FIPS Mode for Cribl Edge (Windows) 530
11.13.3. SELinux (Enforcing Mode) Configuration 536
12. Integrations 542
12.1. Common Data Flows 543
12.1.1. Collect Logs with File Monitor 544
12.1.2. Collect CSV Files with File Monitor 546
12.1.3. Collect Windows Event Logs and Metrics 548
12.1.4. Collect Kubernetes Logs, Events, and Metrics 552
12.1.5. Collect and Visualize Nvidia GPU Metrics 556
12.1.6. Send Data from Cribl Edge to Cribl Stream 561
12.1.7. Send Data to Loki and Prometheus 565

12.2. Sources Overview 567
12.2.1. System 574
12.2.1.1. Exec Source 575
12.2.1.2. File Monitor Source 582
12.2.1.3. Journal Files Source 595
12.2.1.4. Kubernetes Events Source 599
12.2.1.5. Kubernetes Logs Source 605
12.2.1.6. Kubernetes Metrics Source 612
12.2.1.7. System Metrics Source 617
12.2.1.8. System State Source 624
12.2.2. Internal 636
12.2.2.1. Cribl HTTP Source 637
12.2.2.2. Cribl TCP Source 646
12.2.2.3. Cribl Internal Source 653
12.2.2.4. Datagen Source 658
12.2.3. Prometheus 661
12.2.3.1. Prometheus Edge Scraper Source 662
12.2.3.2. Prometheus Remote Write Source 670
12.2.3.3. Grafana Source 680
12.2.3.4. Loki Source 691
12.2.4. Splunk 701
12.2.4.1. Splunk HEC Source 702
12.2.4.2. Splunk TCP Source 719
12.2.5. Windows 730
12.2.5.1. Windows Event Forwarder Source 731
12.2.5.1.1. Client Certificate Authentication for Windows Event Forwarder 750
12.2.5.1.2. Kerberos Authentication for Windows Event Forwarder 754
12.2.5.2. Windows Event Logs Source 759
12.2.5.3. Windows Metrics Source 765
12.2.6. Apple Unified Logs Source 772
12.2.7. AppScope Source 776
12.2.8. Cloudflare Source 777
12.2.9. Datadog Agent Source 790
12.2.10. Elasticsearch API Source 805
12.2.11. HTTP/S (Bulk API) Source 818
12.2.12. Raw HTTP/S Source 832
12.2.13. Metrics Source 846
12.2.14. OpenTelemetry (OTel) Source 855

12.2.15. SNMP Trap Source 869
12.2.16. Syslog Source 877
12.2.17. TCP JSON Source 891
12.2.18. TCP (Raw) Source 900
12.2.19. UDP (Raw) Source 909
12.3. Destinations 917
12.3.1. Manage Destinations 925
12.3.2. Internal 930
12.3.2.1. Cribl HTTP Destination 931
12.3.2.2. Cribl TCP Destination 943
12.3.2.3. Cribl Search Destination 953
12.3.2.4. Disk Spool Destination 963
12.3.2.5. Default Destination 966
12.3.2.6. DevNull Destination 967
12.3.2.7. Output Router Destination 968
12.3.3. Amazon 972
12.3.3.1. Amazon CloudWatch Logs Destination 973
12.3.3.2. Amazon Kinesis Data Streams Destination 980
12.3.3.3. Amazon S3 Compatible Stores Destination 989
12.3.3.4. Amazon SQS Destination 1000
12.3.3.5. Amazon Security Lake Destination 1008
12.3.4. Azure 1016
12.3.4.1. Azure Blob Storage Destination 1017
12.3.4.2. Azure Data Explorer Destination 1025
12.3.4.3. Azure Event Hubs Destination 1039
12.3.4.4. Azure Monitor Logs Destination 1049
12.3.4.5. Microsoft Sentinel Destination 1058
12.3.5. Elastic 1071
12.3.5.1. Elasticsearch Destination 1072
12.3.5.2. Elastic Cloud Destination 1084
12.3.6. Google Cloud 1093
12.3.6.1. Google BigQuery Destination 1094
12.3.6.2. Google Security Operations (SecOps) Destination 1100
12.3.6.3. Google Cloud Chronicle API Destination 1111
12.3.6.4. Google Cloud Logging Destination 1120
12.3.6.5. Google Cloud Observability Destination 1128
12.3.6.6. Google Cloud Pub/Sub Destination 1137
12.3.6.7. Google Cloud Storage Destination 1144

12.3.7. Kafka 1151
12.3.7.1. Kafka Destination 1152
12.3.7.2. Confluent Cloud Destination 1164
12.3.7.3. Amazon MSK Destination 1175
12.3.8. Metrics 1187
12.3.8.1. Graphite Destination 1188
12.3.8.2. StatsD Destination 1193
12.3.8.3. StatsD Extended Destination 1198
12.3.9. New Relic Ingest 1203
12.3.9.1. New Relic Events Destination 1204
12.3.9.2. New Relic Logs & Metrics Destination 1212
12.3.10. Prometheus 1221
12.3.10.1. Prometheus Destination 1222
12.3.10.2. Grafana Cloud Destination 1232
12.3.10.3. Loki Destination 1243
12.3.11. Splunk 1252
12.3.11.1. Splunk HEC Destination 1253
12.3.11.2. Splunk Single Instance Destination 1265
12.3.11.3. Splunk Load Balanced Destination 1273
12.3.12. Alibaba OSS Destination 1286
12.3.13. CrowdStrike Falcon LogScale Destination 1295
12.3.14. ClickHouse Destination 1304
12.3.15. Cortex XSIAM Destination 1317
12.3.16. CrowdStrike Falcon Next-Gen SIEM Destination 1327
12.3.17. Databricks Destination 1337
12.3.18. Databricks Zerobus Destination 1343
12.3.19. Datadog Destination 1350
12.3.20. Dynatrace HTTP Destination 1361
12.3.21. Dynatrace OTLP Destination 1371
12.3.22. Exabeam Destination 1380
12.3.23. Microsoft Fabric Real-Time Intelligence 1387
12.3.24. Filesystem/NFS Destination 1393
12.3.25. Honeycomb Destination 1399
12.3.26. IBM Cloud Object Storage Destination 1407
12.3.27. InfluxDB Destination 1415
12.3.28. MinIO Destination 1423
12.3.29. OpenTelemetry (OTel) Destination 1433
12.3.30. SentinelOne AI SIEM Destination 1445

12.3.31. SentinelOne DataSet Destination 1454
12.3.32. ServiceNow Cloud Observability 1464
12.3.33. SignalFx Destination 1475
12.3.34. SNMP Trap Destination 1483
12.3.35. Sumo Logic Destination 1486
12.3.36. Syslog Destination 1496
12.3.37. TCP JSON Destination 1510
12.3.38. Wavefront Destination 1518
12.3.39. Webhook Destination 1526
12.4. Manage Backpressure 1544
12.4.1. About Persistent Queues 1545
12.4.2. Optimize Source Persistent Queues 1554
12.4.3. Optimize Destination Persistent Queues 1570
12.4.4. About Destination Backpressure Triggers 1591
12.4.5. Backpressure Impacts to Sources 1598
12.5. About Load Balancing 1602
12.6. Transfer Data Between Workspaces or Environments 1605
12.7. Cribl-to-Cribl Compatibility Matrix 1609
12.8. Integrate with Other Services 1616
12.8.1. Cribl Edge as a Sidecar Container in AWS ECS 1617
12.8.2. Amazon Security Lake Integration 1622
12.8.3. Amazon Elastic Kubernetes Services (EKS) Add-On for Edge 1631
13. Monitor Health and Metrics 1636
13.1. Internal Metrics 1654
13.2. Internal Logs 1666
13.2.1. cribl.log 1675
13.2.2. access.log 1680
13.2.3. audit.log 1682
13.2.4. metrics.log 1684
13.2.5. notifications.log 1686
13.2.6. ui-access.log 1688
13.3. Track Data Activity for an Edge Node 1690
14. Work with Data 1696
14.1. Ingest and Inspect Data 1697
14.1.1. Onboard Data 1698
14.1.2. Use Datagens to Simulate Live Data 1701
14.1.3. Create and Share Data Samples 1706
14.2. Event Data Structure and Flow 1720

14.2.1. Event Model 1721
14.2.2. Event Processing Order 1724
14.2.3. Event Breakers 1726
14.2.4. Event Breaker Types 1736
14.2.4.1. Azure Virtual Network (VNet) Flow Event Breaker 1737
14.2.4.2. CSV Event Breaker 1741
14.2.4.3. File Header Event Breaker 1743
14.2.4.4. JSON Array Event Breaker 1746
14.2.4.5. JSON New Line Delimited Event Breaker 1756
14.2.4.6. Regex Event Breaker 1758
14.2.4.7. Timestamp Event Breaker 1761
14.3. Routes 1763
14.4. Pipelines 1770
14.4.1. Validate Pipeline Logic Using Data Preview 1778
14.5. Process Data with AI Assistance 1787
14.5.1. Create Pipelines With Pipeline Builder 1788
14.5.2. Convert Data into a Custom Schema 1795
14.6. Manage Metrics and High Cardinality 1803
14.7. Build Custom Logic to Route and Process Your Data 1813
15. Functions 1818
15.1. Aggregations 1825
15.2. Aggregate Metrics 1835
15.3. Auto Timestamp 1844
15.4. CEF Serializer 1849
15.5. Chain 1851
15.6. Clone 1853
15.7. Code 1855
15.8. Comment 1865
15.9. DNS Lookup 1867
15.10. Drop 1872
15.11. Drop Dimensions 1873
15.12. Dynamic Sampling 1877
15.13. Eval 1880
15.14. Event Breaker Function 1885
15.15. Flatten 1888
15.16. Fold Keys 1891
15.17. GeoIP 1895
15.18. Grok 1898

15.19. JSON Unroll 1901
15.20. Lookup 1904
15.21. Mask 1910
15.22. Numerify 1918
15.23. OTLP Logs 1920
15.24. OTLP Metrics 1929
15.25. OTLP Traces 1946
15.26. Parser 1952
15.27. Publish Metrics 1966
15.28. Redis 1972
15.29. Regex Extract 1983
15.30. Regex Filter 1992
15.31. Rename 1993
15.32. Rollup Metrics 1996
15.33. Sampling 1998
15.34. Serialize 2000
15.35. SNMP Trap Serialize 2003
15.36. Suppress 2006
15.37. Unroll 2009
15.38. XML Unroll 2011
15.39. Windows SID Lookup 2015
15.40. Prometheus Publisher (deprecated) 2017
15.41. Reverse DNS (deprecated) 2019
15.42. Tee (deprecated) 2021
15.43. Trim Timestamp (deprecated) 2024
16. Packs 2026
16.1. Pack-Based Configuration Management 2041
16.1.1. Plan a Pack-Based Strategy 2045
16.1.2. Create a Pack 2055
16.1.3. Version Control Packs in External Git Repos 2064
16.2. Packs Publication Standards 2069
17. Reference 2080
17.1. Knowledge Objects 2081
17.1.1. Variables Library 2082
17.1.2. Regexes 2089
17.1.3. JSON Schemas 2093
17.1.4. Parquet Schemas 2096
17.1.5. AppScope Configs 2105

17.2. Cribl Expressions 2106
17.2.1. C.Crypto - Data Encryption and Decryption 2107
17.2.2. C.Decode and C.Encode - Encoding and Decoding 2110
17.2.3. C.Lookup - Inline Lookup Methods 2118
17.2.4. C.Mask - Data Masking Methods 2122
17.2.5. C.Net - Network Methods 2133
17.2.6. C.Text - Text Methods 2140
17.2.7. C.Time - Time Methods 2144
17.2.8. Miscellaneous Expression Methods 2151
17.3. CLI Reference 2162
17.3.1. auth 2166
17.3.2. boot-start 2171
17.3.3. cloud-workspace 2173
17.3.4. decrypt 2174
17.3.5. diag 2175
17.3.6. encrypt 2181
17.3.7. git 2182
17.3.8. help 2184
17.3.9. keys 2186
17.3.10. limits 2188
17.3.11. mode-master 2189
17.3.12. mode-single 2191
17.3.13. mode-edge 2192
17.3.14. mode-worker 2193
17.3.15. mode-managed-edge 2195
17.3.16. mode-outpost 2197
17.3.17. nc 2199
17.3.18. node 2200
17.3.19. pack 2202
17.3.20. parquet 2206
17.3.21. pipe 2210
17.3.22. pq 2212
17.3.23. reload 2216
17.3.24. restart 2217
17.3.25. start 2218
17.3.26. status 2219
17.3.27. stop 2220
17.3.28. vars 2221

17.3.29. version 2224
17.4. Environment Variables 2225
17.5. Configuration Files 2235
17.5.1. api-limits.yml 2239
17.5.2. breakers.yml 2240
17.5.3. certificates.yml 2243
17.5.4. cribl.yml 2244
17.5.5. fleet-mappings.yml 2256
17.5.6. groups.yml 2257
17.5.7. inputs.yml 2260
17.5.8. instance.yml 2378
17.5.9. job-limits.yml 2383
17.5.10. leader.yml 2386
17.5.11. limits.yml 2390
17.5.12. logger.yml 2395
17.5.13. messages.yml 2397
17.5.14. notifications.yml 2398
17.5.15. outpost.yml 2403
17.5.16. outputs.yml 2406
17.5.17. parsers.yml 2522

1. About Cribl Edge

What Is Cribl Edge?

Cribl Edge helps you collect and process observability data - logs, metrics, and application data - in real time, from your Linux, Windows, and macOS machines, apps, or microservices, and deliver them to Cribl Stream or any supported destination.

With Cribl Edge you can:

- Automatically discover and collect host, container, and application metrics, as well as logs, on endpoints.
- Process data with Functions and Pipelines.
- Forward data to any of the many supported destinations.
- Easily manage configurations while maintaining version control.
- Teleport to the edge for local preview and configuration validation.

Leader Node, Fleets, and Destinations

Conceptual Overview of Cribl Edge

This two-minute video provides a quick overview of the Cribl Edge product.

Who Is Cribl Edge For?

Cribl Edge is built for ITOps and SecOps Engineers and users of operational and security intelligence products and services who want to simplify the process of collecting and analyzing data from a host.

Cribl University offers the Cribl Certified Admin for Edge course where you will learn to implement, optimize, and manage your deployments. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses - but Cribl's training is

1.1. Basic Concepts

Notable features and concepts to get a fundamental understanding of Cribl Edge.

Cribl Edge as an Agent

Cribl Edge is a vendor-neutral agent for unified telemetry collection.

Edge Nodes are individual agents you deploy to endpoints such as servers, desktops, laptops, containers, applications, and microservices. In a typical deployment, Edge Nodes report to a **Leader Node** which handles their configuration and updates.

Edge Nodes are organized in **Fleets**, which are groups of Nodes that share configuration, follow the same update schedule, and participate in the same data flows. Fleets can have multiple **Subfleets**, which take advantage of configuration inheritance. See Manage Fleets of Edge Nodes for more information.

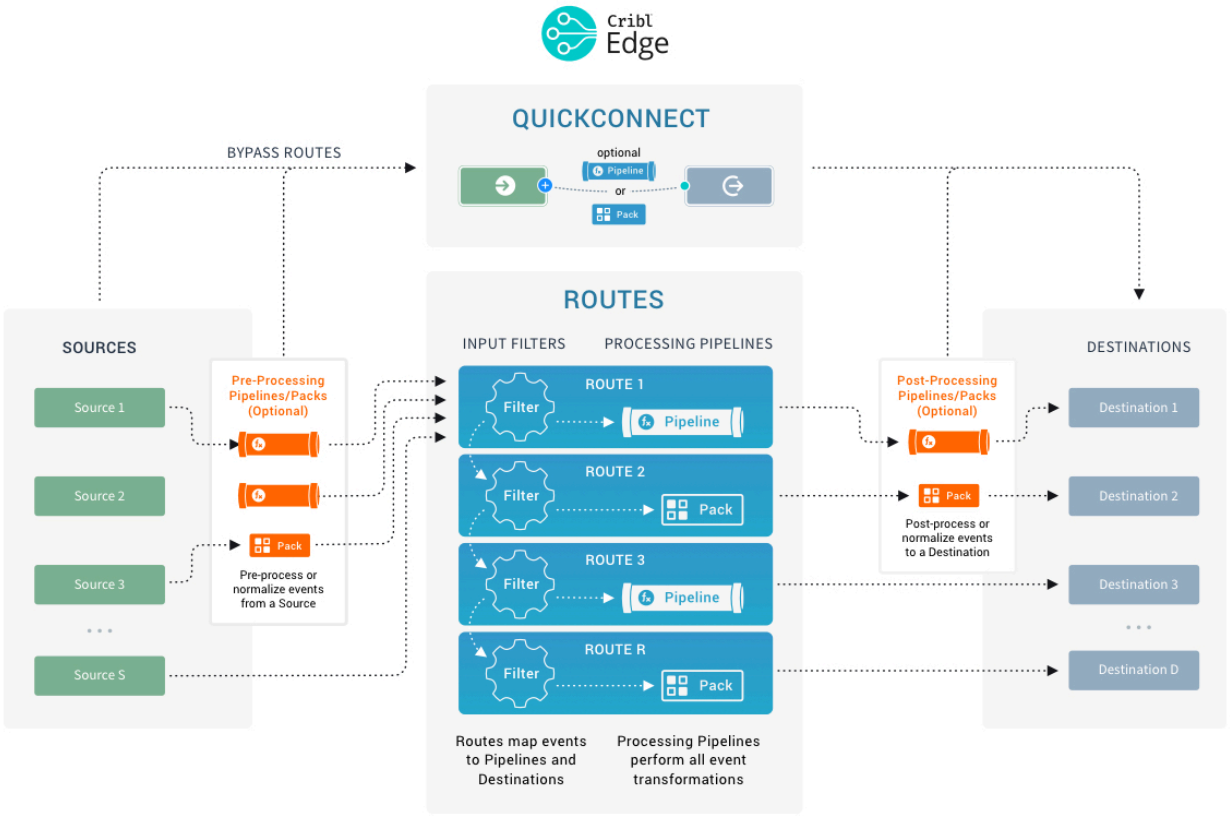
You can use **Outpost Nodes** as intermediaries between Edge Nodes and the Leader. Outposts act as a relay for configuration and update communications in case of restrictions such as firewalls. See Outpost for more information.

Cribl Edge and Data Flow

Edge Nodes collect events, logs, and metrics on their endpoints using Sources. **Sources** are configurations for specific data categories and endpoint types, such as log files or OS-specific metrics. Certain Sources can also receive data from remote senders over protocols such as Syslog or TCP, but Cribl Edge is not designed to ingest large volumes of data from external sources.

Cribl Edge is not intended for collecting data from multiple hosts. If you need to receive and aggregate data from various endpoints, use Cribl Stream instead. Cribl Stream is designed to handle high volume workloads by employing multiple Worker processes.

Data collected by Edge Nodes is sent to **Destinations** using one of two mechanisms:

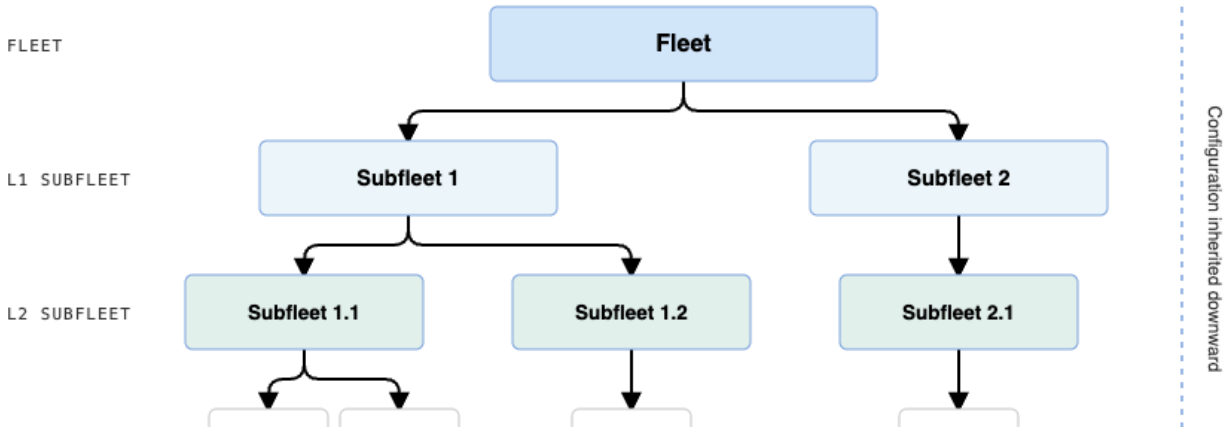


- **QuickConnect** - a graphical interface where you can quickly drag and drop connections between Sources and Destinations, optionally including - or excluding - Pipelines or Packs.
- **Routes** - a complex mechanism for directing events to proper Destinations by filtering them.

See Route Collected Data for more details.

In both mechanisms, you can transform, enrich, drop, and otherwise modify the events by running them through Pipelines containing Functions.

A **Pipeline** defines what changes you want to apply to events. Each Pipeline contains **Functions** that handle specific transformations.



Each Route uses one main Pipeline. Additionally, you can attach other Pipelines as pre-processing or post-processing Pipelines to Sources and Destinations, respectively. See Pipelines and Functions for more information.

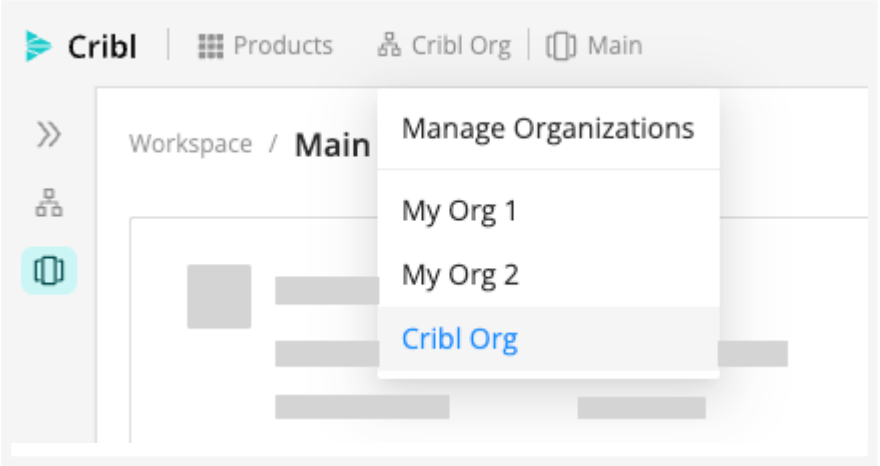
Routes, Pipelines, Functions

Cribl Edge Configuration Management

Cribl Edge configuration (Sources, Destinations, Routes, and Pipelines) happens at Fleet level. Organizing Edge Nodes into a hierarchy of Fleets and Subfleets lets you manage configurations at scale and benefit from configuration inheritance. See Fleet inheritance for more information.

FLEET
Fleet
L1 SUBFLEET
Subfleet 1
Subfleet 2
L2 SUBFLEET
Subfleet 1.1
Subfleet 1.2
Subfleet 2.1
Configuration inherited downward

1.2. Log In To Cribl



When you first log in to a Cribl instance, you will be required to configure your account and authenticate.

Depending on how your Organization is configured, you may need to either authenticate via your SSO provider (such as Okta, Entra ID, or Ping Identity), or create a password for use with your email address.

When creating a new username and password, you will be prompted for account information, such as name, company, or phone number.

Switch Between Organizations

When you are a member of multiple Organizations, you can switch between them on the top bar. Select your current Organization's name on the bar to open a drop-down with all Organizations you have access to.

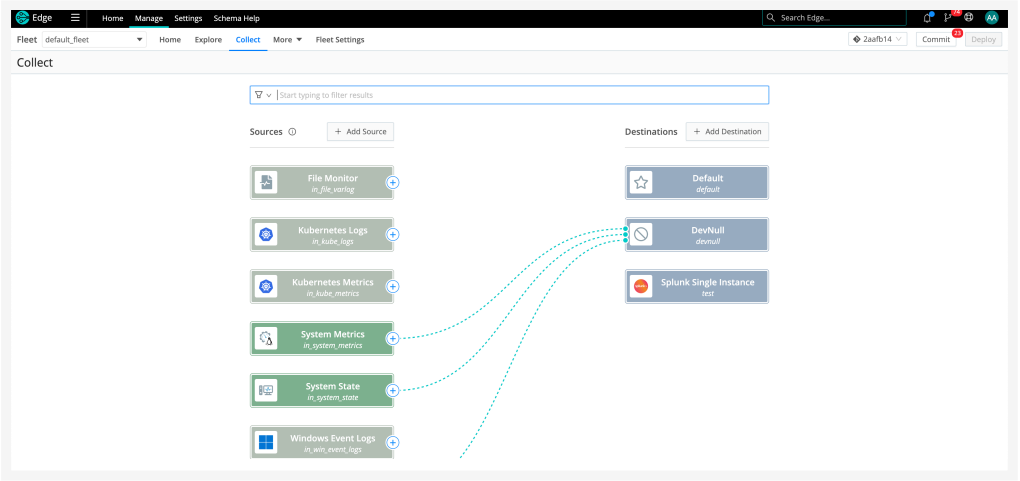
Switching between Organizations

Organizations with Different Authentication Methods

If you switch between Organizations that use different authentication methods (SSO versus username/password), you will be asked to re-authenticate with the appropriate credentials.

If the main Organization uses SSO, and you are switching to an Organization that uses username/password authentication, you will need to authenticate with a password. If you are accepting an invitation to the latter Organization, you will be prompted to create a password and go through a verification process.

If the main Organization uses username/password authentication, and you are switching to an SSO-based Organization, you will need to authenticate via SSO.



1.3. QuickConnect

Use QuickConnect to sent data from Sources to Destinations with drag-and-drop.

The QuickConnect rapid-development UI enables you to visually connect Cribl Edge inputs (Sources) to outputs (Destinations) through simple drag-and-drop.

You can insert Pipelines or Packs into the connections, to take advantage of the full range of data-transformation Functions in Cribl Edge. Or you can omit these processing stages entirely, to send incoming data directly to Destinations - with minimal configuration fuss.

QuickConnect was designed as a simple, quick way to prototype, test, and send data flowing through Cribl Edge. But it's also entirely suitable for configuring a production deployment, if your needs are restricted to sending data through parallel paths, and you don't need to use Routes. (See QuickConnect Versus Routes to help you clarify that choice.)

QuickConnect UI

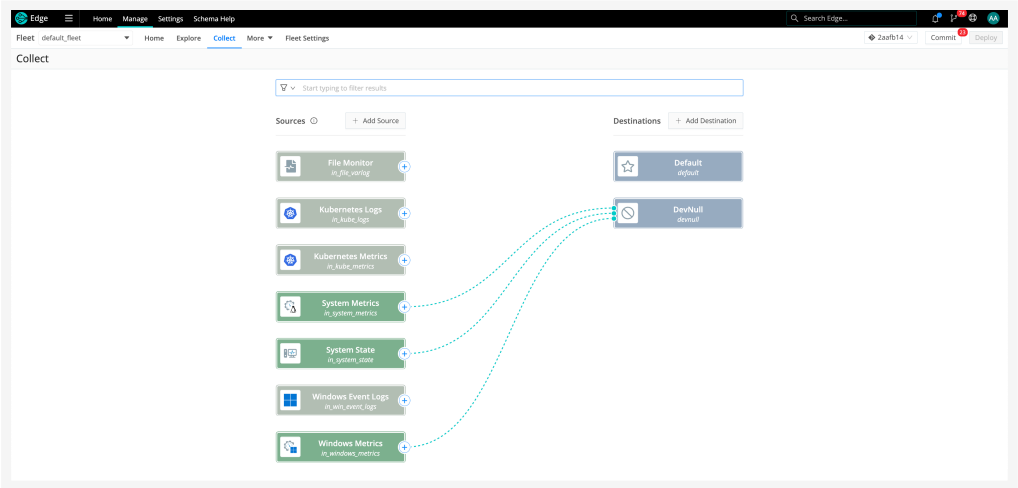
You also have the option to start with simple direct connections, and later add Pipelines' and/or Packs' processing power at up to three stages of each connection.

Initiating QuickConnect

To access QuickConnect, from a single-instance or individual **Edge Node**, select **Collect**.

To display QuickConnect in a distributed deployment, you must first select a **Fleet**. Select the **Manage** link to select the `default` or a different Fleet.

You can switch to Cribl Edge's Routes UI at any time from the top nav by selecting **Routing** > **Data Routes**. To toggle back, select **Routing** > **QuickConnect**.



QuickConnect Versus Routes

QuickConnect provides access to most of Cribl Edge's configuration options, with a few restrictions (in exchange for the simplified visual interface):

- QuickConnect completely bypasses Routes - which is why every QuickConnect path is independent and parallel. There is no Route-level data filtering, and you forego the Cribl Edge Routing table options to clone and cascade data across Pipelines.
- Most Sources are available to fully configure, with a few current exclusions.
- Each supported Source's config can be created in either QuickConnect or Routes, and will reside only in that context. But you can switch a config between the two contexts, or you can create an identical config on the opposite side.
- All Destinations are available to fully configure.
- Everything you configure in QuickConnect exists separately from everything you configure in Data Routes. (But remember that you can use the **Routing** menu to toggle between contexts, and then replicate a QuickConnect configuration on the Data Routes side, or vice versa.)

Using QuickConnect

QuickConnect is designed to be nearly self-documenting. To get you going quickly, it displays the following Sources and Destinations straight out of the box:

QuickConnect UI

Filter Results

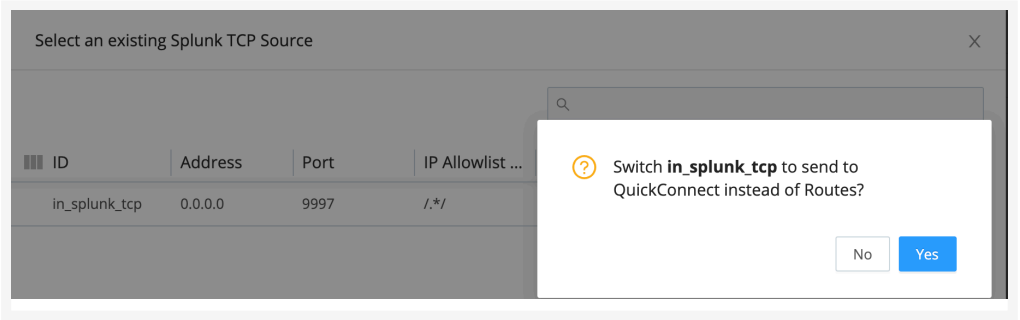
Use the **Filter results** bar at the top of QuickConnect to narrow the Sources and Destinations displayed. Search by Source or Destination ID, type, connected Pipeline or Pack, or tag.

Select the filter icon to the right of the search field to open additional filter options:

- **Connection type** - Show connected or unconnected Sources and Destinations.

- **Source type** - Filter by push, pull, or system/internal Sources.
- **TLS** - Filter by TLS enabled or disabled.
- **Pre/post-processing Pipeline** - Filter by whether a pre- or post-processing Pipeline is set.
- **Persistent Queue** - Filter by whether a persistent queue is enabled or disabled.
- **Enabled only** - When selected, shows only enabled Sources. Off by default, so QuickConnect continues to show both enabled and disabled Sources. This filter applies to Sources only.

When you enable an additional filter, its criteria appear as a tag in the **Filter results** bar. Clear the tag or deselect the check box to remove the filter.



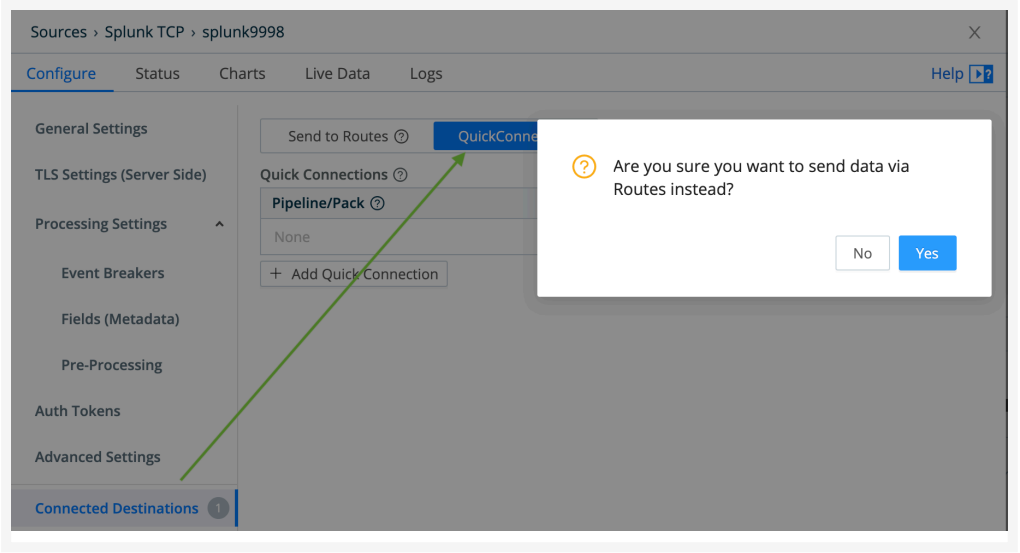
Additional filters are unavailable while you are editing a connection.

Enabling Sources and Destinations

When you select Sources and Destinations, their configuration options will open in a drawer. Fill in a unique **Input ID**, and any other required fields marked by an asterisk (*). Then select **Save**.

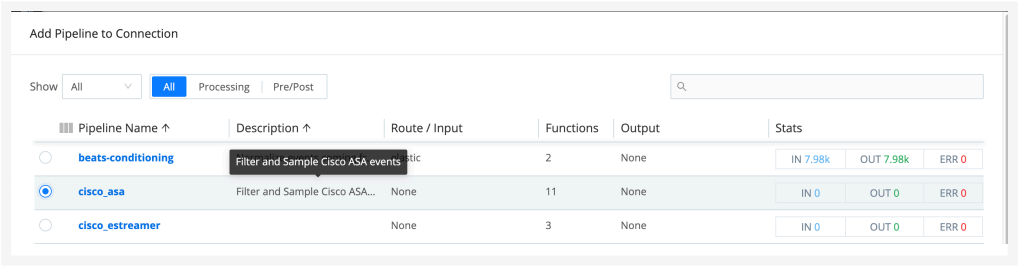
Switching Contexts

If you switch an **existing** Source to QuickConnect - for example, one of the preconfigured Sources that ship with Cribl Edge - you'll see the dialog shown below. This is due to QuickConnect's independence from the Routes interface - you need to confirm your choice to move the existing configuration from the Data Routes world to the QuickConnect world.



Switching a Source/Destination between worlds

If you switch an existing Source config to QuickConnect, its data will no longer flow through its configured Route.



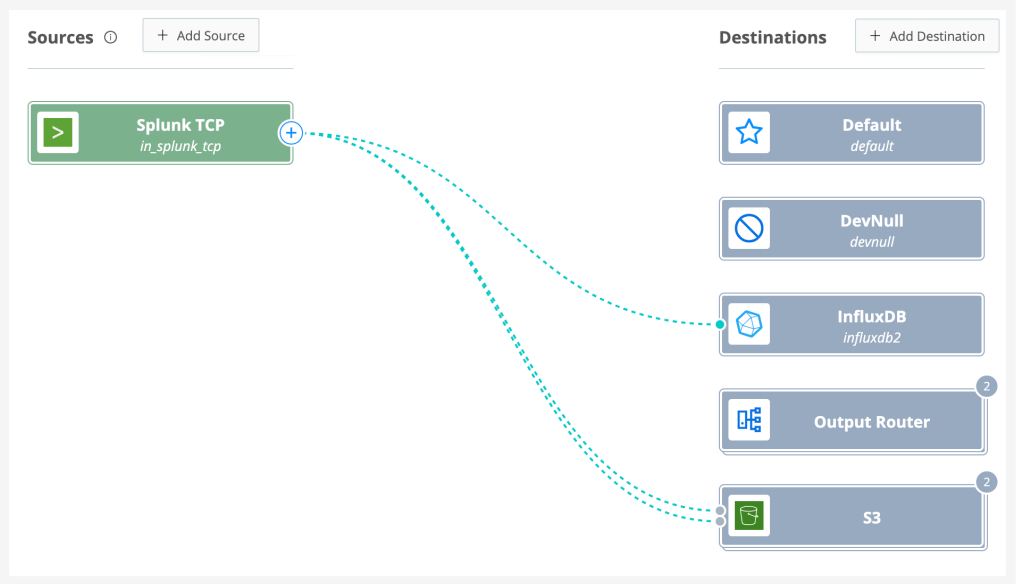
You can also go the opposite way: move a Source originally configured in QuickConnect to the Routing interface. In the Source's drawer or config modal, select the **Connected Destinations** left tab, and then select the resulting **Send to Routes** button. Here again, you'll need to confirm your choice before proceeding.

Switching a Source/Destination between worlds

Selecting a Pipeline or Pack

When you add or modify a connection line, the bottom **Connection Configuration** drawer will prompt you to select a **Passthru**, **Pipeline**, or **Pack** connection. Selecting either **Pipeline** or **Pack** will open an **Add…** modal like this in the bottom drawer:

QuickConnect versus Routing UIs

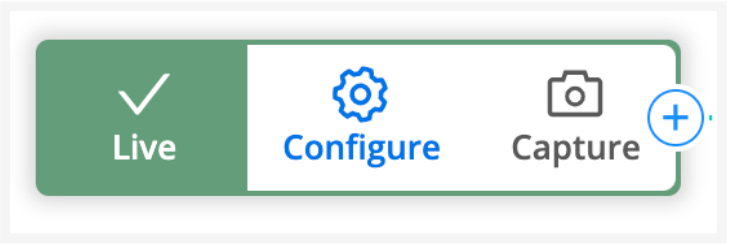


Here, you're selecting among already-configured Pipelines or Packs. **Resist the temptation to select a bold blue Pipeline or Pack name.** (Doing so will open the Pipeline or Pack config in a separate browser tab, which might offer more configuration than you bargained for.)

Instead, select the subtle radio button to the left of the Pipeline or Pack you want to open. Then select **Save** to confirm your choice and close the drawer.

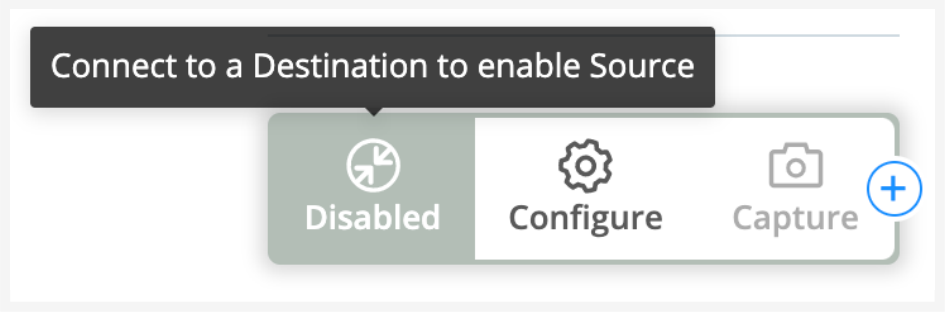
Multiple Connections

You can drag multiple connection lines between a given Source/Destination pair. (You might do this, for example, to configure parallel Pipelines to handle different data types.)



Also, you can connect one Source to multiple Destinations, or multiple Sources to one Destination. Let's isolate examples of both, from the screen capture we started with:

Multiple connections out, multiple connections in



Source/Destination Tiles' Hover Options

Once you've configured a Source or Destination, hovering over its tile will display options like these:

Signed, sealed, delivered: tiles' on-hover options

The leftmost button is an indicator of the Source's/Destination's state. Live means healthy; disabled, error, or warning states will also appear here. Note that a Source will appear as **Disabled** until you connect it to a Destination.

This Source is not misconfigured - it's just lonely

To update the Source or Destination configuration or address any problems, select the middle **Configure** button.

The right **Capture** button captures a sample of data flowing through the Source or Destination. This is visualized in a drawer version of the Live tab.

Group Connections

Once you've configured two or more copies of the same Source or Destination type

- for example, to support different configurations of one integration or protocol - QuickConnect stacks their tiles together to keep the display clean.

4 similar Destinations, stacked

The number inside the stack shows how many tiles it contains.

You can select a stack to change its options. This will expand all the tiles in the group, and each tile will reveal the on-hover options described above.

You can drag multiple connection lines from, or to, the same stack. If you drag or modify a connection from or to a stacked group, the UI will prompt you whether to similarly expand the group to access individual tiles.

1.4. Onboard Faster With Packs

As you get started with Cribl Edge, consider using Packs to help streamline your onboarding process and get more value out of your Cribl deployment quickly.

Packs are self-contained, portable bundles of Cribl objects with pre-built logic that solves typical or specific data processing challenges. They can include configurations or example logic for a variety of objects, such as Routes, Pipelines, and Knowledge objects.

On the Cribl Packs Dispensary, Cribl officially publishes and maintains a variety of validate Packs that you might use to solve a particular challenge or process data from a variety of vendors, including many that do not yet have full Cribl Edge integrations. The Dispensary also hosts validated Packs submitted from the larger Cribl developer and user community.

Search and find for Packs that match your specific use case. Then download and import these Packs to:

- **Reduce manual effort for common vendors and log formats:** Find Packs for validated solutions created by Cribl employees and community members to skip the time-consuming process of writing complex logic for well-known log formats. Instead, import a Pack to begin ingesting, parsing, and enriching logs for common vendors quickly.
- **Learn Cribl best practices:** Use configurations created by experts from Cribl and the community to learn how to build an effective solution for common data processing challenges.
- **Get value from Cribl more quickly:** Move from initial source connection to usable, parsed data more quickly by using pre-programmed logic in Packs that you can adapt for your specific needs.
- **Simplify complex collections:** Use REST Packs to streamline configurations for the REST Collector. These officially supported Packs eliminate manual effort by providing validated authentication, pagination, and event-breaking settings tailored to specific upstream services that do not yet have a dedicated Source or Collector.
- **Perform common data processing tasks:** Use Packs for use cases such as normalizing timestamps, flattening JSON objects, or masking sensitive PII.

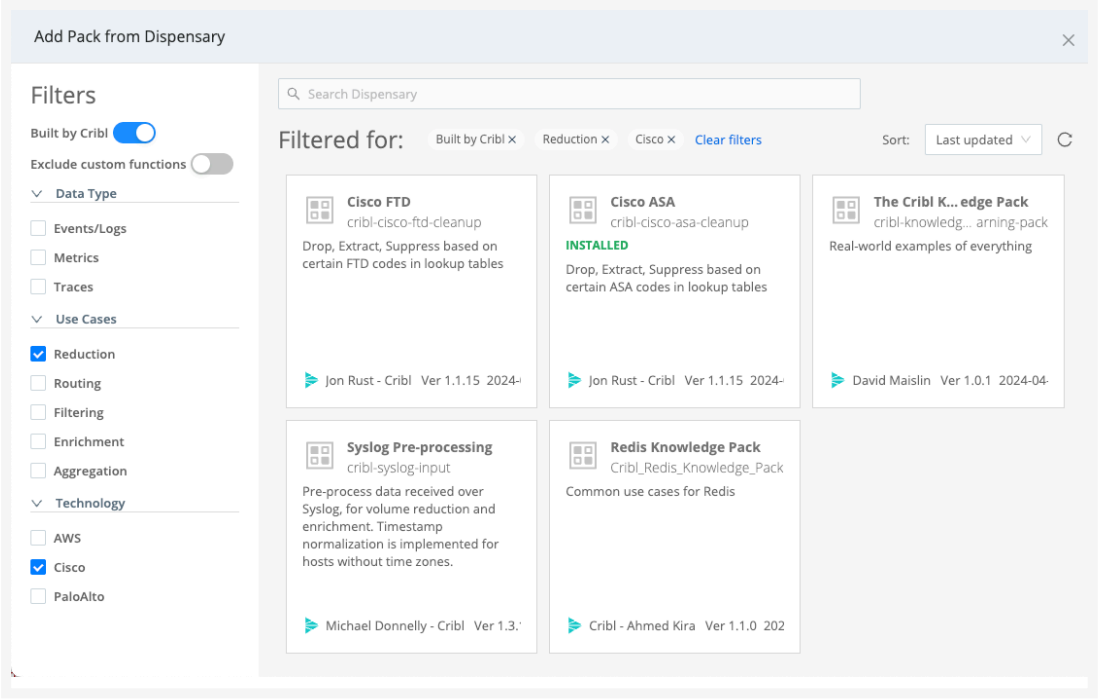
This page describes how to use Packs to accelerate the onboarding process with Cribl Edge. However, you can also use Packs for advanced environment templating as your Cribl Edge deployment becomes more complex and needs to scale. See Pack-Based Configuration Management for more information about this advanced configuration management use case.

1.4.1. Get Pre-Built Pack Content

Packs created by Cribl and the Cribl Community let you speed up configuring your data flows by providing ready-made solutions for many common integrations and use cases.

On the Cribl Packs Dispensary, Cribl officially publishes and maintains a variety of validate Packs that you might use to solve a particular challenge or process data from a variety of vendors, including many that do not yet have full Cribl Edge integrations. The Dispensary also hosts validated Packs submitted from the larger Cribl developer and user community.

Packs created by Cribl and the Cribl Community let you speed up configuring your data flows by providing ready-made solutions for many common integrations and use cases. These Packs are hosted on the Cribl Pack Dispensary. You can download and customize each Pack as needed.

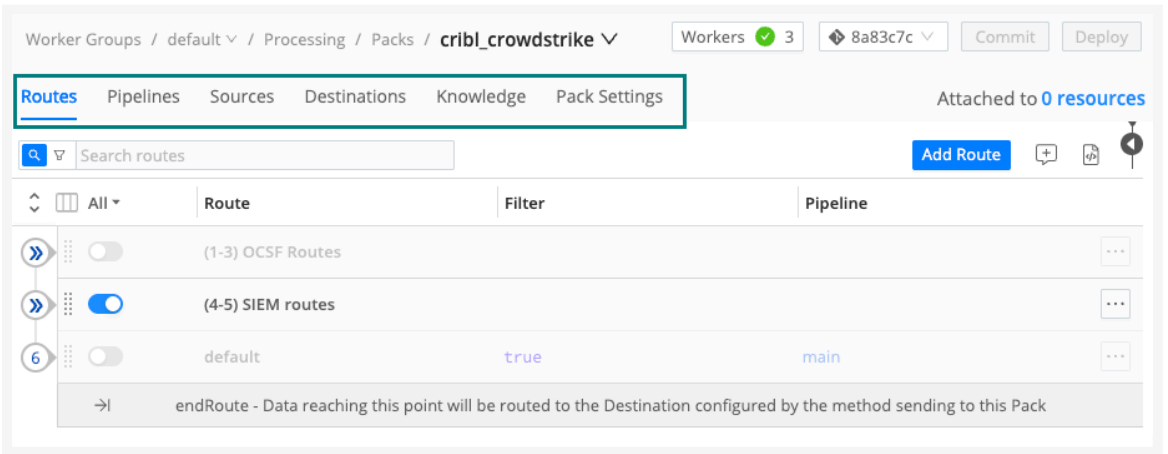


This page describes how to use Packs to accelerate the onboarding process with Cribl Edge. However, you can also use Packs for advanced environment templating as your Cribl Edge deployment becomes more complex and needs to scale. See Packs for more information about this advanced configuration management use case.

Add a Pack From the Dispensary

To import a Pack from the Dispensary directly into your deployment:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet.
2. Navigate to **Processing**, then **Packs** and select **Add Pack**. From the submenu, select **Add from Dispensary**.
3. The Packs Dispensary will open in a drawer.



Cribl Packs Dispensary

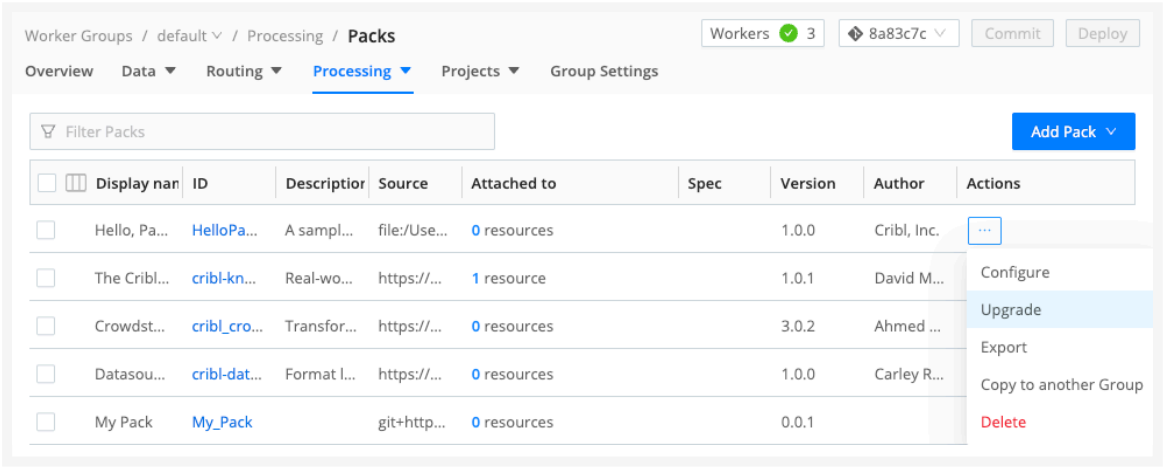
4. Using the drawer controls, browse or search for the Pack(s) you want. (You can use the check boxes at the left to filter by data type, use case, and technology.)
5. Select any Pack tile to display its details page with its README. This will typically outline the Pack's purpose, compatibility, requirements, and installation.
6. To proceed, select **Add Pack** on the Pack details page.
7. If the Pack you are importing binds variables to any fields, you will see a **Configure Variables** button in the notification about successful import.
   Select it to go to the **Variables** page, where you can configure the values for the variables for your deployment.

Explore and Customize the Pack

Click inside the new Pack. In the Pack submenu you can see all the components that the Pack contains: Routes, Pipelines, Sources, Destinations, and Knowledge Objects.

Pack menu showing Routes, Pipelines, Sources, Destinations, and Knowledge Objects

At this point you can edit any elements in the Pack to customize it to your needs. Do it the same way you would when working directly in any Fleet.



Remember that all elements inside the Pack, including Knowledge Objects, are scoped to that Pack. This means you cannot use, for example, a Knowledge Object defined inside a Pack outside it.

Upgrade a Pack from the Dispensary

When a new version of a Pack is published to the Dispensary, you can upgrade your local Pack to get all the latest improvements.

If you didn't introduce local changes to the Pack, you can upgrade the Pack directly from the UI. On the **Packs** page, open the Options ••• menu for your Pack, and then select **Upgrade**.

Upgrading an existing Pack

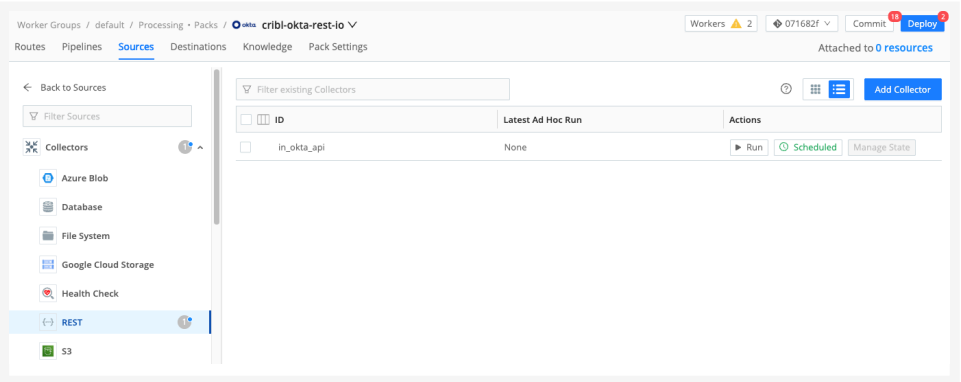
If you've modified the Pack, Cribl Edge will not overwrite it during upgrading, to prevent deletion of your locally created resources. To reconcile your own changes with improvements coming in from a new Pack version:

1. Import the updated Pack as a separate Pack with a new name.
   Give it a name that includes the version number (for example, `cribl-syslog-input-120`).
2. Do a side-by-side comparison of the previous and new versions of the Pack.
   Copy configurations from your modified Pack into the upgraded Pack.
   Review all comments in the upgraded Pack to understand changes introduced in the new version.
3. Enable or disable any Functions in the new Pack as necessary.
4. Update any Routes, Pipelines, Sources, or Destinations that use the previous Pack version to reference the new Pack.

5. If you modified default Cribl Edge Knowledge Objects (for example, lookup files), copy the modified files locally for safekeeping, before upgrading the Pack.
   After you install the upgrade, copy those files back to the upgraded Pack, overwriting the default versions in the Pack.
6. Commit and Deploy.

Troubleshoot Packs from the Dispensary

If you experience unexpected behaviors using Packs from the Dispensary, the following troubleshooting steps can help you resolve the issue quickly. If you continue to have trouble, reach out to Cribl Support.



Imported Pack Does Not Appear in Routes

If a Pack downloaded from the Dispensary does not appear in the **Pipeline** dropdown of your Routing table at the Fleet level, that is likely because the Pack contains either a Source or Destination.

Only Packs scoped exclusively for data processing appear in the **Pipeline** dropdown. Packs that include a Source or Destination are treated as independent integrations, which are intended for end-to-end data flows or as specialized Source-side or Destination-side components. See Purpose and Scope of the Pack for a deeper explanation of how Packs can be scoped.

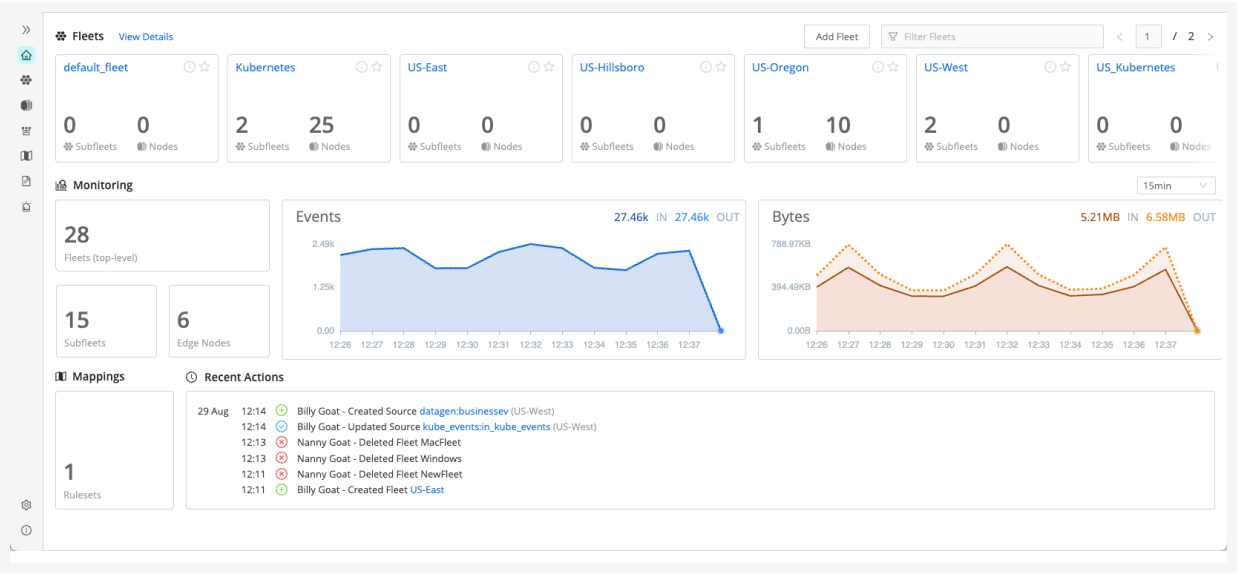
First, verify that the Pack has a Source, Collector, or Destination:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet.
2. Navigate to **Processing**, then **Packs**. Select the name of the Pack from the list.
3. From inside the Pack, select either **Sources** or **Destinations** from the top bar to see the list of configured Sources or Destinations. Verify that the Pack has a Source or Destination, which means it will have a badge with a number that indicates how many Sources, Collectors, or Destinations are contained in that Pack.

Example of a REST Collector contained in a Pack

2. Explore Cribl Edge

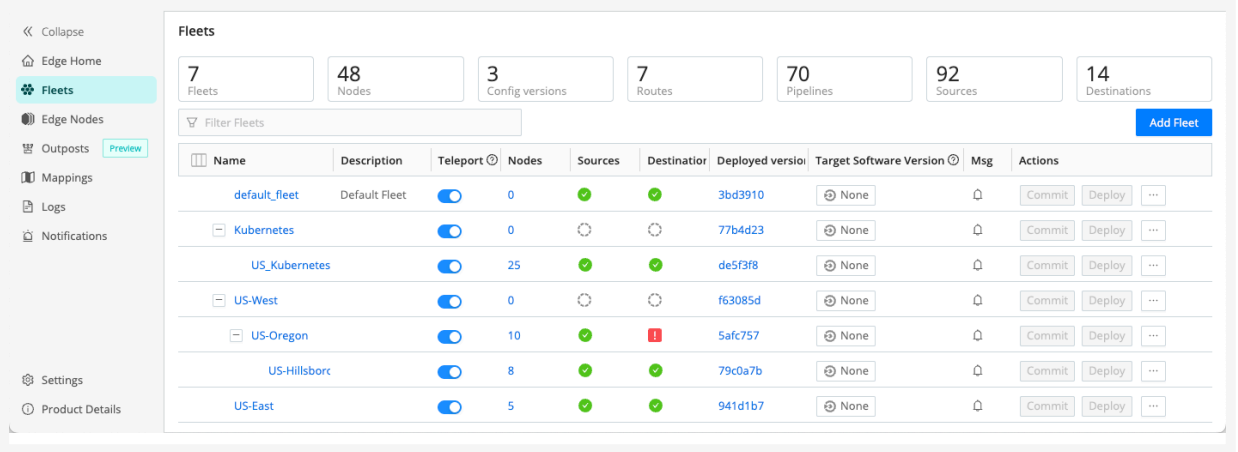
Explore the Cribl Edge UI.



The Cribl Edge UI offers a centralized view to manage, configure, and version-control your Edge Nodes. It also lets you teleport to individual Nodes to locally preview and validate your configurations. Here's a tour of the Cribl Edge UI in Distributed mode.

The available UI options might differ depending on your deployment type (Cribl.Cloud versus on-prem) and the platform the Edge Node is installed on (Linux versus macOS versus Windows).

Edge Home

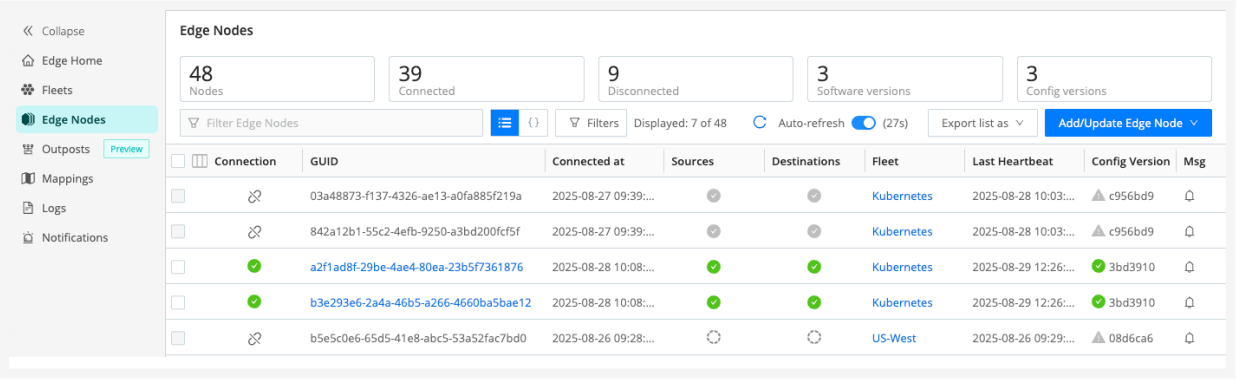


When you first log into Cribl Edge you'll land on the **Edge Home** page. This page gives you an overview of configured Fleets, monitoring information for Fleets, Subfleets, Edge Nodes, and Events and Bytes in and out. At the bottom, you'll see Recent Actions that users have taken in the environment as well as any configured Fleet Mappings.

The Edge Home page

Fleets

Select **Fleets** from the sidebar to access your configured Fleets.



Fleets page

From here, you can select a Fleet name to isolate individual Fleets, or use the filter bar to locate your Fleet.

- For more information about the Fleets interface, see Fleets.
- To learn about creating Fleets, see Creating and Managing Fleets and Subfleets.

Edge Nodes

Select **Edge Nodes** to view all of your Edge Nodes in one list.

Edge Nodes page

The list provides status information for each Edge Node in the selected Fleet, lets you filter Edge Nodes, add, and update Nodes. For more information, see Manage Edge Nodes.

Outposts

Select **Outposts** to view the list of configured Outposts, add and manage them. For more information, see Connect Through Cribl Outpost.

Mappings

You can use Mappings Rulesets to map Edge Nodes to Fleets by defining rules. For more information, see Mapping Edge Nodes to Fleets.

Logs

Cribl Edge generates internal application logs that monitor its own operations and health. They provide valuable insights into the system's behavior, performance, and potential issues. For more information, see Internal Logs.

Notifications

Notifications alert Cribl Edge admins about issues that require their immediate attention. For information on types of Notifications, Notification targets, and managing Notifications, see Managing Notifications.

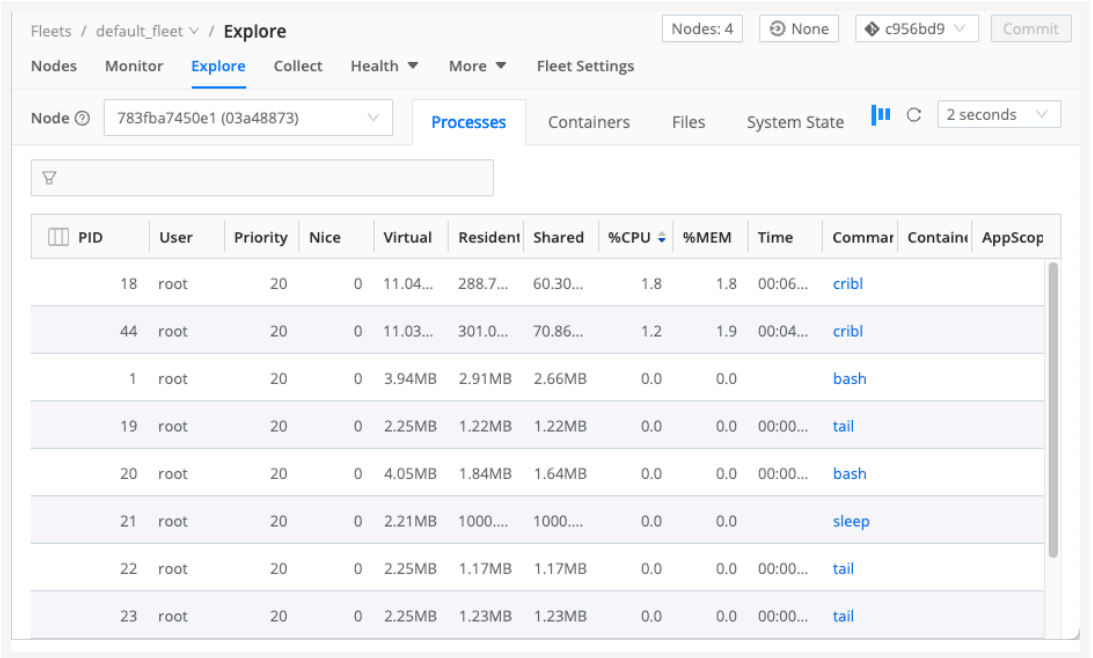
Explore Tab

The **Explore** tab lets you get details about a particular Edge Node.

2.1. Explore Cribl Edge Nodes

Examine Edge Nodes details in the Explore tab.

You can view details of each individual Edge Node by using the **Explore** tab.



To access it, in the sidebar, select **Fleets**, then choose a Fleet and select **Explore**.

In the **Node** drop-down, select one of your hosts to display the following tabs:

- Processes
- Containers
- Files
- System State
- Kubernetes

The available tabs will depend on your deployment environment.

Explore an Edge Node

The **Node** drop-down lists up to 100 Edge Nodes, ordered by hostname. To view the details for a specific Edge Node, enter the hostname or GUID into the **Node** field.

Let's explore each tab in the **Explore** view.

Processes

The **Processes** tab lists all the processes running on the Edge Node.

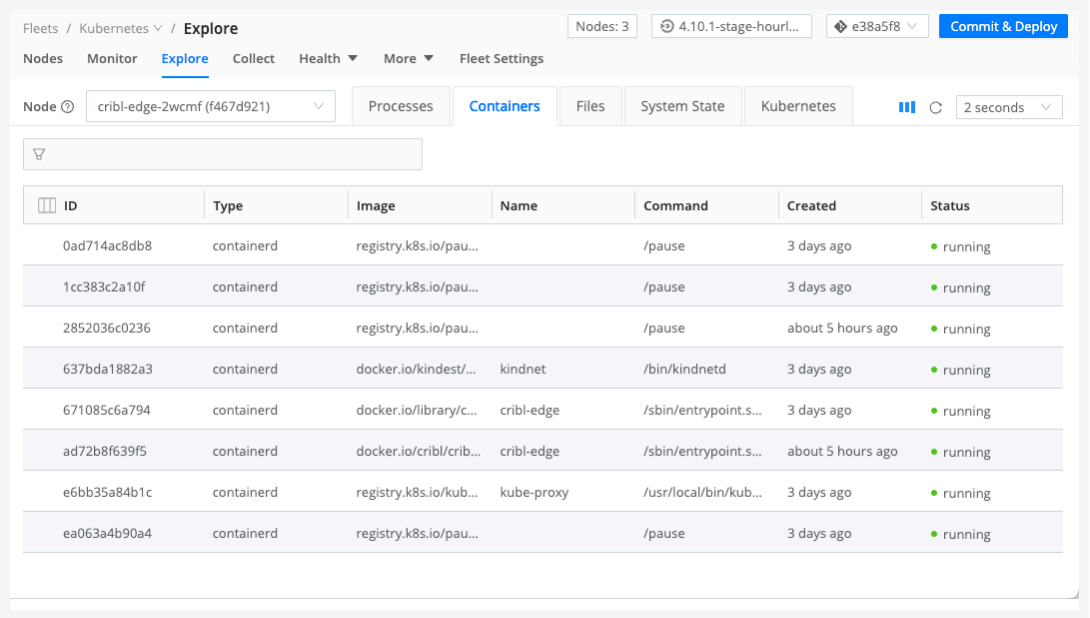
Select any of the rows to display a drawer with basic information on the process. In the drawer's default **Overview** tab, you'll find information such as CPU, Memory, and IO graphs, along with tables for active **Listening**, **Inbound**, and **Outbound** connections, if applicable.

Select **All details** to see the selected process' information out of `/proc`, expressed as key-value pairs. To access this information, you would normally need to SSH to the machine. This view makes troubleshooting across multiple systems much easier.

Process Metrics on Windows

In Windows-based Fleets, you can control the collection method for Process Metrics using a configuration option in the **Fleet Settings** > **Limits** > **Other** section. This setting allows you to choose between using PowerShell cmdlets or the more efficient native module.

When using PowerShell cmdlets on Windows, the environment variables displayed in this tab might be inaccurate. For details, see Other Limits.



Containers

The **Containers** tab, available for Edge Nodes running in containers, lists all the running containers and container metrics including information about images, volumes, status, ports, and so on.

Cribl Edge supports both Docker and `containerd` runtimes.

`containerd` containers have less info than Docker containers, so `Ports`, `IPs`, and `Logs` won't populate.

Containers overview

Select any container to open a drawer with more details, including container logs.

If you run Edge as an unprivileged user, see Making Docker Containers Visible to Edge.

Files

The **Files** tab lists all the log files being actively written to by running applications that Cribl Edge has auto-discovered. You can also specify a list of directories and files to actively monitor.

The **Actions** column allows you to:

- **View**: Displays a representation of the lines this column contains. You can also select any file row. To restrict how much data is displayed, use the search field or time picker on the **Search** tab.
- **Inspect**: Opens the **Inspect File** tab to show file metadata, including details like permissions, file size, user, and modified date.
  When inspected, compressed files (such as `foo.bar.gz`) include a **File preview** that shows the beginning of the file contents.
  Archived files (such as `.zip`, `.tgz`, and `.tar.gz`) include a **File listing** that shows the files within it.
  If a file appears suspicious, select **VirusTotal** or **OpSwat** at the bottom of the modal to see whether the file is flagged as compromised.
- **Monitor**: Displays the File Monitor's configuration modal.
- **Ingest**: Opens the Ingest file modal to send the file content to Routes/Pipelines for further processing or downstream to any destination you have configured. This is useful for testing and troubleshooting your configurations.

The **Files** tab provides the following options.

File Discovery Modes

Select a button at the top to select a discovery mode:

- **Auto**: Tells Cribl Edge to automatically discover files that are open for writing on currently running processes. The **Auto** discovery mode is unavailable on Windows and macOS.
- **Manual**: Tells Cribl Edge to discover the files within the **Path** (directory) and **Allowlist** that you specify, down to the **Max depth**.
- **Browse**: Displays a tree view of all of your directories and files.

Path

The **Path** field tells Cribl Edge to discover the files within the path (a directory) that you specify, down to the **Max depth**.

Allowlist

The **Allowlist** field, available with Auto and Manual discovery, supports wildcard syntax, and supports the exclamation mark (`!`) for negation. For example, you can use `!*cribl*access.log` to prevent Cribl Edge from discovering its own access log. The default filters are `*/log/*` and `*log`.

Select any file to see a representation of the lines it contains. To restrict how much data is displayed, you can use the search field or time picker on the **Search** tab.

If the representation of events shown on the **Search** tab isn't ideally suited to the file's contents, you can use the **Event Breakers** tab to refine it.

Monitor Files

The **Monitor Files** button, available with Auto and Manual discovery, opens a new File Monitor Source. The Source is prefilled with the discovery mode and anything else you specified on the **Files** tab, such as allowlist entries, path, or max depth.

Max Depth

The **Max depth** field, available with Manual discovery, is empty by default. Cribl Edge will search subdirectories, and their subdirectories, downward without limit.

If you enter `0`, Cribl Edge will discover only the top-level files within the specified path. If you specify `1`, Cribl Edge will discover files one level down from the top. Follow this pattern to specify the depth you want.

Monitor a File

Select a file's **Monitor** or **Actions** option to configure your File Monitor Source to generate events from the file's lines or records.

The **Monitor** feature automatically populates the modal with the following settings configured on the **Files** tab:

- **Discovery mode**. Defaults to **Manual** for Windows and macOS.
- **Search path**
- **Max depth**
- **Filename allowlist**

In addition, the **Connected Destinations** section defaults to **QuickConnect**. In the **Connected Destinations** section, you can select a Pipeline or Pack and a Destination. Otherwise, when you save, you'll be routed to the **Collect** page to set up your connections via QuickConnect. For details about making these connections, see File Monitor and QuickConnect.

Ingest a File

To configure options for how and where to send file contents, use the **Ingest file** modal.

You have two options:

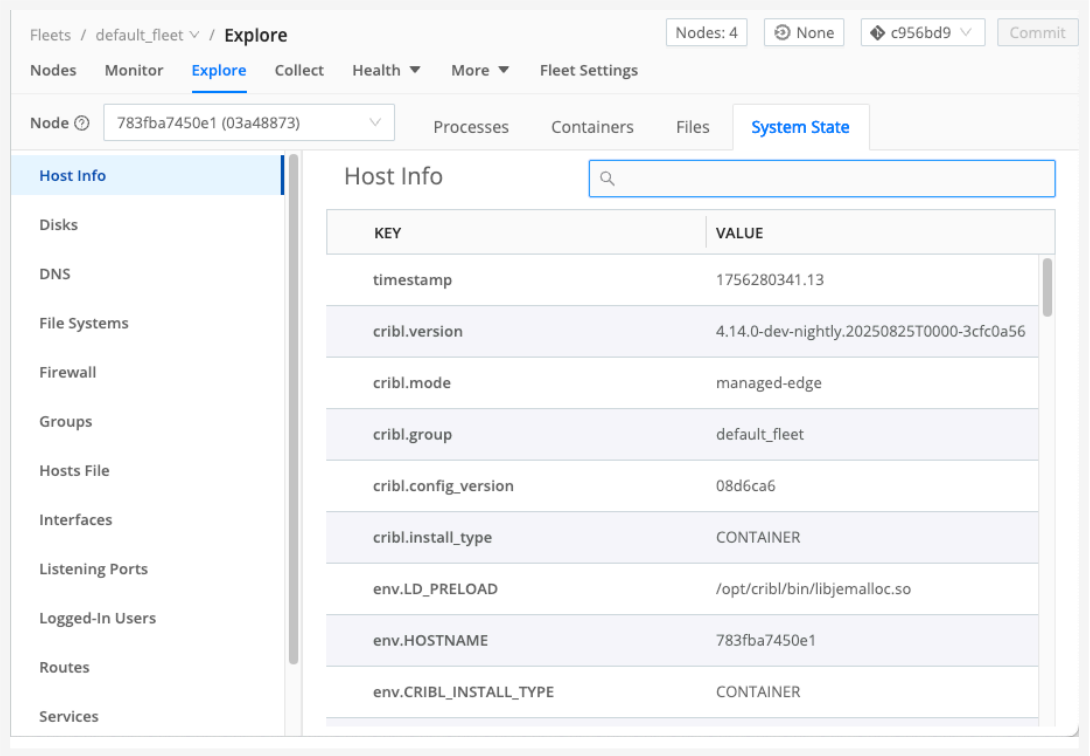
- Send directly to a configured Destination via **QuickConnect** (the default).
- Send to Routes through (an optional) Pre-Processing Pipeline.

You can configure Event Breakers and rulesets for both options.

Explore Files with Event Breakers

When you select a file in the **Files** tab, and Cribl Edge shows a representation of the lines that the file contains, how does that work? What's happening is that Cribl Edge is applying a default Event Breaker to the file.

You are not limited to the default Event Breaker, though. Select the **Event Breakers** tab, then:



- To apply a different (existing) Event Breaker, select **Add ruleset**, then select the desired ruleset from the **Event Breaker rulesets** drop-down.
- To create a new Event Breaker Ruleset, click **Create New**. In the resulting **New Ruleset** modal, proceed as described here. Later, you can reuse the new Event Breaker as part of a Source or a Collector.
  While you create the new ruleset, Cribl Edge pulls the contents of the open file into the Sample File area. Toggle between the **In** and **Out** tabs to compare, respectively, the original content and the content as modified by the Event Breaker you're creating.

Now return to the **Search** tab - the contents of your chosen file will appear with the new Event Breaker applied.

System State

The **System State** upper tab provides access to a collection of information gathered by the System State Source.

To display any of the information, you need to configure and enable the System State Source. Also, make sure that the Source's Collector Settings fields are enabled.

System State for the selected Edge Node

Host Info

Cribl Edge can add a `__metadata` property to every event emitted from every enabled Source. The **System State** tab displays the metadata collected for each Edge Node under **Host Info**.

You can use the metadata surfaced by an Edge Node to:

- Enrich events (with an internal `__metadata` field).
- Display to users as a part of instance exploration.

To customize the type of metadata collected, select **Fleet Settings** > **Limits** > **Metadata**. Use the **Event metadata sources** drop-down (and/or the **Add source** button) to add and select metadata sources.

In Edge mode, all the **Event metadata sources** are enabled by default.

The metadata sources that you can select here include:

- `os`: Reports details for the host OS and host machine, like OS version, kernel version, CPU, and memory resources, hostname, network addresses, and so on.

- `cribl`: Reports the Cribl Edge version, mode, instance GUID, Fleet (for managed instances), tags defined on the instance, and configuration version.
- `aws`: Reports details for an EC2 instance, including the instance type, hostname, network addresses, tags, and IAM roles. For security reasons, we report only IAM role names.
- `env`: Reports environment variables.
- `kube`: Reports details on a Kubernetes environment, including the node, Pod, and container. For details, see __metadata.kube Property.

When these metadata sources are enabled (and can get data), Cribl Edge will add the corresponding property to events, with a nested property for each enabled source.

Some metadata sources work only in configured environments. For example, the `aws` source is available only when running on an AWS EC2 instance.

If your security tools report denied outbound traffic to IP addresses like `169.254.169.168` or `169.254.169.254`, you can suppress these by removing `aws` from the metadata sources described above. If you have a proxy setup, Cribl recommends adding these IP addresses to your `no_proxy` environment variable.

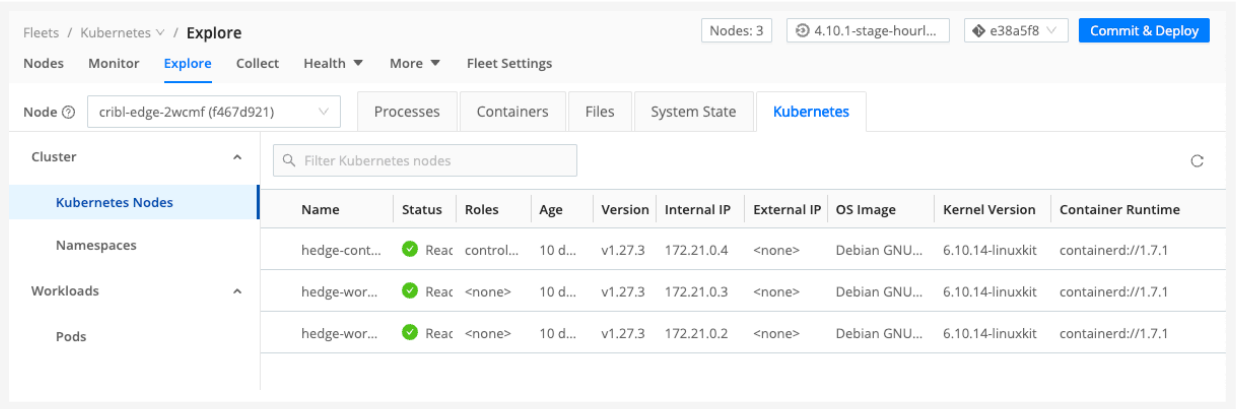
`__metadata.kube` Property

For the `__metadata.kube` property (`kube` in the UI) to report details on a Kubernetes environment, Cribl Edge needs to figure out where it is running. Set the `KUBE_K8S_POD` environment variable to the name of the Pod in which Cribl Edge is running. At this point, the `__metadata.kube` property will have information to report on the `node` and `pod` properties.

If the `/proc/self/cgroup` is working, then the `container` property information will be available, too.

If you leave the `KUBE_K8S_POD` environment variable unset, and `/proc/self/cgroup` is not working, then Cribl Edge will not know what Pod it is running in. This state has multiple implications:

- The Kubernetes Metrics Source will be unable to identify whether or not it is in a DaemonSet. The result will be redundant metrics from each node in the cluster.
- The Kubernetes Metadata Collector will not add the `__metadata.kube property`.
- The Kubernetes Logs Source will also duplicate data. Every node in the cluster will collect logs for every container in the cluster.



Other System State Information

The remaining information in the System State tab is organized into the following tabs:

Tab	Description
Disks	The **Disks** tab displays the inventory of physical disks and their partitions on the host system.
DNS	The **DNS** tab lists the host system's DNS resolvers and search entries.
File Systems	The **File Systems** tab displays an inventory of the mounted file systems on the host system.
Firewall	The **Firewall** tab displays a list of the host's defined firewall rules.
Groups	The **Groups** tab displays a list of the local groups including their names, descriptions, and members on the host system.
Hosts File	The **Hosts File** tab displays the host system's current state.
Interfaces	The **Interfaces** tab displays a list of each of the network interfaces on the host system.
Listening Ports	The **Listening Ports** tab displays a list of listening ports and their associated process identifier (pid).
Logged-in Users	The **Logged-In Users** tab displays a list of currently logged-in users on the host.
Routes	The **Routes** tab displays entries from the network routes on the host system.
Services	The **Services** tab displays a list of each configured service (such as `systemd` and `initd`) along with their running status.
Users	The **Users** tab displays a list of local users on the host system.

Kubernetes

The **Kubernetes** tab, available only for Kubernetes-based Edge Nodes, lists all the Kubernetes clusters, including nodes, pods, and containers.

Kubernetes tab

Select any row to open a summary table for the pod, including:

Tab	Description
Overview	Basic node information, including creation time, labels, taints, lease, and annotations.
Host	Detailed information about the node, including its IP address, capacity, system information, and the number of pods it's currently hosting.
Pods	List of pods running on the node, along with their resource usage and age.

Select **Filter Rules** to view/add more filters. The default filter ignores the `kube-*` namespace, which is typically used by Kubernetes system components and may contain a large volume of irrelevant events.

Filter Rules can be applied to the Kubernetes Logs Source to refine the data ingested into Cribl Edge.

To preview the effects of a new or modified Event Breaker Ruleset, you must commit and deploy the configuration changes.

Kubernetes Namespaces

In the sidebar, select **Namespaces** to view the list of active namespaces in the Kubernetes cluster, along with their status and age.

Select any namespace to view detailed information, including creation time, labels, annotations, resource quotas, and resource limits.

Kubernetes Pods

In the sidebar under **Workloads**, select **Pods** to view a list of pods running in the cluster. For each pod, the list shows its associated name, namespace, readiness, status, restart count, age, IP address, and the node it's running on.

Select any row to view pod information with the following tabs available:

Tab	Description
Overview	General information about the pod, including its name, namespace, status, IP address, labels, annotations, current health conditions, and tolerations.

3. Cribl Edge On Linux

Learn about deploying and configuring Cribl Edge on Linux.

Cribl Edge on Linux offers easy-to-use tools for exploring and collecting events. You can run Cribl Edge on a supported Linux and collect events, logs, and metrics via the full offering of Cribl Edge Sources.

Read the following topics for more information about running Cribl Edge on Linux:

Topic	Description
Installing Cribl Edge on Linux	Basic Cribl Edge deployment requirements and procedures
Enabling Start on Boot	Enable Cribl Edge instances to restart on system boot
Running Edge as an Unprivileged User	Install Cribl Edge an unprivileged user
Installing Edge on Linux via RPM	Securely install Edge using an RPM package
Installing Edge on Linux via .deb	Install Cribl Edge from a Linux .deb package
Anti-Virus Exceptions	Add anti-virus exceptions to facilitate Cribl Edge installation
FIPS Mode for Cribl Edge (Linux)	Running Cribl in FIPS mode
Use ACLs to Allow Cribl Edge to Read Files	Using Access Control Lists to allow Cribl Edge to Read Files

3.1. Install Cribl Edge On Linux

Install and deploy Cribl Edge Nodes on-prem on Linux.

You can install Cribl Edge in a supported Linux environment either connected to a Leader Node, alongside Cribl Stream, or in multiple instances on one host.

You can also install a Linux Edge Node in a Distributed deployment by running the bootstrap script in your command prompt.

Minimum Requirements

The following requirements are the minimum for installing and running an Edge Node on Linux.

Below is a summary of requirements for installing Cribl Edge. See Requirements for more detailed information.

OS Requirements

Cribl Edge Nodes can be installed on any common Linux distribution that fulfils the following criteria:

- 64-bit kernel >= 3.10
- glibc >= 2.17
- OpenSSL >= 3.0 (if FIPS mode is enabled)

Application Requirements

Minimum application requirements for Edge Nodes are:

- ~1 Ghz processor
- 1024 MB RAM
- 5 GB free disk space per volume for operational purposes

Download Cribl Edge

1. First, download the install package, which is the same binary as Cribl Stream, to your Linux machine.
2. Next, ensure that required ports are available (see Ports).
3. Then, you can install and run any of the following:
    - Connected to a Leader Node.

- Cribl Edge and Cribl Stream on the same host.
- Multiple installations of the same product, on the same host.

Install Cribl Edge

These instructions explain how to run Cribl Edge locally on your own machine and connect it to a Leader Node.

1. Un-tar the install package in a directory of choice, and rename the resulting `cribl` directory to `cribl-edge`, for example:

```
cd /opt/
tar xvzf cribl-<version>-<build>-<arch>.tgz
mv /opt/cribl/ /opt/cribl-edge
```

Copy

To prevent issues with Cribl file operations, `/opt/cribl` and all its subdirectories must reside on the same device. Mounting separate devices within `/opt/cribl` is not recommended. For external storage needs, such as lookups or Persistent Queues (PQs), create a completely separate directory outside of `/opt/cribl`. While `/opt/cribl` is the default installation path, Cribl can be installed to other locations if necessary.

2. Set the renamed directory, (for example, `/opt/cribl-edge/`), as your `$CRIBL_HOME` directory.

To make the `$CRIBL_HOME` environment variable available on your command line, you can:

- Assign it once, using the `export` command:
  `export CRIBL_HOME=/opt/cribl-edge`
- Set it as a default, by adding it to your to your terminal profile file.

3. Change the ownership of the installation to run Cribl Edge as a non-privileged user:

```
chown -R cribl:cribl /opt/cribl-edge
```

Copy

4. Start the Cribl service:

```
/opt/cribl-edge/bin/cribl start
```

Copy

5. Ensure you have an authentication token prepared on the Leader. See Create a New Provisioning Token for more information.
6. Set the installation mode to `mode-managed-edge` to connect the Node to the designated Leader:

```
/opt/cribl-edge/bin/cribl mode-managed-edge /
   -H <leader-hostname-or-IP> /
   -p <port> /
   -u <authToken> /
  [-g <fleet>]
```

Copy

   The new Node will be assigned to a Fleet on the Leader, either `default_fleet`, or a different one according to Fleet mappings.
   You can manually point to a specific Fleet by providing its name as `-g <fleet>`, but Fleet mappings will override this choice.

   If you only need a Single-instance deployment of Cribl Edge (without a Leader), use `mode-edge` instead of `mode-managed-edge`. In that case you don't need to provide the Leader token.

7. Configure the installation as a service and restart it:

```
/opt/cribl-edge/bin/cribl boot-start enable -m systemd -u cribl
sudo systemctl restart cribl-edge.service
```

Copy

   To find out more about the `boot-start` command, see Enabling Start on Boot.

8. Finally, go to `http://localhost:9420` (or another port you defined) and log in with default credentials (`admin:admin`). You can now start configuring Cribl Edge with Sources and Destinations, or start creating Routes and Pipelines.

For more ways to configure Leader and Edge Nodes, see Set Up Leader and Edge Nodes.

Cribl Edge and Cribl Stream on the Same Host

You can run an Edge Node with a Leader that is managing Cribl Stream, or an Edge Node and a Stream Worker Node on the same host. To accommodate these scenarios, each product has a distinct service name:

- `cribl-edge.service` for Cribl Edge.
- `cribl.service` for Cribl Stream.

Here, Cribl recommends un-tarring the download package twice, into two separate directories. This setup frees you to update and run each product individually. You could choose, e.g., `/opt/cribl-edge` and `/opt/cribl`:

```
cd /opt
tar zxvf /tmp/cribl-<version>-<build>-<arch>.tgz
mv cribl cribl-edge
tar zxvf /tmp/cribl-<version>-<build>-<arch>.tgz
```

Copy

The installation and configuration sequence will be the same for each product:

1. Change the ownership for both installations.
   Run Cribl Stream as a non-privileged user:

   ```
   chown -R cribl:cribl /opt/cribl
   ```

   Copy

   Run Cribl Edge as a non-privileged user:

   ```
   chown -R cribl:cribl /opt/cribl-edge
   ```

   Copy

> **Do NOT Run Cribl Edge as Root!**
>
> To listen on low ports 1-1024, Cribl Edge needs privileged access. You can enable this on systemd by adding this configuration key to your `override.conf` file:
>
> ```
> [Service]
> AmbientCapabilities=CAP_NET_BIND_SERVICE
> ```

Copy

If you want to add extra capabilities, such as reading certain resources (e.g., `/var/log/*`), add `CAP_DAC_READ_SEARCH` in a space-separated format as follows:

```
[Service]
AmbientCapabilities=CAP_NET_BIND_SERVICE CAP_DAC_READ_SEARCH
```

Copy

Alternatively, you can use ACLs to allow Cribl Edge to read files.

For details, see Running Edge as an Unprivileged User.

2. Set the correct mode, and configure each installation as a service. The `-H` and `-p` parameters are required.
   For Cribl Edge:

```
/opt/cribl-edge/bin/cribl mode-managed-edge -H <leader-hostname-or-IP> -p <port>

/opt/cribl-edge/bin/cribl boot-start enable

sudo systemctl restart cribl-edge.service
```

Copy

   For Cribl Stream:

```
/opt/cribl/bin/cribl mode-worker -H <leader-hostname-or-IP> -p <port> [options]

/opt/cribl/bin/cribl boot-start enable

sudo systemctl restart cribl.service
```

Copy

Managing IP Addresses

By default, Cribl Edge's API listens on port `9420`, instead of on Cribl Stream's default `9000` port. Some things to note:

- You can set the `CRIBL_EDGE` environment variable to any value to bind to `0.0.0.0`, instead of to the `127.0.0.1` address.
- If you are starting Cribl Edge from the CLI, make sure you set the `-H` parameter to `0.0.0.0`.
- If you connect your Edge Node to a Leader, the Node will automatically update the binding IP address to the one configured in the Leader's Fleet Settings. For an Edge Node to always listen on all IP addresses, you must update the Leader's **Host** value. (In the Leader's UI, go to **Fleet Settings** > **System** > **General Settings**, and change the **Host** field to `0.0.0.0`.)
- You can disable listening on the port by toggling **Listen on port** to off in **Fleet Settings** > **General Settings** > **Advanced**.

Continue with Setting Up Leader and Edge Nodes for Edge, and Setting Up Leader and Worker Nodes for Stream.

Multiple Installations of Same Product on Same Host

There are situations where it makes sense to run multiple Cribl Edge or Cribl Stream installations on the same host. For example, suppose two departments want to collect the data at the edge - and each wants to process the data differently, and to deploy its own Helm chart as a daemonset.

To support this: After un-tarring the installation package, copy or move it into a separate directory for each installation. For example, if you're creating two Cribl Edge installations:

```
cd /opt
tar zxvf /tmp/cribl-<version>-<build>-<arch>.tgz
cp -r cribl/ cribl-edge-01/
mv cribl/ cribl-edge-02/
```

Copy

The installation and configuration procedure is the same as described for collocated Cribl Edge and Cribl Stream above, except that you must:

- Omit steps pertaining to the product you are **not** installing.
- Repeat steps pertaining to the product you are **are** installing - once for each instance of the product.

Ensure that each instance of the product runs on its own dedicated port. Either:

- Specify different ports when you run the `mode-managed-edge` or `mode-worker` command; or,
- On the host, set the `CRIBL_AUTO_PORTS` environment variable to `1`.

Troubleshooting Resources

The Cribl University Troubleshooting course on Switching from Cribl Edge to Cribl Stream demonstrates these techniques for integrating Edge with Stream.

3.2. Enable Start On Boot On Linux

Ensure that Cribl Edge starts at boot time.

Cribl Edge ships with a CLI utility that can update your system's configuration to start Edge at system boot time. The basic format to invoke this utility is:

```
sudo $CRIBL_HOME/bin/cribl boot-start [enable|disable] [options] [args]
```

Copy

You must run this command as root, or with `sudo`. For options and arguments, see the CLI Reference.

The script will create a user named `cribl` to install, own, and run Cribl Edge/Stream.

Most, if not all, popular Linux distributions use `systemd` now to start processes at boot, while older or more obscure distributions may still use `initd`. Verify with your Linux distribution vendor if you aren't sure which method your systems use in order to know which procedure listed below to follow.

Using systemd

To **enable** Cribl Edge to start at boot time with **systemd**, you must run the `boot-start` command. Make sure you first create any user you want to specify to run Edge. E.g., to run Edge on boot as existing user `cribl`, you'd use:

```
sudo $CRIBL_HOME/bin/cribl boot-start enable -m systemd -u cribl
```

Copy

This will install a unit file (as shown below) named `cribl-edge.service`, and will start Cribl Edge at boot time as user `cribl`. A `-configDir` option can be used to specify where to install the unit file. If not specified, this location defaults to `/etc/systemd/system/`.

If necessary, change ownership for the Cribl Edge installation:

```
sudo chown -R cribl $CRIBL_HOME
```

Copy

Next, use the `enable` command to ensure that the service starts on system boot:

```
sudo systemctl enable cribl-edge
```

Copy

To **disable** starting at boot time, run the following command:

```
sudo $CRIBL_HOME/bin/cribl boot-start disable
```

Copy

Other available `systemctl` commands are:

```
sudo systemctl [start|stop|restart|status] cribl-edge
```

Copy

Note the file's default `65536` hard limit on maximum open file descriptors (known as a `ulimit`). The minimum recommended value is `65536`. Linux tracks this per user account. You can view the current soft `ulimit` for max open file descriptors with `$ ulimit -n` while logged in as the same user running the `cribl` binary.

Installed systemd File

```
[Unit]
Description=Systemd service file for Cribl Edge.
After=network.target

[Service]
Type=forking
User=cribl
Restart=always
RestartSec=5
LimitNOFILE=65536
PIDFile=/install/path/to/cribl/pid/cribl.pid
ExecStart=/install/path/to/cribl/bin/cribl start
ExecStop=/install/path/to/cribl/bin/cribl stop
ExecReload=/install/path/to/cribl/bin/cribl reload
TimeoutSec=60

[Install]
WantedBy=multi-user.target
```

Copy

Persisting Overrides

By default, disabling and re-enabling boot start will regenerate the `cribl-edge.service` file. To persist any overrides - such as proxy or privileged port usage - use this command:

```
sudo systemctl edit cribl-edge
```

Copy

This opens a text editor that prompts you to enter overrides, then saves them to a persistent file at:

```
/etc/systemd/system/cribl-edge.service.d/override.conf
```

Copy

Using a Literal % Character

To use a literal `%` character, make sure to escape it by using a double `%%`.

For example, suppose that you want to persist the environment variable `CRIBL_DIST_WORKER_PROXY` in a systemd unit file, and the value includes a password that contains the special character `@`: `special@password`. You must encode the `@` as `%40`. However, because `%` is a special character that is used for specifiers in systemd unit files, you must also escape the `%` itself by doubling it.

In this example, `%%40` represents the literal `@` character in the password:

```
Environment=CRIBL_DIST_WORKER_PROXY=socks5://proxyuser:special%%40password@mydomain.c
```

Copy

Avoid Running Cribl Edge as Root

Do not run Cribl Edge as root!

To listen on low ports 1-1024, Cribl Edge needs privileged access. You can enable this on systemd by adding this configuration key to your `override.conf` file:

```
[Service]
AmbientCapabilities=CAP_NET_BIND_SERVICE
```

Copy

If you want to add extra capabilities, such as reading certain resources (e.g., `/var/log/*`), add `CAP_DAC_READ_SEARCH` in a space-separated format as follows:

```
[Service]
AmbientCapabilities=CAP_NET_BIND_SERVICE CAP_DAC_READ_SEARCH
```

Copy

To unlock advanced file monitoring in Cribl Edge, such as scanning open files for running processes, discovering active logs automatically in Explore, and using the File Monitor Source's auto-mode feature, add `CAP_SYS_PTRACE` :

```
[Service]
AmbientCapabilities=CAP_NET_BIND_SERVICE CAP_DAC_READ_SEARCH CAP_SYS_PTRACE
```

Copy

Alternatively, you can use ACLs to Allow Cribl Edge to Read Files.

For details, see Running Edge as an Unprivileged User.

Using initd

To **enable** Cribl Edge to start at boot time with **initd**, you must run the `boot-start` command. If the user that you want to run Cribl Edge does not exist, create that user prior to executing. E.g., running Edge as user `cribl` on boot:

```
sudo $CRIBL_HOME/bin/cribl boot-start enable -m initd -u cribl
```

Copy

This will install an `init.d` script in `/etc/init.d/cribl.init.d`, and will start Cribl Edge at boot time as user `cribl`. A `-configDir` option can be used to specify where to install the script. If not specified, this location defaults to `/etc/init.d`.

If necessary, change ownership for the Cribl Edge installation:

```
sudo chown -R cribl $CRIBL_HOME
```shell

To **disable** starting at boot time, run the following command:

```shell
sudo $CRIBL_HOME/bin/cribl boot-start disable
```

Copy

To control Cribl Edge, you can use the following initd commands:

```
sudo service cribl-edge [start|stop|restart|status]
```

Copy

Persisting Overrides on initd

Notes on preserving required permissions across restarts and upgrades:

> To read file resources on a Linux system that are typically restricted to the root user, you can add the `CAP_DAC_READ_SEARCH` capability. For example:
>
> On some OS versions (such as CentOS), you must add an `-i` switch to the `setcap` command. For example: `# setcap -i cap_dac_read_search=+ep $CRIBL_HOME/bin/cribl`
>
> **Important**: Upgrading Edge will remove the `CAP_DAC_READ_SEARCH` capability from the `cribl` executable, so you'll need to re-run the appropriate `setcap` command after each upgrade.

3.3. OS Tuning For Large Deployments

Large on-prem deployments that handle high connection volumes or data rates may require operating system (OS) tuning to maintain optimal performance. To prevent performance issues on high-load Edge Nodes, you might need to tune your OS.

Review and apply the following OS-level configurations to address common bottlenecks like connection tracking table exhaustion and buffer overruns, ensuring stable operation for your Cribl environment.

The parameters described in this section are Linux kernel and operating system settings, not Cribl Edge configuration options. They directly affect how the OS handles network connections and system resources for high-throughput Cribl Edge workloads.

Connection Tracking (Netfilter)

Applies to: Worker Nodes (handling high volumes of inbound network connections.)

In deployments where you expect a high number of inbound connections, Linux netfilter connection tracking (`conntrack`) could become a bottleneck. Connection tracking is enabled by default on most Linux distributions and maintains a table of active network flows. When this table fills up, the kernel drops packets, which can cause connection failures and data loss.

When to Tune

Monitor your system logs (`/var/log/messages` or `journalctl \-k`) for messages indicating conntrack table exhaustion:

```
nf_conntrack: table full, dropping packet
```

If you observe these messages, you should increase the `conntrack` table size and potentially adjust related parameters.

Key `Conntrack` Parameters

These `sysctl` parameters govern connection tracking behavior:

- `net.netfilter.nf_conntrack_max`: Maximum number of flows tracked concurrently. By default, it derives from the buckets value: `nf_conntrack_max= nf_conntrack_buckets × 4.`
- `net.netfilter.nf_conntrack_buckets`: Hash buckets for the `conntrack` table. If not set at module load, the kernel computes a default from total system memory (roughly `total memory in bytes / 16384`) with floor and ceiling limits applied.

For the full list of netfilter `conntrack sysctls` and their defaults, see Netfilter Conntrack Sysfs variables.

Check Current Values and Live Load

Use the following commands to inspect your current conntrack configuration and active connection count:

```
# Current max entries
sysctl net.netfilter.nf_conntrack_max

# Current active tracked flows (count)
sysctl net.netfilter.nf_conntrack_count

# Alternatively via procfs
cat /proc/sys/net/netfilter/nf_conntrack_max
cat /proc/sys/net/netfilter/nf_conntrack_count
```

Copy

Compare the count against the max. If the count approaches or equals the max during normal operation, you need to increase capacity.

Method 1 (Recommended): Increase the `conntrack` Table Size

This is the standard and generally recommended approach to eliminate `conntrack` bottlenecks by simply giving the table more capacity.

To ensure stability, set the maximum number of tracked flows high enough to maintain adequate margin above your peak observed load. For very large deployments handling hundreds of thousands of concurrent connections, you may need values of 4 million or higher.

```
# For example, to set approximately 2 million tracked connections (adjust per sizing)
echo "net.netfilter.nf_conntrack_max=2097152" >> /etc/sysctl.conf
sysctl -p
```

Copy

Adjust the value based on your deployment's actual connection load.

If you substantially increase `nf_conntrack_max`, review `nf_conntrack_buckets` for balance. By default, the kernel derives buckets from available memory, and max defaults to approximately 4 times the bucket count. Maintaining this ratio helps ensure efficient hash table performance.

Method 2 (Extreme Case): Disable Connection Tracking

In extremely high-throughput, purpose-built environments where Cribl Stream is the only service and network overhead is a top concern, disabling conntrack entirely can be considered an aggressive measure. While this is often the simplest and most effective measure for some on-prem deployments, approach it with caution due to its side effects.

How to Disable conntrack (Persistent)

To prevent the module from loading at boot:

```
echo "install nf_conntrack /bin/true" >> /etc/modprobe.d/disable-conntrack.conf
```

Copy

Disabling conntrack is **NOT generally recommended** and carries significant consequences:

- Breaks stateful firewalls: Most modern firewall rules (iptables, nftables) rely on conntrack for stateful filtering. Disabling it will break stateful firewalls, requiring a complete rewrite of your rules to be stateless.
- Breaks NAT/Kubernetes: Network Address Translation (NAT) and IP masquerading are heavily dependent on conntrack. Disabling it will break networking for container technologies like Kubernetes and Docker.

Kubernetes Deployments

If you run Cribl Edge on Kubernetes, **do not disable netfilter or conntrack**. Kubernetes networking (including kube-proxy and network policies) depends on conntrack for proper operation. Tune conntrack parameters as described in Method 1 instead.

File Descriptor Limits

Applies to: Leader and Worker Nodes

The Cribl Edge systemd unit sets `LimitNOFILE=65536` by default, which aligns with our minimum recommendation. This limit applies per process (not systemwide or per user), meaning the API and each Worker Process can each open up to `65,536` file handles. This is generally more than sufficient for high-volume workloads, including those involving:

- File-based Destinations (S3, Filesystem, etc.), especially with partition expressions that possess a high cardinality. For details, see Amazon S3 Better Practices.
- Large numbers of concurrent inbound and outbound connections

For more information on running Cribl Stream as a service, see Run Cribl Stream.

Diagnosing `Too Many Open Files` Error

The default value is typically sufficient for normal operation. Increasing the limit is generally not the correct fix; it usually only postpones the necessity of identifying and resolving the root cause of the process hitting the resource ceiling.

Start your investigation by determining which process is affected. The `cribl.log` file will reflect a `too many open files` error, referencing one of two error codes:

- `EMFILE (Too many open files)`: This means the per-process limit has been reached. This is the common case that the LimitNOFILE setting addresses.
- `ENFILE (File table overflow)`: This means the systemwide (kernel-level) limit for all open files has been reached. The fix for this (increasing the `fs.file-max sysctl`) is outside the scope of this section, as it's rarely encountered.

The scenario that leads to the common `EMFILE` error is usually the API Process being overwhelmed due to Worker Processes being too busy. The API Process always receives the connection attempt first, then hands the file descriptor off to a Worker Process.

The `EMFILE` condition typically occurs when a large number of clients (on the order of thousands) establish connections that are not closed have excessively long timeouts. Since Worker Processes are often unable to accept the handoff of these file descriptors from the API, the API Process accumulates thousands of connections waiting to be serviced. This accumulation of active or stuck connections rapidly exhausts the file descriptor limit for the API Process. The proper fix, therefore, is to address why the Worker Processes are too busy.

Start by analyzing your Pipelines using the Pipeline Profiling feature to identify bottlenecks and reduce Worker load. For details, see Pipeline Profiling.

How to Increase the Per-Process Open File Limit (if Necessary)

If, after investigation, you've confirmed that the workload legitimately requires more file handles (such as, in extremely large, high-volume, or unique deployments), you can increase this per process limit via a systemd override:

```
# Create or edit the systemd override
sudo systemctl edit cribl
```

Copy

Add the following (example) content:

```
[Service]
LimitNOFILE=262144
```

Copy

Save the file and restart the Cribl Stream service for the change to take effect:

```
sudo systemctl restart cribl
```

Copy

You can verify the current limit for running processes by checking `/proc/<pid\>/` limits for any Cribl Edge process.

```
# For exampalefor PID 7284
cat /proc/7284/limits
```

Copy

UDP Receive Buffers

Applies to: Worker and Edge Nodes (Nodes hosting UDP input Sources).

For high-rate UDP ingest (such as Syslog, NetFlow, or IPFIX), the default kernel UDP receive buffers may be insufficient, leading to packet drops before data reaches Cribl Stream. Increasing these buffers can significantly reduce packet loss.

When to Tune

Cribl recommends tuning UDP buffers to accommodate short-lived but large data spikes. Tuning UDP buffers is recommended to accommodate short-lived but large data spikes.

Before tuning the buffer size, you should confirm that the data is being properly distributed across all the Worker Nodes in the Group. If the data is improperly load-balanced and only hitting a subset of your Nodes, you must address the distribution issue first. Fixing the load balancing might resolve the packet drop problem entirely, making buffer adjustments unnecessary.

For permanent solutions to consistently high data volume, scaling your environment (adding more worker processes or nodes) is the correct approach.

Monitor for UDP packet drops using:

```
# On modern operating systems, check for packet receive errors using ss
ss -ua
# Alternatively, if ss is unavailable
netstat -su
```

Copy

Look for increases in `packet receive errors` or `RcvbufErrors` under the UDP section.

Method 1: Kernel-Level Tuning (System-Wide OS Configuration)

This method applies the buffer increase to **all** UDP sockets on the system.

Increase the kernel's UDP receive buffer sizes:

```
# Set to 25 MB (adjust based on your volume)
echo "net.core.rmem_max=26214400" >> /etc/sysctl.conf
echo "net.core.rmem_default=26214400" >> /etc/sysctl.conf
# Apply the changes immediately without rebooting:
sysctl -p
```

Copy

Method 2: Per-Input via Cribl Stream Configuration

We generally recommend configuring the buffer size within Cribl Stream (on the specific UDP Source) for two main benefits:

- **Portability:** The setting becomes part of your Cribl Stream configuration, ensuring it is automatically applied to newly deployed Nodes without requiring manual OS tuning on each one.
- **Scope:** The larger buffer is applied only to the specific UDP sockets used by Stream Sources that have this setting defined, avoiding the general application to all system sockets.

Start with `25` MB and adjust based on your data rates and observed drop rates.

For detailed UDP tuning guidance specific to Cribl Stream, see:

- Syslog Source - UDP Tuning
- UDP (Raw) Source

SELinux Configuration

Applies to: Leader, Worker, and Edge Nodes.

In hardened environments running SELinux in enforcing mode, ensure proper SELinux contexts are set on Cribl directories to allow Stream to operate correctly. Use SELinux audit logs to troubleshoot any denials and adjust policies as needed.

For detailed guidance on running Cribl Stream with SELinux, see SELinux Configuration.

3.4. Run Edge As An Unprivileged Linux User

Run Cribl Edge as an unprivileged (non-root) Linux user.

Privileged access might be necessary if Cribl Edge needs to read certain resources (e.g., `/var/log/*`), or to listen on low ports 1-1024. Features like auto-discovery of logs and information in the Processes UI also require permissions to access `/proc`. The regular non-root permissions are not sufficient in these cases.

There are two alternatives to running Cribl Edge as `root`:

- Set Linux capabilities that grant Cribl Edge sufficient rights to perform specific privileged tasks. For details, see Set Capabilities for Cribl Edge below.
- Take advantage of Linux systems' option to layer an Access Control List (ACL) over the default Linux permissions. By using ACLs, you can assign a more specific set of permissions to a file or directory without (necessarily) changing the base ownership. For details, see Using ACLs to Allow Cribl Edge to Read Files.

Set Capabilities for Cribl Edge

Capabilities are permissions that grant privileged processes sufficient rights to accomplish a specific task, based on a kernel privilege. To run Cribl Edge as non-root user, consider setting the following capabilities:

Capability	Permissions
`CAP_NET_ADMIN`	Allows Cribl Edge to identify network listeners on the node.
`CAP_NET_BIND_SERVICE`	Allows Cribl Edge to push Sources that bind to TCP/UDP port numbers below `1024`.
`CAP_DAC_READ_SEARCH`	Allows the `cribl` user to access files in **Explore** > **Files** > Manual/Browse, and to access the File Monitor Source's Manual mode feature. This capability bypasses the default Linux permissions for files and directories.
`CAP_SYS_PTRACE`	Allows the `cribl` user to scan open files for running processes, to discover active logs in **Explore** > **Files** > Auto, and to access the File Monitor Source's Auto-mode feature.

For details about setting these capabilities, see Persisting Overrides.

Making Docker Containers Visible to Edge

You can enable Cribl Edge to access statistics and information about any running container on its host. To do this, add the `cribl` user to the `docker` group, then restart Cribl Edge.

OS-Specific Options

To read file resources on a Linux system that are typically restricted to the root user, you can add the `CAP_DAC_READ_SEARCH` capability. For example:

On some OS versions (such as CentOS), you must add an `-i` switch to the `setcap` command. For example: `# setcap -i cap_dac_read_search=+ep $CRIBL_HOME/bin/cribl`

Upgrading Edge will remove the `CAP_DAC_READ_SEARCH` capability from the `cribl` executable, so you'll need to re-run the appropriate `setcap` command after each upgrade.

Fallbacks from Privileged Access

If installing and running Edge with `root`-level privileges is forbidden or impractical in your environment, certain Sources, like Exec and System Metrics, can run on a user with lower permissions. You can also run the File Monitor Source in `Manual` mode, and collect from any files that this user can read.

3.5. Install Edge On Linux Via RPM

Install Edge in a tightly managed Linux environment by using the signed RPM package installation method.

The RPM will create a `cribl-edge` user and a `cribl-edge` group. The `cribl-edge` user will own the `cribl-edge` configuration file (stored in the `/etc/sysconfig` directory). The `config` file contains the Leader's auth token. To keep the Leader's auth token secure, only `root` and the `cribl-edge` user can read/modify the `config` file contents.

Download Cribl Edge as an RPM Package

To download Cribl Edge as a signed RPM package:

1. Go to cribl.io/download.
2. Select the dropdown in the Software area labeled **Select Release Version**.
3. Choose the Cribl Edge RPM version and type: `<version> x64 Cribl Edge RPM`, or `<version> ARM Cribl Edge RPM`.
4. Select **Download now**.

Verifying the RPM Package Signature

To verify the RPM package signature, you'll need to enable local GPG package checking, then download the GPG key, import it, and verify its signature. We'll go over how to accomplish both of these steps below.

Enable Local GPG Package Checking

Your environment may not have the GPG check for local packages enabled by default.

To enable the local package GPG checks for `yum` or `dnf`, add `localpkg_gpgceheck=1` to the `main` stanza in:

- `/etc/yum/conf` for `yum`
- `/etc/dnf/dnf.conf` for `dnf`

For example:

```
[main]
...
localpkg_gpgcheck=1
```

Copy

Download and Import the GPG Key

Cribl's public GPG key ensures the authenticity and integrity of the Cribl RPM package.

1. Import the public GPG key to `rpm` using this command:

```
rpm --import https://cdn.cribl.io/dl/CRIBL_RPM_PUBLIC_GPG
```

Copy

2. Verify the package signature using this command:

```
rpm -Kv <rpm-file>
```

Copy

   This command ensures the package's integrity and authenticity, and returns information about the package. It also checks if anyone has tampered with the package since the original developer or distributor signed it. This helps prevent you from installing potentially malicious or compromised packages.

Installing Edge via RPM

Follow the installation steps to install the RPM package on a Cribl Linux Edge Node.

Out of the box, the RPM will install the software into the `/opt` directory. The RPM package will configure but not enable the Systemd service. You will need to enable the software service separately.

To install Cribl Edge via RPM:

1. Ensure you have an authentication token prepared on the Leader. See Create a New Provisioning Token for more information.
2. Open a CLI and run the following command, drawing the file name from the cribl.io/download page:

```
sudo yum install https://cdn.cribl.io/dl/<version>/<file name>
```

Copy

You can quickly get the CDN file name from the checksum links for each download.

This command does the following:

- Creates the `cribl-edge` user and group, if it doesn't exist.
- Puts the contents of Cribl's TGZ into `/opt/cribl-edge` and makes `root/root` the owner.
- Creates the `cribl-edge` systemd service, which is disabled by default.
- Creates `/etc/sysconfig/cribl-edge.conf` owned by `cribl-edge:cribl-edge` and only accessible by the `cribl-edge` user.
- Creates `/var/lib/cribl-edge/` owned by `cribl-edge:cribl-edge` and only accessible by the `cribl-edge` user.
- Sets `CRIBL_INSTALL_TYPE` to `RPM` in the service destination, to block distributed upgrades, as upgrading from the Leader bypasses the security of RPM.
- Sets `CRIBL_VOLUME_DIR` to `/var/lib/cribl-edge` in the service destination, so configs and logs are saved to the `cribl-edge` directory.

3. Edit the environment variables in `/etc/sysconfig/cribl.conf`, in order for Cribl Edge to connect to a Leader. The RPM installs `cribl-edge` in standalone mode by default (`CRIBL_DIST_MODE = edge`).

   To deploy Edge in a managed deployment, edit these environment variables:

   - `CRIBL_DIST_MODE = managed-edge`
   - `CRIBL_DIST_LEADER_URL=tls://<authToken>@leader:4200`

4. Enable optional Linux capabilities.
   `CAP_DAC_READ_SEARCH` lets you read files without ownership/permission checks (such as `/var/log/nginx` or application logs under service accounts), and `CAP_SYS_PTRACE` lets you trace processes and read `/proc/<pid>/` data.
   To enable them, add this configuration key to the systemd service file, located at `/etc/systemd/system/cribl-edge.service` or `/lib/systemd/system/cribl-edge.service`:

   ```
   [Service]
   AmbientCapabilities=CAP_DAC_READ_SEARCH CAP_SYS_PTRACE
   ```

   Copy

5. Enable the service:

- `sudo systemctl enable cribl-edge` to enable the service on boot.
- `sudo systemctl start cribl-edge` to start it manually.

Upgrading Edge via RPM

See Upgrade RPM Installations.

Uninstalling Edge via RPM

To remove Cribl that you installed via RPM, use the command line:

```
sudo yum remove cribl-edge
```

Copy

Uninstalling Cribl removes the `cribl` or `cribl-edge` service, the `cribl` binary from `/opt/`, and the service file from `/lib/systemd/system`.

Configuration files are maintained, along with any environment variables you edited when you first installed Cribl. This means you can pull in your previous configuration(s) if you decide to reinstall Cribl via RPM.

The `cribl-edge` directory is also maintained, along with the data, logs, and defaults of your configuration.

3.6. Install Edge On Linux Via .Deb

Install Cribl Edge in a Linux environment using a .deb package.

The installation conforms to restrictions for Linux installations, such as system requirements.

Install Cribl Edge from a .deb Package

Follow these steps to install an Edge Node on Linux from a .deb package:

1. Download the Cribl Edge .deb package. Go to cribl.io/download and select the dropdown in the Software area labeled **Select Release Version**.
2. Choose the Cribl Edge .deb version and type: `<version> x64 Cribl Edge DEB`, or `<version> ARM Cribl Edge DEB`.
3. Select **Download now**.
4. Open a CLI and run the following command to install the package with the apt utility:

   ```
   sudo apt install <path-to-deb-package>
   ```

   Copy

   This command does the following:

   - Creates the `cribl-edge` user and group, if it doesn't exist.
   - Puts the contents of the Cribl package into `/opt/cribl-edge` and makes `root/root` the owner.
   - Creates the `cribl-edge` systemd service, which is disabled by default.
   - Creates `/etc/default/cribl-edge` owned by `cribl-edge:cribl-edge` and only accessible by the `cribl-edge` user.
   - Creates `/var/lib/cribl-edge/` owned by `cribl-edge:cribl-edge` and only accessible by the `cribl-edge` user.
   - Adds the Cribl Edge service definition file at `/lib/systemd/system/cribl-edge.service`.
   - Sets `CRIBL_INSTALL_TYPE` to `DEB` in the service definition, to block distributed upgrades, as upgrading from the Leader bypasses the security of a .deb package.
   - Sets `CRIBL_VOLUME_DIR` to `/var/lib/cribl-edge` in the service definition, so configs and logs are saved to the `cribl-edge` directory.
5. Edit the environment variables in `/etc/default/cribl-edge`, so Cribl Edge can connect to a Leader. The .deb package installs `cribl-edge` in standalone mode by default (`CRIBL_DIST_MODE = edge`).

To deploy Edge in a managed deployment, edit these environment variables:

- `CRIBL_DIST_MODE=managed-edge`
- `CRIBL_DIST_LEADER_URL=tls://<authToken>@leader:4200`

6. During installation, the package configures but does not enable the systemd service. Enable the service:
   - `sudo systemctl enable cribl-edge` to enable the service to start on boot.
   - `sudo systemctl start cribl-edge` to start it manually.

To ensure that the `cribl status` command can run correctly when running via systemctl, set the `CRIBL_VOLUME_DIR` environment variable:

```
sudo bash
export CRIBL_VOLUME_DIR=/var/lib/cribl
```

Copy

Upgrade a .deb Installation

See Upgrade .deb Installations.

Uninstall a Cribl Edge .deb Package

To remove Cribl Edge that you installed from a .deb package, run:

```
sudo apt remove <path-to-deb-package>
```

Copy

Uninstalling removes the `cribl-edge` service, the `cribl` binary from `/opt/`, and the service file from `/lib/systemd/system`.

Configuration files are maintained, along with any environment variables you edited when you first installed Cribl. This means you can pull in your previous configuration(s) if you decide to reinstall Cribl via a .deb package.

The `cribl-edge` directory is also maintained, along with the data, logs, and defaults of your configuration.

3.7. FIPS Mode For Cribl Edge (Linux)

Federal Information Processing Standards FIPS represent a set of US government standards and guidelines for information security. You can deploy Cribl Edge in **FIPS mode**. This mainly restricts the cryptographic algorithms used within Cribl Edge and also enforces FIPS compliant password requirements.

Do not start Cribl Edge without FIPS mode enabled, or else you will be unable to run it in FIPS mode later. You must enable FIPS mode as described in this section, after installing **but before starting** Cribl Edge.

Requirements

This section describes the system and password requirements for FIPS mode.

FIPS Mode System Requirements

To run Cribl Edge in FIPS mode, your environment must satisfy the following requirements.

Operating Systems

Must support FIPS 140-2 or FIPS 140-3. Several Linux distributions meet this standard. See NIST's list of tested configurations here.

While RHEL 9 can be configured to run in FIPS mode at the operating system level, this **does not automatically enable FIPS mode within Cribl Edge.** You must still follow the procedures outlined in this document to explicitly enable Cribl Edge's FIPS mode. Cribl Edge relies on its own configuration to ensure FIPS compliance, independent of the OS-level FIPS setting.

OpenSSL

The operating system environment must have a FIPS validated version of OpenSSL installed.

- **For Cribl Edge versions 4.5.0 through 4.8.1**: The FIPS provider version must be 3.0.8 or 3.0.9, and the system-wide OpenSSL version must also be 3.0.8 or version 3.0.9, with its associated certificate.
- **For Cribl Edge starting with version 4.8.2**: The FIPS provider version requirement must be >= 3.0.5, and the system-wide OpenSSL version is no longer a factor. Cribl Edge now verifies the OpenSSL version bundled within the binary.

Enterprise Linux 9 is the only version of Enterprise Linux that includes OpenSSL version 3.0.9 out of the box. While it's possible to manually install compatible versions of OpenSSL on older Enterprise Linux versions, this

process is complex and generally not recommended. Therefore, the minimum recommended Enterprise Linux version for running Cribl Edge in FIPS mode is 9.

Even when running Cribl Edge on a FIPS-enabled RHEL 9 system, you must still explicitly enable Cribl Edge's FIPS mode as described in the Running Cribl Edge in FIPS Mode section below. The OS being in FIPS mode is not sufficient for Cribl Edge to operate in a FIPS-140 compliant manner.

FIPS Mode Restrictions on Cryptographic Algorithms

When running in FIPS mode, Cribl Edge uses only those cryptographic algorithms that satisfy the FIPS standards. This means that Cribl Edge operates exclusively with FIPS-compliant cryptographic algorithms, disallowing the use of non-compliant algorithms like MD5 (message-digest) or CRC-32 (Cyclic Redundancy Check 32) algorithms.

To ensure proper functionality in FIPS mode, the FIPS provider version must be at least `3.0.5`.

Therefore, in FIPS mode:

Cribl expressions **that rely on MD5 or CRC-32 will fail silently.** This includes expressions that use the `C.Mask.md5()` method and can in turn affect the behavior of parent Functions and their existing parent Pipelines.

The UI will hide certain options normally made available by the typeahead feature.

No Source, Destination, or Email Notification target that uses the Amazon AWS SDK v2 will perform checksums. This is because that SDK uses MD5 to verify checksums, and it applies to both incoming or outgoing payloads. Specifically:

- The Amazon Kinesis Data Streams Source will not perform checksums and the **Verify KPL checksums** setting will not be available.
- The Amazon SNS Notification target will not perform checksums.
- The following Destinations will not perform checksums:
    - Amazon CloudWatch Logs
    - Amazon Kinesis Data Streams
    - Amazon SQS
    - Google Cloud Storage
    - MinIO
    - Prometheus

Role-Based Access Control (RBAC) Controls

Cribl Edge's FIPS mode requires RBAC to be enabled for enhanced security. This ensures proper access management within FIPS-compliant environments. To enable RBAC, the Cribl Edge instance has to be running in Distributed mode. FIPS mode is available on certain license tiers. For details, see Pricing.

If FIPS mode is already enabled and RBAC is subsequently disabled, Cribl Edge will automatically disable FIPS mode and log a message stating:

```
"Disabling FIPS due to Role-based Access Control (RBAC) being disabled."
```

Check `<cribl_install_dir>/local/_system/instance.yml` to ensure Cribl is running in Distributed mode. The default installation directory is typically `/opt/cribl`. The `mode` setting in this file should be set to `distributed`. If it is set to `standalone`, you will need to switch to a Distributed deployment to use FIPS mode with RBAC enabled.

FIPS Mode Password Rules

When Cribl Edge is in FIPS mode, all passwords must:

- Contain eight or more characters.
- Use characters from three or more of the following categories:
  - Lowercase letters.
  - Uppercase letters located after the first character in the password.
  - Digits located before the last character in the password.
  - Non-alphanumeric ASCII characters such as `#`, `!`, or `?`.
  - Non-ASCII characters such as `ñ`, `€`, or emoji.

As of Cribl Edge version 4.5.0, these rules apply for all passwords, whether or not Cribl Edge is running in FIPS mode, with one exception:

- For Cribl Edge not running in FIPS mode, local users whose passwords existed before Cribl Edge 4.4.4 was released can continue to use their passwords, even if those passwords do not satisfy the rules.
- When these users change to new passwords, the new passwords must satisfy the rules.
- New users must create passwords that satisfy the rules.

If you get locked out of your account, you need to reset your password manually.

Running Cribl Edge in FIPS Mode

To begin using Cribl Edge with FIPS enabled, complete either the non-systemd or the systemd procedure below, **before you start Cribl Edge for the first time after installing**.

Enabling FIPS Mode on a Non-systemd Distribution

If the Linux distribution on which you run Cribl Edge **does not** use systemd:

1. Complete **either** of the two following steps:
   - Set the `CRIBL_FIPS` environment variable to `1` (true), **or**,
   - Edit `cribl.yml`, adding this top-level element:

     ```
     fips: true
     ```

     Copy

     Note that `fips: true` is the entire top-level element. For this element, the following "stanza" syntax would be incorrect - **do not** use it:

     ```
     # stanza syntax is incorrect for the fips element
     # even if other elements use it
     fips
       fips: true
     ```

     Copy

2. If you have installed a non-default OpenSSL binary (otherwise, skip this step):
   - Run the following command, and in the output, note the values of `MODULESDIR` and `OPENSSLDIR`.

     ```
     <binary_of_non-default_OpenSSL> version -a
     ```

     Copy

   - Set `OPENSSL_MODULES` to the value of `MODULESDIR`.
   - Set `CRIBL_OPENSSL_DIR` to the value of `OPENSSLDIR`.
3. Ensure RBAC is configured in Cribl Edge.
4. Start Cribl Edge.

Finally, verify that you are in FIPS mode as explained below.

Enabling FIPS Mode on a systemd Distribution

If the Linux distribution on which you run Cribl Edge **does** use systemd:

1. Run the following command, and in the output, note the values of `MODULESDIR` and `OPENSSLDIR`. (As shown, the command will run the default OpenSSL binary. If you have installed a different OpenSSL binary, you can modify the command to run that one instead.)

```
openssl version -a
```

Copy

2. Run the following command, replacing the placeholders with the relevant paths from your environment. (This assumes that you do not already have a `nodejs.cnf` file. If you **do** have one, complete the workaround below instead of this step.)

```
<path_to_Cribl_binary> generateFipsConf -d <path_to_OpenSSL_root_directory>
```

Copy

   If you encounter issues generating the FIPS configuration file, a discrepancy in the OpenSSL path might be the cause. For more detailed troubleshooting specific to RHEL 9, refer to the knowledge base article: Installing Cribl Edge in FIPS Mode on RHEL 9.

   An example of a successful command and its output:

```
useralice@123456791234:/# /opt/cribl/bin/cribl generateFipsConf -d /lib/usr/ssl
/opt/cribl/state/nodejs.cnf
```

Copy

   This command creates `nodejs.cnf` - the configuration file that NodeJS uses to run in FIPS mode as Cribl Edge starts.

3. Run the following command to open an empty temporary file in an editor:

```
systemctl edit cribl
```

Copy

4. Add the following content to the file, replacing the first placeholder with the value of `MODULESDIR` that you noted in Step 1, and the second with the path to your `nodejs.cnf` file:

```
[Service]
Environment="OPENSSL_MODULES=<value_of_MODULESDIR>"
Environment="OPENSSL_CONF=<path_to_nodejs.cnf_file>"
```

Copy

5. Save and exit the editor.
6. Run the following commands to reload the systemctl overrides and start Cribl:

```
systemctl daemon-reload
systemctl start cribl
```

Copy

7. Finally, verify that you are in FIPS mode as explained below.

When a `nodejs.cnf` File Already Exists

If you already have a `nodejs.cnf` file, replace Step 2 above with the following workaround:

1. Create a file with the following content, replacing `<placeholder>` with the value of `OPENSSLDIR`. Name the file something other than `nodejs.cnf`.

```
nodejs_conf = nodejs_init
openssl_conf = nodejs_init

.include /<placeholder>/fipsmodule.cnf

[nodejs_init]
providers = provider_sect

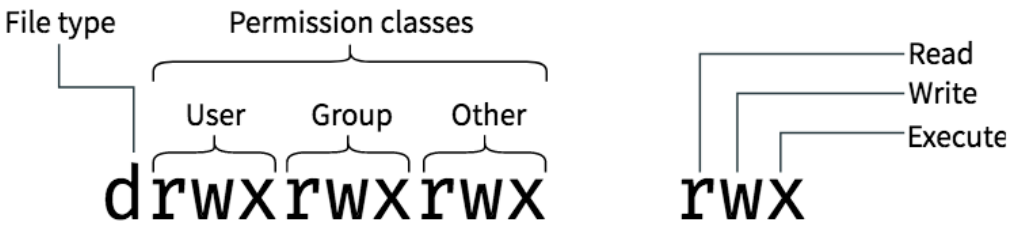
[provider_sect]
default = default_sect
# The fips section name should match the section name inside the
# included fipsmodule.cnf.
fips = fips_sect
[default_sect]
activate = 1
```

Copy

2. Resume the main procedure above, starting with Step 3.

Verify FIPS Mode

- On the Leader or Edge Node, search `cribl.log` for this message:



```
"level":"info","message":"running with FIPS enabled", "OpenSSLVersion":"3.0.13+q
```

Copy

- The presence of the above message confirms that Cribl Edge is in FIPS mode.

3.8. Use ACLs To Allow Cribl Edge To Read Files

Running Cribl Edge as an unprivileged user is a best practice. However, without modifying the default Linux permissions, you will run into issues in accessing files owned by other users.

Default Linux permissions

Linux systems allow you to layer an Access Control List (ACL) on top of the default Linux permission set. With ACLs, you can apply a more specific set of permissions to a file or directory without (necessarily) changing the base ownership and permissions. For details, see Introduction to ACLs.

As an example, you might want to read data from the `/var/log` directory. This directory is typically owned by the `root` user, with a permission set of `750` on the directory. This means the `cribl` user will not be able to read or list the files in the directory, because the `Other` group has zero permissions.

To achieve compliance with benchmarks such as CIS or NIST, we can use the ACLs to grant the `cribl` group access to this folder and any files, without disturbing the current permissions.

CIS Benchmark 4.2.3

Make sure that permissions are configured on all log files. Log files must have the correct permissions to ensure that sensitive data is archived and protected. `Other/world` should not have the ability to view this information. `Group` should not have the ability to modify this information.

To accomplish this, we can grant the `cribl` group `read` and `execute` access to the files and directories inside `/var/log`, by running this command:

```
setfacl -Rm g:cribl:r-X /var/log
```

Copy

Breaking down the command's options':

- `-R` : Recursive
- `-m` : Modify

- `g:cribl` = `cribl` group, this could be `u:cribl` if you wanted to limit to the `cribl` user.
- `r-X`: Read and execute. Capital `X` means execute only on directories.

This modifies only the current files in the directory, if you want the appropriate ACL applied to any future files created here, add the `-d` flag (for default):

```
setfacl -Rdm g:cribl:r-X /var/log
```

Copy

Now, any rotated or created files will apply the ACL set.

Checking the ACLs

To verify the ACLs on a file or directory, run the following command:

```
getfacl <file or folder>
```

Copy

This will output a listing of the applied ACLs, including the directory's defaults:

```
$ getfacl /<directory>
# file: <file>
# owner: <owner>
# group: <group>
user::rwx
group::rwx
other::---
default:user::rwx
default:user:<user>:rwx
default:group::rwx
default:mask::rwx
default:other::---
```

Copy

Installing ACL Utilities

The ACL utilities might not be installed, by default, on the OS. For example, on Ubuntu (Debian-based) systems, you will need to install the `acl` package. For Debian-based tools using apt:

```
apt install acl
```

Copy

For Red Hat-based tools using yum:

```
yum install acl
```

Copy

4. Cribl Edge On Windows

Check the options and limitations for running Cribl Edge on Windows.

Cribl Edge on Windows offers easy-to-use tools for exploring and collecting Windows events. You can run Cribl Edge on a supported Windows environment and collect events via the Windows Events API.

Cribl provides signed installers and executables to ensure installation and runtime integrity, protect against tampering, and facilitate deploying and running Cribl Edge in strictly controlled environments.

Limitations

Cribl Edge on Windows is currently subject to the following limitations:

Modes

Cribl Edge on Windows supports only the following modes:

- `Edge: Single`
- `Edge: Managed Edge (managed by Leader)`

This means you can't switch Cribl Edge on Windows into Cribl Stream mode (Single-instance, Worker, or Leader).

You can, however, switch between the Cribl Edge supported modes via the UI, in **Settings** > **Distributed Settings** > **Mode**.

Do not select an unsupported mode from this drop-down! Doing so will cause the Cribl service to fail.

Sources and Destinations

Cribl Edge on Windows supports the same Sources and Destinations as Cribl Edge on Linux, with the following exceptions:

- The Kubernetes Logs and Kubernetes Metrics Sources. Cribl Edge on Windows does not support Kubernetes deployments.
- The Kafka Destination does not support Kerberos authentication on Windows.

Sources on Windows Only

The following Sources are available **only** when running Cribl Edge on Windows (not on Linux):

- Windows Event Logs

- Window Metrics

Functions

The Grok Function is unavailable on Windows. If you include it in a Pipeline, Cribl Edge processing will skip over it.

Data Formats

Cribl Edge on Windows does not support reading or writing Parquet files. This is a limitation on the following Destinations: Amazon S3, Azure Blob Storage, MinIO, and FileSystem/NFS.

4.1. Install Cribl Edge On Windows

Install and deploy Cribl Edge Nodes on-prem on Windows.

You can install Cribl Edge in a supported Windows environment.

Minimum Requirements

The following requirements are the minimum for installing and running an Edge Node on Windows.

Below is a summary of requirements for a Cribl Edge deployment. See Requirements for more detailed information.

OS Requirements

Cribl Edge supports these versions of Windows:

Version	Notes
Windows 10 and 11	You can deploy Cribl Edge on laptops, desktops, and workstations running Windows 10 and 11. Keep these things in mind when deploying Cribl Edge on Windows 10 and 11 workstations: • Cribl Edge might lose some data sent to TCP Destinations after a workstation resumes from a suspended or sleep state. This happens when the data is in local network buffers but hasn't been sent out to the Destination. Instead, you can send data to an HTTP Destination. • You might see partially broken events after a laptop resumes from a suspended state. • HTTP Destinations might contain duplicate events. • Some users have observed excessive logging when a Leader is unavailable to receive heartbeat messages from an Edge Node.
Windows Server 2016 Windows Server 2019 Windows Server 2022 Windows Server 2025	Functionality is the same as generally supported Windows Server platforms.

Application Requirements

Minimum application requirements for Edge Nodes are:

- ~1 Ghz processor

- 1024 MB RAM
- 5 GB free disk space per volume for operational purposes

Before You Install Cribl Edge on Windows

1. Set a compatible browser as your default browser: Microsoft Edge, Firefox, or Chrome. (Cribl supports the five most-recent versions of these browsers. Cribl Edge does not support Internet Explorer.)
2. Ensure that the required ports are available (see Ports).
3. Ensure you have an authentication token prepared on the Leader. See Create a New Provisioning Token for more information.
4. Review Windows User Permissions and Requirements for important details regarding user accounts and installer settings.
5. Go to the Cribl Download page and set the **Software** drop-down to `Cribl Edge for Windows`.
6. Select **Download Now** to get the `.msi` installer.

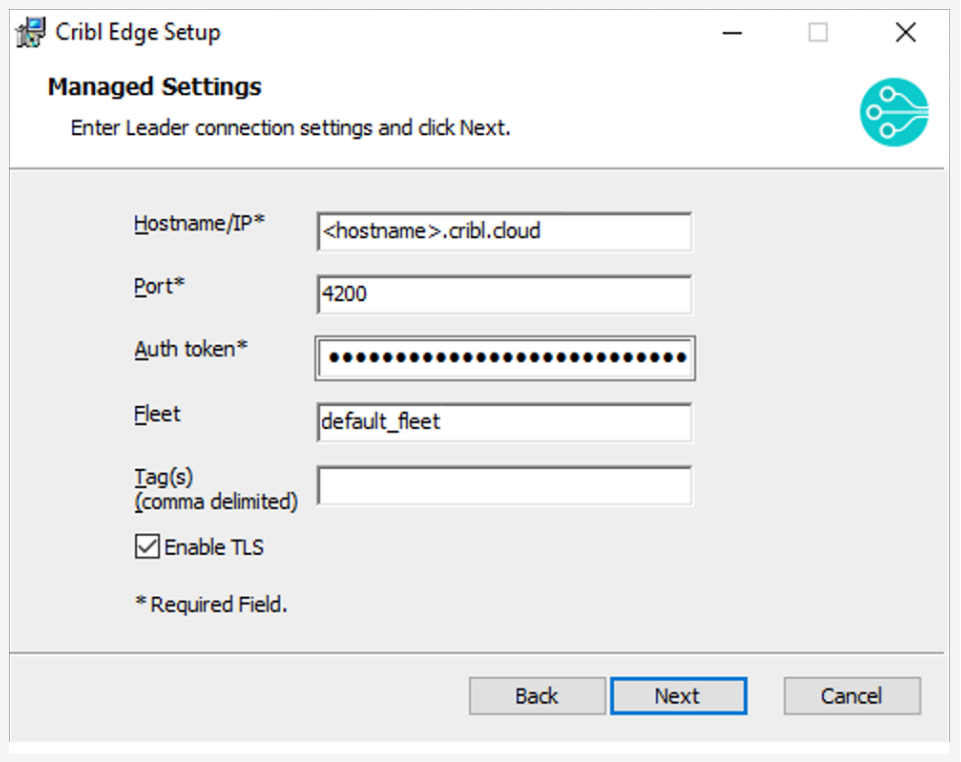
If you want to connect the Edge Node to a Cribl.Cloud Leader, get the **Leader URI** from your Cloud instance like this:

1. Navigate to the **Manage Edge Nodes** page.
2. From the **Add/Update Edge Node** control at upper right, select **Bootstrap new**.
3. Select **Add Windows**.
4. Copy the **Leader or Outpost hostname/IP** value.
5. The **Leader Port** field is `4200`.

To install Cribl Edge, you might need to add exceptions to your antivirus or endpoint security tools (such as Windows Defender). For details, see Stop Endpoint Security from Blocking Edge on Windows.

You now have two installation options:

- Launch the `.msi` to install via an interactive wizard.
- Use the `.msi` to install via a command prompt, or to script bulk installs.



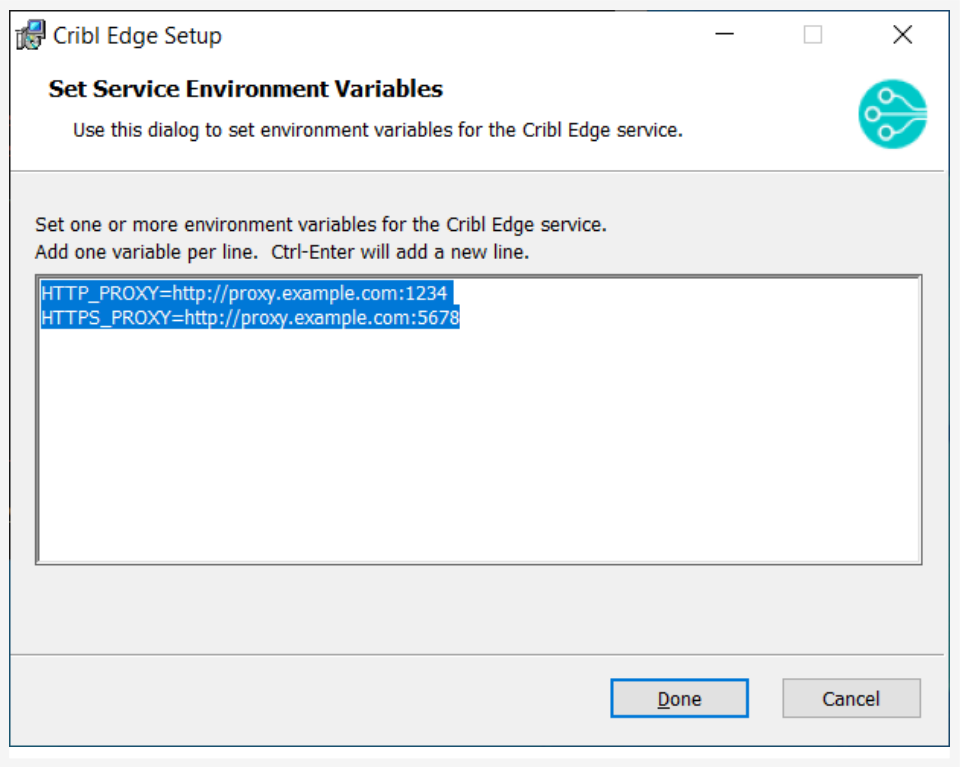
Either method installs Cribl Edge as a Windows service. This enables Cribl Edge to automatically restart whenever the Windows Server reboots.

Install Edge on Windows Using the Wizard

1. Select the Cribl Edge `.msi` to launch the Cribl Edge Setup Wizard. Select **Next** to start.

2. Read the **End-User License Agreement** and check the box to accept the terms. For the most current copy and details, see Terms of Service.
3. On the wizard's next page, confirm or change the **Destination Folder**. (The default path is `C:\Program Files\Cribl`).
4. If the installer detects a config file from a previous Cribl Edge installation, the modal will ask you if you want to keep your current config or create a new config file for the installation. Select **Keep config** to persist your previous configurations stored in the `instance.yml` file.
5. Select either **Managed** or **Single-instance** as the installation type. See Type of Deployment for information on these options.
   If you chose **Keep config** in the previous window, the installer will skip the installation type selection.

   For Cribl.Cloud, select **Managed**.
6. If you select **Managed** mode, enter the Leader hostname or IP address, port, auth token, and optionally the Fleet and any tags. For details on getting these credentials from Cribl.Cloud, see Retrieve Cribl.Cloud Credentials.
   For sites using secure TLS connections to the Leader, including Cribl.Cloud, ensure that **Enable TLS** is selected.

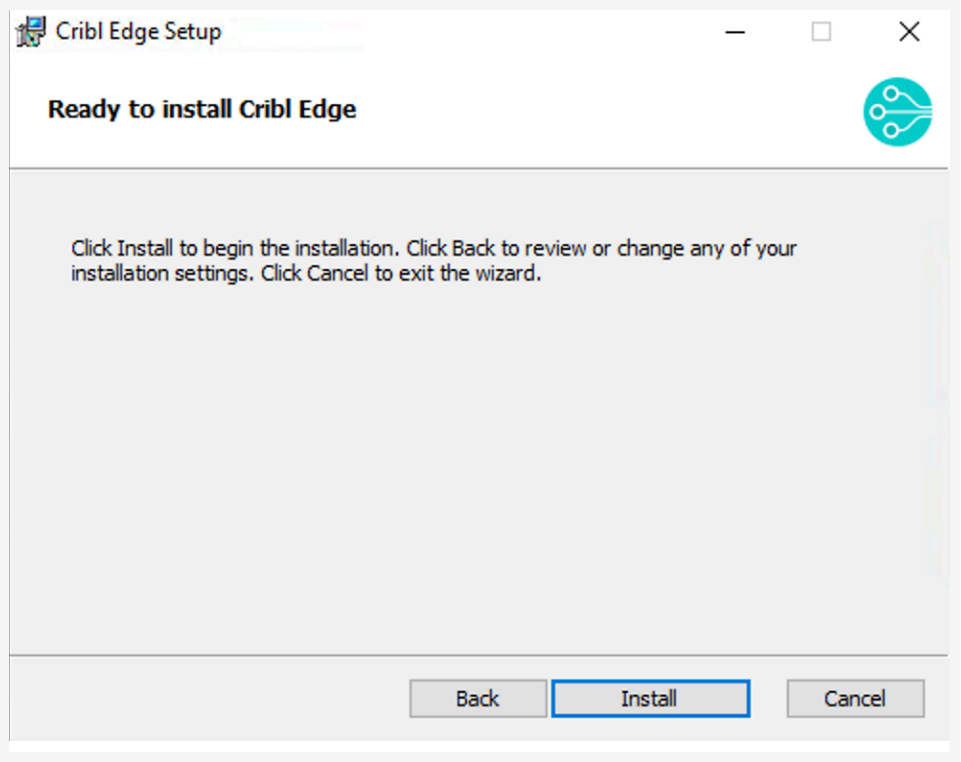


Connection Details

7. Select a Windows account type for the Cribl Edge service:
   - **Local System Account**: The default account type. This is a local Windows service account that does not have a corresponding user profile.

- **Username / Password**: Enter your **Username** and **Password** credentials to run Cribl Edge. To successfully log Cribl Edge as a service, you might need to include the domain name in the **Username**.

8. Optionally, select **Set Environment Variables** to set environment variables for the Edge service during installation. You can only add variables here, not remove them.



Set Environment Variables

In this example screenshot, HTTP and HTTPS proxy settings are being defined to enable Cribl Edge to communicate through corporate proxies, with each variable specified on a separate line.

Setting environment variables is optional and typically not needed for standard installations. This feature is primarily used for special configurations such as configuring proxy settings, enabling FIPS compliance mode, or other advanced scenarios.

If you've already provided environment variables via the command line, or if there are existing variables, the UI will be pre-populated with these values when you open it.

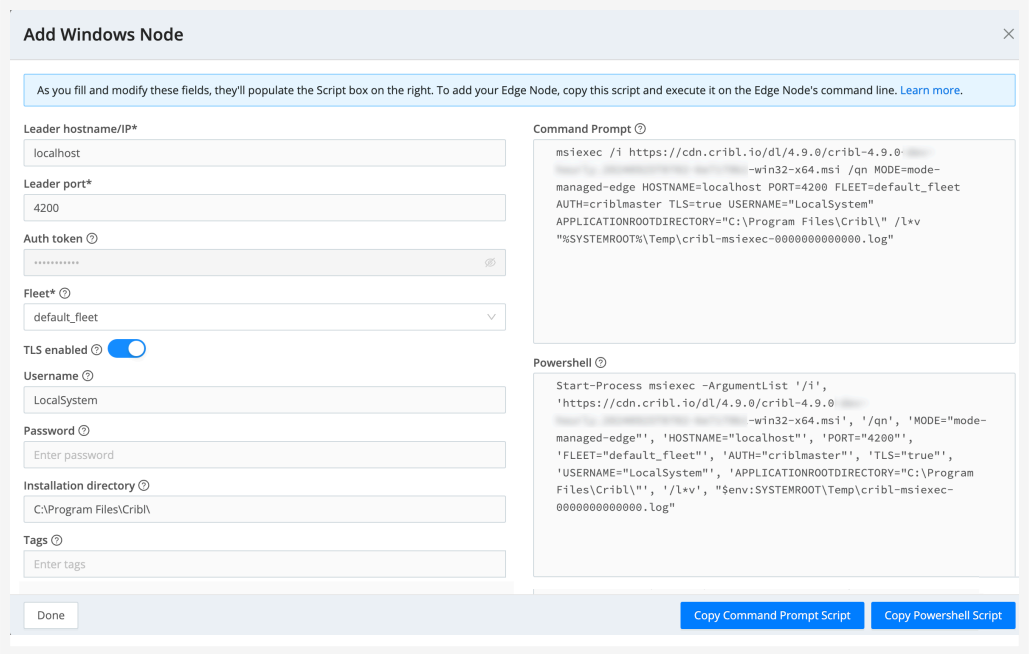
9. Optionally, you can create a desktop shortcut.
10. On the final **Ready to Install** page, select **Install** to confirm.

Installation summary

11. When installation is complete, the Edge Node should report to the Leader.
    In a Single-instance deployment, you can select the Cribl Edge icon on your Desktop or in File Explorer. This will launch the Cribl Edge login page in your default browser. Or go to `http://localhost:9420` and log in with default credentials (`admin:admin`).

Install Edge on Windows Using the Command Line

To install Cribl Edge on Windows from the command line, you can either use the Leader UI to concatenate and copy/paste the bootstrap script, or construct and customize the command yourself.



If you want to configure different installation or data directory locations than the default, see Configure Installation Directories.

Install Edge via Bootstrap Script

Using the Cribl Edge UI, you can add or update Windows Edge Nodes in your existing deployment.

To add or update a Windows Edge Node via a bootstrap script:

1. In your Cribl Edge instance, select **Edge Nodes** from the sidebar (you can also select **Fleets**).
2. Select **Add/Update Edge Node** then **Windows** > **Add** or **Update**.
3. Fill out the fields in the Add Windows Node window. The scripts update in real-time as you change the fields.

Add or update a Windows Edge Node

4. Copy and paste the resulting bootstrap script into a command prompt.
5. The result is a new Edge Node configured with the options you chose. You should see the Edge Node appear in the **Edge Nodes** list.

For more information about adding or updating Edge Nodes via the bootstrap script, see Adding and Updating Edge Nodes.

Log the Time of Installation

The Windows bootstrap script includes a log file with a string of zeros (`/log "%SYSTEMROOT%\Temp\cribl-msiexec-0000000000000.log"`). You can replace the zeros with a timestamp in Unix time (in milliseconds), to log when you first installed the Windows Node.

For example, if you're adding a Windows Node on October 4, 2024 at 6:07:44 PM Pacific Time, update the log file in the script to `/log "%SYSTEMROOT%\Temp\cribl-msiexec-1728090464000.log"`.

This log is included in the Cribl Edge diag, which is helpful for troubleshooting issues with Windows Node deployments.

When the Leader initiates an upgrade of Cribl Edge, the log file name will automatically include Unix time in milliseconds as the timestamp.

Install Edge via Custom Command

To install Cribl Edge via command line directly, use the following command for a silent install:

```
msiexec /qn /i cribl-<version>-<build>-<arch>.msi MODE=mode-managed-edge HOSTNAME=<hc
```

Copy

For example:

```
msiexec /qn /i cribl-4.18.2-fd1f0d2f-win32-x64.msi MODE=mode-managed-edge HOSTNAME=19
```

Copy

Set MSI Installer Properties

You can customize your installation command by using MSI properties. See MSI Installer Properties Reference for a full filst of available properties.

Configure TLS

The installer by default configures the Edge Node to use TLS. If you want to disable TLS, add `TLS=false` to the command.

Set Multiple Environment Variables

To set one or more environment variables during installation, use the `SETENVVARS` parameter with pipe-delimited key-value pairs. The entire string must be quoted:

```
msiexec /qn /i cribl-<version>-<build>.msi setenvvars="HTTP_PROXY=http://203.0.113.1:
```

Copy

Environment variables specified here take precedence over existing environment variables already configured for the service. This ensures that command-line specifications take precedence over existing configurations, while preserving any previously set variables not explicitly overridden.

The variable names and values cannot contain the pipe character ("|") as it's used as the separator.

Persist Data Between Installations

For prior versions, use the flag `COPYDATA=1` to persist data between installs. `COPYDATA` copies the `instance.yml` file from `C:\Program Files\Cribl` to `C:\ProgramData\Cribl`.

You can now manage this node from the specified Leader.

If you want to run Edge as a Single-instance deployment on your own machine, you do not need to provide any parameters to the installer. Instead, enter the following at your command prompt for a silent install:

```
msiexec /qn /i cribl-<version>-<build>-<arch>.msi
```

Copy

Next, go to `http://localhost:9420` and log in with default credentials (`admin:admin`).

Configure Installation Directories

When installing Cribl Edge on Windows via the command line, you can configure the directories for the application binaries and runtime data. These options are intended for first-time installs only. Changing the installation or data directory is explicitly disallowed during an upgrade. To change directories for an existing installation, you must perform a full uninstall and then start a new installation with the desired paths.

Change the Installation Directory

If you want to change the installation directory during a first-time install, use the `APPLICATIONROOTDIRECTORY` property in your `msiexec` command. For example:

```
msiexec.exe /i cribl-<version>-<build>.msi APPLICATIONROOTDIRECTORY="C:\test\" /log '
```

Copy

If you're using PowerShell to run the silent install, add two extra pairs of quotes to escape the command's own quote delimiters. For example:

```
msiexec.exe /i cribl-<version>-<build>.msi APPLICATIONROOTDIRECTORY=""D:\Custom\Crib
```

Copy

Change the Data Directory Location

By default, Cribl Edge stores its runtime data in `C:\ProgramData\Cribl`. To choose a non-default data directory during a first-time install, use the `VOLUMEDIR` property in your `msiexec` command.

`VOLUMEDIR` specifies the runtime data location, not where application binaries are stored. If the directory doesn't already exist, the installer creates it.

```
msiexec /qn /i cribl-<version>-<build>.msi VOLUMEDIR=D:\CriblData MODE=mode-managed-e
```

Copy

This stores runtime data in `D:\CriblData` instead of the default `C:\ProgramData\Cribl`, while keeping application binaries in `C:\Program Files\Cribl`.

If you completely uninstall and then reinstall Cribl Edge but want to reuse the existing data directory, you can add `KEEPDATA=1` to preserve configuration, state, and logs in that directory. For example:

```
msiexec /qn /i cribl-<version>-<build>.msi VOLUMEDIR=D:\CriblData MODE=mode-managed-e
```

Copy

MSI Installer Properties Reference

The following table lists installer properties specific to the Cribl Edge MSI package, along with their descriptions. These properties allow you to customize your Cribl Edge installation when using the `msiexec` command.

Installer Property	Description
`MODE`	Deployment mode for Cribl Edge. For example, use `mode-managed-edge` for a managed node. If not specified, a Single-instance deployment is implied.
`HOSTNAME`	Leader's hostname or IP address used when installing Cribl Edge in `mode-managed-edge`.
`PORT`	Leader port used when installing in `mode-managed-edge`. The default port is `4200`.
`AUTH`	The authentication token required for the Edge Node to connect to the Leader.
`FLEET`	Fleet to assign the new Edge Node to.
`SETENVVARS`	Multiple environment variables to be defined for the installed Cribl Edge service. Pass a string of pipe-delimited `KEY=VALUE` pairs. This property injects environment variables into the service's configuration at installation time.
`KEEPDATA`	How data is treated when Cribl Edge is uninstalled, then reinstalled. When set to `1`, the installer preserves configuration, state, and logs, ensuring your data is not overwritten.

Installer Property	Description
`USERNAME`	Windows account under which the Cribl Edge service will run. Examples include `LocalSystem` (the default) or a specific user account.
`PASSWORD`	Password for the username, only valid when using a specific user account (not LocalSystem).
`APPLICATIONROOTDIRECTORY`	Installation directory for the Cribl Edge application binaries. This is where the core program files will be placed.
`VOLUMEDIR`	Separate directory for Cribl Edge's runtime data, including configurations, logs, and state information. This allows you to store data independently from the application binaries.
`TAGS`	List of comma-delimited tags to assign to the Edge Node.
`TLS`	TLS for Leader communication. Enabled by default. Set to `false` to disable.

Set Logging Options

To debug `.msi` installation or upgrade issues, you can run `msiexec.exe` to set logging options. See Microsoft's Logging Options topic.

Change Configuration After Installation

After the installation is complete, if you need to update any settings you configured during installation, make use of the `mode-managed-edge` command (or `mode-edge` for Single-instance deployment).

Running this command resets all the related options. This means that even if you want to change only one option, you also need to provide values for all the other arguments.

Troubleshooting

Here are some common challenges you can encounter when deploying Cribl Edge on Windows.

Upgrading a Pre-4.3.0 MSI Installation

MSIs older than 4.3.0 install Cribl Edge so it belongs to the user running the installer. If you later try to upgrade it as another user, the upgrade can result in a mix of the old and new package contents on disk.

We recommend adding `ALLUSERS=1` to the `msiexec` command when installing or upgrading versions older than 4.3.0 for testing. Example command:

```
msiexec /i cribl-<version>-<build>.msi /qn MODE=mode-managed-edge HOSTNAME=<yourhostr
```

Copy

Debugging MSI Installations

For troubleshooting an MSI installation that does not pull configuration settings from the Leader Node, you need to know the log path on Windows. The full path depends on where you chose to install.

`$INSTALL_PATH\cribl\log` and `local\edge\` are the log location and conf location, respectively.

Installation Issues with Leader Auth Token

If you encounter problems installing newer versions of Cribl Edge, this may be due to Leader Auth token issues. To resolve:

1. Verify the Auth token is correct, current, and has not been revoked in your Leader Node.
2. Check network connectivity between Edge Nodes and the Leader.
3. Validate successful connections with both Cribl Edge and Cribl Stream products after installation.

Installing or Upgrading Nodes with Endpoint Security

If you are having trouble installing or upgrading Cribl Edge, check for antivirus or other endpoint security tools that may be blocking the `cribl` process (like Windows Defender). To install Cribl Edge, you may need to add temporary or permanent exceptions to these tools.

See Stop Endpoint Security from Blocking Edge on Windows for details.

4.2. Windows User Permissions And Requirements

Learn what user accounts and administrator privileges you need to run Cribl Edge on Windows.

When installing Cribl Edge on Windows, it's important to distinguish between two user accounts:

- **Installer User:** This is the user account you use to run the Cribl Edge installer (MSI). This user must have `administrator` privileges to install the software and create the Cribl Edge service.
- **Service Account:** This is the user account the Cribl Edge service runs under. This account needs appropriate permissions to access your data and APIs. If you want to perform Leader-initiated Edge Node upgrades across a Fleet, the account also requires `administrator` privileges. `LocalSystem` (the default account) already has those privileges. See Service Accounts and Edge Node Upgrades for more information.

Required Administrator Privileges

Ensure you launch the installer (MSI) from a command-line interface (command prompt or PowerShell) that is running with full administrator privileges. Simply being logged in as an `administrator` might not be sufficient; you need to explicitly **Run as administrator**.

Service Account Configuration

You have three options to choose from when selecting the service account to run Cribl Edge as: two passwordless options (`LocalSystem` and MSA/gMSA), and local user.

- **LocalSystem**: Cribl Edge on Windows, by default, runs under the `LocalSystem` account (also referred to as `SYSTEM`). This is a predefined system account with extensive privileges on the local machine. It is a passwordless account, meaning it cannot be logged into interactively, and no password is associated with it.
- **Managed Service Accounts (MSA/gMSA)**: You can use Managed Service Accounts (MSA) or Group Managed Service Accounts (gMSA) for the Cribl Edge service. These accounts provide automatic password management and improve security posture. MSA/gMSA are passwordless options. Refer to Microsoft documentation for details: Group Managed Service Accounts Overview.
- **Virtual Service Account**: You can use Cribl Edge with a Virtual Service Account (VSA), a type of Windows-managed local account that allows the service to run with the necessary permissions without requiring a password. Refer to Microsoft documentation for details: Virtual Accounts.
- **Local user**: You can configure Cribl Edge to run under a local user.

Avoid storing passwords in scripts or config files. Exposed credentials jeopardize the local system and any networked resources accessible by that account.

If you installed Cribl Edge using one service account type, you can't switch to a different type while performing an upgrade. If you want to use a different account type, uninstall and reinstall Cribl Edge with the desired account type.

Service Account Username and Password

During installation, depensing on the service account you are using, you may need to specify the username and/or password for the account. You can do it, for example, by using the `USERNAME` and `PASSWORD` parameters with the `msiexec` command.

The following table summarizes whether username and/or password is required depending on the service account type:

Service Account Type	Username	Password
`LocalSystem`	x	x
gMSA (Managed Service Account)		x
VSA (Virtual Service Account)		x
Local user		

The following is an example `msiexec` command using the `LocalSystem` account (note the absence of `USERNAME` and `PASSWORD` parameters):

```
msiexec /i cribl-<version>-<build>.msi /qn ^
  MODE=mode-managed-edge ^
  HOSTNAME=<leaderHostname> ^
  FLEET=<fleetName> ^
  AUTH=<authToken>
```

Copy

This and following examples use command prompt line-continuation syntax (`^`). If you are using PowerShell, replace `^` with `` ` `` (backtick).

Username with gMSA or VSA

Using gMSA or VSA requires specifying the username in the full form:

- **gMSA**: `domain\gmsaAccountName$`
- **VSA**: `NT SERVICE\Cribl`

These two options do not require you to provide a password.

To install Edge and run the service under a gMSA, you can use the following command:

```
msiexec /i cribl-<version>-<build>.msi /qn ^
  MODE=mode-managed-edge ^
  HOSTNAME=<leaderHostname> ^
  FLEET=<fleetName> ^
  AUTH=<authToken> ^
  USERNAME=<domain\gmsaAccountName$>
```

Copy

To install Edge and run the service under a VSA, use the following command:

```
msiexec /i cribl-<version>-<build>.msi /qn ^
  MODE=mode-managed-edge ^
  HOSTNAME=<leaderHostname> ^
  FLEET=<fleetName> ^
  AUTH=<authToken> ^
  USERNAME="NT SERVICE\Cribl"
```

Copy

Username with a Local User

When running as a local user, the user name can take the form of `domain\user` or `user@domain`. Select **OK** in the installer's user prompt to show the resolved user name.

The following example shows how to specify the local user name and password:

```
msiexec /i cribl-<version>-<build>.msi /qn ^
  MODE=mode-managed-edge ^
  HOSTNAME=<leaderHostname> ^
  FLEET=<fleetName> ^
  AUTH=<authToken> ^
  USERNAME=<domain\user> ^
  PASSWORD=<password>
```

Copy

User Requirements

To successfully run the Edge service under a specific user account, Managed Service Accounts (MSA), Group Managed Service Accounts (gMSA), or Virtual Service Account (VSA), the following requirements must be met.

Group Memberships

The user must be a member of the following groups:

- Event Log Readers
- Network Configuration Operators
- Performance Log Users
- Performance Monitor Users
- Users (default)

User Rights

The user must have the “Manage Auditing and Security Log” right, which can be assigned via Local Security Policy or Group Policy tools.

Service Accounts and Edge Node Upgrades

Upgrading Windows Edge Nodes in a Fleet (Leader-initiated upgrade), is performed by running the MSI installer in the background. The service account that runs the upgrade must have administrator permissions, otherwise the installer will fail.

When you run the Cribl Edge service as `LocalSystem` (default), you can run upgrades in a Fleet without additional steps, because `LocalSystem` already has the required permissions to perform upgrades.

To run a Fleet upgrade with MSA/gMSA, add the account to the local administrators group. Configuring MSA/gMSA as an administrator lets you run Edge Node upgrades, but also grants broader privileges to the service account. If you want to avoid it, keep the MSA/gMSA as a non-admin service account and perform Edge upgrades manually. See Upgrade Edge Nodes Manually for information on how to do it.

Troubleshooting

If you encounter issues, check the Windows Event Viewer for error messages related to the installation or the Cribl Edge service. For detailed installer logs, use the `/log logfile.txt` option with `msiexec`. Also, check the Cribl logs themselves for more application-specific information.

4.3. System Proxy Configuration On Windows

Configure the proxy server to handle HTTP/S requests on Windows.

You can direct all outbound HTTP/S requests to go through proxy servers.

Enable Proxy Server

First, you need to make sure the proxy server is enabled.

There are a two ways to do it, using Windows system settings and Group Policy Objects.

Windows Proxy Settings

To enable the proxy server for all processes and services on a host, you can use the system proxy settings:

1. In Windows settings go to **Network & Internet** > **Proxy**.
2. Under **Manual proxy setup**, toggle **Use a proxy server** to **On**.
3. In the **Address** and **Port** boxes, enter the proxy server name or IP address and (optionally) port.
4. Confirm with **Save**.

Group Policy Object

Alternatively, you can use a Windows Group Policy Object to enable the proxy server across groups of accounts or groups of servers. See Microsoft Q&A thread for a detailed instruction.

Communication with Leader over Proxy

If you outbound TCP connection from an Edge Node to the Leader must go through proxy, you need to set the `CRIBL_DIST_WORKER_PROXY` environment variable:

```
CRIBL_DIST_WORKER_PROXY=<socks4|socks5>://<username>:<password>@<host>:<port>
```

HTTP and/or HTTPS?

Several Cribl Edge endpoints rely on the HTTPS protocol - the Cribl telemetry endpoint - which must be accessed with some license types, as well as the CDN used to propagate application updates, certain documentation features (API Reference and docs PDFs), and config bundle downloads.

You might configure certain other Cribl Edge features that require access to HTTP endpoints. For maximum flexibility, consider setting environment variables to handle both the HTTPS and HTTP protocols.

Authenticating on Proxies

You can use HTTP Basic authentication on HTTP or HTTPS proxies. To do this, during installation set the `HTTP_PROXY` and `HTTPS_PROXY` environment variables and specify the user name and password in the proxy URL:

Variable	Value
`HTTP_PROXY`	`http://<username>:<password>@<proxyhost>:<port>`
`HTTPS_PROXY`	`https://<username>:<password>@<proxyhost>:<port>`

Bypassing Proxies with `NO_PROXY`

If you've set the above environment variables, you can negate them for specified (or all) hosts. Add the `NO_PROXY` environment variable to identify URLs that should bypass the proxy server, to instead be sent as direct requests. Use the following format:

```
NO_PROXY="<list of hosts/domains>"
```

Copy

Cribl recommends including the Leader Node's host name in the `NO_PROXY` list.

`NO_PROXY` Usage

Within the `NO_PROXY` list, separate the host/domain names with commas or spaces.

Optionally, you can follow each host/domain entry with a port. If not specified, the protocol's default port is assumed.

To match subdomains, you must either list them all in full (for example, `NO_PROXY=foo.example.com,bar.example.com`), or apply a wildcard by prefixing the domain name with a period or `*.`: `NO_PROXY=".example.com` or `NO_PROXY="*.example.com`.

To match the whole domain including its subdomains, add it both with and without wildcard to the list: `NO_PROXY="example.com,.example.com`.

To disable all proxies, use the `*` wildcard: `NO_PROXY="*"`. `NO_PROXY` with an empty list disables no proxies.

Cloud `NO_PROXY` Usage

You must include any cloud metadata endpoints (such as the AWS Instance Metadata Service) in the `NO_PROXY` list:

- AWS EC2 and Azure VM instances must include `169.254.169.254` in the list. If using IPv6 on AWS EC2, add `fd00:ec2::254` to the list.
- AWS ECS Fargate tasks must include `169.254.170.2`.
- GCP (Google Cloud Platform) VM instances must include `metadata.google.internal` and `169.254.169.254`.

Where Proxies Apply

Proxy configuration is relevant to the following Cribl Edge components that make outbound HTTP/S requests:

Destinations

- S3 Compatible Stores
- Amazon Kinesis Data Streams
- AWS CloudWatch Logs
- AWS SQS
- Azure Blob Storage
- Azure Monitor Logs
- Cribl HTTP
- CrowdStrike Falcon LogScale
- Elasticsearch
- Grafana Cloud
- Honeycomb
- Loki
- Prometheus
- Splunk HEC
- Webhook

Notification Targets

- PagerDuty
- Webhook

Testing Proxies

To initially test your proxy configuration, consider setting up a simple, free proxy server like mitmproxy (https://mitmproxy.org), and then monitoring traffic through that server. Verify that you can trace proxied requests from your Cribl Edge instance, and can validate that outgoing requests (to Destinations) are working properly.

4.4. Windows Troubleshooting

When running Cribl Edge on Windows, you can encounter the following issues. Read on to find the proposed solutions.

For potential issues you can encounter during installation of Windows Edge Nodes, see Windows Installation Troubleshooting.

Windows Event Fields Configuration

If you're encountering issues when collecting Windows events in both `JSON` and `XML` modes, it's likely due to improper configurations. To resolve:

1. Configure Windows events via `XML` format in Cribl Edge (recommended over `JSON`).
2. Build a basic Pipeline/transformation to ensure all expected fields are present.
3. Verify fields are in the desired format after processing.
4. Consider implementing data reduction in your pipeline to optimize usage.

PowerShell Performance Issues with Windows Sources

PowerShell-based collection for System State, Windows Metrics, and Windows Event Log Sources is a legacy option that will be removed in a future release. We highly recommend keeping this option disabled and using the newer native capabilities.

To disable PowerShell-based collection:

1. Upgrade to Cribl Edge `4.13.x` or newer.
2. Disable **Advanced Settings** > **Use Windows Tools**.

The optimized non-PowerShell collection methods provide better performance and reliable data ingestion.

CPU/Memory Issues on Windows

If you notice high CPU/Memory usage on your Windows Cribl Edge Nodes:

- Create a Fleet dedicated to Windows Nodes, and constrain Windows Sources to that Fleet.
- If you want to collect logs only, disable the Windows Metrics Source.
- The Users and Groups collector in the System State Source can trigger high CPU utilization in the Windows `lsass.exe` process where there are many user accounts on the host. This is not uncommon

on Domain Controllers. Consider disabling the User and Groups collector if you see that process consuming excessive CPU.

To optimize the Windows Event Logs Source:

- During the Windows Event Log capture, run the collection for 10 seconds and tweak the settings if necessary so that collection doesn't always have to catch up. Consider changing the Windows Events Log Batch Size and Frequency.
  Example command to capture a certain number of events:
  ```
  measure-command {Get-WinEvent -Oldest -MaxEvents 500 @{LogName='Security'} | ForEach-Object -Process {ConvertTo-Json -Compress $_}}
  ```
- For Domain Controllers with heavy log volumes, consider using the Windows Event Forwarder and sending the logs to Cribl Stream, instead of using the Windows Event Log Source in Cribl Edge.
- If you're collecting Windows Events Logs in JSON format, you may experience disk space issues. You can either set XML as the event format on the Windows Events Logs Source, or upgrade Cribl Edge to v.4.8.x or newer and toggle off **Use Windows Tools**. See the Windows Event Logs Source topic for more details.

4.5. FIPS Mode For Cribl Edge (Windows)

This guide will walk you through the process of setting up and running Cribl Edge in FIPS (Federal Information Processing Standards) mode on Windows systems.

FIPS 140-2 or FIPS 140-3 compliance is required for software deployed in U.S. Federal Government and regulated industries. Cribl Edge supports operation in FIPS mode to meet these requirements.

Prerequisites

- Cribl Edge Windows installer (.msi).
- Administrative access to the Windows system.
- FIPS-validated OpenSSL provider (instructions below).

What You Need to Know About Pre-Configuration

Before configuring FIPS-enabled Edge Nodes, ensure your Leader environment is already configured and running in FIPS mode.

- When running in FIPS mode, Cribl Edge uses only FIPS-approved cryptographic algorithms, ensuring all data handling meets Federal security standards.
- When connecting to a FIPS-configured Leader, Cribl Edge must also be in FIPS mode for full compliance.

Set up Cribl Edge in FIPS Mode

To set up Cribl Edge in FIPS mode, you'll need to build your own OpenSSL FIPS provider. For details, see OpenSSL: Notes for Windows platforms.

Build Your Own FIPS Provider

This section guides you through the process of building your own OpenSSL FIPS provider.

Install Required Tools

1. Install Strawberry Perl, which includes the Netwide Assembler – (NASM).
2. Microsoft C++ toolchain (Visual Studio).
3. If you have `git` installed, you may need to rename/move its `perl.exe` to avoid conflicts.

Build the Provider

1. Find and open the Visual Studio (20XX) Native Tools Command Prompt for `x64` architecture. You can search for it, by typing `x64` in the **Start** menu. Right-click on it and select **Run as administrator**. (Do not use PowerShell or plain CMD).
2. Download the latest FIPS-validated version of OpenSSL:

   ```
   curl -LO https://www.openssl.org/source/openssl-3.0.9.tar.gz
   tar -xf openssl-3.0.9.tar.gz
   cd openssl-3.0.9
   ```

   Copy

   If you run into an error message: `ERROR: module machine type 'x86' conflicts with target machine type 'x64'`, it means you're not using the right version of the command prompt for what you're trying to do. Make sure you've selected the `x64 Native Tools Command Prompt`.
3. Run the following commands in the Visual Studio Developer Command Prompt (with `x64` architecture selected):

   ```
   perl configure VC-WIN64A enable-fips
   nmake
   ```

   Copy

   The build process might take considerable time to complete. Once the build is complete, you'll have a `providers` directory. The providers directory is created within the OpenSSL build directory (for example, `openssl-3.0.9/providers/`).
4. Once built, you'll need the following files from the build directory:
   - `providers\fipsmodule.cnf` - This specific file from your build is essential as it contains a unique hash that validates the DLL you built.
   - `providers\fips.dll`
   - `providers\legacy.dll`

Set up the Provider

This step creates a dedicated directory for Cribl's FIPS-related files and copies the necessary DLL and configuration files into it, preparing the application for FIPS-compliant operation.

In the same Native Tools Command Prompt, type the following:

```
mkdir "C:\Program Files\Cribl-FIPS"
copy providers\fips.dll "C:\Program Files\Cribl-FIPS"
copy providers\legacy.dll "C:\Program Files\Cribl-FIPS"
copy providers\fipsmodule.cnf "C:\Program Files\Cribl-FIPS"
```

Copy

Generate the `nodejs.cnf` Configuration File

This step creates a necessary configuration file that enables FIPS compliance for the `Node.js` environment used by Cribl. You have two options.

Option 1: Manual Configuration Creation

1. Open an Administrative Command Prompt
2. Run the following command to create and open the configuration file:

```
notepad "C:\Program Files\Cribl-FIPS\nodejs.cnf"
```

Copy

3. Copy and paste the following configuration content into the file:

```
nodejs_conf = nodejs_init
openssl_conf = nodejs_init
.include "C:\\Program Files\\Cribl-FIPS\\fipsmodule.cnf"

[nodejs_init]
providers = provider_sect
alg_section = algorithm_sect

[provider_sect]
default = default_sect
fips = fips_sect

[default_sect]
activate = 1

[algorithm_sect]
default_properties = fips=yes
```

Copy

4. Save the file and close Notepad.

This configuration redirects `Node.js` to use FIPS-compliant cryptographic modules and algorithms. The file includes references to the FIPS module configuration and sets default properties to enforce FIPS compliance across all cryptographic operations.

Option 2: Using the Cribl CLI (Post-Installation)

Alternatively, after installing Cribl Edge, you can generate the configuration file using the Cribl CLI:

```
cribl generateFipsConf -d <fully qualified path to fipsmodule.cnf>
```

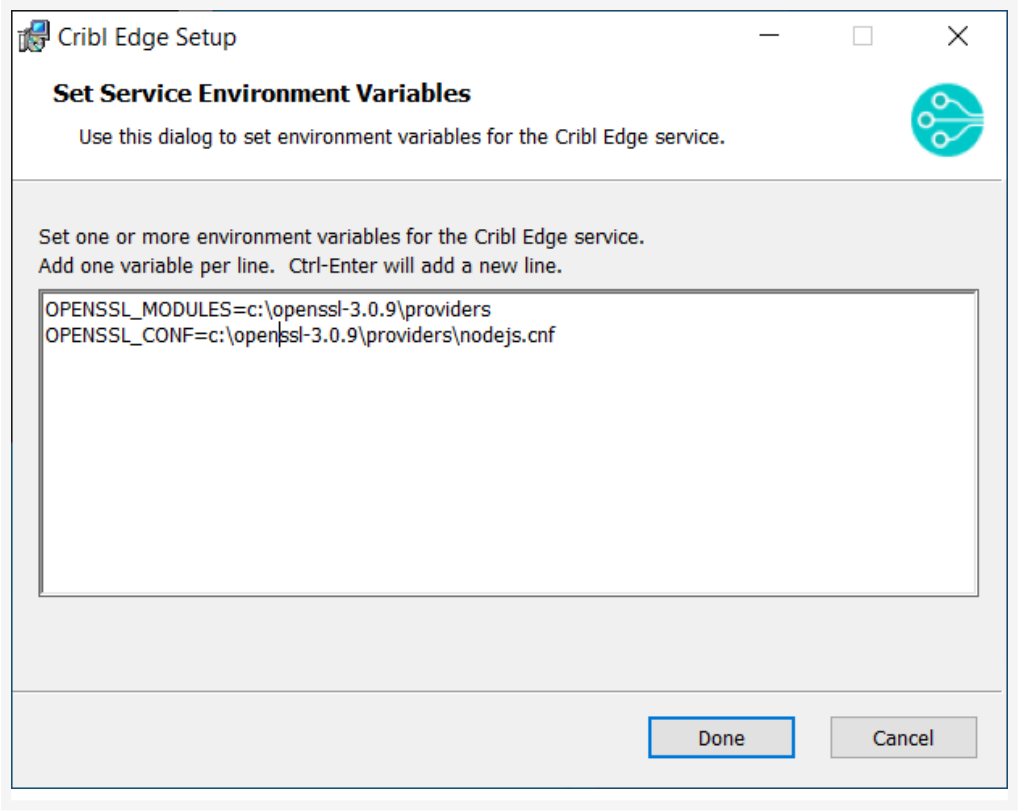
You can generate the `nodejs.cnf` configuration once on any machine and then distribute it to others, eliminating the need to repeat this step on each individual machine.

Install Edge with FIPS Configuration

To install Cribl Edge with FIPS mode enabled:

1. Use the `SETENVVARS` parameter with the MSI installer:

```
msiexec /i CriblEdge-<version>.msi SETENVVARS="OPENSSL_MODULES=C:\Program Files\Cribl
```



Copy

2. This opens the Windows Installer Wizard. Choose `Managed Mode` and complete the configuration to connect to the FIPS-enabled Leader.

When executing the MSI installer command, pay attention to these important parameter requirements:

- The pipe character (|) separates multiple environment variables.
- Make sure to enclose the entire `SETENVVARS` string in quotes.
- `OPENSSL_MODULES` points to the directory containing the provider files.
- `OPENSSL_CONF` points to the specific configuration file.

Alternatively, you can set the environment variables through the Installation Wizard:

Set Environment Variables

For details, see Install Cribl Edge on Windows.

Confirm Cribl Edge is in FIPS Mode

After installation, validate that Edge is running in FIPS mode by checking for FIPS initialization messages:

1. On the Leader or Edge Node, search `cribl.log` for this message:

```
"level":"info","message":"running with FIPS enabled", "OpenSSLVersion":"3.0.13+quic
```

Copy

2. In the UI, navigate to: **Node Settings** > **Diagnostics** > **System Info**.

The presence of the above message confirms that Cribl Edge is in FIPS mode.

Troubleshooting

If Edge fails to start after FIPS configuration:

- Verify that all required files exist in the specified locations.

5. Cribl Edge On MacOS

Learn about running Cribl Edge on macOS.

Cribl Edge on macOS offers easy-to-use tools for exploring and collecting macOS events. You can run Cribl Edge on a supported macOS machine to collect logs and track local files.

Edge on macOS does not include support for system metrics or system state at this time. See below for a more detailed list of limitations.

Limitations

Cribl Edge on macOS is subject to the following limitations.

Modes

Cribl Edge on macOS supports only the following modes:

- `Edge: Single`
- `Edge: Managed Edge (managed by Leader)`

This means you can't switch Cribl Edge on macOS into Cribl Stream mode (Single-instance, Worker, or Leader).

You can, however, switch between the Cribl Edge supported modes via the UI, in **Settings** > **Distributed Settings** > **Mode**.

Do not select an unsupported mode from this drop-down! Doing so will cause the Cribl service to fail.

Sources and Destinations

Cribl Edge on macOS supports the same Sources and Destinations as Cribl Edge on Linux, with the following exceptions.

Unavailable Sources

The following Sources are unavailable on macOS

- System Metrics Source
- System State Source

Unavailable Destinations

The following Destination is unavailable on macOS:

- Amazon Security Lake Destination

Other Limitations on Sources and Destinations

Other limitations include:

- The Kafka Destination does not support Kerberos authentication on macOS.
- The File Monitor Source only allows **Manual** discovery mode, not **Auto**.

Functions

The Grok Function is unavailable on macOS. If you include it in a Pipeline, Cribl Edge processing will skip over it.

Data Formats

Cribl Edge on macOS does not support reading or writing Parquet files. This is a limitation on the following Destinations: Amazon S3, Azure Blob Storage, MinIO, and FileSystem/NFS.

Goat-to Resources

One agent, no headache: Cribl Edge now supports macOS Blog

5.1. Install Cribl Edge On MacOS

Install and deploy Cribl Edge Nodes on-prem on macOS.

You can install Cribl Edge in a supported macOS environment to collect logs and track local files.

Supported MacOS Versions

Cribl Edge supports the following macOS versions:

- 26.x (Tahoe)
- 15.x (Sequoia)
- 14.x (Sonoma).

You can install Cribl Edge using the same universal binary on both Intel and Apple silicon processors.

Before You Install Cribl Edge on MacOS

1. Set a compatible browser as your default browser: Microsoft Edge, Firefox, Safari, or Chrome. (We support the five most-recent versions of these browsers. Cribl Edge is not compatible with Internet Explorer.)
2. Ensure that the required ports are available (see Ports).
3. Ensure you have an authentication token prepared on the Leader. See Create a New Provisioning Token for more information.
4. Go to the Cribl Download page and set the **Software** drop-down to `Cribl Edge for macOS`.
5. Select **Download now** to get the `.pkg` installer.

You can also install a macOS Edge Node in a Distributed deployment by running the bootstrap script in your command prompt. Run the bootstrap script with `sudo`.

Install Cribl Edge

From the command line, you can install and configure Cribl Edge to act either as a Single-instance deployment, or as a managed Node.

1. To install Cribl Edge from the package you downloaded, enter the following at your command prompt:

```
sudo installer -pkg <package-file>.pkg -target /
```

Copy

This will install Cribl Edge to `/opt/cribl/`.

To prevent issues with Cribl file operations, `/opt/cribl` and all its subdirectories must reside on the same device. Mounting separate devices within `/opt/cribl` is not recommended. For external storage needs, such as lookups or persistent queues (PQs), create a completely separate directory outside of `/opt/cribl`.

2. Set `/opt/cribl` as your `$CRIBL_HOME` directory.

To make the `$CRIBL_HOME` environment variable available on your command line, you can:

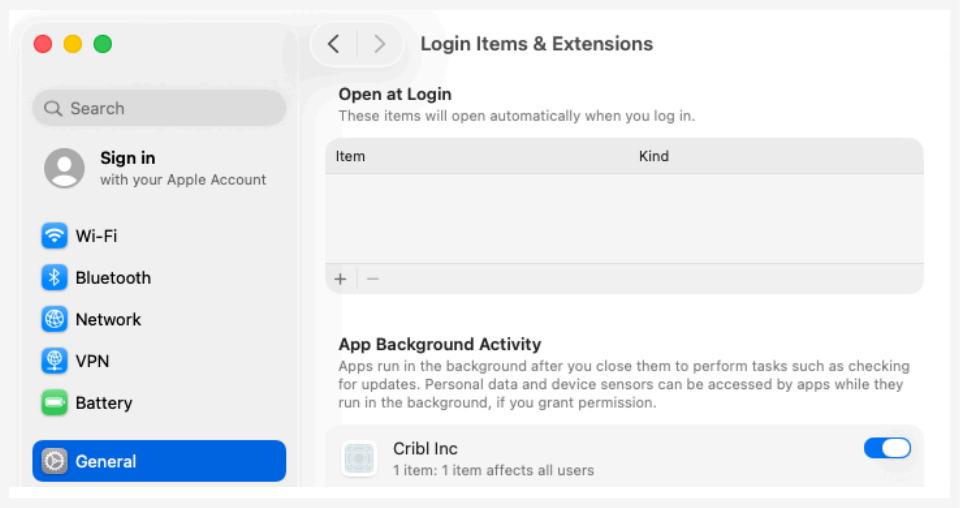
- Assign it once, using the `export` command: `export CRIBL_HOME=/opt/cribl`
- Set it as a default, by adding it to your terminal profile file.

3. Set the installation mode to `mode-managed-edge` to connect the Node to the designated Leader:

```
sudo /opt/cribl/bin/cribl mode-managed-edge /
   -H <leader-hostname-or-IP> /
   -p <port> /
   -u <authToken> /
  [-g <fleet>]
```

Copy

- The new Node will be assigned to a Fleet on the Leader, either `default_fleet`, or a different one according to Fleet mappings.
- You can manually point to a specific Fleet by providing its name as `-g <fleet>`, but Fleet mappings will override this choice.



If you only need a Single-instance deployment of Cribl Edge (without a Leader), do not change the mode. Cribl Edge will run in `mode-edge` automatically.

4. Restart the Cribl service:

```
sudo /opt/cribl/bin/cribl restart
```

Copy

5. Allow Cribl to run in the background. In macOS system settings, select **General**, then **Login Items & Extensions**. Make sure that Cribl is enabled in **App Background Activity**.

Enabling Cribl for background activity in macOS settings

6. You can now log in to your Leader and locate the newly installed Cribl Edge Node and start configuring Sources and Destinations, or creating Routes and Pipelines.

If you installed a single instance of Cribl Edge without a Leader, go to `http://localhost:9420` (or another port you defined) and log in with default credentials (`admin:admin`).

For more ways to configure Leader and Edge Nodes, see Set Up Leader and Edge Nodes.

5.2. Deploy Cribl Edge On MacOS With JAMF

Deploy Cribl Edge on macOS machines managed with JAMF Pro.

If you are using JAMF Pro to manage macOS machines, you may choose to deploy Cribl Edge using JAMF as well. You can do it by getting a bootstrap script for adding Edge Nodes from your Leader, and then configuring a JAMF policy that will run it.

See Add and Update Edge Nodes for more information about the bootstrap script.

Before you start, ensure that your environment meets the OS and System Requirements.

Create Fleet for Edge Nodes on MacOS

First, create a new Fleet that will house your macOS Edge Nodes.

Cribl generally recommends creating separate Fleets for different OS platforms.

1. In the sidebar, select **Fleets**, then select **New Fleet**.
2. Give the Fleet a descriptive **Name**, for example, `MacLaptops`, and confirm with **Save**.

Prepare Bootstrap Script

Now, prepare the bootstrap script that will be used to add new Edge Nodes.

1. In the sidebar, select **Fleets**, then select your new `MacLaptops` Fleet.
2. Select **Add/Update Edge Node**, then **macOS**, then **Add**.
3. Check that the target Fleet, the Leader hostname or IP, port, auth token, and any other options have been prefilled correctly, and correct them if necessary.
4. Copy the generated script.

Use the Bootstrap Script in JAMF

Now you will run the script through JAMF Pro to create new Edge Nodes.

1. Log in to your JAMF Pro console.
2. Navigate to **Settings** in the sidebar. Then, in the **Computer management** section, select **Scripts**.
3. Select **New**, give the new script a name (for example, “Install Cribl Edge”) and add an optional description.
4. On the **Script** tab, enter the bootstrap script you copied from Cribl Edge.

5. Confirm with **Save**.

Configure JAMF Pro Policy

Finally, you need to ensure JAMF runs the script on the desired macOS machines.

1. In the JAMF Pro console, navigate to **Computers** > **Policies**.
2. Select **New** to create a new policy and give it a descriptive name.
3. In the **Trigger** section, enable **Recurring Check-in** to ensure the policy triggers with the recurring check-in frequency.
4. In **Execution Frequency**, select **Once per computer** to ensure JAMF does not attempt to reinstall Cribl Edge.
5. Select **Scripts**, then in the list of available scripts locate the “Install Cribl Edge” script and select **Add**.

With this configuration, JAMF will run the script that deploys Cribl Edge once for every machine it manages, adding the new Edge Nodes to the `MacLaptops` Fleet.

6. Cribl Edge In Containers

You can deploy Cribl Edge in containerized environments using Docker or Kubernetes.

Running Cribl Edge in a container ensures consistent deployment, simplifying installation and upgrades. Containerization enables easy scaling and management via orchestration tools like Kubernetes.

Read the following topics for more information about running Cribl Edge in a container:

Topic	Description
Run Cribl Edge in a Docker Container	Install Cribl Edge in a container using a Docker image.
Deploy Cribl Edge via Kubernetes	Deploy Cribl Edge in Kubernetes Pods to collect logs and metrics.
Upgrading Containers	Upgrade a Cribl Edge instance in a container.

6.1. Run Cribl Edge In A Docker Container

Install Cribl Edge in a container using a Docker image.

You can easily deploy and run Cribl Edge from a container image into a Docker container, making it simple to integrate Cribl Edge into your existing containerized environments.

In this article, you'll learn how to pull the Cribl Edge Docker image, configure it, and manage its lifecycle within your containerized environment.

Add a Docker Node from the Cribl Edge UI

As a best practice, we recommend using the UI to create and copy/paste the bootstrap script for adding a Docker node. See our documentation on how to Add a New Edge Node with a Bootstrap Script.

Start the Container with a Docker Command

For a Single-instance deployment, start the container with the Docker command below (replace `4.13.2` in the last line with the version of Cribl Edge you want to install):

```
docker run -d
 -e CRIBL_EDGE=1 \
 -p 9420:9420 \
 -v /var/run/docker.sock:/var/run/docker.sock \
 -v /:/hostfs:ro \
 --privileged \
 --restart unless-stopped \
 --name cribl-edge \
 cribl/cribl:4.13.2
```

Copy

For a Distributed deployment, edit the Docker command below to replace `INSERT_TOKEN` with a unique, secure token value. Then start the container with the revised command.

```
docker run -d \
 -e CRIBL_DIST_MODE=managed-edge \
 -e CRIBL_DIST_LEADER_URL=tcp://INSERT_TOKEN@leaderhere:4200?group=fleet_name \
 -e CRIBL_EDGE=1 \
 -p 9420:9420 \
 -v /var/run/docker.sock:/var/run/docker.sock \
 -v /:/hostfs:ro \
 --privileged \
 --restart unless-stopped \
 --name cribl-edge \
 cribl/cribl:4.13.2
```

Copy

With a Leader on Cribl.Cloud, encryption is enabled by default. Set the hybrid worker's `CRIBL_DIST_LEADER_URL` environment variable to begin with the `tls://` protocol. For example:

```
CRIBL_DIST_LEADER_URL=tls://<token>@logstream-<tenant>.cribl.cloud:4200
```

Copy

Once that's running, the UI displays on `http://localhost:9420/`

You can now start configuring Cribl Edge with Sources and Destinations, or start creating Routes and Pipelines.

When a Node in a Kubernetes Fleet restarts, it might receive a new GUID, which can cause duplicate entries to appear on the **Edge Nodes** page. To resolve this issue, navigate to **General Settings** > **Fleet Configuration** and set **Time to keep disconnected Nodes** to 0.

Find Edge Nodes Running in a Container

Edge Nodes running in a container report additional metadata about the container to the Leader. This helps you quickly identify which of your Edge Nodes are running in a container from the Leader UI and map them to the appropriate Fleets.

When Cribl Edge is running in a container, you will see the `hostOs` property in events collected by the System State Source. This object will contain properties about the container when they're available, such as:

- `arch`
- `cpu_count`

- `cpu_speed_mhz`
- `cpu_type`
- `interfaces`
- `memory`
- `platform`
- `release`
- `hostname`
- `timezone`

From the **Mappings** menu, you will also see the `hostOs` property in the **Edge Node info** panel. This object will include the `id`, `addresses`, and `version` of the container when available.

`interfaces` is a set of key-value pairs that contain an array of CIDR values.

Run Cribl Edge as a Non-Root User

You can run the Cribl image as a non-root user within a container using Docker's `--user` option or the user setting in Compose. You can specify any desired `UID` (User ID).

To ensure correct functionality, you must set the `CRIBL_VOLUME_DIR` environment variable to a location the non-root user can write to. This is because the software requires write permissions to directories like `/opt/cribl/state`, `/opt/cribl/log`, and `/opt/cribl/local`. Failure to set `CRIBL_VOLUME_DIR` will result in a warning and potential functional issues.

If you mount a persistent volume, setting `CRIBL_VOLUME_DIR` to the mount point is strongly recommended for optimal performance and reliability. While `/tmp/cribl_data` might be used, a dedicated persistent volume ensures data integrity and prevents potential data loss or corruption.

We recommend specifying `CRIBL_VOLUME_DIR` whenever running as a non-root user to avoid unexpected behavior.

See example below:

```
docker run -d \
 -u 999:999
 -e CRIBL_DIST_MODE=managed-edge \
 -e CRIBL_DIST_LEADER_URL=tcp://INSERT_TOKEN@leaderhere:4200?group=fleet_name \
 -e CRIBL_EDGE=1 \
 -p 9420:9420 \
 -e CRIBL_VOLUME_DIR=/tmp/ \
 -v /var/run/docker.sock:/var/run/docker.sock \
 -v /:/hostfs:ro \
 --restart unless-stopped \
 --name cribl-edge \
 cribl/cribl:4.13.2
```

Copy

To prevent issues with Cribl file operations, `/opt/cribl` and all its subdirectories must reside on the same device. Mounting separate devices within `/opt/cribl` is not recommended. For external storage needs, such as lookups or Persistent Queues (PQs), create a completely separate directory outside of `/opt/cribl`. While `/opt/cribl` is the default installation path, Cribl can be installed to other locations if necessary.

Override Default Ports

You can override default ports in the following configuration files:

- Edge UI port (`9420`): Default definitions for `host`, `port`, and other settings are set in `$CRIBL_HOME/default/cribl/cribl.yml`, and can be overridden by defining alternatives in `$CRIBL_HOME/local/cribl/cribl.yml`.
- Data Ports, for example HTTP In (`10080`), TCPJSON in (`10420`) have default definitions for `host`, `port` and other settings defined in `$CRIBL_HOME/default/cribl/inputs.yml`, and can be overridden by defining alternatives in `$CRIBL_HOME/local/cribl/inputs.yml`.

In the case of an API port conflict, the process will retry binding for 10 minutes before exiting.

Update the Docker Image and the Packaged OS

For details, see the following topics:

- Updating the Docker Image

- Updating the Packaged OS

Shut Down Docker Containers

To shut down Docker containers that are running Cribl Edge, use `docker stop` instead of `docker kill`. This allows Docker to shut down the container cleanly. When you run `docker stop` for your Cribl Edge containers, the following happens:

- The container runs `cribl stop` and waits for all `cribl` processes to exit before shutting down.
- Docker waits up to 10 seconds by default. If this is not enough time for your processes to exit, you can

6.2. Deploy Cribl Edge Via Kubernetes

Deploy Cribl Edge in Kubernetes Pods to collect logs and metrics.

Cribl Edge supports both Docker and `containerd` runtimes.

Considerations

Cribl Edge connects to the Kubernetes Cluster API and the `kubelet` API on each node to read logs and metrics. To prevent under- or over-collection of logs and metrics, you must deploy the Cribl Edge agent as a DaemonSet in your Kubernetes cluster. Ensure that Cribl Edge is able to detect that it's running inside a Kubernetes Pod, by setting the `CRIBL_K8S_POD` environment variable.

To run the Kubernetes Sources (Metrics, Logs) inside a cluster, use the default `ServiceAccount`, and mount the connection details in `var/run/secrets/kubernetes.io/serviceaccount`. If you want the Source to look in a different directory, use the `CRIBL_SERVICEACCOUNT_PATH` environment variable to set the new path to the `ServiceAccount`.

Optionally, you can run the Kubernetes Sources (Metrics, Logs) outside of a cluster, by specifying connection details in a `kubeconfig` file (like `kubectl`). Either place the file in `$HOME/.kube/config`, or use the `$KUBECONFIG` variable to point to it.

If you are enabling role-based access control (RBAC) in your Kubernetes cluster, Cribl Edge requires a `ClusterRole` to authorize the Service Account to read logs and metrics. This is a `read-only` role, which does not require `write` permissions. Plan ahead with your Kubernetes admins and security team to authorize the installation of this `ClusterRole`.

If your Kubernetes deployment doesn't use valid certificates, then set the `CRIBL_K8S_TLS_REJECT_UNAUTHORIZED` environment variable to `0` to disable that expectation. When you disable this environment variable, all Kubernetes features (including Metadata, Metrics, Logs, and workload instrumentation metadata) will tolerate invalid TLS certificates (i.e., expired, self-signed, and so on.) when connecting to the Kubernetes APIs. If this environment variable is not defined or set to `1` and the certificate validation fails, then all connection attempts to the Kubernetes API will be rejected. For details, see Which Certificate Does kubelet Use?

All other Cribl Edge Kubernetes components can run inside a namespace of your choice. This page uses the example namespace `cribl-edge`.

Configure a Service Account

You can configure the Leader deployment to use a Kubernetes ServiceAccount for accessing cloud resources. This approach proves especially beneficial when you need to grant IAM roles directly to the Leader pod. A common use case is leveraging AWS KMS as the KMS provider without the need for access key IDs and secrets.

To configure a ServiceAccount for the Leader chart, you can modify the following options within your `values.yaml` file or by using the `--set` parameters during Helm deployment:

Value	Default	Description
`serviceAccount.create`	`false`	If set to `true`, the chart will create a new ServiceAccount specifically for the Leader Pod.
`serviceAccount.name`	`undefined`	Name of the ServiceAccount to use: • If `create: true` and this value is unset, the name defaults to `<release>-leader`. • If `create: true` and this value is set, the service account will use the provided name. • If `create: false`, this value **must** match the name of an existing ServiceAccount.
`serviceAccount.annotations`	`{}`	A key/value map of annotations to be added to the newly created ServiceAccount.

When `serviceAccount.create` is set to `false` and a `name` is provided, the chart assumes you are referencing an existing, pre-configured ServiceAccount. Conversely, if `serviceAccount.create` is `true`, the chart will generate a new ServiceAccount, either with a default name or the name you specify. When creating a service account, you can include annotations to declare the specific IAM roles that the service account should have permission to access.

Example configuration for creating a ServiceAccount with IAM role annotations:

```
serviceAccount:
  create: true
  name: "cribl-leader-sa"
  annotations:
    [eks.amazonaws.com/role-arn](https://eks.amazonaws.com/role-arn): "arn:aws:iam::1
```

Copy

Deploying

To deploy the Cribl Edge agent in your Kubernetes cluster, you can use our Helm charts. These charts provide the minimum configuration required to install Cribl Edge correctly.

Our deployment has been tested across multiple Kubernetes platforms on several cloud service providers. The Cribl Helm Charts provide a fast, repeatable, and consistent way of deploying and upgrading an entire Kubernetes environment.

You can customize our Helm charts with additional configurations required for your Kubernetes platform - such as annotations for load balancers, environment variables for secrets, etc. For details, follow the link above.

A simple deployment example using Cribl's Helm chart:

```
helm repo add cribl https://criblio.github.io/helm-charts/

helm install -n cribl-edge --set "cribl.leader=tcp://<token>@leader:4200" cribl-edge
```

Copy

You can also use the UI to concatenate and copy/paste the bootstrap script for adding a Kubernetes node.

If you are building your own manifests, the DaemonSet pods must be configured with the following environment variables:

- `CRIBL_DIST_LEADER_URL: <changeme>`
- `CRIBL_DIST_MODE: managed-edge`
- `CRIBL_EDGE: true`
- `CRIBL_K8S_POD :<must match the name of the pod>`

Tolerations

By default, Kubernetes will not schedule a Pod on a node that has taints. You must configure your deployment to allow scheduling on these nodes; otherwise, Cribl Edge will be unable to collect logs and metrics from them.

The defaults in our Helm chart's `values.yaml` file are configured like this:

```
tolerations:
  - operator: Exists
```

Copy

Kubernetes CPU Limit Configuration

The Cribl Edge Helm chart ensures that the number of Worker Processes is determined by the CPU resources allocated to the pod, rather than the physical CPU count on the host.

To achieve this, it sets the `CRIBL_K8S_CPU_LIMIT` environment variable to the value of the `resources.limits.cpu` setting on the pod. Cribl Edge then uses the value as a CPU limit to determine how many Worker Processes to start.

We recommend maintaining the default configuration of the `CRIBL_K8S_CPU_LIMIT` environment variable, to prevent performance problems like resource contention and pod instability from exceeding CPU limits.

Updating Helm Charts for OpenShift or Non-Root Environments

To make sure your deployments run smoothly on OpenShift or non-root environments, you'll need to configure the security context through the `values.yaml` file. The `values.yaml` file allows you to override default settings and customize your deployment without altering the core Helm chart templates.

To add or update the `values.yaml` :

1. Locate or create a local `values.yaml` file.
2. Modify the `securityContext` section.
3. Customize the capabilities to match your environment's needs:

```
securityContext:
  capabilities:
    add:
      - CAP_NET_BIND_SERVICE
      - CAP_SYS_PTRACE
      - CAP_DAC_READ_SEARCH
      - CAP_NET_ADMIN
```

Copy

4. Install your updated values to Helm, using this command: `helm install -f /bar/values.yaml`

For a description of the capabilities, see Set Capabilities for Cribl Edge.

RBAC

Cribl Edge's Kubernetes Logs and Kubernetes Metrics Sources use the Kubernetes API to read logs and metrics from the cluster. If you have role-based access control (RBAC) implemented, you will need to authorize the Cribl Edge Pod Service Account to read the relevant data.

Kubernetes Events Source

To collect cluster-level events, the Kubernetes Events Source needs watch access to the Kubernetes API.

An example RBAC rule is:

```
- apiGroups:
    - "events.k8s.io"
  resources:
    - events
  verbs: ['watch']
```

Copy

Kubernetes Logs Source

The Kubernetes Logs Source requires the ability to get, list, and watch Pods in all namespaces.

An example RBAC rule is:

```
- apiGroups:
    - ""
  resources:
    - pods
  verbs: ['get', 'list', 'watch']
```

Copy

Kubernetes Metrics Source

The Kubernetes Metrics Source reads metric information from many resources in your cluster. The minimum permissions required are:

```
- apiGroups:
    - ""
  resources:
    - configmaps
    - endpoints
    - limitranges
    - namespaces
    - nodes
    - persistentvolumeclaims
    - pods
    - replicationcontrollers
    - secrets
    - services
    - strategicMergePatches
    - nodes/log
    - nodes/metrics
    - nodes/proxy
    - nodes/spec
    - nodes/stats
  verbs: ['get', 'list', 'watch']

- apiGroups:
    - "apps"
  resources:
    - daemonsets
    - deployments
    - replicasets
    - statefulsets
  verbs: ['get', 'list', 'watch']
- apiGroups:
    - "batch"
  resources:
    - cronjobs
    - jobs
  verbs: ['get', 'list', 'watch']
- apiGroups:
    - "autoscaling"
  resources:
    - horizontalpodautoscalers
  verbs: ['get', 'list', 'watch']
- apiGroups:
    - "policy"
```

```
    resources:
      - poddisruptionbudgets
    verbs: ['get', 'list', 'watch']
  - apiGroups:
      - "networking.k8s.io"
    resources:
      - ingresses
      - networkpolicies
    verbs: ['get', 'list', 'watch']
  - apiGroups:
      - "admissionregistration.k8s.io"
    resources:
      - mutatingwebhookconfigurations
      - validatingwebhookconfigurations
    verbs: ['get', 'list', 'watch']
  - apiGroups:
      - "certificates.k8s.io"
    resources:
      - certificatesigningrequests
    verbs: ['get', 'list', 'watch']
  - apiGroups:
      - "storage.k8s.io"
    resources:
      - storageclasses
      - volumeattachments
    verbs: ['get', 'list', 'watch']
```

Copy

Prometheus Edge Scraper

The Prometheus Edge Scraper Source requires specific Kubernetes RBAC rules depending on the **Discovery type** you configure.

Kubernetes Node and Kubernetes Pods

To discover Kubernetes Nodes or Pods, the Source must be able to list Pods across all namespaces.

```
  - apiGroups:
      - ""
    resources:
      - pods
    verbs: ['list']
```

Copy

Kubernetes Service Monitor (v4.18+)

To discover `ServiceMonitor` custom resources and their associated Services, the Source needs the following permissions:

```
  - apiGroups:
      - "monitoring.coreos.com"
    resources:
      - servicemonitors
    verbs: ['list']
  - apiGroups:
      - ""
    resources:
      - services
      - namespaces
    verbs: ['list']
```

Copy

The `namespaces` permission is required only when any `ServiceMonitor` in the cluster defines `namespaceSelector.any: true`, causing the source to enumerate all namespaces. If you know your `ServiceMonitor` resources use only the `matchNames` selector or default to their own namespace, you can omit `namespaces` from the rule.

Health Checks

An example health-check configuration for Kubernetes is:

```
readinessProbe:
    httpGet:
        path: /api/v1/health
        port: 9420
        scheme: HTTP
    initialDelaySeconds: 15
    timeoutSeconds: 1
livenessProbe:
    httpGet:
        path: /api/v1/health
        port: 9420
        scheme: HTTP
    initialDelaySeconds: 15
    timeoutSeconds: 1
```

Copy

If you have Fleets running Edge Nodes with version 4.8.2 and older, you can encounter failing health checks that require specific API server configuration.

By default, the Cribl Edge API listens on port 9420, instead of on Cribl Stream's default 9000 port. This requires special care when you configure your Edge Fleet in the Cribl UI.

On Fleets running Edge Nodes with version 4.8.2 and older, the API server is configured be default to listen on the loopback interface (`127.0.0.1`). For your Nodes to remain reachable, you must change the listening interface address to `0.0.0.0` in **Fleet Settings** > **General Settings** > **API Server Settings** > **General**. This will bind to all IPs in the container. If you do not make this change, your health checks will start failing after the Edge agent downloads its initial config bundle.

Another side effect of not changing the Listening Interface address, is the Edge Node will not appear on the Leader UI.

Environment Variables

You can use the following environment variables to configure Cribl Edge on Kubernetes:

- `CRIBL_SERVICEACCOUNT_PATH` - by default, set to: `/var/run/secrets/kubernetes.io/serviceaccount`.
- `CRIBL_K8S_POD` - the name of the Kubernetes Pod in which Cribl Edge is deployed.
- `KUBECONFIG` - set this for local testing.

- `CRIBL_K8S_TLS_REJECT_UNAUTHORIZED` - set to `0` to disable certification validation when connecting to the Kubernetes APIs. When you disable this environment variable, all Kubernetes features (including Metadata, Metrics, Logs, and workload instrumentation metadata) will tolerate invalid TLS certificates (i.e., expired, self-signed, etc.) when connecting to the Kubernetes APIs.

See also our list of all Cribl Environment Variables.

Upgrading Kubernetes Edge Nodes

For details, see Upgrading Kubernetes Edge Nodes.

Uninstalling

To remove the Cribl Edge agent from your Kubernetes cluster, run the following command:

```
helm uninstall -n <namespace> <releasename>
```

The `helm uninstall` command automatically deletes all deployed resources associated with the Cribl Edge Helm Chart.

7. Set Up Cribl Edge

Cribl Edge offers different types of deployments that you can choose based on your needs:

- Cribl.Cloud, including a hybrid option.
- Customer-managed deployments, including:
    - A Single-instance deployment, where you deploy a single Edge Node on Linux, Windows, or macOS.
    - A Distributed deployment, where you set up Leader and multiple Edge Nodes.

You can also run Cribl Edge on Docker, or deploy it via Kubernetes.

To prepare for a deployment and gather decision-making information, consult Deployment Planning.

7.1. Get Started With Cribl Edge

Quickly set up a working instance of Cribl Edge.

This quick start guide shows you how to get Cribl Edge running.

You can either start with a free Cribl.Cloud instance, or deploy the Cribl Edge agent on a physical or virtual machine. We'll cover both options below, so feel free to jump to the relevant section in this article:

- Download and Install Cribl Edge.
- Quick Start with a Cloud Instance.

Check the Minimum Deployment Requirements

Before you proceed, make sure that the hosts for all Cribl Edge agents - and for any Leader that you install on your own infrastructure - meet the System Requirements that we list for Linux, Windows, and macOS.

Download and Install Cribl Edge

To install Cribl Edge, select the Linux or Windows tab below and follow the corresponding steps.

Linux Windows macOS

To avoid permissions errors, install and run Edge as the same Linux user. For details on creating a new user, see Enabling Start on Boot.

1. Navigate to the Cribl Downloads page.
2. Select either `x64` or `ARM` Cribl Suite from the drop-down. You can also copy and paste one of the provided `curl` scripts into a command-line interface.
3. Open a command-line interface and navigate to the `/opt/` directory:

```
cd /opt/
```

Copy

4. Un-tar the resulting `.tgz` file in the `/opt/` directory.

```
tar xvzf cribl-<version>-<build>-<arch>.tgz
```

Copy

For example:

```
tar xvzf cribl-4.3.1-12f82b6a-linux-x64.tgz
```

Copy

Edge is now installed in a `cribl` subdirectory, by default: `/opt/cribl/`.

5. Move it to the `cribl-edge` directory with:

```
mv /opt/cribl/ /opt/cribl-edge
```

Copy

6. In your terminal, go to `/opt/cribl-edge/bin` and switch your installation to Edge mode:

```
./cribl mode-edge
```

Copy

Run Cribl Edge

Now you can start, stop, and verify the Cribl Edge server using these `./cribl` CLI commands:

- **Start**: `./cribl start`
- **Stop**: `./cribl stop`
- **Get status**: `./cribl status`

For other available commands, see CLI Reference.

1. In your browser, open `http://127.0.0.1:9420` and log in with default credentials (`admin`, `admin`).
2. Register your copy of Cribl Edge when prompted.
   After registering, you'll be prompted to change the default password.

Quick Start with a Cloud Instance

As mentioned above, the Leader Node can reside in a free Cribl.Cloud account. You'll get a ready-to-use Cribl Leader that includes Cribl Edge functionality. For a detailed comparison, see Cribl.Cloud vs. Self-Hosted.

To get a Cribl.Cloud account:

1. Go to https://cribl.cloud/signup/ and register an account.
2. On the **Create Organization** page, optionally enter an **Organization Name** (a friendly alias for the randomly generated ID that Cribl will assign to your Organization).
3. Select an AWS Region to host your Cribl.Cloud Leader. Cribl currently supports the following Regions:
    - `US West (Oregon)`
    - `US East (Virginia)`
    - `US East (Ohio)`
    - `Europe (Frankfurt)`
    - `Europe (London)`
    - `Europe (Zurich)`
    - `Asia Pacific (Sydney)`
    - `Asia Pacific (Singapore)`
    - `Canada (Central)`

For details on Cribl.Cloud Organizations, refer to Cribl.Cloud documentation:

- Register Cribl.Cloud Organization.
- Manage Cribl.Cloud organization.

Add Edge Nodes

You now have a Cribl Leader running with Cribl Edge capabilities enabled, but still need to add Edge Nodes. To do this:

1. From Cribl Edges's top nav, select **Manage** > **Edge Nodes**.
2. On the resulting **Edge Nodes** tab, click **Add/Update Edge Node** at the upper right and then select **Linux** > **Add**
3. Copy the resulting script to your clipboard and close the modal.
4. Paste the script onto your Edge Node's command line and execute it.

To add an Edge Node on a Windows or using Docker or Kubernetes, refer to Add and Update Edge

Nodes.

7.2. Cribl.Cloud Vs. Self-Hosted

Learn how a Cribl.Cloud deployment differs from an on-prem installation.

A Cribl.Cloud deployment differs in several ways from a customer-managed (on-prem) deployment of Cribl Suite software on your own infrastructure. Keep in mind these differences as you choose how to launch Cribl Edge. Also consider these differences as you navigate the product's UI, in-app help (including tooltips), and documentation.

Cribl Edge and Cribl.Cloud

A Cribl.Cloud deployment lets you connect your Edge Nodes to a Cloud-hosted Leader Node.

In contrast with Cribl Stream, where you have the option to use Cribl-managed Worker Groups, Cribl Edge Fleets can only be customer-managed. They still benefit from all the features of running a Cloud-hosted Leader Node that are listed on this page.

Cloud-Only Features

Certain Cribl products and features are available **only** on Cribl.Cloud:

- Cribl Search, an application for searching, exploring, and analyzing machine data in place and at API endpoints.
- Cribl Lake, a data lake solution for long-term, full-fidelity data storage.
- Workspaces, an option for isolating parallel Cribl Leaders with separate access controls and other configurations.

For details about how all Cribl products interoperate to manage data, see the Full Suite Reference Architecture.

Simplified Administration

Cribl.Cloud has been designed with options to accommodate everyone - from first-time evaluators to Enterprise customers who manage a worldwide network of private-cloud, public-cloud, and/or data-center deployments.

Cribl.Cloud's Free offering is designed to help you launch Cribl Edge - and to start processing data - as quickly and easily as possible. Upgrading to a paid Standard or Enterprise plan provides expanded deployment and configuration options.

For a comparison of features in Free, Standard, and Enterprise Cribl.Cloud plans, see Pricing.

Simplified Distributed Architecture

Cribl.Cloud is preconfigured as a Distributed deployment. A Free or Standard plan allows only a single Fleet, and some Distributed Settings cannot be configured.

Git Preconfigured

Without an Enterprise plan, the **Settings** > **Global** > **System** > **Git Settings** section is omitted. However, a local `git` client is preconfigured in your Cribl.Cloud Organization. On the top nav, use the **Version Control** button (with a branched symbol) to commit/push changes to `git`. Select **Deploy** to deploy your committed changes. Cribl.Cloud does not support Git remote repos.

Automatic Restarts and Upgrades

Without an Enterprise plan, the **Settings** > **Controls** link is omitted. Cribl handles Leader and Fleet restarts automatically on your behalf.

Simplified Access Management and Security

In Cribl.Cloud, you can manage access control for your Organization by selecting **Organization** in the sidebar and then selecting **Members & Teams**. The options on this tab will vary depending on your plan.

If you have a Cribl.Cloud Enterprise plan, you can use the Key Management Service (KMS), which maintains the keys Cribl Edge uses to encrypt secrets on Fleets and Edge Nodes. Go to **Settings** > **Security** > **KMS** to configure KMS.

If you add an Enterprise Plan, cloud and hybrid Leaders support Local and Google SSO authentication, along with OpenID Connect (OIDC) and SAML federated authentication. Cribl.Cloud does not currently support LDAP.

Permission- and Role-based access control (RBAC) is simplified in Cribl.Cloud. For details, see Permissions.

Security Features Comparison: Self-Hosted vs. Cribl.Cloud

The following table outlines the security responsibilities for self-hosted and Cribl.Cloud deployments, highlighting key differences in deployment security, data protection, threat detection, and access control.

Feature	Self-Hosted	Cribl.Cloud
Deployment Security	Customer responsible for securing the deployment environment (network isolation, physical access control, user access management).	Cribl manages the security of the cloud infrastructure.

Feature	Self-Hosted	Cribl.Cloud
Configuration Security	Customer responsible for securing configuration files and tokens.	Cribl manages the security of configuration files and tokens.
Git Configuration Security	Customer responsible for securing the Git repository.	Cribl manages the security of the Git repository.
Data at Rest	Customer responsible for encryption and key management.	Encrypted at rest by using industry standard encryption (e.g., AES-256) for storage services.
Data in Motion	Customer configures encryption (TLS) for data in transit.	Preconfigured TLS for some Sources. Can be further configured.
Threat Detection & Response	Customer responsibility. Use Cribl Stream security features (limited) and external tools.	Cribl bolsters its security posture with internal security teams and an external MSSP, ensuring comprehensive protection for its production and corporate environments through threat detection, workload scanning, and vulnerability management.
Patch Management	Customer responsible for applying security patches to Cribl Stream and underlying infrastructure.	Cribl manages patching of Cribl.Cloud (Cribl-managed) infrastructure.
Access Control	Customer configures user Roles and Permissions (RBAC).	Simplified RBAC with Enterprise plans offering advanced options (SSO, KMS).
Authentication	Customer configures authentication methods.	Local and SAML/OIDC IDP with Enterprise plans (additional options).
Key Management	Customer manages encryption keys.	Enterprise plans offer Key Management Service (KMS) for key storage.
Compliance	Customer responsible for adhering to compliance standards.	SOC 2 Type II compliant and GDPR-compliant (Cribl.Cloud).

Transparent Licensing

The Cribl.Cloud sidebar does not display a **Settings** > **Global** > **Licensing** link, nor does the **Monitoring** > **System** submenu include **Licensing**. Your plan is managed by your Cribl.Cloud Organization, and you can check credits and usage history in the FinOps Center.

Other Simplified Settings

These features are available only in on-prem deployments:

- **Settings** > **Global** > **Scripts** (if enabled - Cribl.Cloud does not support configuring or running shell scripts).

Configuring persistent queues in a Cribl.Cloud deployment requires an Enterprise plan. You can freely define the **Queue size limit** on your Edge Nodes, based on the disk space you provision.

Available Ports and TLS Configurations

To get data into Cribl.Cloud, your Cribl.Cloud Organization provides several Sources and ports already enabled for you, plus 11 additional TCP ports (`20000-20010`) that you can use to add and configure more Cribl Edge Sources. Additionally, external port `443` is available for TCP-based services - it maps internally to port `10443`. For details, see Cribl.Cloud Ports.

TLS Details

TLS encryption is pre-enabled for you on several Sources, also indicated on your Workspace's **Data Sources** tab.

Cribl HTTP and Cribl TCP Sources/Destinations

Use the Cribl HTTP Destination and Source, and/or the Cribl TCP Destination and Source, to relay data between Edge Nodes that are either connected to the same Leader or different Leaders. For more information about

7.3. Learn About Connected Environments

If you have one or more on-prem Cribl Edge environments and Cribl.Cloud Organization(s), you can configure **Connected Environments**.

Connected Environments enables you to:

- **Use Cribl.Cloud with on-prem deployments.** Connect an on-prem Leader to Cribl.Cloud to use Cloud infrastructure management, the credit-based billing model, and Cribl Lake and Cribl Search. For example, you can send Cribl metric data to Cribl Lake or Cribl Search, then build dashboards to monitor throughput and performance.
- **Move data from on-prem to Cribl.Cloud.** Onboard data from on-prem Edge Nodes to Cribl.Cloud Edge Nodes without incurring double billing costs. See Send Data from On-Prem to Cribl.Cloud for details.

Connected Environments does not support proxied connections. Make sure the connection between your on-prem Leader and Cribl.Cloud does not pass through a proxy.

To set up Connected Environments, create a connection between the on-prem Leader and the Cribl.Cloud Leader. Then use the **Connections** page in your Cribl.Cloud account to manage credit consumption for all of your on-prem environments from one interface. This feature is called Universal Subscription.

Understand Environment Compatibility

For supported Stream and Edge combinations, auth tokens, recommended transports, and known limitations, see Cribl-to-Cribl compatibility matrix.

Before You Begin Connecting On-Prem Leaders

Confirm that your environments meet these requirements before you connect an on-prem Leader to Cribl.Cloud:

- **Cribl.Cloud plan**: Your Cribl.Cloud account uses an Enterprise plan. See Cribl.Cloud pricing.
- **On-prem version**: Your on-prem Cribl Edge deployment runs version 4.8.2 or newer.
- **Distributed mode**: Your on-prem deployment runs in Distributed mode. Only a Leader can connect to Cribl.Cloud. Single-instance (standalone) deployments aren't supported.
- **Port**: Port `4200` is open on the on-prem Leader, using the TCP protocol.
- **TLS**: The connection uses TLS. Cribl Edge enforces TLS for the connection.
- **No proxy**: The connection does not pass through a proxy.

Connection Methods

Cribl supports two methods for connecting an on-prem Leader to a Cribl.Cloud Leader:

- From the Cribl.Cloud account in **Connections** > **Connected Environments**.
- From the on-prem Leader in **Distributed Settings** > **Cloud Connection**.

Credits serve as the virtual transaction currency in the Cribl product suite. Each Cribl product has a predefined usage rate, and as you use the products, credits are deducted from your initial pool.

Configuration Considerations

Take these considerations into account for your on-prem Leader, allowlists, security groups, and Workspaces:

- **Ports**: Make sure that port `4200` is open on the Leader, with TCP protocol. See Leader Ports for more information.
- **TLS**: The connection between the Cribl.Cloud Leader and the on-prem Leader must be encrypted using TLS. When you configure the `CRIBL_CLOUD_WORKSPACE_URL` environment variable, the value must start with `tls://`, which enforces TLS. Cribl Edge validates the Cribl.Cloud Leader's certificate against public certificate authorities, so you can't disable certificate validation or supply a custom CA path for this connection.
- **Connection host**: The connection URL must point to a Cribl.Cloud hostname, such as `<your-workspace>-<organization-id>.cribl.cloud`.
- **Static IPs**: For IP address allowlist or security group rules, you can find the static IPs of your Cribl.Cloud Leader in **Workspace** > **Access** > **Leader NLB IPs**. You can also use the `nslookup` command to obtain static IPs.
- **Private Link**: As an alternative to allowlisting static IPs, eligible Enterprise Organizations can reach the Cribl.Cloud Leader over AWS PrivateLink, so the connection stays on your cloud provider's private network instead of the public internet. Leader Private Link is AWS only, and the connecting environment must be able to create an AWS VPC interface endpoint. An on-prem Leader that cannot create an AWS interface endpoint cannot use Private Link for this connection. See Private Link for Cribl.Cloud.
- **Workspaces**: Workspaces are separate infrastructure. For allowlists and security groups, ensure that you add each IP address individually as each Workspace has a unique IP.

7.3.1. How To Connect On-Prem Leaders To Cribl.Cloud

To connect existing on-prem Cribl Edge Distributed deployments to Cribl.Cloud, select an on-prem Leader that is running Cribl Edge 4.8.2 or newer, then follow the steps.

If you have multiple environments, such as staging and production environments when using GitOps, you must connect each environment individually.

1. On the top bar, select **Products**, and then select **Cribl**.
2. In the sidebar, select **Workspace**, and then select **Connections**.
3. Select **Configure New Environment** and fill out the following fields:

Field	Description	Example
Environment name	A name for your environment. This name will display on the **Connected Environments** page. You can search for and filter environments by name.	Goat Farm East Production
Workspace hostname/ID	Hostname of your Cribl.Cloud Workspace. This field is read-only.	`main-random-goat-a12bcdef.cribl.cloud`
Workspace port number	Port number that the Workspace Leader uses to communicate with the on-prem Leader.	`4200`
Workspace token	The auth token defined in the Cribl.Cloud Leader.	`a12bcDEFgHiJKLmnOpQRstuvw3x4z56`

Script type	The format of the script to connect to the on-prem Leader:
	◦ Environment variable
	◦ CLI
		Environment variable:
		`CRIBL_DEPLOYMENT="Goat Farm West Product`
		`CRIBL_CLOUD_WORKSPACE_URL="tls://a12bcDE`
		CLI:
		`./cribl cloud-workspace`

Field	Description	Example

		`-d “Goat Farm West Production”`
		`-H main-random-goat-a12bcdef.cribl.cloud`
		`-p 4200`
		`-u a12bcDEFgHiJKLmnOpQRstuvw3x4z56`

Use a Command-Line Script

If you’re using the CLI option, follow these steps, in order:

1. Select **Copy Script**.
2. Open a command-line window in the Leader environment that you want to connect to Cribl.Cloud.
3. Navigate to the `$CRIBL_HOME/bin` subdirectory.
4. Paste the script results onto the command line, and run the script.

Use an Environment Variable

The **Environment Variable** script populates with the details you enter when you’re configuring a new environment. For example:

```
CRIBL_DEPLOYMENT="On-prem Stream"
CRIBL_CLOUD_WORKSPACE_URL="tls://a12bcDEFGHIjKLMnopPqr123@main-random-goat-a12bcdef.c
```

Copy

If you’re using the environment variable, copy its output, and set it when - or before - you run `cribl start`. How you set this variable depends on your deployment.

- For example, if your Cribl Edge deployment is running in a container, set the environment variable in the container via run call or configuration.
- If you’re running your own server, you can set environment variables for the `cribl` user, or you can declare the variable along with the `start` command. For details, see our CLI Reference.

High Availability Leader Configuration

Before you configure a connected environment with a High Availability (HA) Leader, ensure you are comfortable setting up and managing Leader HA. See Leader High Availability/Failover for more information.

When you set up the primary Leader to connect to Cribl.Cloud in an HA environment, set the `CRIBL_DEPLOYMENT` and `CRIBL_CLOUD_WORKSPACE_URL` environment variables. You can do this in the

Cribl.Cloud UI, using the CLI, or directly in your environment. These variables use the same format that the **Environment variable** script shows in the UI:

```
CRIBL_DEPLOYMENT="aws_leader_prod"
CRIBL_CLOUD_WORKSPACE_URL="tls://a12bcDEFgHiJKLmnOpQRstuvw3x4z56@main-random-goat-a12
```

Copy

If you manage the primary Leader as a `systemd` service, set the same variables in the `[Service]` section of the unit file using `Environment=` entries:

```
Environment=CRIBL_DEPLOYMENT=aws_leader_prod
Environment=CRIBL_CLOUD_WORKSPACE_URL=tls://a12bcDEFgHiJKLmnOpQRstuvw3x4z56@main-rand
```

Copy

The failover Leader inherits the configuration from the filesystem changes made by the primary Leader.

Enable the On-Prem Leader Connection to Cribl.Cloud

You can connect a Leader Node to an existing Enterprise Cribl.Cloud Organization.

1. In the sidebar, select **Settings**.
2. On the **Global** tab, select **Distributed Settings**.
3. Select **Cloud Connection**.
4. Toggle **Join Cribl.Cloud Workspace** on.
5. Fill in the required fields:

Field	Description
Connection URL	The **Cribl.Cloud URL** to connect to this Leader. 1. In your Cribl.Cloud Organization, locate the URL field value on the sidebar **Workspace** > **Access** tab. 2. Copy the URL and paste it into the **Connection URL** field, using the format: `main-random-goat-a12bcdef.cribl.cloud`.
Connection port	The port for the Cribl.Cloud Leader. Default is `4200`.
Connection auth token	The authentication token for the Cribl.Cloud Leader. You'll need to get this from the Cribl.Cloud environment:

Field	Description
	1. Navigate to **Workspace** > **Connections** and select **Configure New Environment**. 2. Copy the value in the **Workspace token** field. 3. In the on-prem environment, paste the Workspace token from Cribl.Cloud.

6. Select **Save**.
7. In the Cribl Subscription Services Agreement modal, select **Agree** to accept the agreement.
8. In the confirmation modal, select **Yes** to save changes and restart.

Once you connect an on-prem Leader to a Cribl.Cloud Organization, the license type changes to a Cribl.Cloud billing account. This means the **Licensing** page will not be accessible. To return to using an on-prem license, toggle **Join Cribl.Cloud Workspace** off, select **Save**, and select **Yes** in the confirmation modal to save changes and restart.

7.3.2. Simplify Billing With Universal Subscription

This feature requires an Enterprise Plan.

If you have multiple instances of Cribl Edge on-prem, you're likely managing multiple licenses. Instead of letting license management run your life, you can take advantage of the Universal Subscription feature. Universal Subscription lets you manage an existing on-prem license with Cribl.Cloud credits.

To get started, connect your on-prem Leader to your Cribl.Cloud Leader to send billing data payloads. Once your environments are connected, you can use the FinOps Center to get a unified, all-product view of your Cribl Edge usage and spending.

This replaces an on-prem license, and gives you the flexibility to maintain your on-prem deployments without managing multiple licenses and tracking spend across environments.

An on-prem Cribl Edge environment consists of at least one Leader Node (the control plane) and one or more Fleets.

Connecting your on-prem Leader license to Cribl.Cloud billing allows you to:

- Monitor credit consumption for each of your on-prem Cribl Edge environments from one user interface.
- Create a billing- and usage-based connection between the Cribl Edge on-prem Leader and the Cribl.Cloud Leader, which receives metrics from the on-prem Leader. For information about the data payloads, visit Data Payloads for Connected Environments.

Configure Connected Environments

For the setup procedure, go to How to Connect On-Prem Leaders to Cribl.Cloud, then come back here to explore how to view credit and usage data for your on-prem Connected Environments.

Full access to Connected Environments requires you to upgrade Cribl Edge to 4.8.2 or newer.

Explore Credit Consumption for Connected Environments

Once you set up a Connected Environment, you can view the incoming usage data and credit consumption for your on-prem and Cloud deployments of Cribl Edge. You must be an Organization Owner to view this data.

For more information on Cribl.Cloud billing, go to the FinOps Center page.

View Usage Data

1. In the sidebar, select **Organization**, then **FinOps Center**.
2. Select **Usage Overview**.
3. Go to **Per Product Consumption** and expand either Cribl Edge or Cribl Stream.
4. Find **Connected < Product > GBs In**.

View Credit Consumption

1. In the sidebar, select **Organization**, then **FinOps Center**.
2. On the **FinOps Center** submenu, select **Invoices**.
3. Select a month to expand the cost items. Select **Stream** or **Edge**.
4. View **Connected < Product > GBs In** usage and cost.

Here, you will see each on-prem environment that is connected to this Cribl.Cloud Organization, and the credits each environment is consuming.

Limitations of the Universal Subscription Feature

Connected Environments has some usage limitations:

- The Connected Environments feature is available only on Enterprise Cribl.Cloud plans. For Enterprise plan details, see Pricing.
- Single-instance deployments of Cribl Edge aren't eligible for a Universal Subscription.
- The Distributed deployment on-prem Leader must be running Cribl Edge 4.8.2 or newer.

7.3.3. Data Payloads For Connected Environments

In a Connected Environment setup, on-premises Leaders connect to a Cribl.Cloud Leader in the same way that Edge Nodes connect to a Leader. The Cribl.Cloud Leader sends down a license, and the on-premises Leader sends up a heartbeat that includes telemetry, which encompasses metrics and other metadata.

Why Is the Telemetry Important?

The telemetry sent from an on-premises Leader to a Cribl.Cloud Leader is encapsulated in an event. This event serves as a heartbeat, confirming that the connected environment is active and functioning properly. It includes key metadata such as the system's status, timestamp, configuration details, and metrics. Cribl.Cloud uses this data to:

- Monitor connectivity between the on-premises Leader and the cloud.
- Track system health by evaluating fields like status, edgeNodes, and metrics.
- Ensure compliance with licensing by verifying the config.featuresRev field.
- Provide insights into data flow, such as input and output metrics.

How Often Is the Heartbeat Sent?

The heartbeat interval is determined by the **Task heartbeat period** field, which specifies the number of seconds between each event. In the provided example below, the heartbeat is sent every `10` seconds. This interval is configurable, meaning administrators can adjust it to optimize performance based on their needs. For details, see Task Manifest and Buffering Limits in Fleet Settings.

What Happens if the Heartbeat Is Missed?

If a heartbeat event is not received within the expected interval, the following actions may occur:

- **Retries** - The on-premises Leader may attempt to resend the heartbeat after a short delay.
- **Alerting** - Cribl.Cloud can generate an alert if the heartbeat is missing for an extended period, indicating a potential issue.
- **Failure detection** - A prolonged absence of heartbeats may be interpreted as a disconnection or system failure, prompting further investigation or automated recovery steps.

On-Premises Leader to Cribl.Cloud Leader Payload

This section describes the structure of the event payload sent from an on-premises Leader to a Cribl.Cloud Leader in a Connected Environment.

Sample Event

Here is a sample event that Cribl.Cloud received from a connected environment.

```
{
  "__criblEventType": "event",
  "type": "info",
  "_time": 1737577024.567,
  "status": "healthy",
  "localTime": 1737577024,
  "config.hbPeriodSeconds": 10,
  "config.featuresRev": "YbK7TIGe4jp2rdujnFiJqq0OBV67r2FKGvrHr4C6I5g=",
  "edgeNodes": 50,
  "__socketAddr": 192.168.1.100:443,
  "__srcIpPort": 10.0.0.5:52314,
  "metrics": [
    [
      0,
      0,
      "total.in_bytes",
      233,
      1737578280038,
      1737578340038,
      [
        "ci",
        "tcp:in_tcp",
        "input",
        "tcp:in_tcp",
        "input_type",
        "tcp",
        "__worker_group",
        "default",
        "__dist_mode",
        "worker",
        "__worker_node",
        "46731aec-d220-4cb0-9971-0dd0a7907d54",
        "__product",
        "stream"
      ],
      null,
      "float32"
    ]
  ],
  "__raw": "{\"type\":\"info\",\"_time\":173757...}"
}
```

Copy

Event Payload Fields

The following table describes the important fields in the event payload.

Field	Usage	Example
__criblEventType	Type of event	event (always)
type	Type of event	info (always)
_time	Timestamp of the event in Unix	1737577024.567

7.3.4. Send Data From On-Prem To Cribl.Cloud

You can use Connected Environments to send data from an on-prem deployment to a Cribl.Cloud deployment. For example, if you previously had an on-prem deployment of Cribl and you are moving forward with a Cloud-first or Cloud only solution, you can use connected environments to onboard your data from a on-prem Edge Nodes to their counterpart Cribl.Cloud Edge Nodes.

You can transfer data from on-prem Edge Nodes to the Cribl.Cloud Edge Nodes without incurring any data transfer costs.

Overview of the Data Migration Workflow

The workflow for migrating data from on-prem Edge Nodes to Cribl.Cloud Edge Nodes has these phases:

1. Create a Connected Environment. This process generates the information you need to set up the data flow between the on-prem Edge Nodes and the Cribl.Cloud Edge Nodes.
2. On-Prem Edge Nodes: Configure HTTP or TCP Destination. Add an auth token on the on-prem Edge Nodes to configure the first half of the connection between the on-prem Destination and the Cribl.Cloud Source.
3. Cribl.Cloud Edge Nodes: Configure HTTP or TCP Source. Add a matching auth token on the Cribl.Cloud Edge Nodes to complete the connection.
4. Validate the Data Flow. Confirm that the data is properly flowing from the on-prem Edge Nodes to the Cribl.Cloud Edge Nodes.

Create a Connected Environment

To begin the process of migrating data from on-prem to Cribl.Cloud, you need to first set up a Connected Environment on the on-Prem Leader. This process generates the information you need to set up the data flow between on-prem Edge Nodes and the Cribl.Cloud Edge Nodes.

To set up a Connected Environment, follow the instructions on How to Connect On-Prem Leaders to Cribl.Cloud. These instructions also explain how to:

- Optionally set up environment variables at the time you create the Connected Environment.
- Use a command-line script to set up a Connected Environment if needed.

Ensure that you also follow the instructions to Enable the On-Prem Leader Connection to Cribl.Cloud.

On-Prem Edge Nodes: Configure HTTP or TCP Destination

On the on-prem deployment, select a Edge Node and configure a new or existing Cribl HTTP or Cribl TCP Destination. These Destinations enable internal data transfer between Cribl nodes to prevent data transfer billing costs.

To configure an HTTP or TCP Destination:

1. Follow the general configuration instructions on the Cribl HTTP or Cribl TCP Destination documentation.
2. In the **Auth Token** section of the configuration modal, select **Auth Token** to set up a shared secret between this Destination and the Cribl.Cloud Source:
    - **Token secret (text secret):** Select the name of the secret that you have created previously or create a new secret using the **Create** button. See Create and Manage Legacy Secrets for specific instructions about creating secrets.
    - **Enable token:** Toggle the token on to enable it.
    - **Description:** Optionally, enter a description summarizing the purpose of the secret.

If you don't see the **Auth Token** section of the Destination, it means you have not set up a Connected Environment for your on-prem Leader.

3. Commit and deploy the changes.

You can add multiple tokens if you need to rotate auth tokens.

Cribl.Cloud Edge Nodes: Configure HTTP or TCP Source

On the Cribl.Cloud deployment, select a Edge Node and configure a new or existing Cribl HTTP or Cribl TCP Source. These Sources enable internal data transfer between Cribl nodes to prevent data transfer billing costs.

To configure an HTTP or TCP Source, follow the same steps listed in the previous section about Configuring HTTP or TCP Destination for the on-prem Edge Nodes.

When you select or create the secret from the **Token secret (text secret)** menu, this secret must match the value of the secret used on the on-prem Cribl HTTP or Cribl TCP Destination.

Commit and deploy after making these configuration changes.

Validate the Data Flow

As a final step, confirm that the data is properly flowing from the on-prem Edge Nodes to the Cribl.Cloud Edge Nodes. A few methods for confirming data flow include:

- Capture sample data on your Cribl HTTP or TCP Source on your Cribl.Cloud Edge Nodes and verify it looks correct. See Add Sample Data for specific instructions.
- In the configuration modal for your Cribl HTTP or TCP Source on your Cribl.Cloud Edge Nodes, select the **Charts** tab to view data events coming in to verify you see activity. You can also compare this to the outgoing data on the Cribl HTTP or TCP Destination on your on-prem Edge Nodes.

7.4. Tutorials

Follow these tutorials to get a one-stop overview of the interface and data flow functionalities of Cribl Edge.

- Route Collected Data explains the options for routing data collected by Cribl Edge to other products or Destinations.
- Forward Custom Data with Cribl Edge Tags shows how to add unique identifiers or metadata to each event for better control of data at scale.
- Monitoring your Infrastructure with Cribl Edge presents how to monitor infrastructure by collecting, processing, and forwarding data with low overhead cost and resources.
- Monitor and Troubleshoot Cribl Edge explores key metrics to monitor for optimal Cribl Edge operation, discusses how to gather this information, and provides effective monitoring strategies and general troubleshooting guidelines.
- Migrate from Third-Party Agents to Cribl Edge shows how to migrate your data collection infrastructure from third-party agents to Cribl Edge.

7.4.1. Route Collected Data

Process and route data collected by Cribl Edge.

You can route data collected in Cribl Edge in several ways:

- **To Cribl Stream:** For further processing and scalable distribution. See Send Data from Cribl Edge to Cribl Stream.
- **To Cribl Search:** For analysis or visualization. Use the Cribl Search Destination or see Collect and Visualize Nvidia GPU Metrics for an example use case.
- **Directly to Destinations:** Such as cheap storage, SIEMs, or other security and IT tools.

Cribl Edge is not intended for extensive data manipulation. Limit Pipelines on Edge Nodes to basic Cribl Functions. Avoid complex operations, to prevent bottlenecks and ensure optimal performance.

A typical workflow offloads major processing from Cribl Edge Nodes, for example by:

1. Collecting data locally.
2. Filtering out unwanted data, using the Drop Function.
3. Routing the remaining data to Cribl Stream for further processing and delivery to your desired Destinations.

You can check the Pipeline Profiler to access statistics on each Pipeline's performance.

QuickConnect vs. Routes in Cribl Edge

QuickConnect and **Data Routes** are both interfaces for managing data flow in Cribl Edge, but they serve distinct purposes, based on the complexity of your routing needs.

QuickConnect is ideal for simple, straightforward scenarios with a given Source sending the same set of data through an optional Pipeline to one or more Destinations. It offers ease of use and speedy configuration.

Data Routes, which are the default option, are better suited for complex data routing involving conditional processing. They provide flexibility, advanced logic, and scalability for handling intricate data flows.

Choose QuickConnect for rapid, minimal configuration setups, and opt for Routes when your data requires more sophisticated routing and processing.

Processing Cribl Edge Data with Pipelines

Once you have collected your data, you have options to transform it before sending it to your Destinations.

You can transform data within pre-processing, processing, or post-processing Pipelines. Some examples of common operations performed in Pipelines in Cribl Edge include dropping events and enriching them with metadata.

Drop Events to Lower Ingest Cost

By using the Drop Function, you can effectively eliminate data from your ingestion pipeline without incurring additional costs.

There are few ways you can take advantage of this Function:

- Use pre-processing Pipelines to filter and drop specific events, based on criteria like event codes.
- Use processing Pipelines to drop data before cloning events to send them to multiple Destinations. This reduces data volume.
- Safely experiment with configurations, without incurring costs, by routing data to the DevNull Destination.

The number of dropped events that lower the ingestion cost is calculated based on average event size. This means it may not represent the exact number of bytes you drop.

Enrich Events by Adding Metadata

To enrich and refine your data within Cribl Edge, effectively use the Eval Function's **Add Field** option. This feature enables you to dynamically create new fields based on existing data elements - such as tags from mapping rules, or event metadata. By converting tags and metadata to fields, you can enhance data analysis and manipulation capabilities.

For instance, a File Monitor might be collecting IIS logs from a Windows server. To ensure that these events are stored correctly in your final analysis system, you could specify a value of `index = 'IIS'`. This creates a new field named `index` with the value `IIS`, providing essential context for your data.

Goat-to Resources

Get More Out of Cribl Edge by Dropping Events — Blog

7.4.2. Forward Custom Data With Cribl Edge Tags

Add unique identifiers to events forwarded from Cribl Edge by using tags.

Organizations often need to add unique identifiers or metadata to each event forwarded from Cribl Edge to supported Destinations. Whether you're managing a small deployment or thousands of nodes, incorporating Edge tags into your events provides the context needed to make sense of your data at scale. These identifiers can help:

- Track the source of events across a large enterprise
- Associate events with specific departments, teams, or business units
- Maintain custom organizational taxonomy in log data
- Enable better filtering and searching in the Destination systems

This guide will show you how to set tags during Cribl Edge Installations and use the Preprocessing Pipeline to forward custom data points to a Destination.

Embed Source Context with Cribl Edge Tags

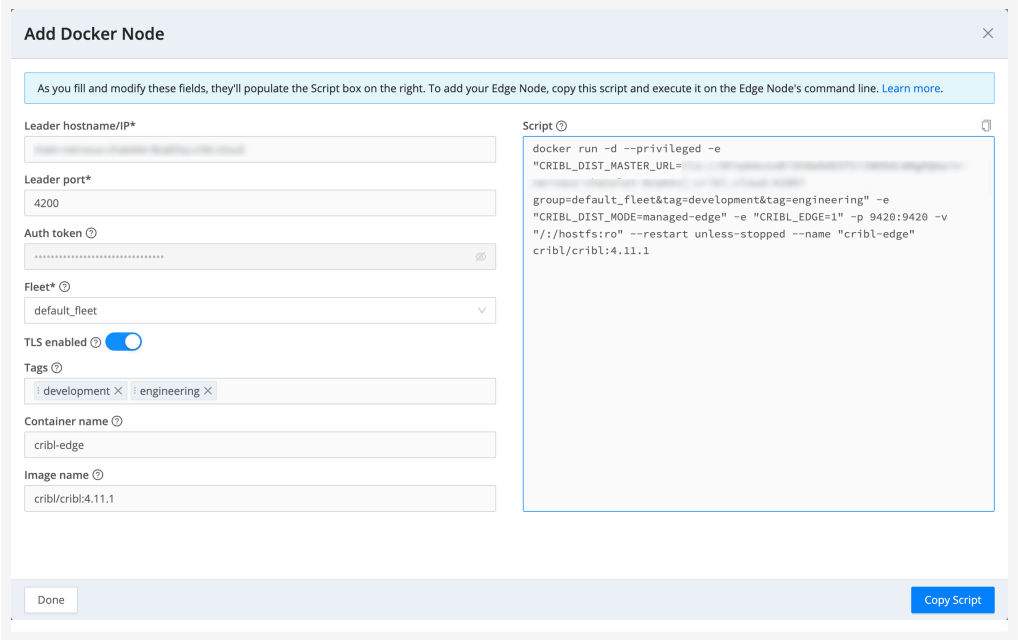
In this guide, we will follow Data Detective Dave, an operator with a knack for getting to the bottom of data origins. His current case involves enriching data streaming from all Development servers within the Engineering Organization before it's dispatched to a central analytics platform. Dave needs to ensure every piece of data clearly shouts its server role and department.

Here are the steps Data Detective Dave will follow:

1. **Set meaningful tags while installing Cribl Edge:** Dave's first move is to tag each Development server right at the Source, while installing Cribl Edge. He'll use the installation script to attach labels `development` and `engineering` – ensuring each server wears its identity from the get-go.
2. **Gather the metadata evidence:** Cribl Edge, like a good informant, automatically collects metadata, including the tags Dave just applied. He'll double-check that the `cribl` metadata option is active in the Fleet Settings, confirming that this crucial data is being gathered.
3. **Set Up the "Interrogation Room" (Preprocessing Pipeline):** Dave will create a new Pipeline in Cribl Edge, which he'll cleverly name `host_tags`. This will be his interrogation room where the data will be questioned and its secrets revealed (in this case, the tags).
4. **Use the "Eval-uator" to surface the clues (Eval Function):** Inside the `host_tags` Pipeline, Dave will employ an **Eval** Function – his "Eval-uator." This function will dig into the `__metadata.cribl.tags` array, where the installation tags are stashed. It will then create new, easy-to-read fields in the data: `role` and `department`, clearly displaying the tag values.

5. **Apply the interrogation to the Source:** Next, Dave will apply the `host_tags` Pipeline to the specific Source(s) feeding data from the Development servers. This ensures that all incoming data undergoes interrogation and reveals its tags.
6. **Verify the findings with Live Capture:** To ensure his "Eval-uator" is working correctly, Dave will use the **Live Data** capture feature on the configured Source. By examining the data before it's routed, he can confirm that the `role` and `department` fields are present and accurate - case closed (almost)!
7. **Ensure the Destination doesn't lose the evidence:** Finally, Dave will make sure the central analytics platform – the Destination – is set up to receive and hold onto these newly revealed role and department fields. He might even need to set up specific routes to handle this tagged data appropriately.

If you'd like to follow along Data Detective Dave's journey, we outlined the detailed steps for you below.



Set Tags During Edge Installation

When installing Cribl Edge, you can set tags during the installation. Regardless of your deployment environment (Docker, Linux, Windows, macOS, or Kubernetes), the Bootstrap script via the UI, gives you an option to add tags. These tags help identify and categorize your Edge Nodes such as environment type, geographic location, or server role.

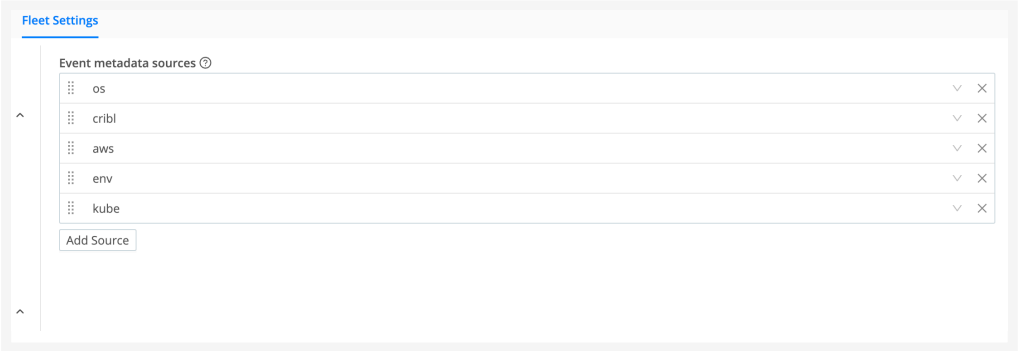
As you modify the fields within the script interface, it updates in real-time, reflecting all the configuration choices you make on that screen, including any tags you've added. The result is a new Edge Node configured with the specific options you've selected.

In this example, we're setting two tags:

- Server Role: `development`
- Department: `engineering`

You can also add tags after you install the Edge Nodes by teleporting directly into the Node. For details, see Add Tags to Edge Nodes in Teleport View.

Configure Host Info/Metadata Collection



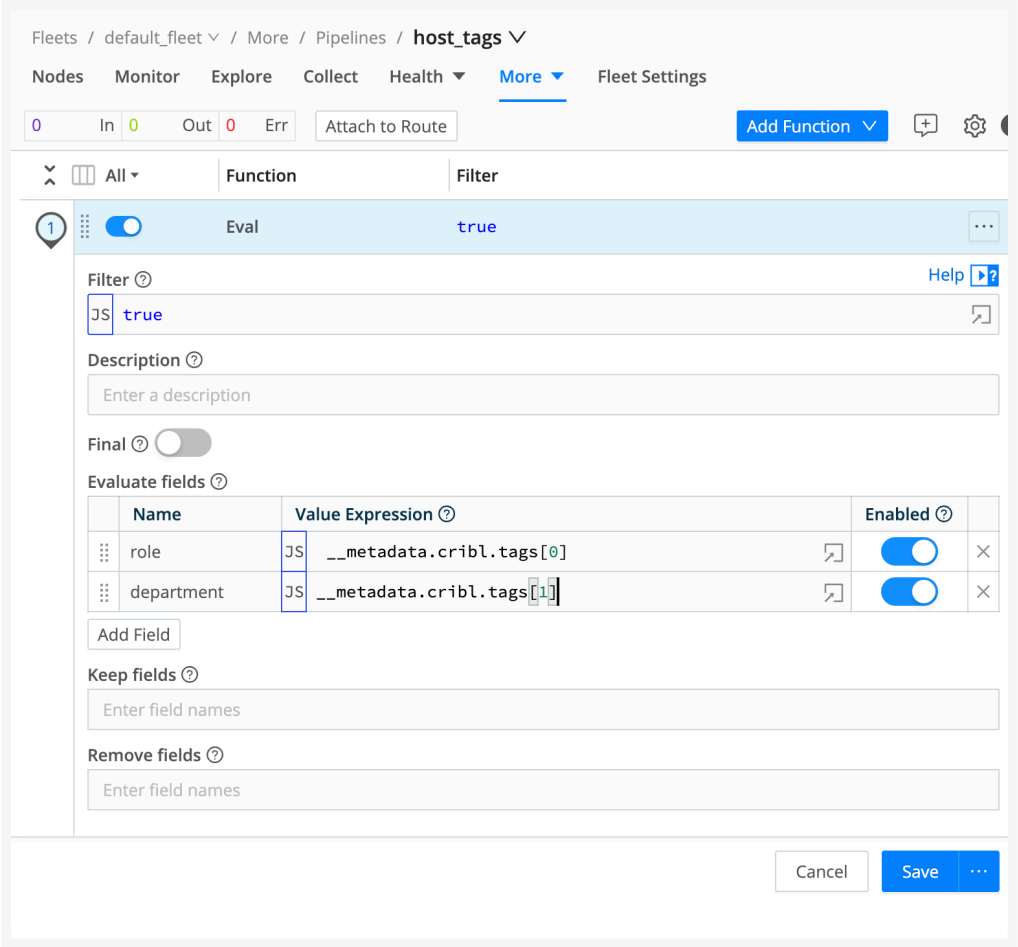
Cribl Edge allows you to configure Event metadata sources to enrich events with additional context. In Edge mode, all the Event metadata sources are enabled by default.

The Event metadata sources add a `__metadata` property to every event emitted from enabled sources. This metadata can be used to:

- Enrich events with additional context.
- Display metadata for instance exploration.

Ensure the `cribl` metadata option is enabled by checking in:

1. Navigate to **Fleet Settings** > **Limits** > Metadata.
2. Use the **Event metadata sources** drop-down or the **Add source** button to enable and select metadata sources. Ensure the `cribl` option is enabled.



Event Metadata Sources

Create a Pre-Processing Pipeline

To add tags or other custom identifiers to events:

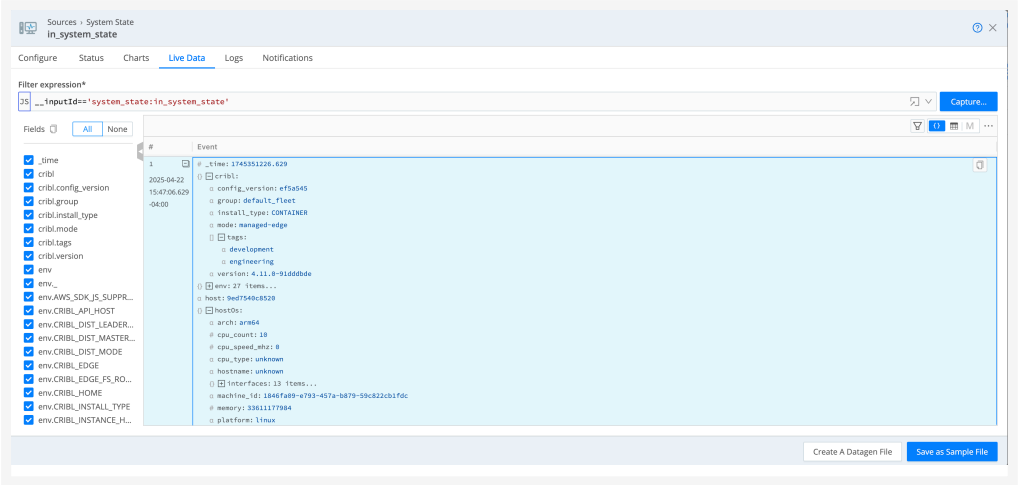
1. Navigate to your **Fleet** > **More** > **Pipelines** in your Cribl Edge interface.
2. Add a new Pipeline (e.g., `host_tags`). Pipelines ID can contain only letters (`A-Z`, `a-z`), numbers (`0-9`), and the characters `_` and `-`.
3. Add an **Eval** Function to the Pipeline.
4. Configure the Eval function to surface the tags by adding the following to the **Evaluate fields** section:

1. In the first row enter:
   Name: `role`
   Value Expression: `__metadata.cribl.tags[0]`
2. Select **Add Field** and enter:
   Name: `department`
   Value Expression: `__metadata.cribl.tags[1]`

Eval Function

1. Save the Pipeline.

Apply the Pre-Processing Pipeline



To make sure this Pipeline runs for all your data:

1. Go to **Sources > [Your Source]**.
2. In the Source configuration modal, find the **Pre-Processing Pipeline** option.
3. Select your newly created `host_tags` Pipeline.
4. Save the configuration.

Verify the Output

To verify that your custom fields are correctly added:

1. On your Source configuration modal, select **Live Data** > **Capture**.
2. In the **Capture** modal, under **Where to capture?**, select `2. Before the Routes.`
3. Verify that the `role` and `department` fields appear in the events.

Live Data

Destination Configuration

Ensure that your Destination configuration isn't dropping these custom fields:

1. Navigate to **Data** > **Destinations**.
2. Configure the Destination.
3. If needed, create a Route that specifically handles these tagged events.

7.4.3. Monitor Your Infrastructure With Cribl Edge

Monitor your infrastructure and visualize performance using Grafana.

Cribl Edge helps you monitor your sprawling infrastructure by collecting, processing, and forwarding data with low overhead cost and resources. Cribl Edge simplifies agent administration and data collection for your endpoints, and provides a number of charts, graphs, and alerts for the web when connected to supported data sources.

To enhance the performance of your environments, combine Cribl Edge with your data visualization tool of choice (this guide uses Grafana as an example). Now, you can identify and investigate issues and monitor applications faster than ever before.

Useful Metrics Dashboards

Cribl has configured a Prometheus dashboard to display system metrics, which is available in Grafana's public library. This is a relatively simple dashboard, suitable for showing basic aggregate metrics.

Another useful dashboard for displaying Linux metrics is the Node Exporter Full dashboard, commonly used with Prometheus and its Node Exporter agent. This dashboard can handle highly detailed metrics.

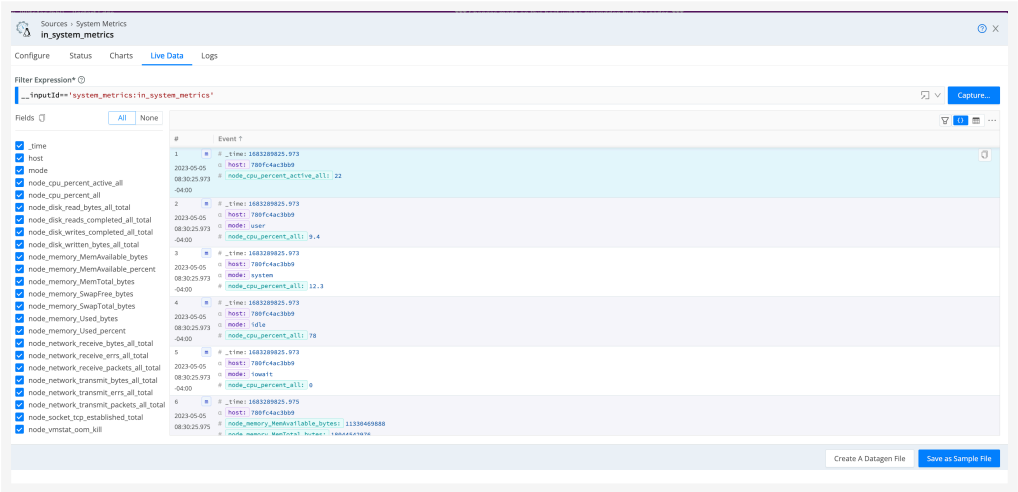
To display Windows metrics, consider one of Grafana's Windows dashboards.

Guide Overview

This setup guide will walk you through these configuration steps:

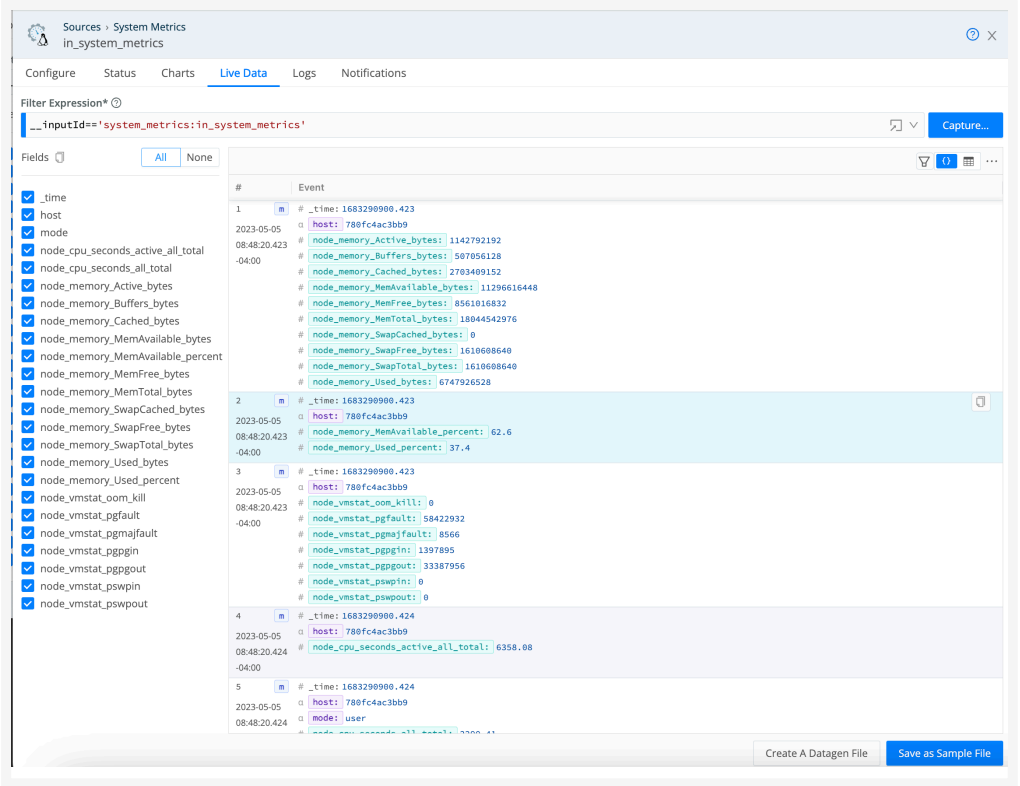
1. Configure your Cribl Edge Sources. Depending on your endpoints, you can use the System Metrics Source for Linux, Windows Metrics, or Kubernetes Metrics.
2. Configure the Grafana Cloud Destination to send data to Grafana Cloud.
3. Access Grafana Cloud to see the metrics and visualizations.

Configure the System Metrics Source on Cribl Edge



1. In Cribl Edge, start by configuring and enabling the applicable Source for system metrics:
    - Linux System Metrics Source
    - Windows Metrics
    - Kubernetes Metrics
2. Decide what level of metrics detail you want to collect and display.

In the System Metrics Source and Windows Metrics Sources, go to the **Host Metrics** and **Container Metrics** tabs:

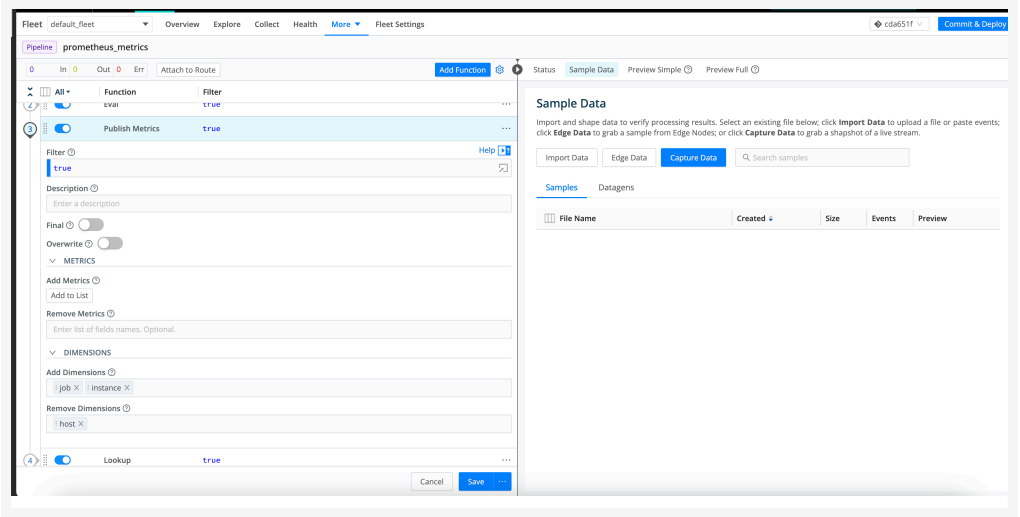


- For the relatively simple dashboard showing aggregate metrics, choose the **Basic** mode for most of your metrics.
- For the highly detailed metrics visualizations dashboard, choose the **All** mode for all of your metrics.

For the Kubernetes Metrics Source, use the **Filter Rules** to specify the Kubernetes objects that the Source should parse to generate metrics. If you specify no restrictive rules here, the Source will emit all events.

1. For all of the Sources, select **Processing Settings** > **Pre-Processing**, then select the `prometheus_metrics` **Pipeline**.
2. When you're finished, **Commit** and **Deploy** the changes. Before you move on to the next step, check the **Live Data** tab to make sure the metrics are generated.

Basic System Metrics

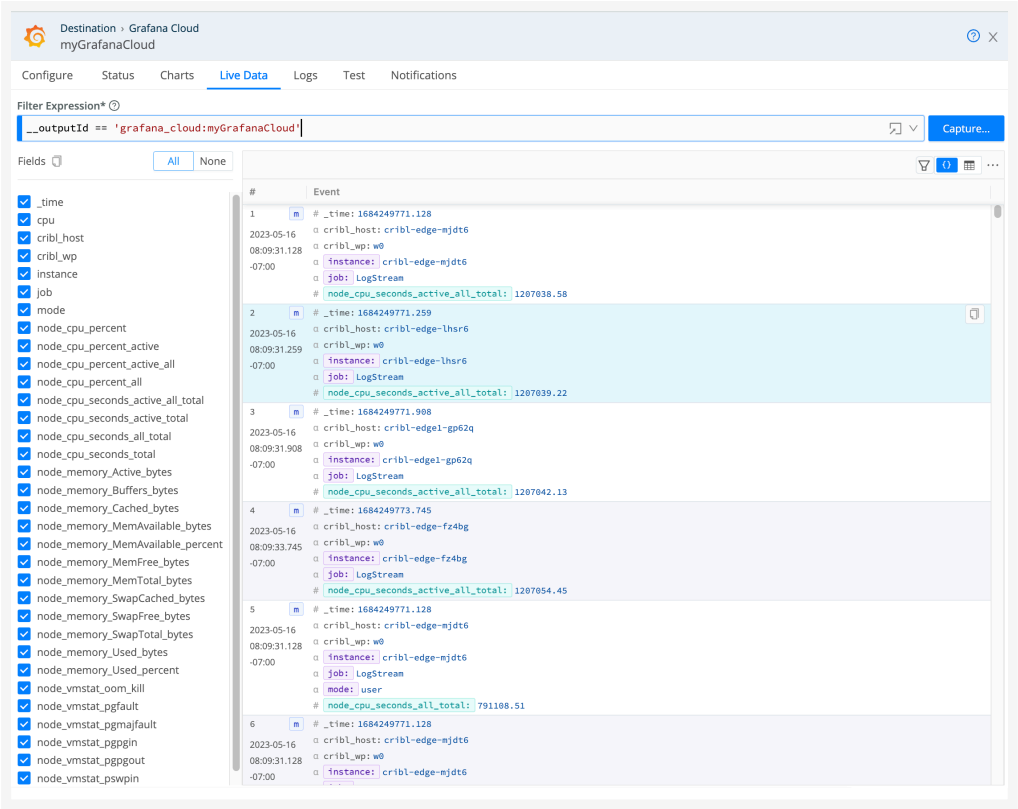


Detailed System Metrics

(Optional) Adjust the `prometheus_metrics` Pipeline

Optionally, you can adjust the `prometheus_metrics` Pipeline to include the `host` dimension, or to add/remove more dimensions.

Access the `prometheus_metrics` Pipeline by selecting **More** > **Pipelines** in the Fleet submenu.

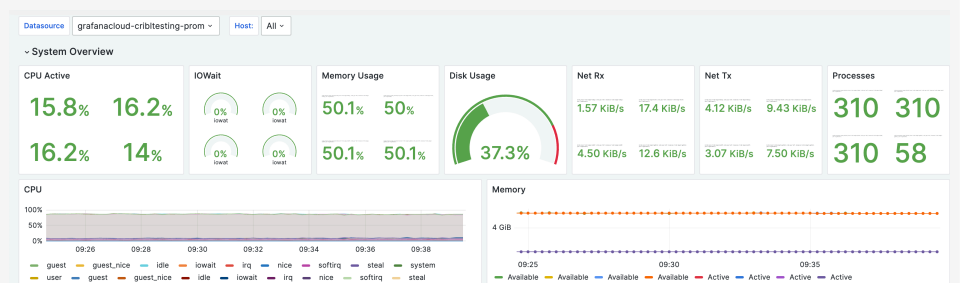


Customizing the Pipeline's dimensions

Configure the Grafana Cloud Destination

Next, head over to Grafana Cloud Destination to configure the Destination and send data to Grafana Cloud.

Preview your data on the Grafana Cloud config modal's **Live Data** tab.



Preview Live Data

Visualize the Data in Grafana

You can now visualize metrics in Grafana Cloud. To get started:

1. Navigate to your Grafana Cloud instance, and select **Explore** on the left panel to review the Node metrics. You can select metrics and run a query to produce a chart and table of metric events, which you can add to new or existing dashboards for analysis. If expected metrics are missing, try adjusting the variables in your Grafana Cloud instance. See Grafana's Variables topic for details.
2. Use Grafana's **Filter** option to browse the dashboards for your Prometheus data. Below are sample dashboards with the basic and detailed metrics shown.
    - To show basic aggregate metrics, use the Cribl Node Observability dashboard.

7.4.4. Monitor And Troubleshoot Cribl Edge

Monitor and troubleshoot your Cribl Edge deployment.

Cribl Edge is a data collection agent for Windows, Linux, macOS, and Kubernetes. Even robust agents like Cribl Edge can encounter issues that disrupt data flow. To maintain optimal performance and reliability, it's essential to implement effective monitoring and troubleshooting strategies.

In this topic, we explore key metrics to monitor for optimal Cribl Edge operation, discuss how to gather this information, and provide effective monitoring strategies and general troubleshooting guidelines.

Additionally, we highlight the importance of integrating Cribl Edge with your existing IT monitoring and alerting tools to gain comprehensive visibility into its health and performance.

Cribl Edge and Resource Constraints

Cribl Edge is designed to be a lightweight agent that often runs on machines that have limited resources. Unlike Cribl Stream, Edge uses a single Worker Process to limit resource usage and avoid affecting other functions of that machine.

While this is beneficial for resource-constrained environments, it's important to remember two things when implementing Edge:

- **Data consumption:** A single Worker Process can handle a limited amount data. If you try to ingest a massive amount of data, the process might become overloaded. For guidelines, see Performance Considerations and Sizing and Scaling.
- **Data manipulation:** Extensive manipulations within Pipelines can also strain the single Worker Process. Be strategic about the transformations you apply to the data.

Key Metrics to Monitor

Cribl Edge offers you multiple ways to monitor your deployments in order to get an operational view of the health of your Fleets, Edge Nodes, Sources and Destinations, and more.

Edge Node Status

The Edge Nodes page provides status information for each Edge Node in the selected Fleet. You can use this page to quickly answer the following questions:

- Is the agent running?
- Is it connected to Cribl Leader?

Edge Node Connectivity

To verify the connectivity of your Edge Nodes, check the **Health** column in the **Edge Nodes** page. A status of "alive" indicates that the Edge Node is running and successfully communicating with the Cribl Leader.

For details, see View Edge Node Status Information and Tracking Data Activity for an Edge Node.

Set Up Continuous Monitoring for Your Edge Nodes

While the Edge Nodes page provides essential information, it's important to note that disconnected Edge Nodes may be automatically removed after a certain period. To ensure continuous monitoring of your Edge Node health and performance, consider implementing centralized monitoring with a third-party solution like Grafana. By configuring your Edge Nodes to send internal metrics to a centralized monitoring solution, you can gain real-time insights into their statuses and troubleshoot potential issues proactively. For details and resources, see the Centralized Monitoring section below.

Sources and Destinations Health

To maintain optimal performance and data reliability, monitor the health of your Sources and Destinations at both the Edge Node and Fleet levels. Monitoring at the Edge Node level provides granular insights into the performance of individual Nodes, while Fleet-level monitoring offers a broader view of overall system health and potential bottlenecks.

You can monitor and track the health of Sources and Destinations associated with an Edge Node on the **Edge Nodes** page. By filtering the list to display only Edge Nodes with "Warning" or "Error" statuses for their Sources or Destinations, you can quickly identify and troubleshoot potential issues. For details, see Monitor Source and Destination Health on Edge Nodes and Filter Edge Nodes.

Alternatively, you can monitor the health of Sources and Destinations within a specific Fleet. To do this, navigate to the desired Fleet, select **Health**, and then choose either **Sources** or **Destinations**. This will display a color-coded health status for each Source or Destination, providing a quick visual overview of their operational status. For details, see Overall Source and Destination Health.

Data Throughput

There are several pages you can use to monitor the rate at which data is collected and transmitted (data throughput) across your Edge Nodes. This information can help you determine if an Edge Node is capable of handling the current data generation rate and if data is being successfully transmitted to Destinations.

- **Cribl Edge home page:** The Cribl Edge home page displays the aggregate data for all Fleets, Subfleets, and Edge Nodes. The charts display information about traffic in and out of the system. For details, see Monitor Health on the Edge Home Page.
- **Fleets page:** The **Fleets** page gives you access to more information about each of your Fleets and the health of Sources and Destinations associated with the Fleets. You can view the **Monitor** tab of a selected Fleet to analyze the traffic flowing through your Fleet. For details, see Monitor Fleet Information.

- **Edge Nodes page:** To monitor the activity of your Edge Node and identify potential issues with Sources, Destinations, Routes, Pipelines, or Packs: Navigate to the **Edge Nodes** page, pick a specific Node and click anywhere on the row to launch the **Node Info** modal. Then, select **Data Activity**. This will provide detailed insights into the Node's data flow without teleporting into the Node itself. For details, see Viewing the Data Activity for a Node.

Resource Utilization

To effectively monitor the health and performance of your Edge Nodes, use node and process information as well as details from logs.

Sources of node and process information include:

- **System Activity** tab: Gain a detailed view of your Edge Node's health, including CPU usage, memory consumption, network traffic, and disk operations. Please note that these metrics represent the total system usage and may not solely reflect the resource utilization of the Edge Node itself. To view **System Activity**, click the row for an Edge Node. For details, see Viewing the System Activity for a Node.
- **Process-Level Monitoring**: Delve deeper into specific processes, such as `cribl` processes, to pinpoint resource bottlenecks and optimize performance. For details, see Processes.

Logs to analyze include:

- **API Server Logs**: Examine the `cribl.log` file at `$CRIBL_HOME/log/cribl.log` for high-level system telemetry and license validation information.
- **Worker/Edge Node Process Logs**: Analyze the `cribl.log` files at `$CRIBL_HOME/log/worker/N/cribl.log` to scrutinize detailed resource utilization metrics for each Worker/Edge Node Process at a granular one-minute interval.

Combine these approaches to proactively identify and address potential performance issues and ensure optimal data processing and system stability.

Effective Monitoring Strategies

This section explores various strategies for effectively monitoring your Cribl Edge deployments. We'll delve into Edge Node logging, centralized monitoring, and network monitoring techniques to ensure optimal performance and data flow.

Edge Node Logging

Cribl Edge logs at the default `Info` level, providing a good balance between detail and performance for most environments. Analyze logs regularly to identify trends and potential issues.

If you encounter a specific issue or need more detailed information, Cribl Edge settings allows you to adjust the log level for individual channels. However, frequently changing log levels from the default `Info` might indicate

an underlying issue requiring further investigation.

By carefully selecting the appropriate log level, you can obtain valuable troubleshooting information without compromising performance. For details, see Logging Settings.

Centralized Monitoring

Centralized monitoring allows you to efficiently collect and analyze data from multiple Edge Nodes. This approach helps you proactively detect issues by enabling you to:

- **Implement alerts:** Set alerts for critical metrics, such as agent failures or performance degradation.
- **Create dashboards**: Visualize key metrics and gain valuable insights into the overall system health.

Combine Cribl Edge with your existing IT monitoring tools to gain a unified view of your deployment's health. This allows you to identify and address issues before they impact performance. By sending Cribl Edge logs to platforms like Elastic, Grafana, or Loki, you can:

- **Centralize log management:** Consolidate logs from various Sources for efficient analysis and troubleshooting.
- **Create advanced dashboards:** Visualize complex metrics and correlations to gain deeper insights.
- **Implement sophisticated alerts:** Set up alerts based on specific conditions and triggers to proactively address issues.

For details, see Monitoring your Infrastructure with Cribl Edge. Additionally, you can use CriblVision to troubleshoot specific issues in CriblSearch, Grafana, and Splunk.

Network Monitoring

Monitor network traffic between the Edge Node and the Cribl Leader to identify and resolve network-related issues. Use third-party network monitoring tools to track network performance and troubleshoot connectivity problems efficiently.

Troubleshooting Edge Nodes

To troubleshoot potential issues with your Edge Nodes, consider the following:

- Start by verifying the Edge Node's configuration, including connection settings, data collection intervals, and permissions.
- Analyze the logs in Cribl Edge. For details, see Search Internal Logs. To isolate issues related to a specific Edge Node, filter the logs by the Edge Node's IP address. This will help you identify any error messages or exceptions that may require attention.
- Check network connectivity between the Edge Node and the Cribl Leader by reviewing the Health column on the Edge Nodes page.

- To monitor Edge resource utilization, examine the API server logs and Worker Process logs. These logs provide detailed information on CPU usage, memory consumption, network traffic, and other relevant metrics. You can also monitor the System activity for the entire host by Viewing the System Activity for a Node.

Refer to Common Challenges on the Edge topic for other troubleshooting tips.

7.4.5. Migrate From Third-Party Agents To Cribl Edge

Migrate your data collection infrastructure from third-party agents to Cribl Edge

---

This guide provides strategic considerations for migrating your data collection infrastructure from traditional third-party agents to Cribl Edge. Whether you're migrating from Splunk Universal Forwarders (UFs), Fluentd, Filebeat, or other agent technologies, the fundamental migration principles remain consistent.

Any migration to Cribl Edge generally follows the same path:

1. Decide on your migration strategy
2. Complete pre-migration planning
3. Implement your Edge configuration
4. Rollout your changes in a controlled environment

We'll examine each phase and what you need to consider along the way.

This is a considerations guide, not step-by-step instructions. Complex migrations require careful planning and benefit from professional services engagement.

For specific details on UF migrations, see: Migrating from Splunk Universal Forwarders to Cribl Edge.

Migration Strategy Overview

Your migration success depends heavily on choosing the right approach from the start. The complexity of your current deployment, available resources, and timeline constraints will all influence which path you should take. Understanding these options upfront will save time and reduce risk throughout the migration process.

Choosing Your Migration Approach

Before beginning any migration, you must decide between two primary approaches:

- Customer-managed migration
- Professional services engagement

Customer-managed Migration

- **Best for:** Simple deployments with limited configuration complexity.
- **Challenges:** Trying to migrate complex agent deployments, beyond simple deployments, can be challenging and time-consuming. Requires deep understanding of both current infrastructure and Cribl Edge architecture.

- **Suitable for:** Organizations with dedicated resources and Cribl Edge expertise, or proof-of-concept implementations.

Professional Services Engagement

- **Best for:** Large-scale or complex agent deployments.
- **Provides:** Automated migration tools, in depth analysis, and enhanced support.
- **Recommended for:** Organizations requiring minimal downtime, deployments with extensive customization, time-sensitive migrations.

Pre-Migration Planning

This phase involves understanding your current environment, identifying potential challenges, and ensuring you have the necessary resources in place.

Environment Assessment

The first step in migration planning is gaining a complete understanding of your current deployment. This comprehensive assessment will inform every subsequent decision and help identify potential migration challenges before they become problems.

Begin by conducting a thorough inventory of your current deployment, document both essential infrastructure components and organizational factors that could impact your migration strategy.

Required inventory items:

- OS types and versions across your infrastructure.
- Current data volumes and peak load patterns.
- Existing input configurations and custom settings.

Additional considerations that may impact your migration:

- Company span, subsidiaries, separate entities.
- Network topology, connectivity, and bandwidth constraints.
- Change control processes for your infrastructure.
- Rollback plan documentation before beginning the migration.

Configuration Analysis

The goal of configuration analysis is to determine the data flow and topology of your current system, so that you can use this information to inform your Fleet design. For example, in environments using centralized

configuration management (like Splunk's Deployment Server), the way your current server classes are organized will significantly impact your Edge Fleet design decisions.

Key areas to document include:

- Centralized configuration management systems and their hierarchies
- Application or configuration packages deployed to agents
- Client-to-configuration mappings
- Custom configurations and transformations

For example, in Splunk UF environments specifically, you would examine:

- Deployment Server configuration using serverclass.conf
- Splunk Apps stored in $SPLUNK_HOME/deployment-apps
- Client-to-serverclass mappings

Resource Requirements Planning

Inadequate resource planning is one of the most common causes of migration failures. Cribl Edge introduces new components and data flow patterns that require careful capacity planning. Understanding these requirements upfront prevents performance issues and data loss during the migration.

Leader Scaling

For Cribl.Cloud deployments, first assess your current Leader's performance before adding Edge Nodes. Evaluate whether your Leader is already overtaxed or operating smoothly, examining CPU utilization, memory usage, disk space availability, and disk I/O performance. For details, see Monitoring Health and Metrics.

Once you've confirmed your Leader can handle additional load, ensure Leader resources are scaled to support expected Fleet/Worker Group counts. To spin up the right number of connection processes, add the number of Edge Nodes you will deploy into the Edge Nodes Count field. This field crunches numbers in the background and automatically spins up the correct number of Edge connection processes for you. For on-prem deployments as well as other considerations, see Deployment Planning.

Cribl Stream Worker Nodes

Ensure Stream Worker Nodes receiving data from Edge Fleets are properly sized for peak load. Undersized infrastructure can cause performance bottlenecks and data loss during high-volume periods.

Data Routing and Flow

Cribl Edge offers more sophisticated data routing capabilities than traditional agents, but this flexibility requires careful planning to avoid performance bottlenecks and ensure reliable data delivery.

Key considerations:

- Configure appropriate outputs based on your data routing needs
- Consider routing complexity when routing from Cribl Edge to Cribl Stream then to Destinations
- Plan for backpressure management, especially when routing to multiple Destinations

Understanding Architectural Differences

Most third-party agent migrations involve fundamental architectural changes that affect every aspect of your migration planning. Understanding these differences is critical for designing an effective migration strategy.

Configuration Management Models

Traditional agents often use different configuration management approaches than Cribl Edge.

Composition vs. Inheritance

- **Traditional agents:** Many use composition models where a single agent can belong to multiple configuration groups or classes
- **Cribl Edge:** Uses inheritance where one Edge Node belongs to a single Fleet/Subfleet

For example, in Splunk UF environments, one UF can belong to multiple serverclasses, but in Cribl Edge, one Edge Node belongs to a single Fleet/Subfleet.

Fleet Design Strategy

Fleet design is perhaps the most critical decision in your migration. Poor Fleet architecture can lead to management complexity, performance issues, and operational challenges. The goal is to balance functionality with maintainability while leveraging Cribl Edge's strengths.

Fleet Rationalization Approach

- Review your current configuration management to understand what needs to be collected
- Use tags, Pipelines, and Cribl Stream to reduce configuration variability
- Consolidate similar configurations to minimize Fleet count
- Group by function rather than direct configuration translation

Fleet Count Optimization

- Keep Fleet counts to a minimum for optimal performance
- Avoid direct translation of existing configuration groups to Edge Fleets (leads to Fleet proliferation)

Direct translation of existing configuration management structures to Edge Fleets often leads to

> management complexity and potential performance issues.

- Consider creating Fleets for unique combinations of configuration requirements only when necessary

Configuration Translation Challenges

Understanding these caveats upfront allows you to plan alternative approaches and avoid migration roadblocks.

Automatic Metadata Population

One advantage of Cribl Edge is its automatic handling of common metadata fields, reducing configuration complexity compared to traditional agents. Cribl Edge automatically populates these metadata fields without additional configuration:

- `sourcetype`
- `index`
- `source`
- `host`
- `connection_host`

Configurations Requiring Alternative Approaches

Some agent configurations have no direct equivalent in Cribl Edge and require additional steps. Common examples include:

- **Path-based host extraction:** Some agents (like Splunk UF) can automatically extract the hostname from the file path itself. For example, the `host_regex` and `host_segment` settings from UF don't translate directly. However, you can achieve the same functionality using Cribl Edge's Pipeline processing to extract and transform the hostname data as needed.
- **File handling behaviors:** Some agents often have granular control over how they interact with files. Cribl Edge may not have equivalent settings for every file handling behavior. For example, symbolic linking or file opening behavior.
- **Custom transformations:** Some agents can perform data transformations at the collection point. Cribl Edge operates on a different model where most data transformation happens in Cribl Stream rather than at the edge. While Cribl Edge can do some processing, it's not designed to replicate all the transformation capabilities that agents might have built-in.

Alternative Implementation Methods

- Create corresponding Pipelines in Cribl Edge

- Use Edge Node metadata mapping for system information
- Implement data transformation through Routes (all inputs forward to Routes)

Migration Implementation Considerations

Once you've completed your planning phase, the implementation phase requires attention to configuration details and platform-specific considerations.

Configuration Review Areas

Each configuration area requires careful review to ensure optimal performance and functionality.

File Monitor Settings

- Determine whether to start from the beginning or end of files
- Consider the impact of large file sizes or many old events
- Assess network bandwidth and Destination capacity implications

System State Configuration

The System State Source is enabled by default on Cribl Edge Fleets, but you can disable the Source or specific collectors if System State data is not needed.

Pipeline Configuration

- Review existing agent configurations and enable similar functionality in Cribl
- Optimize regexes for performance
- Consider data transformation requirements previously handled in agents

Persistent Queue Management

- Review Persistent Queue settings in your agents, Cribl Edge, and Stream
- Ensure proper queue sizing for expected data volumes

Platform-Specific Considerations - Windows Environments

Windows environments present unique challenges during migration, particularly around policy management.

Group Policy Objects

Check for Group Policy Objects (GPOs) that might automatically reinstall or enable removed third-party agents, and update policies before migration to prevent conflicts.

PowerShell Usage

For optimal performance on Windows Edge Nodes, ensure the “Use Windows Tools” setting is disabled for all data Sources. When disabled, the system uses native Windows Management Instrumentation (WMI) API methods for faster and more reliable data collection. When enabled, the system falls back to legacy PowerShell cmdlets.

The PowerShell-based collection methods will be removed in future releases as native methods provide superior speed and reliability.

Policy Management

Some sites might have policies to re-enable/re-install agents if missing/removed. Update or exclude policies before migration.

Windows Event Log Read Mode

When configuring the **Windows Event Log** Source, always review the **Read mode** setting. The default is **From last entry**, which only collects new events. While this is the recommended setting, you have the option to change it to read the **Entire log**. For machines that have been in use for a long time, this can cause a massive, one-time spike in data ingestion as it sends years of historical events. This sudden influx can easily overwhelm your infrastructure, causing performance issues and data loss. Sticking with the default setting helps you avoid this risk.

Addressing Inheritance Limitations

When working with Edge’s inheritance model, be aware of these challenges:

- **Configuration integrity**: Changes to a Source/Destination in a Subfleet can break inheritance from the parent
- **Limited flexibility**: Sources that allow only one configuration at a time create inheritance challenges when customization is needed

Migration Rollout Strategy

The rollout phase is when your plans become reality. A good rollout ensures things go smoothly, problems are fixed fast, and your data collection isn’t interrupted.

Controlled Rollout Process

A controlled rollout allows you to validate your migration approach on a small scale before committing to full deployment. This approach significantly reduces the risk of widespread issues and provides opportunities to refine your process.

Progressive Batch Sizing

- Start with test servers
- Then proceed to small batches (e.g., 200 machines)
- Progress to larger batches (400, 800, 2000 machines, etc.)
- Validate system performance and data flow at each stage
- Only proceed when previous stage is validated

Validation Requirements

- Execute controlled rollout with proper validation at each stage
- Address any issues early in rollout before expanding
- Maintain visibility into migration rollout progress

Continuous Monitoring

To ensure a smooth migration, you need to monitor everything. This means watching both how things are performing technically and making sure your important data is flowing correctly. Additionally, monitor the Edge Nodes themselves as they get onboarded to track their connectivity status. Cribl Edge v.4.13 introduced Disconnected Node Tracking to help you identify and troubleshoot nodes that lose connection during the migration process.

Resource Utilization

Monitor Cribl Edge, Leader, and Stream components continuously to watch for performance bottlenecks or data loss indicators. Validate data flow and collection accuracy throughout the process.

Rollback Capabilities

Maintain (previously-documented) rollback capabilities in case issues are discovered.

TL;DR

Migrating from third-party agents to Cribl Edge requires careful planning and a systematic approach. The key to success lies in understanding the architectural differences between your current system and Cribl Edge, properly planning your Fleet design, and executing a controlled rollout process.

Remember that this is a considerations guide, and complex migrations often benefit from professional services engagement to ensure success and minimize risk to your data collection infrastructure.

7.5. Deployment Planning

Plan your Cribl Edge deployment, taking into account requirements, deployment types, scaling, and billing.

When you're planning an Edge deployment, consider these key factors:

- The amount of data (metrics, logs, custom command outputs, and so on) that you plan for Edge to collect from the endpoint and ingest per unit of time. For example, MB/s or GB/day.
- The amount of processing that will happen on incoming data. For example, are there a lot of transformations, regex extractions, parsing functions, field obfuscations, and so on?
- Routing and/or cloning: Is most data going to a single Destination, or is it being cloned and routed to multiple places? This is important, because Destination-specific serialization tends to be relatively expensive.
- Deploying onto servers with no internet access: If you plan to deploy Edge Nodes on air-gapped on-prem servers (servers with no internet access), you must ensure that every Edge Node can communicate with a Leader that is also on-prem (that is, not in Cribl.Cloud).

See Requirements for detailed information about system and OS requirements for a Cribl Edge deployment.

Types of Deployment

- Cribl.Cloud: Quickly launch a Cribl-managed deployment of the combined Cribl applications suite (Edge, Stream, Search, and Lake). In Cribl.Cloud, Cribl provisions and manages all infrastructure on your behalf.
- **Managed Edge**: A central Leader Node controls, manages, and pushes configuration updates to all managed Edge Nodes. This deployment type provides a centralized view for multiple Edge instances, which is beneficial for large-scale deployments of Cribl Edge.
- **Single-instance**: Single-instance Edge Nodes operate without a central Leader. You will configure and manage Edge Nodes locally. Single-instance Edge is suitable for smaller deployments or environments with limited network connectivity.

When you have a large number of Edge Nodes to manage, you can use Fleets to group Nodes together and apply configurations centrally. Use Fleet Management to accommodate increased load. See Add and Update Edge Nodes to streamline deploying Edge Nodes via scripting.

Leader Scalability

Our System Requirements suffice for on-prem Leaders handling up to 10,000 Edge Nodes. To support more than 10,000 Nodes, see our Planning Large-Scale Deployments of Cribl Edge guide.

For large on-prem deployments handling high traffic, review the recommended OS-level tuning detailed in OS Tuning for Large Deployments.

About Billing and Usage

Cribl.Cloud offers a one-page view of your total credits consumed and remaining credits for the current active contract in place. This is called Cribl FinOps Center. Here, you can view per-product consumption for the Cribl products you use. The **Invoices** tab lets you download and export your usage by month. For more details, go to the FinOps Center docs.

On-Prem Licenses

If you're deploying on-prem, there are three license options. The Cribl Plans page provides details feature comparisons for each license.

You can configure Connected Environments to use the Cribl.Cloud FinOps Center billing model with your on-prem deployments instead of managing multiple licenses.

Permissions and Rights

You do **not** need elevated privileges to install Edge. However, you will need:

- Administrator (or equivalent) rights in order to enable Edge to start on boot.
- Sufficient rights to access the resources that need monitoring - files, metrics, and so on.

> **Network Requirement (DPI/IPS Exclusion)**
>
> Deep Packet Inspection (DPI) and Intrusion Prevention Systems (IPS) on network devices situated between your Edge Fleets can cause high resource utilization and connection instability in all environments (both Cribl.Cloud and on-prem). Explicitly exclude all Cribl data streams from DPI/IPS inspection for stable operations and optimal performance.

Performance Considerations

As with most data-collection and -processing applications, Cribl Edge's expected resource utilization will be proportional to the data volume and type of processing. For instance, a Function that adds a static field on an event will perform faster than one that applies a regex to find and replace a string.

- Processing performance is proportional to CPU clock speed.
- All processing happens in-memory.
- Processing does not require significant disk allocation.

Thinking about your planned Edge deployment as a whole, it's critical to consider **cardinality**: how many Fleets, of what size, will send metrics to a given Leader. In a very low-cardinality deployment, a Leader Node might aggregate metrics from one small Fleet; in a very high-cardinality deployment, a Leader Node might aggregate metrics from many large Fleets.

Too many Edge Nodes sending too many metrics can degrade Leader performance and/or integrity. By carefully choosing what metrics each Fleet sends to its Leader Node, you can ensure that you collect the metrics most important to you, within the limits of the Leader's capacity to process them.

As part of your deployment planning, decide which of the following four sets of metrics each Fleet in your deployment will send to its Leader Node:

- **Minimal**: Limited to metrics for events and bytes in and out. Recommended for high-cardinality deployments.
- **Basic** (the default set): All the metrics required to display all monitoring data available in the Edge UI. Contains all the metrics in the **Minimal** set, and more.
- **All**: All metrics, sent without filtering.
- **Custom**: Only metrics that match a JavaScript expression that you define.

For a listing of the metrics each set provides, see Control Metrics in Cribl Edge.

Configure Edge Node Count

Enter the estimated number of Edge Nodes in this deployment, which is used to calculate how many Edge-specific connections service processes to spawn. Changing this number could restart any currently running service processes. If left blank, defaults to 0.

To configure the Edge Node Count:

1. From **Settings**, select the **Global** tab, then select **General Settings**.
2. In an on-prem deployment, select **Limits**, and then **Others**.
3. Enter the number of Edge Nodes in the **Edge Nodes count** field.

Configure Connection Processes

To configure the connection processes for your Edge Nodes in an on-prem deployment:

1. From **Settings**, select the **Global** tab, select **Service Processes**, and then select **Services**.
2. Confirm that **Connections listener number of processes** is set to its default `1`.

The **Connections listener number of processes** is automatically determined by the **Edge Node Count** setting you enter above. Any value you enter manually will be overridden by this calculation.

7.5.1. OS And System Requirements

For a successful Cribl Edge deployment, verify that your system meets the minimum hardware and software specifications outlined below.

All the quantities listed below are **minimum** requirements. Adjust them as needed based on your specific use case.

OS Requirements

You can install Cribl Edge Nodes on Linux, Windows, and macOS systems.

Linux Requirements

Cribl Edge Nodes can run on any common Linux distribution that fulfils the following criteria:

- 64-bit kernel >= 3.10
- glibc >= 2.17
- OpenSSL >= 3.0 (if FIPS mode is enabled)

Highly customized or rare Linux distributions might not be supported even when based on a supported kernel version.

Enforcing mode in SELinux is supported, but not required.

Tested Linux Platforms

Cribl tests the following Linux versions to confirm compatibility with the supported kernel. This list does not constitute a comprehensive record of all supported distributions and versions.

- Ubuntu 24.04
- RHEL 9, 9.3
- CentOS Stream 9
- SUSE Linux Enterprise Server 15.6
- Amazon Linux 2023

As of October 16, 2024, Cribl has deprecated support for the CentOS Linux 7 distribution, which reached its end of life on June 30, 2024.

Windows Requirements

Cribl Edge supports these versions of Windows:

Version	Notes
Windows 10 and 11	You can deploy Cribl Edge on laptops, desktops, and workstations running Windows 10 and 11. Keep these things in mind when deploying Cribl Edge on Windows 10 and 11 workstations: • Cribl Edge might lose some data sent to TCP Destinations after a workstation resumes from a suspended or sleep state. This happens when the data is in local network buffers but hasn't been sent out to the Destination. Instead, you can send data to an HTTP Destination. • You might see partially broken events after a laptop resumes from a suspended state. • HTTP Destinations might contain duplicate events. • Some users have observed excessive logging when a Leader is unavailable to receive heartbeat messages from an Edge Node.
Windows Server 2016 Windows Server 2019 Windows Server 2022 Windows Server 2025	Functionality is the same as generally supported Windows Server platforms.

MacOS Requirements

Cribl Edge supports the following macOS versions: 26 (Tahoe), 15 (Sequoia), 14 (Sonoma).

You can install Cribl Edge on both Intel and Apple silicon processors.

System Requirements

Edge Nodes should have sufficient CPU, RAM, network, and storage capacity to handle your specific workload. While minimum specifications are provided, optimal configurations vary widely. Consider data volume, types, processing needs, and organizational standards when selecting hardware.

Make sure to test the performance of your Edge Nodes before deploying to production.

Minimum application requirements for Edge Nodes are:

- ~1 Ghz processor
- 1024 MB RAM
- 5 GB free disk space per volume for operational purposes

If your installation uses multiple volumes (for example, one volume to store persistent queues and one for Destination staging directories), 5GB is the minimum disk space for each of those volumes. You can configure the disk space limit per Fleet with the **Min free disk space** setting.

See also Cribl Stream Requirements to learn about the requirements for the Leader Node.

Browser Support

The Cribl Edge UI can run on Chrome, Firefox, Safari, and Microsoft Edge, on their five most-recent versions.

7.5.2. Plan Large-Scale Deployments Of Cribl Edge

Learn how to scale on-prem Cribl Edge deployments to support one Leader managing up to 250,000 Nodes.

Our standard Deployment Planning guide is a great place to start if you intend to deploy 10,000 or fewer Nodes in your Cribl Edge environment.

For larger deployments, an on-prem Leader can support a maximum of 250,000 Edge Nodes when metrics are set to **Minimal** mode and 100,000 Edge Nodes with metrics set to **Basic**.

This guide covers:

- The specific Leader configuration we recommend for best performance.
- Overview of upgrading a large Cribl Edge deployment.
- Limitations to the UI resulting from a large number of Edge Nodes.

Recommended On-Prem Leader Configuration

The base configuration detailed on Cribl Stream Sizing and Scaling is a good starting point.

From there, you can configure these settings on the on-prem Leader so it can manage up to 250,000 Edge Nodes:

- Add 2GB of RAM for every 10,000 Edge Nodes.
- Deploy one vCPU core for every 10,000 Edge Nodes.
- For Cribl Edge to support up to 100,000 Nodes, you can configure internal metrics to **Basic** in **Fleet Settings**.
- For 250,000 Nodes, you must configure internal metrics to **Minimal** in **Fleet Settings**.

  You should configure these metrics for every Fleet if your Edge Node count is more than 10,000. See Performance Considerations for more information.

- To spin up the right number of connection processes, add the number of Edge Nodes you will deploy into the **Edge Nodes Count** field. This field crunches numbers in the background and automatically spins up the correct number of Edge connection processes for you.
- There is no change to the default values when pushing config bundles from the Leader.

Recommended Fleet Configuration

There are additional settings you'll need to configure for each Fleet you intend to create:

- Add 1 vCPU per Fleet.

- Add 2GB of RAM per Fleet.

Upgrading a Large Number of Edge Nodes

The upgrading framework allows Edge Nodes to pull down upgrade packages from the Leader asynchronously, rather than the Leader pushing packages to Nodes all at one time. Nodes communicate to the Leader every 60 seconds via a heartbeat.

Additionally, Nodes request upgrade packages from the Leader in batches of 500. This allows you to upgrade Nodes without overloading the Leader, even with a large number of Nodes.

In our controlled test environment, we found that upgrading can take 25-40 minutes. This is an expected time frame to upgrade that number of Nodes.

User Interface Limitations

For Fleets with a large number of Edge Nodes, the UI is limited in certain places where a complete list of Nodes can't be displayed.

Searching for Nodes in the Explore Tab

The Node field in the **Explore** tab returns only the first 100 matching Nodes. When you start typing, the results match the search query and are sorted alphabetically by hostname.

Previewing Node Mappings

Preview Node mappings by selecting **Mappings** in the Leader Node's sidebar. (Only the first 10,000 mappings are displayed.)

Other Limitations

- **Logs**: The drop-down where you can select an Edge Node will display a maximum of 100 Nodes.
- **Import Edge Data**: The **Import Edge Data** window in Cribl Stream returns a maximum of 100 Edge Nodes.
- **Test tab**: The **Test** tab on Destinations displays a maximum of 100 results.
- **KMS Status report**: In **Fleet Settings**, the **KMS Status report** (under **Security**) does not display all Nodes. Instead, search for your desired Node.

7.6. Set Up Leader And Edge Nodes

Configure a Leader Node and a Cribl Edge Node.

This page covers how to:

- Configure a Leader Node
- Configure an Edge Node

Configure a Leader Node

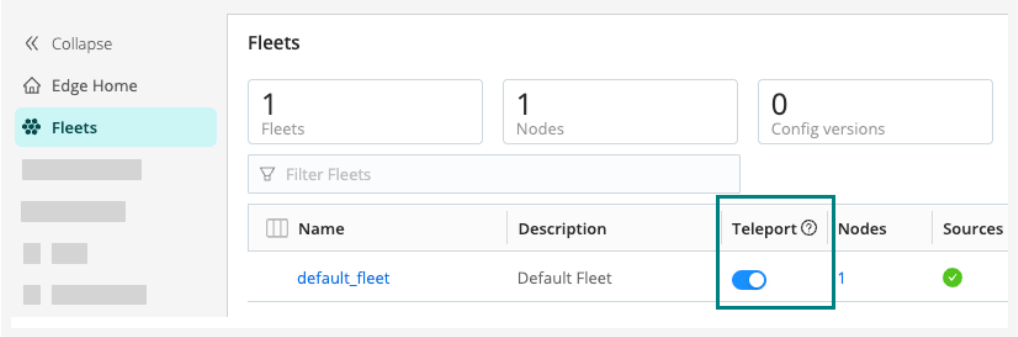
You can configure a Leader Node either through the UI or through the `instance.yml` config file.

Use the UI

1. Navigate to **Settings** > **Global** > **Distributed Settings** > **General Settings**.
2. Select **Mode**: **Leader**.
3. Select the **Leader Settings** menu.
4. Confirm or enter the required Leader settings (**Address** and **Port**).
5. Confirm Leader API Access: Toggle **Forward to Leader API** on (default) to enable API requests on the distributed port and provide backward compatibility.
6. Customize the optional settings if desired.
7. Select **Save** to restart the Cribl Edge server.

Add Authentication Tokens

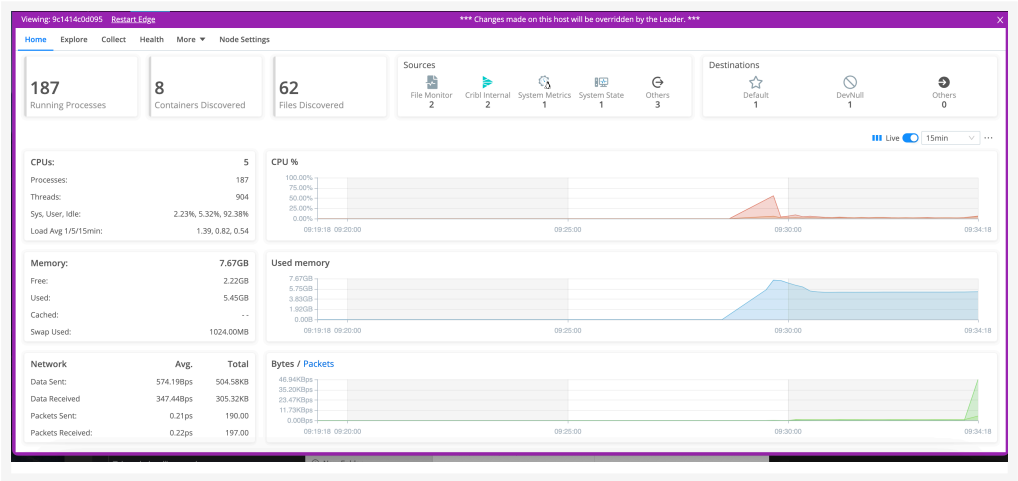
To enable the Leader to communicate with Edge Nodes, you need to create an authentication token. A provisioning token lets you deploy multiple Edge Nodes.



See Create a New Provisioning Token for information on how to create and manage authentication tokens.

Edge Node UI Access

This useful option enables you to click through from the Leader's **Edge Nodes** page to an authenticated view of each Node's UI. We call this Teleporting into an Edge Node. The instructions below correspond to enabling the `groups.yml` file's `workerRemoteAccess` configuration key.



To enable teleporting (remote UI access) to Nodes from the Leader's UI:

1. Select **Fleets** from the sidebar.
2. For each desired Fleet, toggle on **Teleport**.

Manage Fleets

3. From the sidebar, select **Edge Nodes**.
4. On the **Edge Nodes** page, click the link for any Node you want to teleport into.
   To confirm that you are remotely viewing a Edge Node's UI, Cribl Edge displays a purple border, with a badge labeled **Viewing host:** `<host/GUID>`.

Authenticated view of an Edge Node

The Leader will override any changes that you make directly to this Edge Node.

Use the YAML Config File

In `$CRIBL_HOME/local/_system/instance.yml` (`C:\ProgramData\Cribl\local\_system\instance.yml` on Windows), under the `distributed` section, set `mode` to `master`:

$CRIBL_HOME/local/_system/instance.yml or C:\ProgramData\Cribl\local_system\instance.yml

```
distributed:
  mode: master
  master:
    host: <IP or 0.0.0.0>
    port: 4200
    forwardToLeaderApi: true
    tls:
      disabled: true
    ipWhitelistRegex: /.&ast;/
    authToken: <auth token>
    enabledWorkerRemoteAccess: false
    compression: none
    connectionTimeout: 5000
    writeTimeout: 10000
```

Copy

Persisting Socket Connections

A distributed deployment creates socket files for inter-process communication (IPC) between the Leader and distributed processes and services. These sockets are essential for ensuring that Edge Nodes successfully connect to the Leader, and for certain metrics services. On the Leader's host, the default location for these files is the operating system's temp directory (for example, `/tmp`).

Many Linux distros maintain a system cleaner service (for example, systemd-tmpfiles) that removes files from this directory periodically, such as every 10 days. If Cribl's sockets are removed, this breaks certain UI pages, such as those for Fleets and Monitoring. You can protect the sockets in either of two ways.

Block the Cleaner

Stop the host OS from cleaning socket files out of `/tmp/cribl-*` subdirectories. For example, on Amazon Linux 2 instances, add a new `tmp.conf` file to `/etc/tmpfiles.d` with the line: `X /tmp/cribl-*`.

To restart the system cleaner here and reload its configuration, use this command:

```
sudo systemctl restart systemd-tmpfiles-clean.service
```

Copy

Move the Sockets

Alternatively, you can move Cribl's socket files to a different directory. This directory must be outside your operating system's temp directory, and the user that owns the `cribl` process must have the necessary permissions to write to it.

In Unix-like operating systems, the maximum length for Unix domain socket paths is 108 bytes. To minimize the path length, use a directory that is close to the root, such as `/var/tmp`.

In the UI, you specify the directory at **Settings** > **Global Settings** > **System** > **Distributed Settings** > **Leader Settings** > **Helper processes socket dir**.

Configure an Edge Node

On each endpoint, you can configure Cribl Edge variously through the UI, the `instance.yml` config file, environment variables, or the command line.

Use the UI

1. Navigate to **Settings** > **Global** > **Distributed Settings** > **General Settings**.
2. Select **Mode**: **Managed Edge**.
3. Select the **Leader Settings** menu.
4. Confirm or enter the required **Address** (for example, `criblleader.mycompany.com`). Customize the optional settings if desired.
5. Select **Save** to restart the Cribl server.

Use the YAML Config File

In `$CRIBL_HOME/local/_system/instance.yml` (`C:\ProgramData\Cribl\local\_system\instance.yml` on Windows), under the `distributed` section, set `mode` to `managed-edge`:

```
$CRIBL_HOME/local/_system/instance.yml or C:\ProgramData\Cribl\local\_system\instance.yml
```

```
distributed:
  mode: managed-edge
  envRegex: /^CRIBL_/
  master:
    host: <master address>
    port: 4200
    authToken: <token here>
    compression: none
    tls:
      disabled: true
    connectionTimeout: 5000
    writeTimeout: 10000
  tags:
       - tag1
       - tag2
       - tag42
  group: teamsters
```

Copy

Use Environment Variables

You can configure Edge Nodes via environment variables, as in this example:

```
CRIBL_DIST_LEADER_URL=tcp://<authToken>@<leaderHostname>:4203 ./cribl start
```

For additional details, see Configure Environment Variables.

Use the Command Line

You can configure an Edge Node using CLI commands of this form:

7.7. Connect Nodes To Leader Through Cribl Outpost

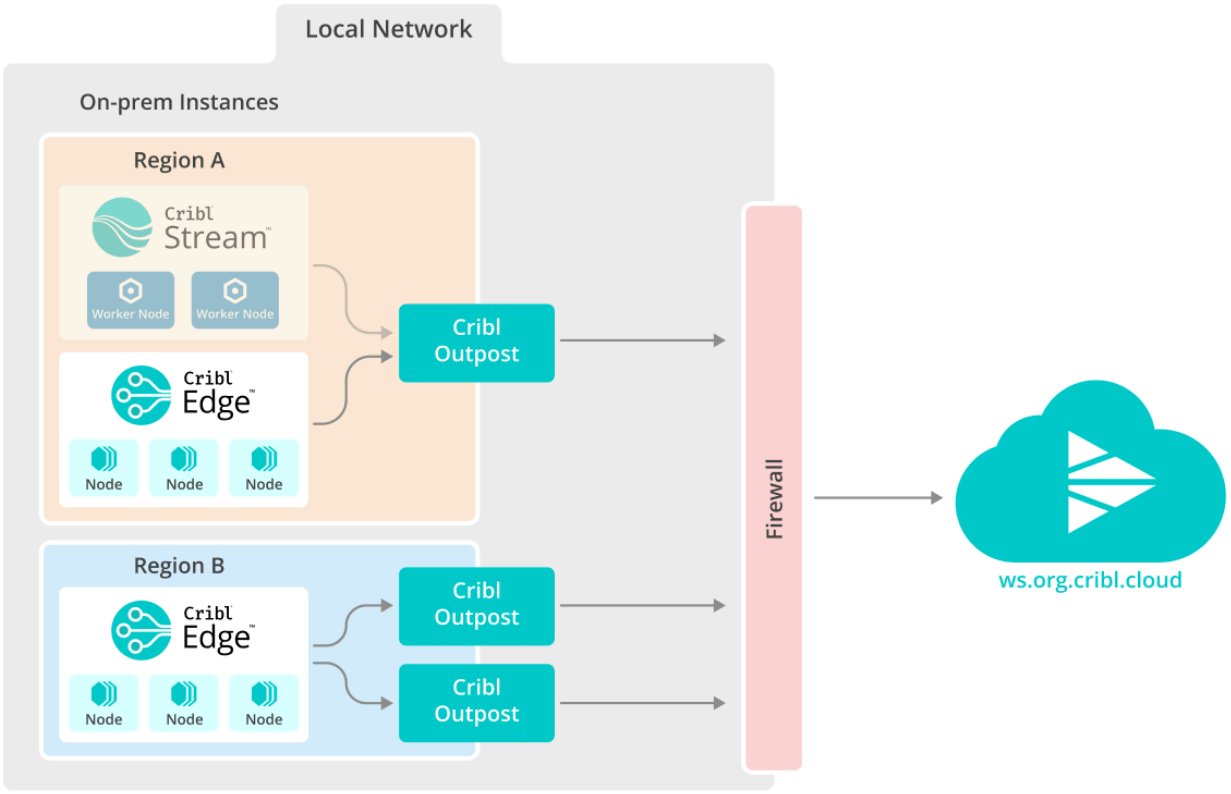
Simplify Node-to-Leader communication with Cribl Outpost.

Cribl Outpost simplifies management of deployments by acting as a relay between individual Edge Nodes or Stream Workers and the Leader Node.

Once you establish an Outpost and configure it to accept traffic from Edge Nodes or Stream Workers, control plane communication between those Nodes and the Leader will pass through the Outpost.

Cribl Outpost is ideal in situations where you can't establish direct communication between Edge Nodes or Workers and the Leader, for example due to restrictions in opening up firewall ports.

Using an Outpost limits the need to set up third-party proxies and simplifies maintenance by reducing the complexity of firewall setups.



Cribl Outpost requires an Enterprise plan or Enterprise license. For details, see Pricing.

If you connect an Outpost to a Leader that does not have a proper plan or license, the Outpost node will close the listener for communication incoming from Edge Nodes or Workers, but will be shown as healthy on the Leader.

How Outpost Works

An Outpost is a special type of Node that rests between Edge Nodes or Stream Workers and the Leader.

Overview of how Outpost connects Leader with Edge Nodes and Stream Workers

For an individual Edge Node or Worker, an Outpost is indistinguishable from the Leader: Nodes communicate with the Outpost the same way they would with a Leader, using the same configuration (for example, using the URL defined in the `CRIBL_DIST_LEADER_URL` environment variable or in `instance.yml`).

Instead of connecting directly to multiple Nodes (possibly thousands), the Leader maintains those connections with one Outpost only. This means you only need to configure communication lines such as firewall exceptions once per Outpost.

Outpost Capacity

You can connect a maximum of 28,000 Edge Nodes to a single Outpost. The specific number of possible connections up to this limit depends on the Outpost Node specifications, in particular on CPU and RAM.

The recommended specifications for serving a given number of Edge Nodes are as follows:

Number of Edge Nodes	vCPU	RAM	Connection listener processes
up to 10,000	2	4 GiB	1
10,000 - 25,000	4	8 GiB	2

While the maximum limit is 28,000 Edge Nodes, if you need to connect more than 25,000 Nodes, Cribl recommends using more than one Outpost to share the load.

High Availability for Outposts

7.7.1. Set Up Cribl Outpost

Create a Cribl Outpost to relay communication between Edge Nodes and the Leader.

Prerequisites

Cribl Outpost requires an Enterprise plan or Enterprise license. For details, see Pricing.

You can install Cribl Outpost on Linux only. Do not run an Outpost Node on the same host as a Stream Worker to avoid both Nodes competing for resources.

Before deploying an Outpost Node, ensure you have an authentication token created on the Leader. See Create and Manage Authentication Tokens for information on how to create and manage authentication tokens.

Prepare Outpost Group

The Outpost Group defines the listener URL on which Edge Nodes connect to the Outpost, TLS settings that secure that connection, as well as other options such as the retention time for disconnected Outpost Nodes.

Before you add an Outpost Node, revise the settings in the `default_outpost` Group and, if needed, change them, or create a new Outpost Group.

To create a new Outpost Group:

1. In the sidebar, select **Outposts**, then select **Add Outpost Group**.
2. Enter a **Name** for the group, an optional **Description**, and **Tags**.
3. In **Time to keep disconnected Outposts**, define how long the Group should retain information about an Outpost that disconnects from the Leader. Leave empty to use the default of one day.
4. Select **Save**.
5. Select the new Group you created, and then **Settings** to configure its more advanced parameters.
6. In **Distributed Settings** > **Listener Settings**, configure **Address** and **Port**. These will form the URL that Edge Nodes will use to connect to Outposts in this Group.
7. In **Distributed Settings** > **TLS Settings**, enable **Use TLS** to secure Outpost-Edge Node communication with TLS. If you enable TLS, you also need to provide certificate and private key information, as needed.
8. Optionally, configure any other Outpost Group settings. Refer to Outpost Group Settings for more information.

In versions older than v4.16, TLS information for Outposts was included in the individual Outpost Node settings instead of the Outpost Group. On upgrade to v4.16, Outposts Nodes running older versions are

> placed in the `default_outpost` Group.

Create an Outpost

There are two ways of adding a new Outpost Node:

- using the bootstrap script provided in the UI
- from a binary file

Add an Outpost with a Bootstrap Script

To add a new Outpost Node using a CLI bootstrap script:

1. From the sidebar, select **Outpost**, then select an Outpost Group.
2. Select **Add/Update Outpost Node**, then select **Add**.
3. Fill and modify the deployment option fields:
    - The **Install package location** defaults to `Cribl CDN`. If desired, change this to `Download URL`.
    - Enter the authentication token in **Auth token**. (For more information about creating tokens, see Create a New Provisioning Token.)
    - As needed, correct the target **Outpost Group**, as well as the **Leader hostname/IP** (URI).
    - As needed, correct the **User** and **User Group** to run Cribl as.
    - As needed, correct the **Installation directory**.
4. Optionally, add **Tags** that you can use for filtering and grouping Outposts. Use a tab or hard return between (arbitrary) tag names.
5. Copy the resulting script to your clipboard.

Finally, to add the Outpost, paste the script onto the command line where you want to set up the node, and execute it.

If your script successfully added the Outpost, you will see it in the **Outposts** list for your selected group.

Add an Outpost from a Binary File

To add a new Outpost Node using a downloaded binary file:

Download and Untar the Binary

1. Go to the Cribl Download page and set the **Software** drop-down to `Cribl Suite (Edge and Stream)` for your processor architecture.
2. Select **Download now** to get the `.tgz` archive.

3. Un-tar the install package in your directory of choice:

```
cd /opt/
tar xvzf cribl-<version>-<build>-<arch>.tgz
```

Copy

Set Installation Mode

Set the installation mode to `mode-outpost` to connect the Outpost to the designated Leader. Use one of the authentication tokens as `<authToken>` to allow Nodes to connect to the Leader:

```
/opt/cribl/bin/cribl mode-outpost /
   -H <leader-hostname-or-IP> /
   -p <port> /
   -u <authToken> /
   -S 1
```

Copy

You can use SOCKS proxies for the communication between Outpost Nodes and the Leader. See Configure SOCKS Proxy for more information.

Token

`<authToken>` must match an existing authentication token. For more information about creating tokens, see Create a New Provisioning Token.

TLS

The `-S 1` parameter enables secure communication between the Outpost Node and the Leader via TLS. If you omit this parameter, the connection will not use TLS. However, TLS must be enabled for the Outpost Node to connect to a Leader in Cribl.Cloud.

Group

By default, a new Outpost Node will be placed in the `default_outpost` group.

You can specify a different Group by providing the `-g` parameter to the `mode-outpost` command, for example:

```
/opt/cribl/bin/cribl mode-outpost /
   -H <leader-hostname-or-IP> /
   -p <port> /
   -u <token> /
   -g <myGroup> /
   -S 1
```

Copy

Configure Installation as a Service

Finally, configure the installation as a service and start it:

```
sudo /opt/cribl/bin/cribl boot-start enable -m systemd -u cribl
sudo systemctl restart cribl-outpost.service
```

Copy

At this point your Cribl Outpost is ready for use and you can start configuring Edge Nodes to connect to it.

Connect Nodes to an Outpost

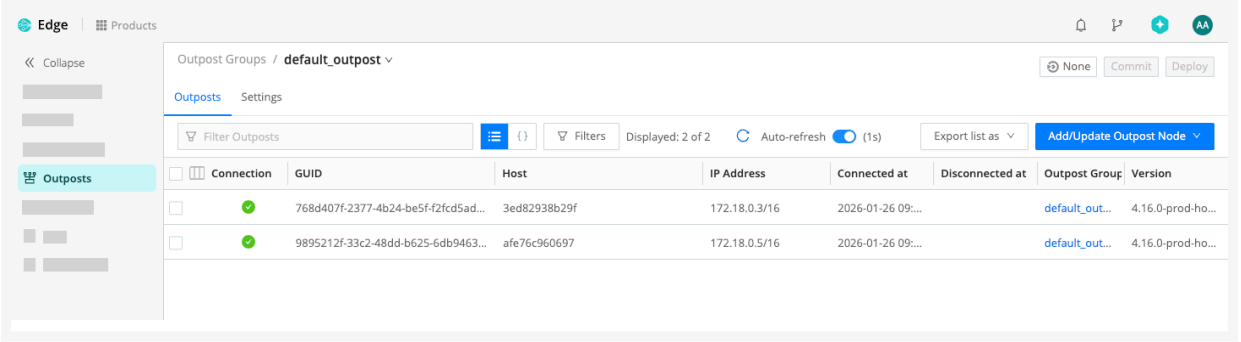
Edge Nodes see Outpost in the same way as a Leader Node. This means that, to connect a Node to an Outpost, you only need to provide the Outpost listener URL and the Leader auth token.

The Outpost doesn't have a separate auth token. When configuring Node connection, use the auth token of the Leader.

Configure the connection either from Settings (**Global** > **Distributed Settings** > **Leader Settings**), or by setting the `CRIBL_DIST_LEADER_URL` environment variable:

```
CRIBL_DIST_LEADER_URL=tcp://<leader-token>@<outpost-hostname>:<outpost-port>
```

Copy



7.7.2. Manage Cribl Outpost

Control, diagnose, and upgrade your Cribl Outposts.

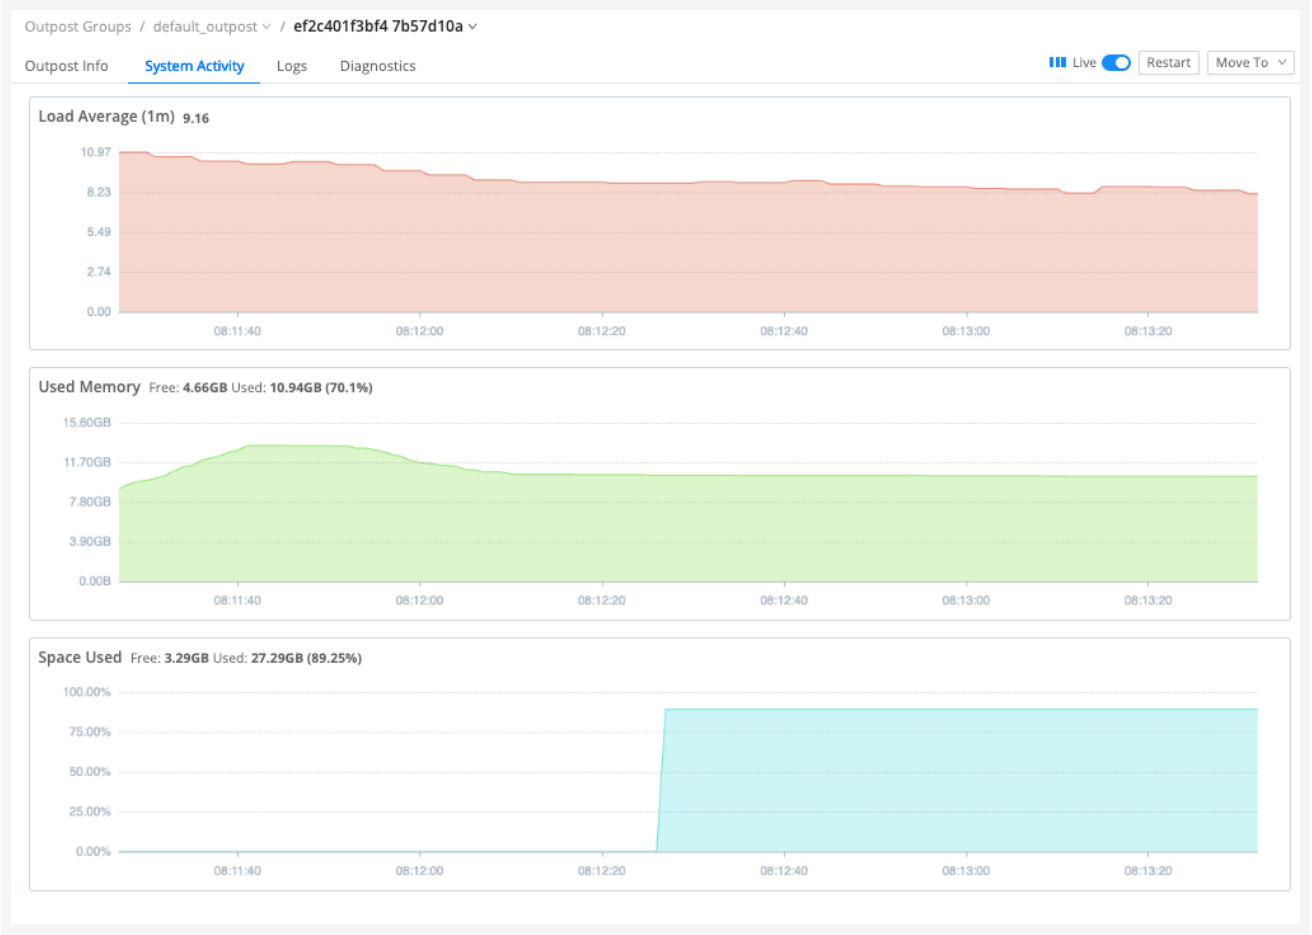
View Outposts

The **Outposts** page displays all Outposts configured in your deployment, including those that are currently disconnected.

1. On the top bar, select **Products**, and then select **Edge**.
2. In the sidebar, select **Outposts**. You will see a list of all Outpost Groups.
3. Select any group to see its Outposts, including disconnected ones.

List of Outposts

4. Select any row in the table to see detailed information about the Outpost.



Alternatively, select **List View** above the Outpost Group table to view all Outposts in all groups.

To export the filtered list of Outposts in JSON or CSV format, select **Export list as** above the table.

Check Outpost Activity

To view the data flow through an Outpost Node, select an Outpost Group and an individual Outpost, then select the **System Activity** tab. This tab displays charts for:

- Load Average (1m)
- Amount of memory used
- Amount of disk space used

Outpost System Activity charts

View Outpost Logs

To view Outpost logs, consult the **Logs** tab in the Outpost screen. For more information about Outpost logs, see Internal Logs.

Create Outpost Diagnostic Bundle

In the outpost screen you also create a diagnostic bundle to share with Cribl Support as help in diagnosing any issues. To do so, on the **Diagnostic** tab, select **Create Diagnostic Bundle**. To learn more about diagnostic bundles, see Diagnose Issues.

You can also create diagnostic bundles by using the `diag` command.

Restart an Outpost

Required Permission: **Admin/Owner**

To restart an Outpost:

1. On the top bar, select **Products**, and then select **Edge**.
2. In the sidebar, select **Outposts**, then select one of the Outpost Groups.
3. Select the check box in the row of the Outpost or Outposts you want to restart and select **Restart Selected**.
4. Confirm with **Restart**.

Manage Outpost Groups

Outpost Groups let you manage configurations for Outposts in bulk. The **Settings** tab in Outpost Group view lets you configure preferences for the group. The settings available are a subset of the settings for a Worker Group (in Cribl Stream) or an Edge Fleet (in Cribl Edge).

Outposts created in versions older than 4.16.0 will always stay in the `default_outpost` group. To move those Outposts between groups, first upgrade them to version 4.16.0 or newer.

Outpost Connectivity

You can configure how long the Leader should keep track of disconnected Outposts by configuring the **Time to keep disconnected Outposts** Outpost Group setting. By default the Leader retains information about disconnected Outposts for one day. You can set it to any value between 0 (which means Outposts are removed within a few minutes) and 90 days.

Outpost Upgrades

Defining a target version for an Outpost Group lets you upgrade all Outposts from that group in bulk. See Upgrade Outpost for more information.

Move Outpost to Another Group

You can move an Outpost to another group by selecting its check box and selecting **Move To** below the Outpost table.

Moving an Outpost to another group can temporarily disconnect it from the Leader. If the new group has a target software version selected, the Outpost will upgrade to that version on move.

Moving an Outpost via the **Move To** button will be impossible for Outposts that have any `DIST_` environment variables set.

7.7.3. Configure Outpost Group Settings

Configure settings for an Outpost Groups, including connection parameters, retention of disconnected nodes, proxy, storage, and TLS settings.

Required Permission: **Admin**

To edit Outpost Group settings:

1. In the sidebar, select **Outposts**.
2. Select an Outpost Group, then go to the **Settings** tab.

General Settings

Outpost Group Configuration

You can configure the following general Outpost Group options on the **Overview** tab:

Outpost Group Configuration Setting	Description
Description	Optionally, add or edit the Outpost Group description.
Tags	Use tags to organize Outpost Groups into logical categories.
Time to keep disconnected Outposts	Configure how long the Outpost Group should retain information about an Outpost that disconnects from the Leader. Format examples: `8h`, `5d`, `1w` (format defaults to days if you only specify a number). Default: 1 day.

API Server Settings

General

You can set the following options for the API server.

API Server Setting	Description
Host	The hostname or IP address you want to bind the API server to. • Defaults to `0.0.0.0`.

API Server Setting	Description
	• You can override the value with the `CRIBL_API_HOST` environment variable.
Port	API port to listen to. • Defaults to `9000`. • You can override the value with the `CRIBL_API_PORT` environment variable.

TLS

For information on TLS options, see Configure TLS.

Proxy Settings

Proxy Setting	Description
Use proxy env vars	Honors the `HTTP_PROXY/HTTPS_PROXY` environment variables. Defaults to toggled on. Cribl prioritizes environment variables for proxy settings in this order: Process, User, and System. If your Cribl service is managed by a service manager other than systemd (such as upstart or init), the `Use proxy env vars` toggle might not behave as expected because Cribl might prioritize environment variables set by the service manager instead of using the proxy settings you intended.

Limits

The **Limits** tab provides access to controls for metrics, storage, metadata, jobs, the Redis cache and connections to it, and CPU settings.

Storage

You can configure the following options for storage:

Storage Setting	Description
Min free disk space	The minimum amount of disk space on the host before various features take measures to prevent disk usage (KB, MB, and so on). Default: `5 GB`. To avoid the "Unable to write to the filesystem, disk space low" error,

Storage Setting	Description
	ensure that the available disk space remains above this threshold by monitoring disk usage and configuring alerts.

Metadata

Event metadata sources: List of event metadata sources to enable. Available sources: `os`, `cribl`, `aws`, `env`, and `kube`. No sources are enabled by default.

SNI

SNI Setting	Description
Disable SNI-based connection routing	This setting affects how the Cribl Edge control plane routes connections.

Do not change this setting without consulting Support first.

Support

Support Setting	Description
Feature Flag Overrides	Cribl thoroughly tests all releases in Cribl.Cloud environments to ensure stability and reliability. However, new features can sometimes behave unpredictably in customer-managed data environments. The scale of some environments and the complexity of many possible configurations make it difficult to test for every possible scenario, occasionally leading to unforeseen issues. To ensure the stability of your production environment, Cribl Stream includes a safety mechanism that makes it possible to disable specific new features if they are causing unexpected issues. This is a customer-first tool designed to minimize impact and avoid the need to roll back upgrades or wait for a full patch release. If you suspect that a new feature is impacting your environment, please contact the Support team for assistance. This process ensures that Cribl can quickly stabilize your environment while also collecting the necessary information to improve Cribl Stream for everyone. **Do not change this setting without consulting Support first.**
Log file max size	Maximum size of each log file before rotation. Enter a numeral with units of KB or MB (for example, “5 MB”, “1024 KB”). Default: 5 MB. Minimum: 1 MB.

Support Setting	Description
Number of log files to keep	Number of rotated log files to keep before purging. Default: 5. Range: 1-100. Only new rotations use this limit. Existing files above the previous limit are not removed.

Distributed Settings

Listener Settings

Listener Setting	Description
Address	The hostname or IP address you want to bind the API server to.
Port	API port to listen to.
IP allowlist regex	Regex matching IP addresses that are allowed to establish a connection.

TLS Settings

For information on TLS options, see the documentation for any Source or Destination that supports TLS.

Service Process

Services

Services Setting	Description
Number of connection listener processes	The number of Outpost connection listeners to spawn. Positive numbers specify an absolute number of listeners. Negative numbers specify a number of listeners relative to the number of CPUs in the system. The default is `-2`.

7.8. Set Up Version Control

As part of the Cribl Edge installation process for on-prem deployments, verify that Git is installed on the hosts running your deployment. Git is a required component for various reasons:

- It is a dependency for many Cribl Edge features.
- The Monitoring > Licensing dashboard will display configuration change markers only if you have `git` installed.
- All configuration changes must be committed before they are deployed. The Leader notifies Edge Nodes that a new configuration is available, and Edge Nodes pull the new configuration from the Leader Node.

See Commit and Deploy Changes for more information about how to deploy changes with the UI. You can also use the Cribl API to automate commit and deploy commands. Read Commit and Deploy Changes in the API documentation for more information.

Requirements

Cribl Edge requires Git **1.8.3.1.** or later.

For distributed deployments, `git` **must** be installed and available locally on the host running the Leader Node.

Verify Git

To verify that `git` is available and running the required version, run:

```
git --version
```

Copy

Install Git

To install Git, see the Git Installation steps in the official Git documentation.

7.9. Manage Edge Node Config Bundles

Learn about Edge Node config bundles and how to manage them

Config Bundles

Config bundles are compressed archives of all config files and associated data that an Edge Node needs to operate. Both Leader and Worker Nodes automatically manage config bundles in the following ways.

Bundle Storage and Delivery

The delivery mechanism for config bundles depends on where your Leader resides:

- **Cribl.Cloud Leader**: Bundle storage is managed for you in a Cribl-owned Amazon S3 bucket. You do not need to configure S3 settings. Edge Nodes will automatically attempt to pull from the Cribl S3 bucket first, then fall back to the Leader over port `4200`. For details on preventing deployment delays by white-listing the required S3 and Leader endpoints, see Network Access for Config Bundles.
- **Customer-managed Leader**: By default, the Leader serves bundles directly. To reduce Leader load, you can store bundles in S3 using your own bucket. For details, see Store Bundles Remotely.

For details on ports, see Ports and Required Ports in Cribl.Cloud.

Bundle Lifecycle and Retention

Regardless of where bundles are stored, Cribl Edge maintains a cleanup policy to optimize disk space.

Leader Node Bundles

The Leader creates bundles upon Deploy, and manages them as follows:

- Bundles are wiped clean on startup.
- While running, at most 5 bundles per group are kept.
- Bundle cleanup is invoked when a new bundle is created.

Edge Node Bundles

The Edge Node pulls bundles from the Leader and manages them as follows:

- Last 5 bundles and backup files are kept.
- At any point in time, all files created in the last 10 minutes are kept.
- Bundle cleanup is invoked after a reconfigure.

Store Bundles Remotely

For customer-managed Leaders, you can optionally reduce Leader load by storing bundles in an Amazon S3 bucket. This offloads bundle distribution from the Leader to your designated S3 bucket. Edge Nodes will pull bundles directly from S3, minimizing Leader strain.

You can configure bundling in S3 through the following ways:

- **UI**: Configure the Leader settings on the Leader Node. In the sidebar, select **Settings**. In the **Global** tab, select **System** > **Distributed Settings** > **Leader Settings**. In the **S3 Bundle Bucket URL** field, specify an S3 bucket for remote bundle storage. Format: `s3://${bucket}`.
- **YAML**: In the `instance.yml` config file, specify the S3 bucket in `master.configBundles.remoteUrl`.
- **Environment Variable**: Use the `CRIBL_DIST_LEADER_BUNDLE_URL` environment variable.

Optimized Bundle Delivery from S3

Cribl prioritizes efficient updates for Edge Nodes, regardless of their network environment. Here's how:

- **Direct S3 Downloads (Preferred)**: Cribl prioritizes downloading upgrade packages directly from Amazon S3 (S3) whenever possible, ensuring efficient updates for Edge Nodes connected to Cribl.Cloud or an on-premise Leader. The source is specified in the Leader's **Global Settings** > **Upgrades** > **Package source** setting.
- **Automatic Failover**: If the S3 download fails, a built-in failover automatically retrieves the bundle from the Leader itself (port `4200`). This redundancy guarantees updates even in challenging network environments, including private networks with restricted internet access. For these networks, Cribl prioritizes a CDN download before reverting to the Leader Node as a final resort.
- **Allowlist S3 Access (Optional)**: To further optimize downloads for Edge Nodes with internet access, consider allowlisting the regional Amazon S3 endpoint used by your bundle bucket in your firewall or proxy configuration. For example, endpoints look like `s3.eu-central-1.amazonaws.com` or `s3.us-west-2.amazonaws.com`, and dual-stack variants look like `s3.dualstack.us-west-2.amazonaws.com` or `bucket-name.s3.dualstack.us-west-2.amazonaws.com`.

S3 endpoints are regional and do not share a single wildcard hostname, so patterns such as `*.s3.amazonaws.com` are not sufficient for firewall or proxy allowlists. Refer to the AWS documentation: Using Amazon S3 dual-stack endpoints for the complete and current list of S3 regional and dual-stack endpoints.

Authenticating to S3

When storing configuration bundles in an Amazon S3 bucket, Cribl Edge needs appropriate credentials to access the bucket. There are several ways to provide these credentials, with IAM roles being the most secure and recommended approach.

IAM Roles (Recommended)

The best practice is to configure an IAM role with read access to your S3 bucket and attach this role to the EC2 instance (or other AWS service) where your Leader and Edge Nodes are running. Cribl Edge will automatically use the instance's IAM role to authenticate to S3. This method avoids the need to manage AWS credentials directly within Cribl and is the most secure option.

To authenticate via IAM roles:

1. Create an IAM role with the `AmazonS3ReadOnlyAccess` policy (or a custom policy with more restrictive permissions if needed) for the S3 bucket containing your bundles.
2. Attach this IAM role to the EC2 instance(s) running your Leader and Worker Nodes.
3. Provide the path to your S3 bucket using the CRIBL_DIST_LEADER_BUNDLE_URL environment variable or the S3 Bundle Bucket URL field in the **Distributed/ Leader** settings (For example, `s3://your-bucket-name/path/to/bundles`). `path/to/bundles` is optional.

AWS Access Keys

Alternatively, you can provide AWS access keys directly. Ensure the environment in which Cribl Edge runs in contains the following variables:

```
export AWS_ACCESS_KEY_ID="YOUR_ACCESS_KEY_ID"
export AWS_SECRET_ACCESS_KEY="YOUR_SECRET_ACCESS_KEY"
export CRIBL_DIST_LEADER_BUNDLE_URL="s3://your-bucket-name/path/to/bundles"
```

Copy

Encryption and Backward Compatibility

If your Edge Nodes are running versions older than 4.9.0 and your Leader is v.4.9.0 or newer, deployments will always use Leader-hosted bundles. This happens because of how encryption works:

- Newer Leaders encrypt bundles when uploaded to S3 to enhance security and prevent the exposure of sensitive information like secret keys.
- Older Edge Nodes check the code for errors by comparing its checksum (a unique identifier).
- Since the Edge Nodes check the encrypted code, they will always find errors because the checksum changes after encryption.

You might see an error similar to the one below in your logs: `Checksum mismatch, expected=f781b2bace2e1869e840b0ee200b57378ecae985, found=a59af697c140521ea7f42af7630ac1fce88e4ff0"**`

7.10. Configurations And Restart

In a Distributed deployment, Edge Nodes poll the Leader for configuration changes. Many of these changes require a quick reload to read the new configuration, while others require a restart of the Cribl processes on the Edge Node.

You can **Restart** and **Reload** via the UI. In the sidebar, select **Settings**, then **Global**. Under **System** > **Controls** select **Reload** or **Restart**.

Upon restarts, be aware of the following:

- Syslog data still being received over UDP might be dropped.
- Edge Nodes will temporarily disappear from the Leader's **Workers** or **Edge Nodes** page.
- Aggregation and suppression operations will start over.
- Edge Nodes' local copies of Monitoring metrics will be dropped.
- Cribl Edge will drop any events still in RAM that were bound for persistent queues. (However, PQ data already written to disk will persist through the restart.)

Changes that require reloads include configuration changes to:

- Functions
- Pipelines
- Packs
- Routes
- Lookups
- Parquet schemas
- Global variables
- Fleet Settings > Limits
- Fleet Settings > Logging > Levels

Changes that require restarts include configuration changes to:

- Distributed mode (Leader versus Managed Edge Node or Single instance)
- Fleet assignment
- Event Breakers
- QuickConnect configs
- Sources
- Destinations

- Fleet Settings > General Settings > TLS
- Fleet Settings > General Settings > Advanced
- Fleet Settings > Worker Processes > Process count and Memory

How Configuration Changes Apply

In a Distributed deployment, how a change applies across each Edge Node in a Fleet depends on the type of change:

- **Sources and Destinations**: Cribl Edge restarts Worker Processes on each Edge Node to apply the change.
    - In Cribl Stream, a Worker Node can run multiple Worker Processes, so they restart in a rolling fashion and the Node keeps processing data during the change. For the rolling rollout mechanics and configurable settings, see Worker Process Configuration Rollout in the Cribl Stream docs.
    - In Cribl Edge, each Edge Node runs a single Worker Process, so it simply restarts that process.
- **Routes, Pipelines, and Lookups or other knowledge objects**: Cribl Edge reloads the configuration without restarting Worker Processes, so data flow continues uninterrupted.
    - In Cribl Stream, reloads also roll out in batches across Worker Processes. If a Worker Process does not finish reloading within the configured timeout, Cribl Stream restarts it. For details, see Worker Process Configuration Rollout.
- **Fleet settings that involve the API Process** (such as API, TLS, Proxy, and Security settings): Cribl Edge restarts all Worker Processes at once rather than in a rolling fashion. All Worker Processes stop before the API Process restarts, and then the API Process starts them again.

Some general guidelines to keep in mind:

- Most UI interactions, such as changing the order of Functions in a Pipeline or changing the order of Routes, do not require restarts.
- Some configuration changes in the **Settings** UI do require restarts. These prompt you for confirmation before restarting.
- All direct edits of configuration files in `$CRIBL_HOME/local/` require restarts.
- Edge Nodes might temporarily disappear from the Leader's **Workers** or **Edge Nodes** tab while restarting.
- A `git commit` command on the Leader Node's host (using a freestanding `git` client not embedded in Cribl's CLI or UI) requires either a reload or restart.
- When using the Cribl App for Splunk, changes to Splunk configuration files might or might not require restarts. Please check current Splunk docs.

7.11. Leader High Availability/Failover

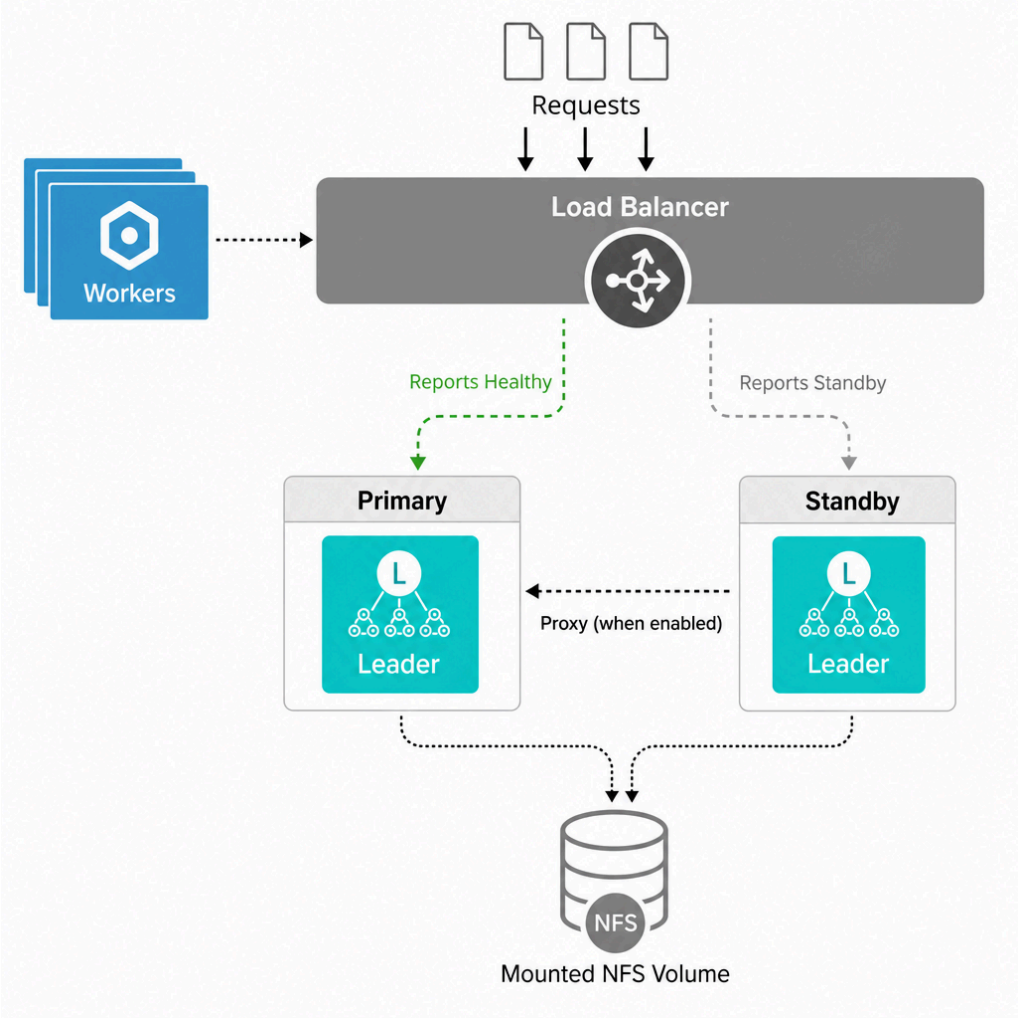
To handle unexpected outages in on-prem Distributed deployments, Cribl Edge supports configuring standby Leaders for failover. In this High Availability (HA) scenario, if the primary Leader goes down, one of the other Leaders, called standby Leaders, take its place. This ensures continuity of operation, including functions that require the Leader, such as Collectors and Collector-based Sources, which can ingest data without interruption.

For scheduling Collector jobs, High-availability Collectors complements Leader HA. An eligible Fleet can elect a temporary Worker Captain to orchestrate jobs when the Leader is unreachable, without shared Network File System (NFS).

High-availability Collectors does not replace standby Leaders (or a Cribl.Cloud-managed Leader) when you need full control plane resilience. It only covers Collector job orchestration inside the Fleet. While the Leader is down, you still lack an active Leader for anything that requires one, including the Leader UI and API, new commit and deploy changes, ad hoc Collector runs started from the Leader, license updates to restarted nodes, Leader-side metrics aggregation, and notifications generated on the Leader. During a Leader outage, those capabilities still rely on Leader HA (self-hosted) or on Cribl.Cloud operating the Leader for you.

Cribl.Cloud handles High Availability and configuring standby Leaders automatically, requiring no configuration or action on your part.

For license tiers that support configuring standby Leaders, see Cribl Pricing.



Primary and Standby Leaders

Only one Leader Node is the elected primary at any given time, and only the primary Leader owns Leader state. A standby Leader (or Leaders) takes over as primary in the event of failover, when the primary Leader becomes unavailable.

Leader state backed by SQLite, such as Worker connection data, is always written to local disk, because SQLite file locking is not compatible with NFS. With Leader replication enabled, the active git repository is also on local disk and is replicated to the failover volume rather than being read and written across NFS. All changes to configurations and git commits are replicated to a shared failover NFS volume, and from it to the standby Leaders. The shared volume coordinates the Leaders and holds replicated configuration, git data, and shared Leader state. It is not where you install Cribl Edge. See High Availability Requirements for the distinction between the installation directory and the NFS failover volume.

If the primary Leader becomes unavailable, a standby Leader takes its place. The standby then pulls the required configuration and the latest git commits from the failover volume. All Edge Nodes will connect to the new primary Leader, which retains the state and metrics of the old primary Leader.

By default, a standby Leader reports a standby status from the `GET /health` endpoint, so the load balancer routes client requests only to the primary Leader. When you enable Active-Active (Proxy) Mode for HA Leaders, the load balancer can route requests to either Leader, and the standby proxies incoming requests to the primary.

Leader High Availability/Failover Design

Git-Backed Configuration and Leader Replication

In Leader High Availability (HA) deployments with GitOps enabled, Leader replication aligns branches. The local Git branch for the active Leader Node matches the branch on the failover (HA) volume repository.

For more information about `CRIBL_GIT_REMOTE`, `CRIBL_GIT_BRANCH`, and related bootstrap behavior, see usage notes for `CRIBL_GIT_REMOTE`.

Leader Settings in High Availability Setups

When you first configure Leader High Availability, Cribl Edge will create a new `leader.yml` file in the local `$CRIBL_HOME/local/cribl` directory and will upload it to the failover volume. Configuration stored in the

`leader.yml` file on the failover volume will take precedence over what is stored in the local `instance.yml` file.

The `leader.yml` file replicates most of the content of the local `instance.yml`, but leaves out the failover configuration.

While running in failover mode, when you change **Settings** > **Distributed Settings** via the UI, Cribl Edge applies those changes to `leader.yml` in the failover directory.

See Configure Standby Leader Nodes for information on how to prepare standby Leaders for a failover scenario.

7.11.1. High Availability Requirements

Before adding a standby Leader, ensure that you fulfill all requirements in this section.

Disk Space Requirements

Ensure that all Leaders, both the primary and the standby ones, have enough disk space available. You need enough space to hold the contents of the failover volume (except the `state` directory), all your configuration files, plus at least 10 GB in reserve for future use.

Leader Health Check Timeouts

Configure adequate timeout for Leader health checks to ensure the Leader has enough time to pull all the configuration and the git repository from the failover volume. Too low timeout could results in the Leader being terminated prematurely.

The recommended timeout scales with the number of Worker Groups and Fleets the Leader manages. The exact value depends on the size of the git repository, size of the `groups` directory, and the total number of configuration files. Approximate recommendations are:

- 2 minutes for smaller deployments
- 5 minutes for deployments with > 50 Worker Groups/Fleets
- 10 minutes for deployments with > 100 Worker Groups/Fleets

Git Configuration Requirements

If you have git timeout configured in `local/cribl.yml`, ensure that it is equal or greater than the system default of 10 minutes.

Auth Token Requirements

All Leaders must have matching auth tokens. See Create and Manage Authentication Tokens for more information about creating and managing authentication tokens.

NFS Requirements

The failover volume is not the installation directory

The NFS failover volume is separate from each Leader's installation directory. Install Cribl Edge on fast local disk on every Leader, both primary and standby. Network filesystems (NFS, EFS, and similar) are not supported for the installation directory. Use NFS only for the failover volume, which coordinates Leaders and holds replicated configuration, git data, and shared Leader state. A running Leader in

failover mode resolves the `$CRIBL_HOME` variable to a path that depends on its replication state. Read this requirement as applying to the installation directory rather than to `$CRIBL_HOME`. See OS and System Requirements and Leader High Availability/Failover.

- On all Leader Nodes, use the latest version of the NFS client. **NFSv4 is required.**
- Ensure that the NFS volume has at least 100 GB available disk space.
- Ensure that the NFS volume's IOPS (Input/Output Operations per Second) is ≥ 200. (Lower IOPS values can cause excessive latency.)
- Ensure that ping/latency between the Leader Nodes and NFS is < 50 ms.
- Ensure your NFS system supports updating `mtime`.

You can validate the NFS latency using a tool like `ioping`. Navigate to the NFS mount, and enter the following command:

```
ioping .
```

Copy

For details on this particular option, see the ioping docs.

NFS Mount Option Requirements

The Leader Node will access large numbers of files whenever you use the UI or deploy configurations to Edge Nodes. When this happens, NFS's default behavior is to synchronize access time updates for those files, often across multiple availability zones and/or regions. To avoid the problematic latency that this can introduce, Cribl recommends that you add one of the following NFS mount options:

1. `relatime`: Update the access time only if it is more than 24 hours ago, or if the file is being created or modified. This allows you to track general file usage without introducing significant latency in Cribl Edge. To do the same for folders, add the `reldiratime` option.
2. `noatime`: Never update the access time. (Cribl Edge does not need access times to be updated to operate correctly.) This is the most performant option - but you will be unable to see which files are being accessed. To do the same for folders, add the `nodiratime` option.

Recommended NFS Configuration

If you are on AWS, we recommend the following:

- Use Amazon's Elastic File System (AWS EFS) for your NFS storage.
- Ensure that the user running Cribl Edge has read/write access to the mount point.

- Configure the EFS **Throughput mode** to `Enhanced` > `Elastic`.
- For details on NFS mount options, see Recommended NFS mount options.

For best performance, place your Leader Nodes in the same geographic region as the NFS storage. If the Leader and NFS are distant from each other, you might run into the following issues:

- Latency in UI and/or API access.
- Missing metrics between Leader restarts.
- Slower performance on data Collectors.

Load Balancer Requirements

Configure all Leaders behind a load balancer.

- Port `4200` must be exposed via a network load balancer.
- Port `9000` can be exposed via an application load balancer or network load balancer.

Active-Active (Proxy) Mode for HA Leaders

By default, a standby Leader returns a standby status (HTTP `420`) from `GET /health`, so a load balancer that routes only to Leaders returning `200` sends client requests to the primary Leader. UI/API requests that reach the standby on port `9000` are proxied to the primary.

You can enable Active-Active (Proxy) Mode to simplify load balancer routing. In this mode, both primary and standby Leaders report healthy (`200`), allowing the load balancer to route client requests to either Leader. The standby proxies incoming requests to the elected primary, which preserves single-writer semantics because only the primary owns Leader state.

To enable proxy mode, set `connection_proxy.procs` to a nonzero value on each Leader, either in `service.yml` or on the Leader's **Service Processes** > **Services** settings page.

The standby must be able to reach the primary over port `9000` to forward UI/API traffic. With proxy mode enabled, control-plane connections on port `4200` are also proxied. Ensure firewall rules allow Leader-to-Leader communication on these paths.

Load Balancer Health Checks

To ensure reliable load balancing for your Leader Nodes, configure health checks using the `GET /health` endpoint. Load balancer health checks are supported only on port `9000`. Configure TLS to use `https` for health checks. Otherwise, use `http`.

Load balancers that support such health checks include:

- Amazon Web Services (AWS) Network Load Balancer (NLB). Suitable for TCP, UDP, and TLS traffic.

- AWS Application Load Balancer (ALB). Application-aware, suitable for HTTP/HTTPS traffic.
- HAProxy.
- NGINX Plus.

For optimal performance and to avoid potential throttling, adhere to the following guidelines:

- **Polling frequency**: Set your load balancer to check the health endpoint every `60` seconds. This interval aligns with Cribl.Cloud's internal monitoring and prevents excessive API calls.
- **Avoid overly frequent checks**: Polling more often than every `60` seconds (for example, every `5` seconds) can overload the Leader's API Process.
- **Load balancer routing**: Configure your load balancer to direct traffic exclusively to Leader Nodes that return a `200` status code from the health check.

For detailed information on query and response formats for the `GET /health` endpoint, refer to the code example for querying the health endpoint.

> **AWS Network Load Balancers**
>
> If you need to access the same target through a Network Load Balancer, use an IP-based target group and deactivate client IP preservation. For details, see:
>
> - Why can an instance in a target group not reach itself via NLB?
> - Why can't a target behind my Network Load Balancer connect to its own Network Load Balancer?

Source-Level Health Checks

For many HTTP-based Sources, you can enable a Source-level health check endpoint in the **Advanced Settings** tab. Load balancers can send periodic test requests to these endpoints, and a `200 OK` response indicates that the Source is healthy.

Frequent requests to Source-level health check endpoints can trigger throttling settings. In such cases, Cribl will return a `503 Service Unavailable` response, which can be misinterpreted as a service failure. A `503` response may indicate that the health checks are running too frequently instead of an actual service failure.

7.11.2. Configure Standby Leader Nodes

To prepare your deployment for High Availability, in the configuration for all Leaders, both primary and standby, you must specify the same failover volume - a shared Network File System (NFS) volume.

You can configure standby Leader Nodes in the following ways. These configuration options are similar to configuring the primary Leader Node:

- Using the UI
- Updating the YAML config file
- Using the Command Line
- Using Environment Variables

Remember, the `$CRIBL_VOLUME_DIR` environment variable overrides `$CRIBL_HOME`.

Use the UI

For all Leader Nodes, both primary and standby, configure the following:

1. In **Settings** > **Global** > **Distributed Settings** > **General Settings**, select **Mode**: `Leader`.
2. Next, on the **Leader Settings** left tab, select **Resiliency**: `Failover`. This exposes several additional fields.
3. In the **Failover volume** field, enter the NFS directory that the configurations and git commits will be replicated to. This directory must be outside of the installation directory. One valid solution is to use `CRIBL_DIST_LEADER_FAILOVER_VOLUME=<shared_dir>` (alternatively `CRIBL_DIST_MASTER_FAILOVER_VOLUME`). See Use Environment Variables for more information.
4. Optionally, adjust the **Lease refresh period** setting, which determines how often the primary Leader tries to refresh its hold on the Lease file, and the **Missed refresh limit**, which determines how many Lease refresh periods elapse before standby Nodes attempt to promote themselves to primary.
   Increase these two values to avoid unnecessary failovers if your NFS has higher latency or is occasionally slow.
5. Select **Save** to restart.

When you save the **Resiliency**: `Failover` setting, further **Distributed Settings** changes via the UI will lock for both the primary and backup Leader. (This prevents errors in bootstrapping Workers due to incomplete token synchronization between the two Leaders.) However, you can still update each Leader's distributed settings by modifying its configuration files.

Use the YAML Config File

For all Leader Nodes, both primary and standby, configure the following in `$CRIBL_HOME/local/_system/instance.yml`, under the `distributed` section:

1. Set `resiliency` to `failover`.
2. Specify a volume for the NFS disk to automatically add to the Leader Failover cluster and trigger automated data migration.

$CRIBL_HOME/local/_system/instance.yml

```
distributed:
  mode: master
  master:
    host: <IP or 0.0.0.0>
    port: 4200
    resiliency: failover
    failover:
      volume: /path/to/nfs
```

Copy

Note that `instance.yml` configs are local, not on the shared NFS volume.

Use the Command Line

For all Leader Nodes, both primary and standby, use a command of this form:

```
./cribl mode-master -r failover -v /mnt/cribl
```

For all options, see the CLI Reference.

Use Environment Variables

For all Leader Nodes, both primary and standby, configure environment variables listed in Environment Variables Reference: Adding Fallback Leaders.

Address HA Migration Timeouts

When enabling Leader High Availability (HA) on a production system with a lot of data, or when booting up new Leader Nodes, the process of moving data can sometimes take longer than expected. If the system runs out of time during this move, it might only copy part of the data, which can cause problems when the system restarts.

To mitigate the risk of incomplete data transfers, temporarily increase the system's transfer time prior to enabling HA. You can do this by adjusting a setting called `TimeoutSec` in the `cribl.service` configuration file. Locate the **Service** section and add or modify the `TimeoutSec` directive. For example, set it to `600` seconds (10 minutes):

```
[Service]
TimeoutSec=600
```

Copy

A successful data transfer will be confirmed by specific messages in the system's log, such as:

```
{"time":"2025-02-
17T22:01:46.295Z","cid":"api","channel":"ResiliencyConfigs","level":"info","message":"fa
migration is complete"}
```

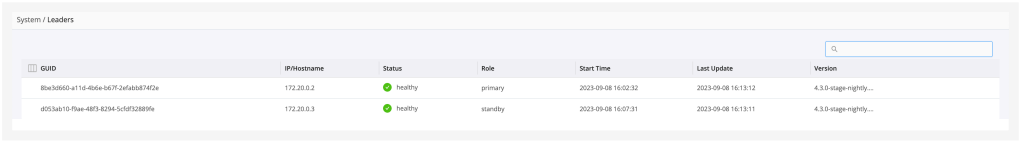
A failed migration due to timeout might show logs ending with a system shutdown, like this:

```
{"time":"2025-02-
06T15:29:15.416Z","cid":"api","channel":"ShutdownMgr","level":"info","message":"Starting
shutdown ...","reason":"Got SIGTERM","timeout":0}
```

After the HA setup is complete, revert the `TimeoutSec` setting to its original value. Leaving the timeout extended indefinitely can lead to prolonged Leader downtime if a problem occurs during a future failover. Make sure to document the original setting before making changes to facilitate easy reversion.

7.11.3. Manage High Availability Deployment

Manage your High Availability deployment by monitoring Leaders, performing an upgrade, and disabling standby Leader Nodes.



Monitor Primary and Standby Leader Nodes

To view the status of your Leader Nodes:

1. On the top bar, select **Products**, and then select **Stream**.
2. In the sidebar, select **Monitoring**, then **System**, then **Leaders**.
3. In the **Leaders** table, you can see the status of all your Leader, including the roles they play (primary or standby).

This page is only accessible when you have a standby Leader configured.

Monitoring Leader Nodes

Upgrade a High Availability Deployment

Upgrading the Leader Node through the UI is not supported for Distributed deployments with a standby Leader. Instead, use the command line (CLI) to upgrade.

Follow this upgrade order:

1. Stop the standby Leader first.
2. Upgrade the standby Leader.
3. Start the standby Leader.
4. Stop the primary Leader; the upgraded standby will take over automatically through the HA failover mechanism.
5. Upgrade the now-stopped former primary Leader for your Stream or Edge deployment.
6. Start the former primary Leader. It will rejoin and assume the standby role (since the other Leader is currently active).
7. Upgrade Edge Nodes in rolling batches; do not upgrade them to a version newer than the Leader.

Disable a Standby Leader

Cribl recommends that you maintain a standby Leader to ensure continuity in your on-prem Distributed deployment. Should you decide to disable it, contact support to assist you.

7.12. Anti-Virus Exceptions

Configure your antivirus to prevent accidental blockage of Cribl Edge.

If you are running anti-virus software on an Edge instance's host OS, here are general guidelines for minimizing accidental blockage of Edge's normal operation.

Your overall goals are to prevent the anti-virus software from locking any files while Edge needs to write to them, and from triggering any changes that Edge would detect as needing to be committed.

First, if persistent queues are enabled on any Destinations, exclude any directories that these Destinations write to. This is especially relevant if you're writing queues to any custom locations outside of `$CRIBL_HOME`.

Next, for any non-streaming Destinations that you've configured, exclude their staging paths.

Next, exclude these subdirectories of `$CRIBL_HOME`:

- `state/`
- `log/`
- `.git/` (usually only exists on Leader Nodes)
- `groups/` (on Leader Nodes)
- `local/` (on Edge or Leader)

Finally, avoid scanning any processes. Except for the queueing/staging directories already listed above, Edge runs everything in memory, so scanning process memory will slow down Edge's processing and reduce throughput.

Stop Endpoint Security from Blocking Edge on Windows

Antivirus or other endpoint security tools on Windows (such as Windows Defender) may block the `cribl` process.

To tell Windows Defender to exclude the Cribl Edge process from its security scan, you can run these commands on the appropriate Windows Edge Nodes:

```
Add-MpPreference -ExclusionProcess "C:\Program Files\Cribl\bin\nssm.exe"
Add-MpPreference -ExclusionProcess "C:\Program Files\Cribl\bin\cribl.exe"
Add-MpPreference -ExclusionPath "C:\ProgramData\Cribl"
```

Copy

7.13. Ports

Learn which ports need to be open for Cribl Edge and its integrations to function.

Cribl Edge requires certain ports to be open, and additional ports are needed if you intend to use specific integrations or options to work.

Leader

In a Distributed deployment, the following ports must be open on the Leader Node. Ensure that the Leader is reachable on those ports from **all** Edge Nodes.

Default Port	Protocol	Purpose	Direction
`9000`	HTTP/S	Cribl Edge UI.	In
`9000`	HTTP/S	Bootstrapping Fleets from Leader (on-prem).	In
`443`	HTTP/S	Bootstrapping Fleets from Leader (Cribl.Cloud).	In
`4200`	TCP	Heartbeat/Metrics/Leader requests/notifications to clients (for example: live captures, teleporting, status updates, config bundle notifications, and so on). This traffic is separate from the Notifications feature and its external Notification targets such as email, PagerDuty, Slack, webhooks, or AWS SNS.	In
`4200`	HTTP/S	Software upgrade (via path, not CDN).	In

External Notification targets: If you configure external Notification targets (for example, email, PagerDuty, webhooks, Slack, or AWS SNS), the Leader must be able to initiate outbound network connections to those services. Ensure your firewall rules allow outbound traffic from the Leader to each target endpoint over the ports and protocols required by that service (commonly HTTPS/443, or SMTP ports for email). Because these ports are target-specific, they are not listed individually here.

Outpost

The following ports are used by Cribl Outpost.

Default Port	Protocol	Purpose	Direction
`9000`	TCP	Cribl Outpost UI. Login is disabled, but the Health endpoint is available.	In

Default Port	Protocol	Purpose	Direction
`443`	HTTP/S	Optional port for config bundle downloads from S3 endpoints for Leader-initiated upgrades. When this port is not open, Outpost falls back to bundle downloads from the Leader over HTTP/S 4200.	Out
`4200`	TCP	Communication between the Outpost and the Leader.	Out
`4200`	TCP	Communication between the Outpost and Edge Nodes.	In
`4200`	HTTP/S	Config bundle downloads from the Leader.	Out
`4200`	HTTP/S	Receiving config bundle requests from Edge Nodes.	In

Edge Nodes

The following ports are used by Edge Nodes.

Default Port	Protocol	Purpose	Direction
`9420`	TCP	Cribl Edge UI.	In
`9000`	HTTP/S	Communication with the Leader for bootstrapping (on-prem).	Out
`443`	HTTP/S	Communication with the Leader for bootstrapping (hybrid deployment), and with `https://cdn.cribl.io` to download configurations from CDN.	Out
`4200`	TCP	Heartbeat/Metrics/Leader requests/notifications to clients (for example: live captures, teleporting, status updates, config bundle notifications, and so on).	Out
`4200`	HTTP/S	Config bundle downloads from the Leader.	Out

Other Ports

Common Ports

Default Port	Protocol	Purpose	Direction
53	UDP	DNS lookups.	Out
389	TCP	LDAP Auth (non-TLS).	Out

Default Port	Protocol	Purpose	Direction
443	HTTP/S	OIDC Auth (TLS).	Out
636	TCP	LDAP Auth (TLS).	Out

Integrations and Apps

Integrations with specific services via Sources and Destinations or apps may require opening dedicated ports on Edge Nodes.

The defaults are listed below, but when configuring each Source or Destination you can choose another port.

Default Port	Protocol	Purpose	Direction
162	UDP	SNMP Trap collection (non-TLS). The preconfigured SNMP Trap Source listens on port 9162.	In
162	UDP	SNMP Trap Destination (non-TLS).	Out
443	HTTP/S	Collection from and output to multiple HTTPS-based Sources and Destinations.	In / Out
4317	TCP	Collection from OpenTelemetry (gRPC).	In
5986	HTTP/S	Windows Event Forwarder Source.	In
8081	TCP	Kafka Schema Registry.	Out
8088	TCP	Splunk HEC input and output.	In/Out
8089	TCP	Splunk Search.	In
8125	TCP/UDP	Output to StatsD, StatsD Extended, and Graphite (non-TLS).	Out
9090	TCP	Collection/discovery from Prometheus Scraper.	Out
9092	TCP	Output to Confluent Cloud or Kafka, used when no port is provided.	Out
9093	TCP	Output to Azure Event Hubs.	Out
9200	HTTP/S	Elasticsearch API Source.	In
9514	TCP/UDP	Syslog Source.	In
9997	TCP	Splunk TCP Source.	Out

Default Port	Protocol	Purpose	Direction
`10060`	TCP	TCP (Raw) data.	In
`10070`	TCP	TCP JSON data.	In
`10080`	TCP	Collection from HTTP JSON Sources.	In
`10200`	HTTP/S	Cribl HTTP Destination.	In
`10300`	TCP	Cribl TCP Destination.	In

Cribl.Cloud

Cribl.Cloud provides a set of ports linked to Sources enabled by default for your Workspace. To view them:

1. From your Cribl.Cloud Organization's top bar, select **Products**.
2. Then from the sidebar, select **Cribl** > **Workspace**, and then **Data Sources**.

Additionally, Cribl.Cloud makes the `20000 - 20010` port range available for configuring other Sources.

Available Ports	Protocol	Purpose	Direction
`443`	TCP	Mapped to `10443` internally. Available for TCP-based Sources that require port `443`.	In
`20000 - 20010`	TCP	Additional Sources in Cribl.Cloud.	In

Reusing Port 443 for Other Services

External port `443` is transparently mapped by the load balancer to internal port `10443` on the Fleet. You can use this port for TCP-based services that require port `443` (such as DocuSign).

To use port `443` for a service:

1. Configure a Source to listen on port `10443` internally.
2. External clients connect to your Cribl.Cloud endpoint on port `443`, which the load balancer routes to port `10443` on the Edge Node.

If multiple services share this port, differentiate traffic using a pre-processing Pipeline. For example, inspect `__headers` or other request metadata to identify the data source.

No other custom ports can be opened for Cribl-managed Worker Groups in Cribl.Cloud beyond port `443` and ports `20000–20010`.

7.14. Configure Environment Variables

Configure environment variables to control Cribl Edge behavior.

The procedure for configuring environment variables depends on the operating system the Cribl Edge Node is deployed to.

Whenever you change environment variables, you must restart Cribl Edge on the affected Nodes.

For a full list of available variables, see Environment Variables.

Configure Environment Variables on Linux

Set Variables with systemd

If Cribl Edge runs as a systemd service, add environment variables to the systemd override file (for example, `/etc/systemd/system/cribl-edge.service.d/override.conf`) so they persist across restarts and upgrades.

1. Open the override file for editing:

```
sudo systemctl edit cribl-edge
```

Copy

2. Add the variables under the `[Service]` section:

override.conf

```
[Service]
Environment=CRIBL_NOEXEC=1
Environment=HTTP_PROXY=http://proxy.example.com:3128
```

Copy

3. Reload the systemd daemon and restart Cribl Edge:

```
sudo systemctl daemon-reload
sudo systemctl restart cribl-edge
```

Copy

For details on persisting overrides, see Persisting Overrides.

Set Variables Without systemd

If you are not using systemd, add `export` lines to a shell profile file (such as `/etc/environment` or the Cribl user's `~/.bashrc`) so they load on login:

```
export CRIBL_NOEXEC=1
export HTTP_PROXY=http://proxy.example.com:3128
```

Copy

Configure Environment Variables on Windows

Set Variables During Installation

You can configure environment variables while installing Cribl Edge on Windows using either the interactive wizard or a parameter for the MSI installer.

- **Wizard**: In the setup wizard, in the **Set Environment Variables** modal, enter one variable per line. See Install Edge on Windows Using the Wizard for more details.
- **MSI installer**: When installing via MSI, use the `SETENVVARS` parameter with pipe-delimited key-value pairs. The entire string must be quoted:

```
msiexec /qn /i cribl-<version>-<build>.msi ^
  SETENVVARS="HTTP_PROXY=http://203.0.113.1:8080|HTTPS_PROXY=http://203.0.113.1:
  MODE=mode-managed-edge ^
  HOSTNAME=<yourhostname> ^
  PORT=4200 ^
  AUTH=myAuthToken ^
  FLEET=myfleet
```

Copy

  See Install Edge on Windows Using the Command Line for the full syntax.

Set Variables After Installation

Environment variables specified during installation are stored in the Windows registry under `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\cribl` under the `Environment` key.

To add or modify variables after installation, edit this registry key directly.

Restart the Cribl Edge service for the changes to take effect.

Configure Environment Variables on macOS

Add Variables to the LaunchDaemon Plist

To define environment variables to a macOS deployment of Cribl Edge, you need to add them to the `io.cribl.plist` file.

1. Open the Cribl plist file, for example: `sudo vi /Library/LaunchDaemons/io.cribl.plist`.
2. Locate the `EnvironmentVariables` key and add your variable under it. For example, to define the `NODE_EXTRA_CA_CERTS` variable, add:

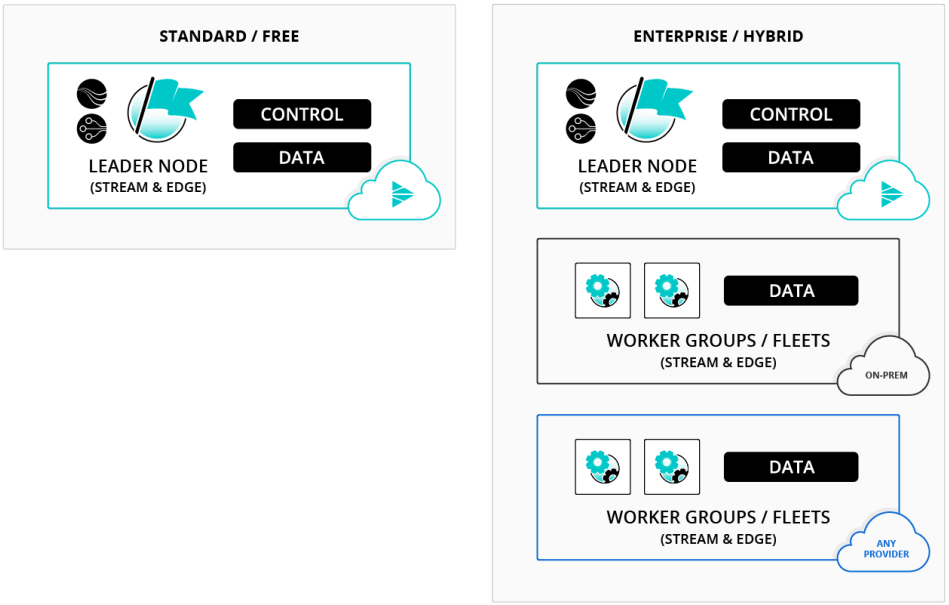
```
<key>EnvironmentVariables</key>
<dict>
   <key>NODE_EXTRA_CA_CERTS</key>
   <string>path/to/cert/ca.pem</string>
   <!-- other keys -->
</dict>
```

Copy

3. Reload the plist file by running:

```
sudo launchctl unload /Library/LaunchDaemons/io.cribl.plist
sudo launchctl load /Library/LaunchDaemons/io.cribl.plist
```

Copy



The environment variable added this way is retained when upgrading the Edge Node in a Fleet. However, if you upgrade via the bootstrap script, the plist file is replaced. In that case, re-add the environment variable.

7.15. About Cribl.Cloud

In a Cribl.Cloud deployment, Cribl assumes responsibility for hosting and managing your Cribl Edge infrastructure.

Cribl.Cloud comes in both free and paid versions. A free Cribl.Cloud account allows up to 1 TB/day of data throughput (data ingress + egress), but does not have the option to have multiple Fleets. By upgrading to a Cribl.Cloud Enterprise plan, you can implement a hybrid deployment of any complexity.

In hybrid deployments, the Leader resides in Cribl.Cloud, and manages Stream Workers and Edge Nodes regardless of their location. Your data processing configuration can consist of any combination of Workers and Edge Nodes: Cribl-managed, in private cloud instances that you manage, or in your data centers.

Standard/free versus Enterprise/hybrid deployment

For a comparison of features an capabilities of Cribl.Cloud vs an on-prem deployment, see Cribl.Cloud vs. Self-Hosted.

For an overview of additional features available on Enterprise plans, see Pricing.

If you're new to Cribl Edge, please see Cribl Edge Basic Concepts and the Getting Started Guide for help onboarding. Cribl.Cloud always runs in Distributed mode - for details about this, see Simplified Distributed Architecture.

Cloud Pricing

7.15.1. Register Cribl.Cloud Organization

To get started with Cribl.Cloud, sign up on the Cribl.Cloud portal, to create your Cribl.Cloud Organization.

Your Organization will have a dedicated portal with its own network and access boundaries, isolating your Cribl resources from other users. For more information, see the Full Suite Reference Architecture.

By default, your instance of Cribl.Cloud will be on the **free** Cribl.Cloud plan, which includes certain throughput and administration limits. When you need more capacity or features, you can upgrade to a paid or Enterprise plan. To upgrade, select **Go Enterprise** in your Cribl.Cloud portal.

You can find the Cribl.Cloud Suite on the AWS Marketplace. When you're ready to upgrade, you can use your Enterprise Discount Program (EDP) credits to run Cribl products, billed directly through your AWS account. There is no need for a separate procurement process.

Note that each user can register only one active Organization on the free tier. For details, see notes on Member Permissions.

To sign up for a free Cribl.Cloud instance and register your Organization:

1. Go to https://cribl.cloud/signup/ and create an account using your work email address.
2. Follow the instructions to set up your Organization, select its region for your Cribl.Cloud deployment, and to provide some information about your goals in using Cribl.

When you complete the registration steps, you will see your new Cribl.Cloud deployment home page. The home page suggests possible actions you can take based on the answers you provided during registration.

From there, consider completing the Getting Started Guide tutorial for a walk-through of the main features and common use cases for Cribl Edge.

Cribl.Cloud Organization Regions

The Organization region defines where the Leader Node resides.

Once you select a region when registering your Organization, you cannot change it. You can, however, create Cribl-managed Stream Worker Groups in different AWS and Azure regions.

In Cribl Search, the Organization region is the physical location where searches are executed. In Cribl Lake, the region defines the location where data is stored.

Troubleshooting Resources

If you get stuck during registration, Cribl University has a troubleshooting guide on How to Log Into Cribl.Cloud walks you through the registration and login workflow. To follow the direct course link, first log into your Cribl University account. Once logged in, check out other useful short courses:

- Troubleshooting Criblets
- Advanced Troubleshooting

7.15.2. Manage Cribl.Cloud Organization

The Cribl.Cloud portal is the place where you get an overview of and manage your organization, configure network settings, and control user access and billing information.

Switch Organizations

When you own or are a Member of multiple Cribl.Cloud Organizations, you can switch between the Organizations:

1. In the top bar, hover over the name of your Organization.
2. In the drop-down, select the Organization you want to switch to.

Alternatively, in the drop-down you can select **Manage Organizations**. You will move to an Organization landing page, displayed to an Organization's Owners and Admins, where you can view details of all your Organizations, switch to any of them, add a new one or delete one, if you have proper permissions.

Configure Organization Details

To customize your Organization information, in the sidebar, select **Organization**.

You can modify the following information:

Field name	Description
Organization Name	A "friendly" name for your Organization. Upon signing in, Members will see this alias above the Organization ID on the Select Organization page.
Description	Add further details about your Organization.
Opt in to beta features	If displayed, this check box enables access to new options that Cribl has not yet made generally available. As with all beta features, expect some instability in exchange for advancing to the cutting edge of your Cribl.Cloud.

Select **Save** to immediately apply your changes.

You can check additional information about your Organization, including the AWS Cloud region in which it's located, the software version, and license, by selecting **Organization Details** at the bottom of the sidebar.

Find Your Cribl.Cloud Organization Region

To locate your Cribl.Cloud region, click **Organization Details** in the sidebar of your Cribl.Cloud portal page (for Admins and Owners) or on any Cribl product home page (any user). It's helpful to know the Organization region

when there is a release or maintenance upgrade, because Cribl.Cloud Organizations can use specific upgrade windows based on the Leader region. The Organization region might not match your physical location.

Ingress Ports

Your Cribl.Cloud Organization's preconfigured and user-configurable ports for inbound data are set at the Workspace level. For details, see Cribl.Cloud Ports.

Get Support

In the top bar, select the **Support** icon to access a set of links with additional resources about Cribl Edge, including:

- Sandboxes (free, interactive tutorials on fully hosted integrations)
- Cribl University
- Concept/demo videos

Refer to Cribl Status for information about Cribl.Cloud availability, including current and historical uptime data, and incidents, split by component and AWS Region.

You can also subscribe there to incident notifications via email, text, Slack, or RSS.

Manage Personal Settings

Use the **Account** menu in the top right of the Cribl.Cloud portal to configure your personal settings.

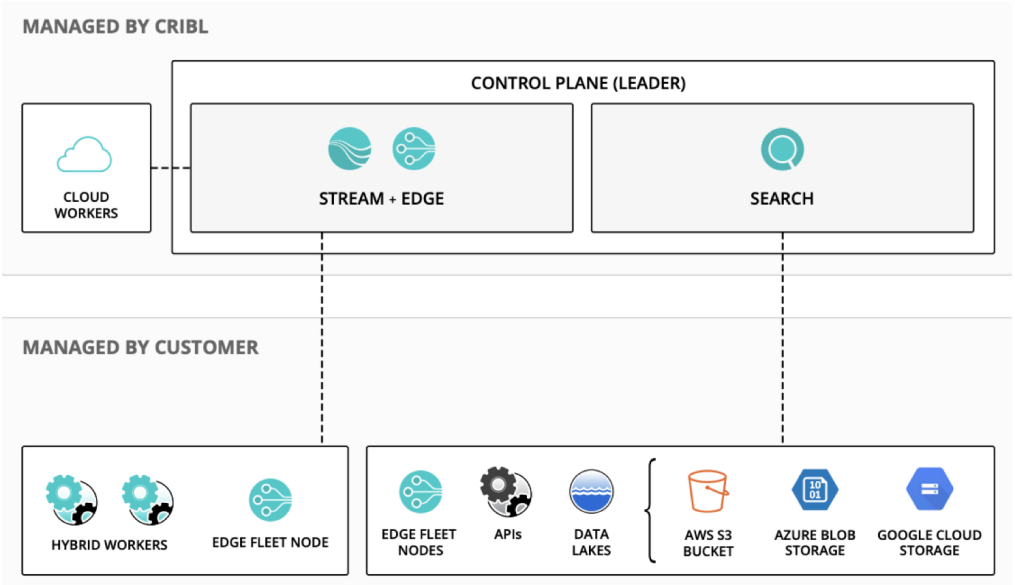
Select **My profile** to update your personal information. Here, you can also reset the configured biometric authentication. Do this, if you want to re-configure the authentication, or if you don't want to be prompted to log in through fingerprint or face recognition.

7.15.3. Cribl.Cloud Enterprise

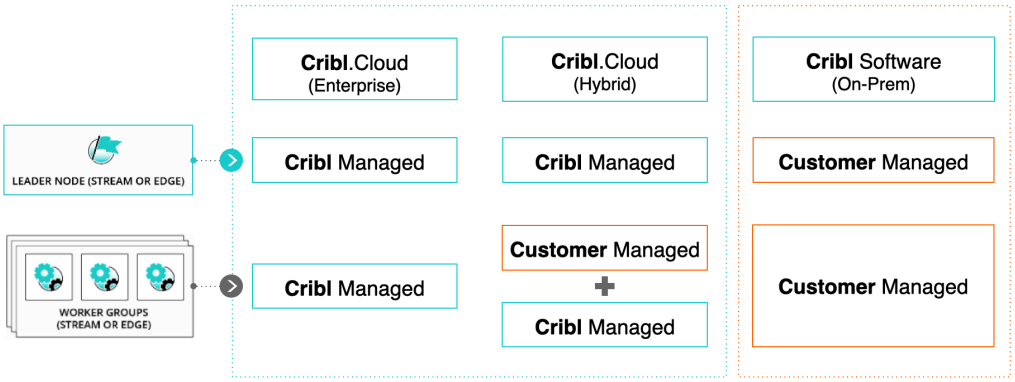
With a Cribl.Cloud Enterprise plan, you have these options and workflow flexibility:

- Configuring and managing multiple Worker Groups and Fleets.
- Notifications within Cribl apps, to PagerDuty, and/or to other services via webhook.
- Fine-grained, role-based control of Member Permissions on your Cribl.Cloud Organization and on individual product resources.
- Single sign-on/SSO authentication from external identity providers.
- The hybrid deployment option, described just below.

With an Enterprise Plan, the Leader resides in Cribl.Cloud, and controls a flexible mix of Cribl-managed and/or customer-managed Fleets. Cribl manages the Leader's high availability on your behalf.



For other Enterprise features, see our Pricing page.



Hybrid Deployment

The diagrams below show the comparative flexibility of a hybrid Cribl.Cloud deployment. The Leader (control plane) resides in Cribl.Cloud, while the Workers that process the data can be in any combination of the following environments:

- In Cribl.Cloud, managed by Cribl.
- In public or private cloud instances that you manage.
- On-prem in your data centers.

Enterprise hybrid deployment, with control plane and Cribl-managed Workers in Cribl.Cloud

Enterprise hybrid deployment, with only control plane in Cribl.Cloud

As the footprint of your operations grows or changes, this flexibility makes it easy to reconfigure Cribl Edge in tandem. You can rapidly expand Cribl Edge observability into new cloud regions - and replace monitored hardware data centers with cloud instances - all while maintaining one centralized point of control.

You can also add Workers or Edge Nodes, and reassign them to different Fleets, by easily auto-generating Stream or Edge command-line scripts within Cribl Edge's UI.

Hybrid Requirements

A hybrid deployment imposes these configuration requirements:

- Hybrid Workers (meaning, Workers that you deploy on-prem, or in cloud instances that you yourself manage) must be assigned to a different Fleet than the Cribl-managed `default` Group - which can contain its own Edge Nodes.
- All Edge Nodes' hosts must allow outbound communication to the Cribl.Cloud Leader's port 4200 at `https://main-<Organization-name>.cribl.cloud:4200`, to enable configuration and workload management by the Leader.
- On all Edge Nodes' hosts, firewalls must allow outbound communication on port 443 to the Leader and to `https://cdn.cribl.io`. This port is also used to bootstrap hybrid Workers from the Leader.
- All Edge Nodes require connectivity to `https://cdn.cribl.io/telemetry/`. For details on testing this connectivity, on the metadata transmitted to Cribl, and on how we use that data, see Telemetry Data.
- If this traffic must go through a proxy, see System Proxy Configuration for configuration details.
- To verify your Leader's region and public URL, open the Access Details modal.

Note that you are responsible for data encryption and other security measures on Edge Node instances that you manage.

Adding (Bootstrapping) Workers

To add Workers to your hybrid Cribl.Cloud deployment, Cribl recommends that you use the script outlined in Bootstrap Workers from Leader. Hosts for the new Workers must open the same ports (4200 and 443) listed in Hybrid Requirements.

You have three options for generating the script, outlined in these subsections of the Bootstrap topic linked above:

- Auto-generate it from the Leader's UI.
- Make a `GET` API request to the Leader.
- curl the same API request.

In Cribl Edge, you access all these bootstrap options via the Manage Edge Nodes page's **Add/Update Edge Node** control.

Hybrid Cribl HTTP/TCP Configuration

If you use the Cribl HTTP Destination and Source pair, or the Cribl TCP Destination and Source pair, to relay data between Edge Nodes connected to the same Leader, configuring hybrid Workers demands particular care.

The Edge Nodes that host each pair's Destination and Source must specify exactly the same Leader Address. Otherwise, token verification will fail - breaking the connection, and preventing data flow. In hybrid Cribl.Cloud deployments, the Leader's Address format is `main-<your-Org-ID>.cribl.cloud`. When configuring a hybrid Worker, use that format in the **Address** field.

To configure hybrid Workers:

1. Log directly into their UI, then select **Settings** > **Global** > **Distributed Settings**. Make sure the **Mode** is set to **Stream: Managed Worker (managed by Leader)** or **Edge: Managed Edge (managed by Leader)** (which might require a restart).
2. Then select **Leader Settings**, and ensure a consistent entry in the **Address** field.

8. Manage Fleets Of Edge Nodes

Get started with managing Fleets of Edge Nodes in a Distributed deployment.

In a distributed environment, a single Leader Node can centrally manage Edge Nodes. The Leader is responsible for keeping configurations in sync, tracking Edge Node status, and monitoring metrics.

Concepts

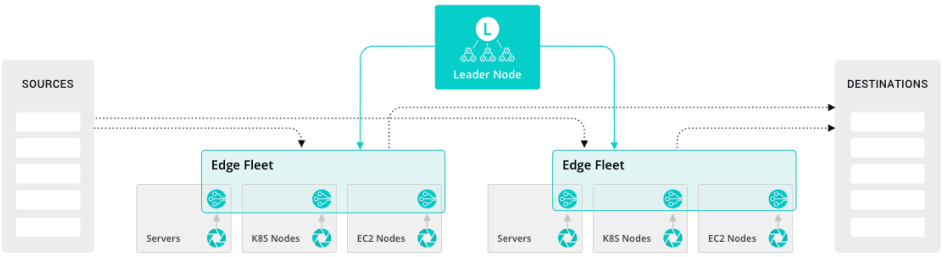
Single Edge Node - a single Cribl Edge instance, running as a standalone (not distributed) installation on one server/endpoint.

Leader Node - an instance running in **Leader** mode, used to centrally author configurations and monitor Edge Nodes in a distributed deployment.

Managed Edge Node - an instance running as a **Managed Edge**, whose configuration is fully managed by a Leader Node. (By default, will poll the Leader for configuration changes every 10 seconds.)

Fleet - a collection of Edge Nodes that share the same configuration. You map Nodes to a Fleet using a Mapping Ruleset.

Subfleet - a Subfleet groups and manages Edge Nodes that share the same configuration. Each Subfleet inherits configurations from its parent Fleet. Updating and deploying parent-level configurations applies the changes to the Subfleets. The Subfleets then deploy the configuration changes to their Edge Nodes.



Worker Process - a Linux process within a Single Instance, or within Edge Nodes, that handles data inputs, processing, and output. The process count for Edge Nodes is constrained to 1.

Mapping Ruleset - an ordered list of filters, used to map Nodes into Fleets.

Multiple Fleets are very useful in making your configuration reflect organizational or geographic constraints. E.g., you might have a U.S. Fleet with certain TLS certificates and output settings, versus an APAC Fleet and an EMEA Fleet, each with their own distinct certs and settings.

Architecture

This is an overview of a distributed Edge deployment's basic components. (The type/s of Nodes within each Fleet will vary depending on your overall architecture:)

Distributed deployment architecture

Leader Node

- API Process - Handles all the API interactions.
- *N* Config Helpers - One process per Fleet. Helps with maintaining configs, previews, etc.

Edge Node

- Single Process - Handles everything; collection, processing and communication with the Leader Node.

Leader Node Requirements

- **OS**: Linux: RedHat, CentOS, Ubuntu, AWS Linux (64bit)
- **System**: +4 physical cores, +8GB RAM, 5GB free disk space
- **Network**:
  - Heartbeat Port: `4200`: managed Edge nodes communicate with the Leader Node on port `4200` by default.
  - UI/API Port: `9000`: users access the Leader on port `9000` by default.
- **Git**: `git` must be available on the Leader Node. See details below.
- **Browser Support**: The five most-recent versions of Chrome, Firefox, Safari, and Microsoft Edge.

We assume that 1 physical core is equivalent to 2 virtual/hyperthreaded CPUs (vCPUs). All quantities listed above are minimum requirements. We recommend deploying the Leader on stable, highly available infrastructure, because of its role in coordinating all Edge instances.

Edge Node Requirements

See Deployment Planning for requirements and other details.

Version Control with `git`

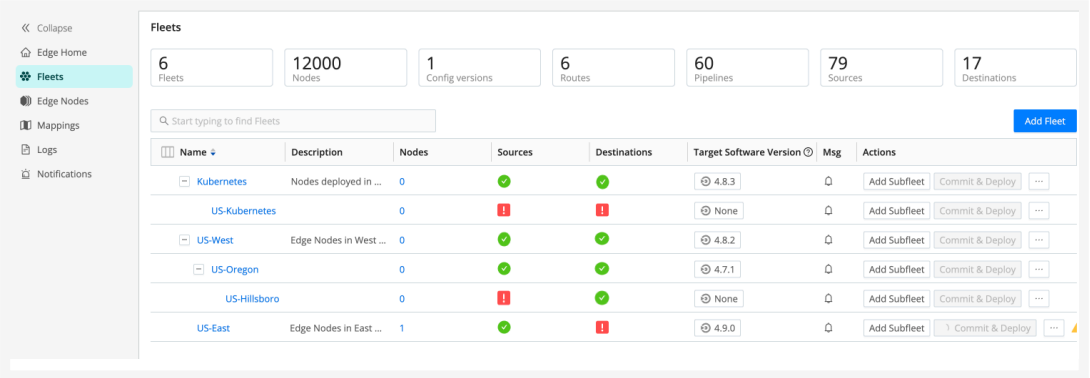
Leader Node requires `git` (version 1.8.3.1 or higher) to be available locally on the host.

Configuration changes must be committed to git before they're deployed.

If you don't have `git` installed, check here for details on how to get started.

The Leader node uses `git` to:

- Manage configuration versions across Fleets.
- Provide users with an audit trail of all configuration changes.



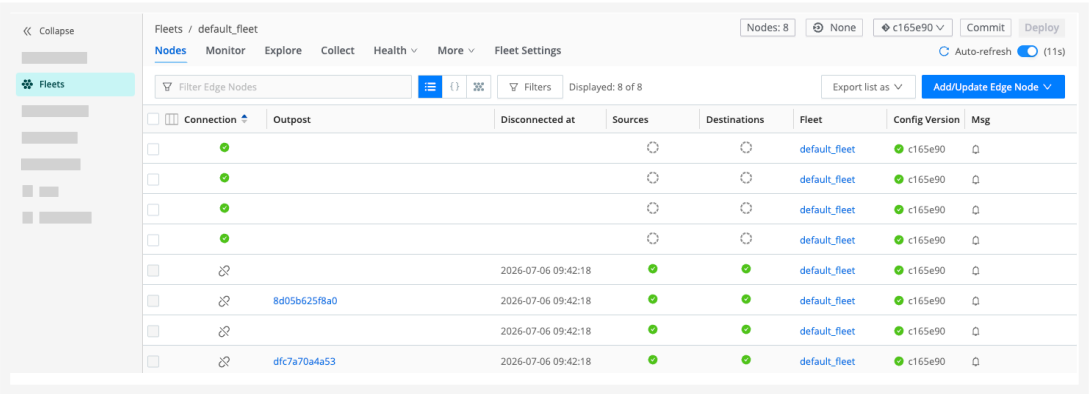
8.1. Fleets

Learn how to access your Fleets in Cribl Edge.

The **Fleets** page is available on certain plan/license tiers. For details, see Pricing.

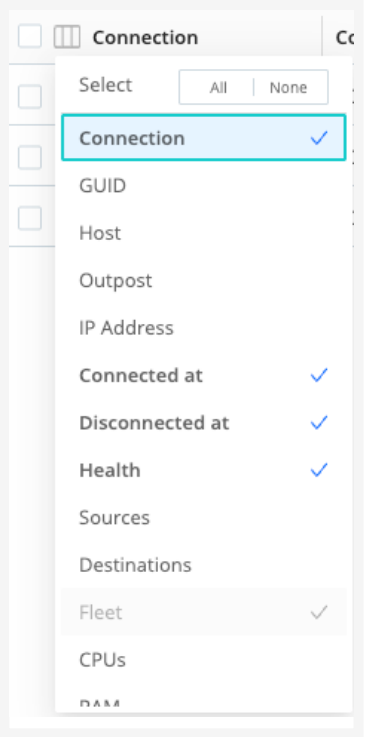
Access the Fleets Page

In Cribl Edge, select **Fleets** from the sidebar. This view shows all of the Fleets and Subfleets you have access to in the instance or Organization.



Manage Fleets

To explore more information for each of your configured Fleets, select a Fleet **Name** to open it.



View Edge Nodes in a Fleet

When you open a Fleet, you'll land on the **Nodes** page, in **List View**.

Fleet Landing page

You can use the column selector to show and hide columns in this view. Select the column icon in the table header.

Edge Nodes column selector

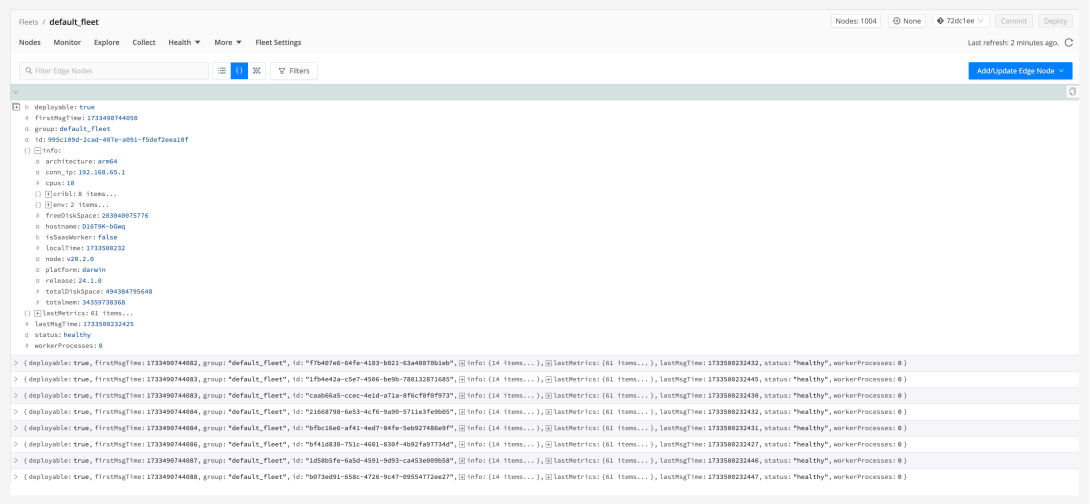
A few highlights on some of the options:

Field	Description
Health column	This column displays an icon indicating the overall health of the Edge Node.
Sources	Shows the individual health statuses of the Edge Node's Sources. You can sort and filter these Sources by their health status, which helps you quickly identify Nodes that are experiencing issues with a Source.
Destinations	Shows the individual health statuses of the Edge Node's Destinations. You can sort and filter these Destinations by their health status, which helps you quickly identify Nodes that are experiencing issues with a Destination.
Edge Version	Displays a status icon next to the version number. This icon can provide information about the upgrade status for a Node. For more information on upgrade status, read View the Status of Fleet Upgrades.
CPU	Shows the CPU utilization for the Edge Node. Use the column selector icon to reveal this option.
RAM	Displays the memory usage of the Edge Node. Use the column selector icon to reveal this option.

The Edge Nodes list also serves as the "transporter room," allowing you to teleport into each of the Node's interfaces.

Understand the Health Status Icons

The Source and Destination health icons represent the following statuses:



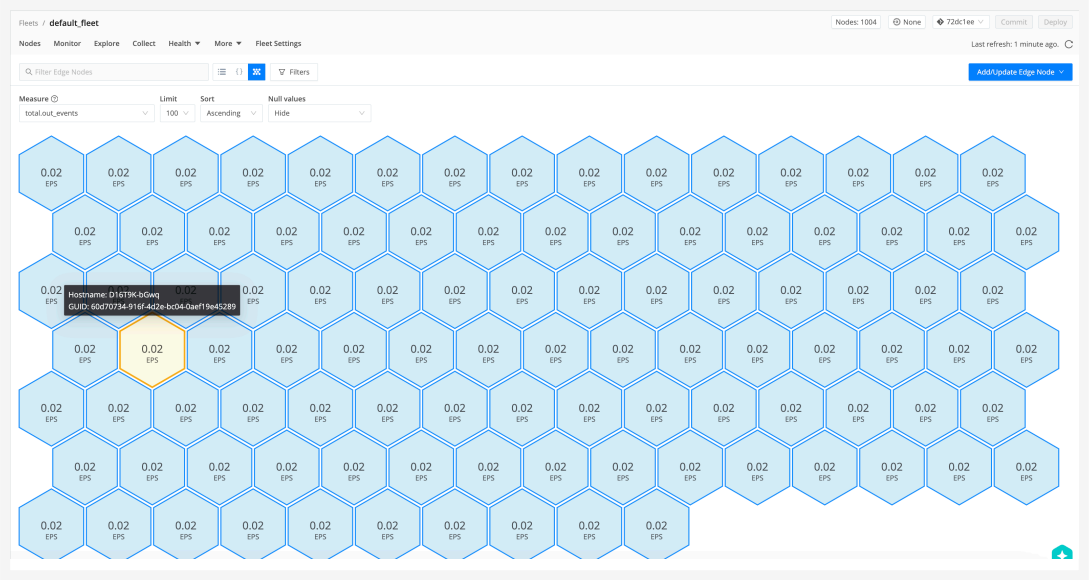
- Green checkmark: Everything is good! All Sources and Destinations are healthy.
- Yellow warning icon: Attention needed. One or more Sources or Destinations are in a warning state.
- Red exclamation point: Critical issue! One or more Sources or Destinations have encountered an error.
- Indeterminate: No data available yet for Sources or Destinations.

Ways to View Nodes

To switch between the three Edge Node views, select the List View icon, JSON View { } icon, or Map View icon.

List View: A list of all the Nodes and their statuses in the Fleet.

JSON View: Displays each Node and its status in the Fleet as an expandable JSON object. The JSON view provides inputs to create custom Node filters in **Advanced** mode. For details, see Filter Modes.



JSON View

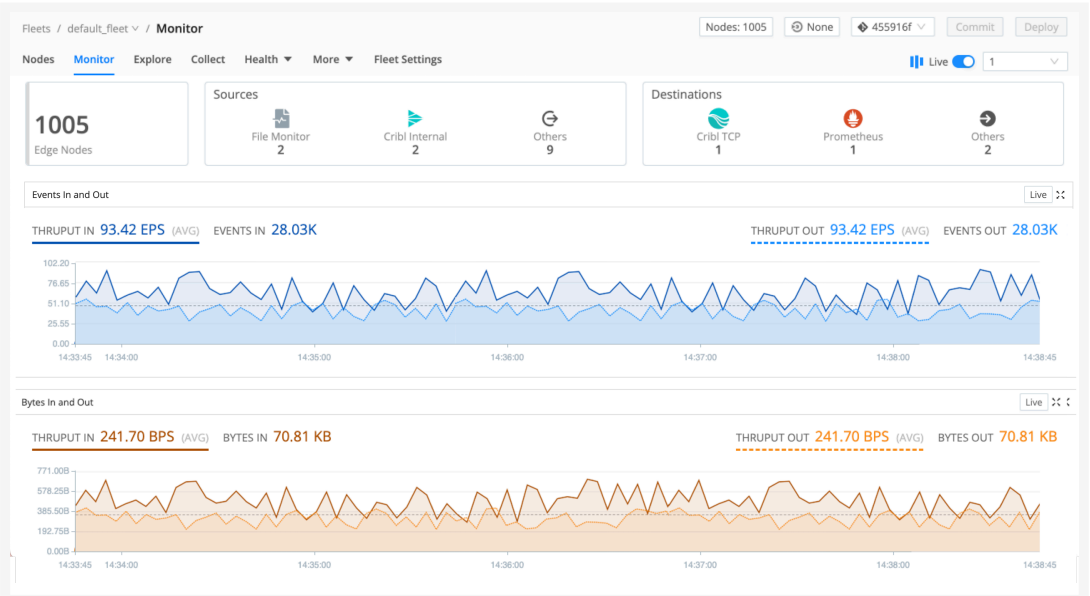
Map View: Here, a query builder allows you to display metrics from the Edge Nodes in the Fleet.

The metrics that appear in the **Measure** list depend on the option selected in **Fleet Settings** > **Limits** > **Metrics** under **Metrics to send from Edge Nodes**. The metrics `total.in_bytes`, `total.in_events`, `total.out_bytes`, and `total.out_events` always appear in the list; the display of any other metrics depends on what the Edge Nodes are sending to the Leader. To learn more about these metrics options, see Control Metrics.

A hexagon-based map view displays the resulting metric combination for each of your Edge Nodes. Hovering over on one of the hexagons displays the **GUID** and **Hostname** of the Edge Node.

Map View

Select any of the hexagons to view the Node Info modal containing details on the Edge Node. For details on this panel, see our Tracking Data Activity for an Edge Node topic.



Teleport into an Edge Node

To teleport from the Leader into the Edge Node, you must turn on **Enable teleporting to Nodes** in Fleet Settings. Then, navigate to the Edge Node page and select **Teleport**.

For more information on what you can do while teleported into an Edge Node, see Manage Edge Nodes.

Monitor Fleets

The **Monitor** tab displays information about your configured Edge Nodes. For more information about monitoring, see our topic on Monitoring Health and Metrics.

Here, view the following information:

Name	Description
Number of Edge Nodes	The number of Edge Nodes configured in this Fleet.
Target Version	If you have a target version selected for the Fleet, it will appear on this button. If not, the button will show **None** (the default). To learn more about this feature, see Upgrade Edge Nodes in a Fleet.
Events In	Total number of Events in the last 5 minutes of data collected. You can change the display's granularity from the default `last 5 min`, selecting a variety of time ranges from 1 min up to 1 day. (The latter covers the preceding 24 hours, and this maximum window is not configurable.)
Bytes In	The uncompressed amount of data in the last 5 minutes of data collected. You can change the display's granularity from the default `last 5 min`, selecting from a variety of time ranges from 1 min up to 1 day. (The latter covers the preceding 24 hours, and this maximum window is not configurable.)
Sources	List of configured Sources.
Destinations	List of configured Destinations.

8.1.1. Design Fleet Hierarchy

Design your Fleets into a practical hierarchy.

Cribl Edge enables you to group Edge Nodes into logical Fleets and Subfleets. A well-designed Fleet hierarchy is extremely important for the health of the Leader Node and lets you take advantage of configuration inheritance.

Pay particular attention to designing the hierarchy when migrating from other agents to Cribl Edge. Avoid the common pitfalls of configuring a single Fleet for all your Edge Nodes, or creating Fleets to replicate other agent configurations. These approaches can lead to inefficient data collection and management. By instead creating targeted Fleets, you can optimize your data collection, processing, and flow.

Fleet Design Better Practices

Always design your Fleet hierarchy before deploying your Edge Nodes. For details, see Designing Your Fleet Hierarchy.

Consider Leader Health

To ensure the health of your Leader Node, follow these guidelines:

- Consider the number of Edge Nodes restarting at once, since they will all be pulling their configurations from the Leader at the same time.
- For deployments with over 100,000 Edge Nodes, change the default metrics controls to `minimal`.

Deploy Nodes to Specific Fleets

Use the bootstrap script in the Add/Update Edge Node modal to deploy Edge Nodes to a specific Fleet. Depending on your Fleet design, Cribl recommends adding tags to the bootstrap script to uniquely identify the Fleet. You can use these tags for automatic mappings.

Use `default_fleet` as Fallback for Stray Nodes

Do not map Edge Nodes to `default_fleet`. It should serve as fallback for mapping errors.

Create mappings for all the Fleets so that Edge Nodes are automatically placed in the Fleet when they bootstrap and connect to the Leader. This way, if any rogue Edge Node gets deployed, it will automatically show up in `default_fleet`. You can then monitor `default_fleet` to catch those Nodes and reassign them.

If you disable all the Sources in the `default_fleet`, there will be no impact on data consumption.

This guidance doesn't apply to the free license, where the only option is `default_fleet`.

Design Your Fleet Hierarchy

If your organization is deploying a significant number of Edge Nodes, it's essential to thoroughly plan and design your Fleet architecture. If you are moving from other agent-based systems, avoid exactly replicating the previous structure, as Cribl Edge operates differently.

The first question you should ask is, do you need Subfleets? In some cases, a single-level, flat design is sufficient.

In more complex environments, layering the configurations can help you to manage a large number of Edge Nodes that share common yet differentiated configurations. For example, as an administrator, you might need multiple layers of configurations to manage the following: `Org` > `Department` > `OS`. In this case, the Edge Nodes at the `OS` level can inherit and share configurations from the `Department` level. You can update a parent-level configuration (Fleet) and have it applied to all Subfleets and their respective Edge Nodes, reducing the time and effort needed to manage them.

Maintaining a large number of Fleets can introduce operational complexities and increase the overhead of managing your Cribl Edge deployment. Before creating a large number of Fleets, explore whether your requirements can be effectively addressed by leveraging Cribl Stream as a central Destination and using Pipelines within a more streamlined Fleet structure to manage routing and processing logic.

Fleet Hierarchy Options

There are several ways you can build the hierarchy:

- Geographical: If your organization collects different data categories in different regions, consider this option.
- Data center: This is a good option if you maintain data centers in different regions.
- Server function (web server, database, and so on): Another good way to organize your Fleets can be based on server functions.
- OS-based: If you are running an environment with machines on different platforms, consider separating them into different Fleets per OS.

Fleet Limitations and Recommendations

When designing your Fleet hierarchy, consider the following recommendations:

- **Recommended Depth:** To promote manageability and performance, limit your Fleet hierarchy to no more than **two levels** of Subfleets below the top-level Fleet.

- **Cloud Environment Restriction:** Cribl.Cloud environments have a current limitation of **250 Fleets** per deployment. Carefully plan and optimize your Fleet design to stay within the limit.

If you are working in a large organization and find these limitations insufficient, **engage with your Cribl account team and Cribl design partners** to develop an optimized Fleet design that meets your specific needs.

Fleet Naming

Consider naming your Fleets and Subfleets in a way that helps you recognize the configurations at a glance.

For example, you can use the top-level Fleet name as part of your lower-level Fleets. Naming your Fleet with a logical `<parent-fleet>-<subfleet1>-<subfleet2>` will easily provide you with context whether you are viewing at the Fleet, Subfleet, or Edge Node level. It can also help identify Edge Nodes that are out of place or mapped incorrectly.

Here's an example of naming a Fleet with two levels of Subfleets:

- BZT
    - BZT-NewYork
        - BZT-NY-Linux
        - BZT-NY-Windows
    - BZT-LA
        - BZT-LA-K8s
        - and so on

Other guidelines to keep in mind when naming your Fleets:

- Fleet names can't have spaces in them; use a dash or underscore instead.
- You can't reuse a Fleet name.
- Once you create a Fleet, you can't edit the name.
- You can't delete a Fleet if there are Subfleets under it.

Plan Fleet Inheritance

An efficient Fleet hierarchy design lets you take full advantage of Fleet inheritance. Each Subfleet will inherit the configurations of every parent Subfleet before it. To learn more about how inheritance works, see Fleet Inheritance.

Here are some guidelines to keep in mind, as you think about layering your configurations.

Top-Level Fleets (Grandparents)

Assign the top-level Fleets for company-wide configurations. Use this level to:

- Apply certificates and other company-wide settings.
- Avoid OS-specific or site-specific configurations.

Level 1 Subfleets (Parents)

Per-site configurations. Use this level to:

- Configure site-specific Sources/Destinations.
- Specify any site-specific configurations, like common Destinations.

Level 2 Subfleets (Children)

Configurations used by groups of similar systems. Use this level to:

- Apply OS-specific configurations at this level. For example, an “All Linux” and “All Windows” for a given site.
- Group common OS-specific metrics and common log files into OS-specific Fleets.

Level 3 Subfleets (Grandchildren)

While Cribl typically doesn’t recommend creating more than two levels of Subfleets, if your specific complex organization requires them, use the third level to apply function-specific Subfleets to add specific metrics, logs, and/or Windows Event sources. For example, you can group by:

- Apache HTTPD
- Database
- SMTP servers
- Active Directory
- IIS
- Exchange

8.1.2. Fleet Inheritance

Manage Fleet configuration with inheritance.

Inheritance simplifies and speeds up Fleet setup by allowing configurations to automatically propagate to Subfleets.

When creating a new Fleet, you can indicate a parent that the new Fleet will inherit configurations from. Your new Fleet will become a Subfleet of the parent. Whenever you modify configurations in the parent, its Subfleets will receive the same changes.

To take advantage of inheritance, you can organize your Fleets and Subfleets into a hierarchy of configuration layers. Layering the configurations simplifies managing a large number of Edge Nodes that share common yet differentiated configurations. To learn more about planning Fleets and Subfleets, see Design Fleet Hierarchy.

How Inheritance Works

When you save and commit a configuration change in a Fleet, its Subfleets (and their Subfleets, that is, all its descendants) will receive the same configuration change.

You can view the configuration changes that can be inherited in the **Git Changes** modal before committing them. This view represents the files that contain configuration changes. See Configuration files for more details about those files.

When you make changes to a parent Fleet configuration, use the **Commit and Deploy with Subfleets** option. This way, you are always keeping the inherited configurations in sync.

Overriding Inheritance

If you change a configuration setting in a Subfleet, the inheritance link with the parent Fleet breaks. Any further changes to the modified setting in the parent will no longer propagate to the Subfleet and its further descendants.

To revert broken inheritance (that means, to allow a Subfleet to inherit again from its parent after inheritance has been broken), manually reset the values for a given configuration key to the same state as the parent.

Consult the **Git Changes** modal after resetting to make sure no unintended Subfleet-level configuration is left.

Sources, Destinations, Packs, Knowledge Objects, and other objects, are inherited as a whole. If you modify the configuration for an object in a Subfleet, this object will no longer inherit further changes, even in other

settings.

To revert broken inheritance in an object configuration, select that object and select **Revert to Parent Configuration**. This will remove any local changes made to the configuration and return it to the state inherited from the parent. If you had committed the changes on the Subfleet before, you need to **Commit & Deploy** again for the revert to take effect.

Removing Inherited Sources or Destinations

If you delete an inherited Source or Destination from the Subfleet, the Subfleet will inherit it again from its parent Fleet. If you want to ensure a Source or Destination does not propagate again to the Subfleet, **disable** it instead of deleting.

Inherited Configurations

Subfleets inherit the following Fleet-level configurations:

- Fleet Settings
- Sources and Destinations
- Routes and Pipelines
- Packs (including local modifications to Packs installed from an external source)
- Knowledge Objects
- Data samples
- Certificates and shared Secrets

Settings configured on the **Overview** tab of **Fleet Settings**, such as **Description**, **Tags**, and **Time to keep disconnected Nodes**, are not inherited by Subfleets.

Certificate Inheritance

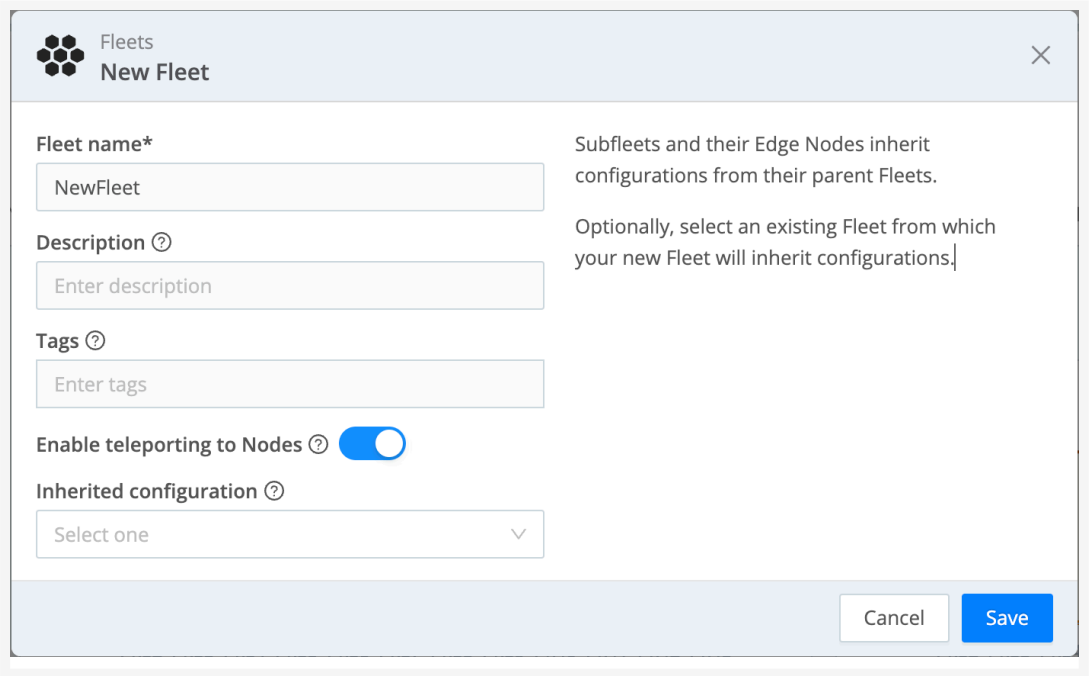
Certificates, configured in **Fleet Settings** > **Security** > **Certificates**, are inherited by Subfleets alongside other Fleet settings. They are stored locally on each Edge Node in the `local/edge/auth/certs/` directory.

For more information about certificates, see Secure Sources and Destinations with TLS and mTLS.

8.1.3. Create And Manage Fleets And Subfleets

Learn how to create Fleets and Subfleets in Cribl Edge.

Fleets and their corresponding Subfleets allow you to author and manage configuration settings for a particular set of Edge Nodes, so you can flexibly group Edge Nodes into logical Fleets and Subfleets. These Fleets and Subfleets can share and reuse configurations.

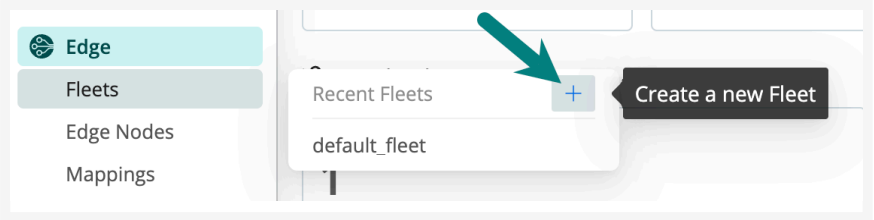


You can assign Fleet-level permissions to users. For details, see Members and Permissions.

Create a Fleet

Required Permission: Cribl Edge Admin

To create a new Fleet:



1. In the sidebar, click **Fleets**.
2. Click **New Fleet**.
3. Enter a descriptive **Fleet name**, and optionally, a relevant **Description** and Tags.

Add a new Fleet

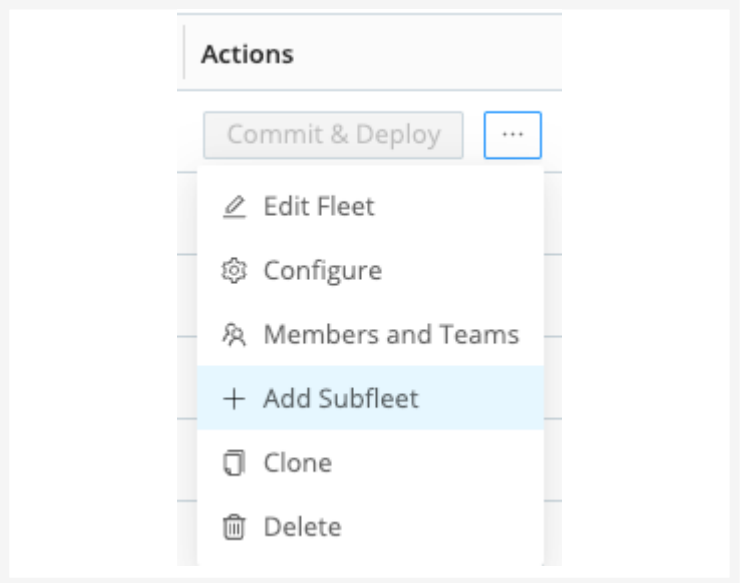
To enable teleporting to the Edge Nodes via the Leader's UI, toggle **Enable teleporting to Nodes** to **Yes**, then click **Save**.

You can also create a new Fleet by selecting **Products** on the top bar, hovering over **Fleets** in the sidebar, and selecting the + button.

Creating a New Fleet from **Products** Sidebar

Cribl.Cloud Fleet Limits

In Cribl.Cloud, you can create up to a combined total of 250 Fleets and Subfleets - for example, 50 Fleets + 200 Subfleets.

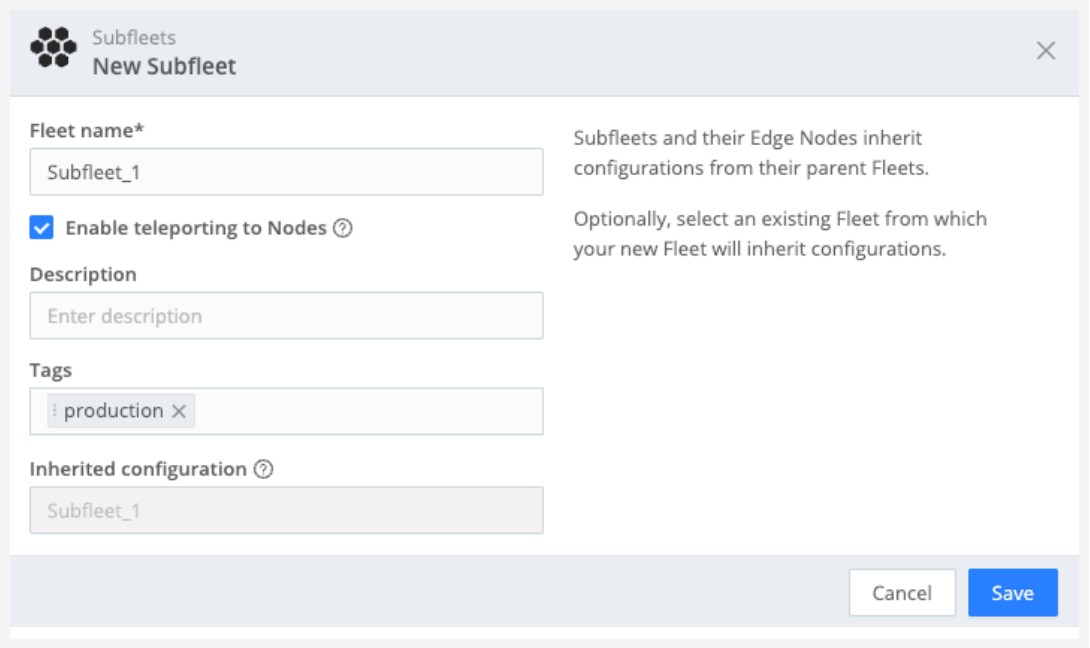


You can contact Cribl Support for an increase if you have a use case that requires more than 250 Fleets/Subfleets.

Add a Subfleet

Cribl recommends no more than two levels of Subfleets nested below a parent Fleet, but if your setup requires, you can create up to four levels of Subfleets. For each Subfleet, you can choose which parent Fleet it will inherit configurations from. For more information about inheriting configurations, see Fleet Inheritance.

To add a Subfleet:

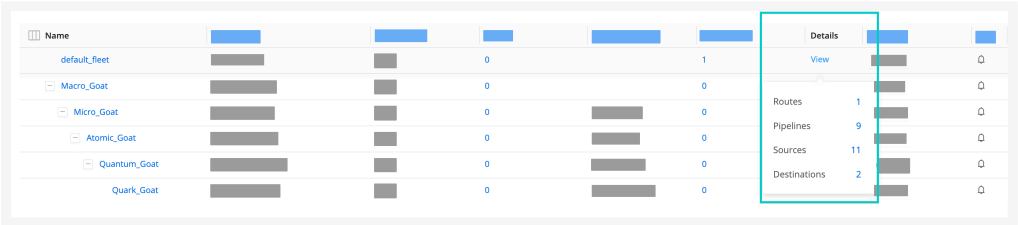


1. In the row of your desired Fleet, select the **Options** (···) menu, then select **Add Subfleet**.

Menu showing the Add Subfleet option from Options

2. Enter a descriptive **Fleet name** and optional **Description** and Tags.
3. Select an existing Fleet from the **Inherited configuration** drop-down. The Subfleet will inherit its configuration from the selected Fleet.

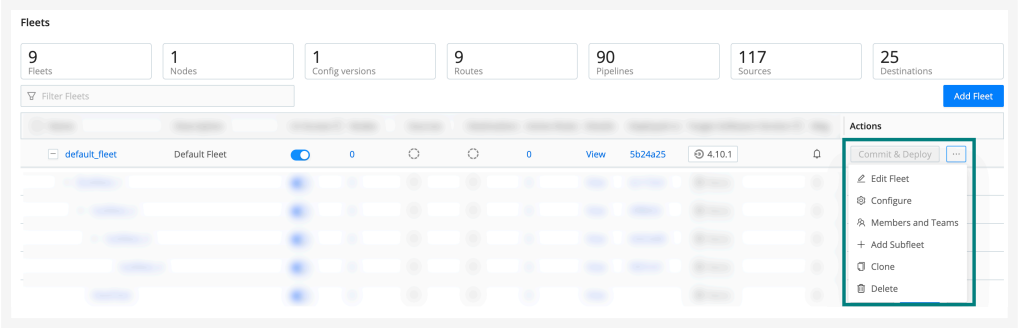
4. Click **Save**.



Add a Subfleet

Similarly, you can create a Subfleet in a selected Subfleet. Each Subfleet will inherit the configurations of every parent Subfleet before it.

View Subfleet Details and Options

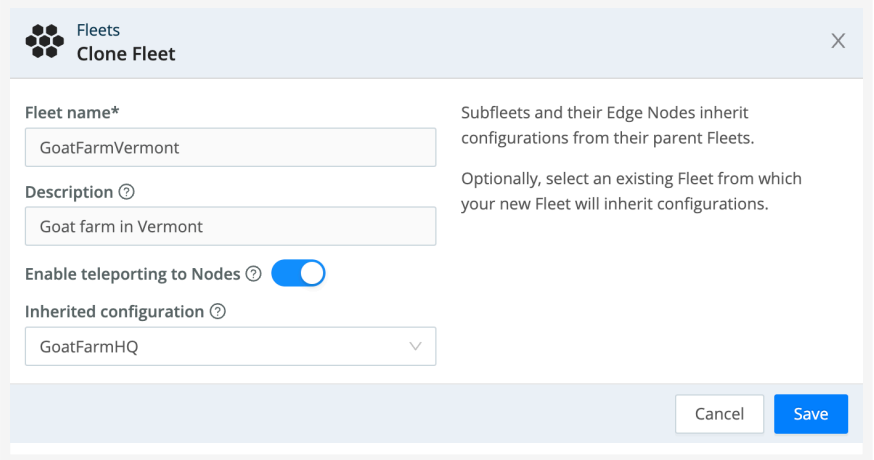


To display the number of Routes, Pipelines, Sources, and Destinations in a Fleet, click **View** in the **Details** column of a Fleet or Subfleet.

View Subfleet details

On Cribl.Cloud, you'll also see a **Group Type** column, showing whether the deployment is **Hybrid** or **Cloud**.

To display the **Edit Fleet**, Configure, **Members and Teams**, **Add Subfleet**, **Clone**, and **Delete** options, select the **Options** (⋯) menu.



A menu flyout listing the Fleet options

Clone and Delete a Subfleet

Cloning a Fleet copies the Fleet's settings, while cloning a Subfleet inherits the parent's configurations.

To clone a Subfleet, click its **Options** (···) menu and select **Clone**.

Clone a Subfleet

To delete a Fleet or Subfleet, click **Delete** in the **Options (•••)** menu. You will be prompted to confirm your decision to delete the Fleet/Subfleet, click **Yes** to confirm.

You can also commit and deploy changes to Fleets and Subfleets on this page. For details, see Committing and Deploying Fleet Configurations.

Configuring multiple Fleets is available with an Enterprise plan. For details, go to the Edge - Cloud Ingest guide.

Edge Node GUID

When you install and first run the software, a GUID is generated and stored in a `.dat` file located in `CRIBL_HOME/local/cribl/auth/`.

For example:

```
# cat CRIBL_HOME/local/cribl/auth/676f6174733432.dat

{"it":1570724418,"phf":0,"guid":"48f7b21a-0c03-45e0-a699-01e0b7a1e061"}
```

When deploying Cribl Edge as part of a host image or VM, be sure to remove this file, so that you don't end up with duplicate GUIDs. The file will be regenerated on the next run.

8.1.4. Configure Fleets And Deploy Changes

Learn how to configure Fleets and Subfleets, then commit and deploy the changes.

Cribl Edge provides you with the ability to configure Fleet and Subfleets. At the Fleet and Subfleet level, you can add, update, and remove:

- Sources
- Destinations
- Routes
- Pipelines
- Packs

To access these configuration options:

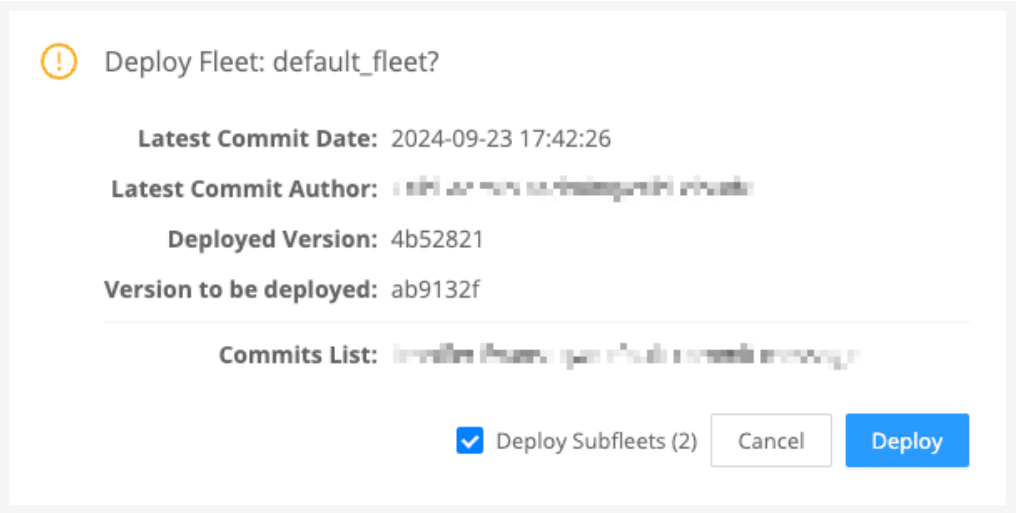
- Click the **Options (•••)** menu on a Fleet/Subfleet, then click **Configure**. This takes you to **Collect**, where you can use QuickConnect to quickly set up data collection Sources and hook them up to Destinations.
- Click a Fleet **Name**, then click **Collect** or use the **More** drop-down.

When you make changes to a Fleet, you must commit and deploy the changes in order for the Edge Nodes to receive the updated configs.

Example Configuration Deployment Workflow

Here's a typical workflow for deploying Edge configurations:

1. Make configuration changes on a Fleet.
2. Save your changes.
3. Commit (and optionally push).
4. Locate your desired Fleet and click **Deploy**.



Once you save and commit your configuration changes, you can deploy the updated configs to the Edge Nodes. You deploy new configurations at the Fleet level.

Deploy Subfleets

To make new configurations visible and available to Subfleets, you must first **Commit** the changes within parent Fleets' configurations.

When you commit changes to a parent Fleet, you have the option to **Deploy Subfleets** at the same time.

When you **Deploy Subfleets**, the Subfleets will receive the new inherited configuration. For guidelines on deploying to a large number of Edge Nodes, see Leader Scalability.

Deploy Subfleets

Edge Nodes that belong to the Fleet/Subfleet will start **pulling** updated configurations on their next check-in with the Leader.

Can't log in to the Edge Node as Admin User?

When an Edge Node pulls its first configs, the admin password will be randomized, unless specifically changed. This means that users won't be able to log in on the Edge Node with default credentials. For details, see User Authentication.

Configuration Files

On the Leader, a Fleet's configuration resides in this directory:

`$CRIBL_HOME/groups/<FleetName>/local/edge/`

Where each Fleet gets its own directory that contains a collection of `.yml` config files.

The managed Edge Node pulls configs and extracts them under:

`$CRIBL_HOME/local/edge/.`

Some configuration changes will require restarts, while many others will require only reloads. For details, see Configurations and Restart. Upon restart, individual Edge Nodes might temporarily disappear from the Leader's **Nodes** tab, before reappearing.

Notable Environment Variables for a Fleet

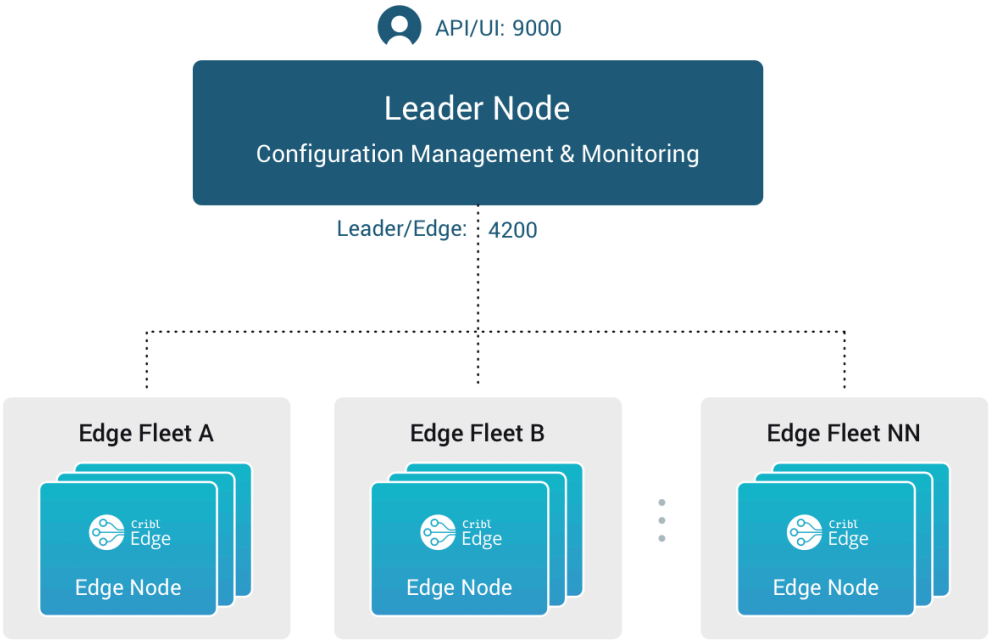
- `CRIBL_DIST_LEADER_URL` - URL of the Leader Node. Format: `<tls|tcp>://<authToken>@host:port?group=default_fleet&tag=tag1&tag=tag2&tls.<tls-settings below>`.
  Example: `CRIBL_DIST_LEADER_URL=tls://<authToken>@leader:4200`
  Parameters:
  - `group` - The preferred Fleet assignment.
  - `resiliency` - The preferred Leader failover mode.
  - `volume` - The location of the NFS directory to support Leader failover.
  - `tag` - A list of tags that you can use to assign the Edge Node to a Fleet.
  - `tls.privKeyPath` - Private Key Path.
  - `tls.passphrase` - Key Passphrase.
  - `tls.caPath` - CA Certificate Path.
  - `tls.certPath` - Certificate Path.
  - `tls.rejectUnauthorized` - Validate Client Certs. Boolean, defaults to `false`.
  - `tls.requestCert` - Authenticate Client (mutual auth). Boolean, defaults to `false`.
  - `tls.commonNameRegex` - Regex matching peer certificate > subject > common names allowed to connect. Used only if `tls.requestCert` is set to `true`.
- `CRIBL_DIST_MODE` - Set to one of: `managed-edge` (managed Node), `leader` (Leader instance), or `edge` (single instance).
- `CRIBL_HOME` - Auto setup on startup. Defaults to parent of `bin` directory.
- `CRIBL_CONF_DIR` - Auto setup on startup. Defaults to parent of `bin` directory.
- `CRIBL_DIST_LEADER_BUNDLE_URL` - AWS S3 bucket (format: `s3://${bucket}`) for remote bundle storage.
- `CRIBL_TMP_DIR` - Defines the root of a temporary directory.
  Sources use this directory to stage downloaded Parquet data. The format of derived temporary directories is: `$CRIBL_TMP_DIR || os.tmpdir())/cribl_temp[/<componentPath>/<PID>]`
  ... where: `<componentPath>` = `<inputId>`; `<PID>` = Worker Process ID; and `os.tmpdir()` defaults to `/tmp` on Linux. Override that default using this `CRIBL_TMP_DIR` environment variable.
- `CRIBL_VOLUME_DIR` - Sets a directory that persists modified data between different containers or ephemeral instances.
- `CRIBL_DIST_WORKER_PROXY` - Communicate to the Leader Node via a SOCKS proxy. See `CRIBL_DIST_WORKER_PROXY` for more details.

8.1.5. Recover A Deleted Fleet

Learn how to recover deleted Fleets in Cribl Edge.

If you delete a Fleet, you can no longer access its **Version Control** menu. As a result, you also lose the option to directly recover the Fleet.

However, you can still recover a deleted Fleet using the command line. This method works only in on-prem environments. To revert the deletion commit:



1. Stop the Cribl server.
2. Using a command line interface, look at the version control history for the Leader Node and identify the commit which deleted the Fleet.
3. Revert to the last commit before the Fleet was deleted.
4. Restart the Cribl server.

8.2. Edge Nodes

Learn how Edge Nodes and Leader Nodes work together

The Leader Node has two primary roles:

1. Serves as a central location for Edge Nodes' operational metrics. The Leader ships with a monitoring console that has a number of dashboards, covering almost every operational aspect of the deployment.
2. Serves as a central location for authoring, validating, deploying, and synchronizing configurations across Fleets.

Leader Node/Edge Nodes relationship

Network Port Requirements (Defaults)

- UI access to Leader Node: TCP 9000.
- Edge Node to Leader Node: TCP 4200. Used for Heartbeat/Metrics/Leader requests/notifications to clients (such as live captures, teleporting, status updates, and config bundle notifications).
- Edge Node to Leader Node: HTTPS 4200. Used for config bundle downloads.
- Edge Node bootstrapping/update: HTTPS 443.

Leader/Edge Node Communication

Edge Nodes will send a heartbeat to the Leader every 60 seconds. This heartbeat includes information about the Nodes and a set of current system metrics. The heartbeat payload includes facts - such as hostname, IP

address, GUID, tags, environment variables, and current software/configuration version - that the Leader tracks with the connection.

When an Edge Node checks in with the Leader:

- It sends a heartbeat to Leader with “facts” about itself.
- The Leader uses Edge Node’s facts and Mapping Rules to map it to a Fleet.
- The Edge Node pulls its Fleet’s updated configuration bundle, if necessary.

Edge Nodes that don’t maintain their connection to the Leader will eventually disappear from the Edge Nodes page.

The Leader is unaware of the platforms on which Edge Nodes within a Fleet run. So the ConfigHelper omits platform-specific limitations. Therefore, when you manage Edge Nodes on heterogeneous platforms, create OS-specific Fleets (for example, a Windows Fleet, a macOS Fleet) and mapping. See Design Fleet Hierarchy.

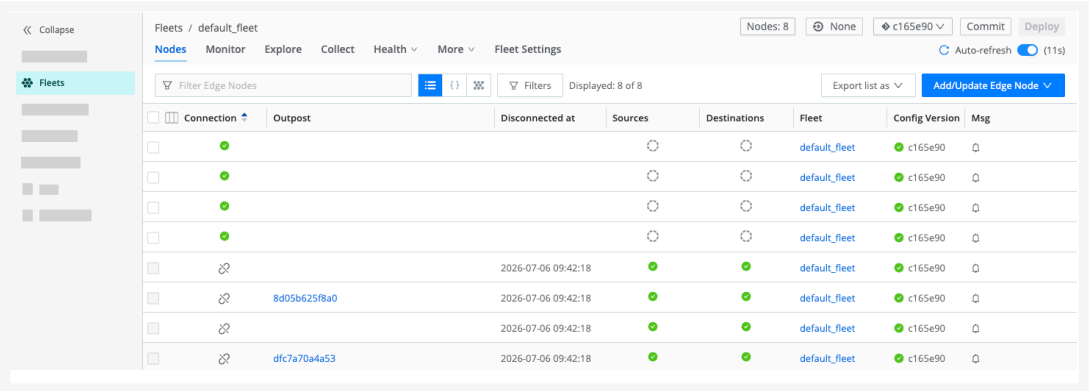
Leader Disconnection and Telemetry

Cribl Edge is built to keep your data flowing smoothly, even if it temporarily loses connection with the Leader Node. This means you won’t experience disruptions during network hiccups or if the Leader is briefly unavailable. Cribl Edge periodically sends telemetry to verify its license with Cribl’s servers. This is different from its connection to the Leader. If the telemetry fails for an excessive time, processing might be interrupted.

This telemetry is disabled for Cribl.Cloud-managed Edge Nodes.

Cribl Edge Nodes that are disconnected from the Leader will resume operation after an Edge restart, using their last settings and license. In most cases, an Edge Node gets its license from the Leader and saves a copy. If the Node restarts while the saved copy is valid, it will use the saved license. If the saved copy is expired, missing, or unreadable, it will use the Free license until it connects to the Leader again. For details, see Licensing on Managed Node Startup.

While the Edge Node is disconnected, you won’t see real-time updates in the main monitoring dashboard, and the Node won’t receive any new configuration changes.



8.2.1. Manage Edge Nodes

How to manage Edge Nodes in a Fleet and perform tasks like teleporting and exporting a list of Nodes.

View Edge Node Status Information

The **Edge Nodes** page provides status information for each Edge Node in the selected Fleet, as well as a UI for adding and updating Nodes.

In Cribl Edge, select **Edge Nodes** from the sidebar.

Edge Nodes page showing a list of Nodes

Monitor Edge Node Connectivity

You can track which Edge Nodes are connected to the Leader Node in the **Edge Nodes** page. Disconnected Edge Nodes show an icon in the **Connection** column and will have information about the time the Leader last received their heartbeat.

By default, Cribl Edge will retain information about disconnected Nodes between restarts. To change this behavior on-prem, toggle **Disable Node persistence** on in **Global Settings** > **System** > **General Settings** > **Limits** > **Other**. This will also affect Cribl Stream Workers.

Disable Node persistence is a deprecated setting that will be removed in a future version. Toggling **Disable Node persistence** will restart the Leader Node.

You can configure how long the Leader should keep track of disconnected Nodes by configuring the **Time to keep disconnected Nodes** Fleet setting (**General Settings** > **Fleet Configuration**). By default the Leader retains information about disconnected Nodes for one day. You can set it to any value between 0 (which means Nodes are removed within a few minutes) and 90 days.

For Fleets with Edge Nodes that frequently restart with a new GUID, such as those in a Kubernetes environment, Cribl recommends setting the **Time to keep disconnected Nodes** to 0.

The **Time to keep disconnected Nodes** setting is not inherited by Subfleets.

Monitor Connectivity of Older Edge Nodes

A Leader Node that is running version 4.13 or newer can monitor Edge Nodes that are using an older version. However, Cribl always recommends upgrading your Edge Nodes to the newest available version.

Monitor Source and Destination Health on Edge Nodes

You can monitor and track the health of Sources and Destinations associated with an Edge Node on the **Edge Nodes** page. This is useful when you have a large number of Nodes, and want to quickly identify and troubleshoot issues with Sources and Destinations.

To open the Node Info page and view specific monitoring information, select a health icon. For more information, see Track Data Activity for an Edge Node.

Filter Nodes in the List

You can filter the Edge Nodes that appear in the list using the **Filters** option. For details, see Filter Edge Nodes.

Find Edge Nodes Running in a Container

Edge Nodes running in a container report additional metadata about the container to the Leader. This helps you quickly identify which of your Edge Nodes are running in a container from the Leader UI and map them to the appropriate Fleets.

When Cribl Edge is running in a container, you will see the `hostOs` property in events collected by the System State Source. This object will contain properties about the container when they're available, such as:

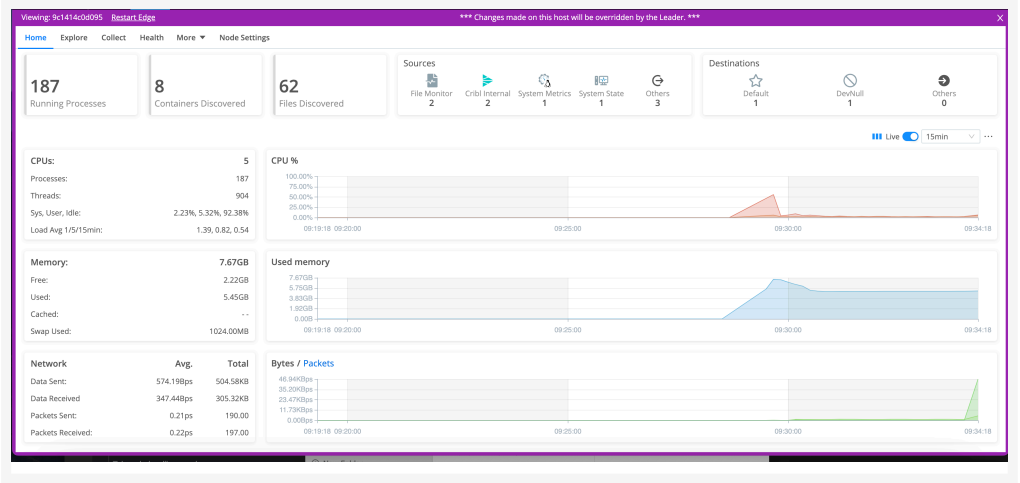
- `arch`
- `cpu_count`
- `cpu_speed_mhz`
- `cpu_type`
- `interfaces`
- `memory`
- `platform`
- `release`
- `hostname`
- `timezone`

From the **Mappings** menu, you will also see the `hostOs` property in the **Edge Node info** panel. This object will include the `id`, `addresses`, and `version` of the container when available.

`interfaces` is a set of key-value pairs that contain an array of CIDR values.

Export a List of Edge Nodes

To export the list of Edge Nodes, click the **Export list as** drop-down. Select `JSON` or `CSV` as the export file format. If you filter the list before exporting, the exported list will maintain that filter. You can export the entire list by removing all filters.



Teleport into an Edge Node

On the Edge Node page, select **Teleport** to teleport from the Leader into the Node. Here, you can explore the metrics and log data that the Node has discovered automatically, and can manually discover and explore other data of interest.

You can use the discovered data to perform root-cause analysis, to troubleshoot, and to restart the host. If you want to monitor and troubleshoot the Node data without teleporting, check out the Node Info Panel.

The page displays metadata for the Node, and below it, graphs of system activity. A magenta border indicates you are remotely viewing a host, and identifies the host's name.

Click **Restart Edge** to restart the Node. To return to the **Edge Nodes** page, click the **X** close button on the upper right.

Teleporting into an Edge Node

Changes that you make on an Edge Node will not propagate to the Leader. Also, the Leader will override any changes that you make directly on a Node.

Add Tags to Edge Nodes in Teleport View

You can add tags to an Edge Node you've teleported into. Tags help the Leader map an Edge Node to a Fleet. Note that changing the tags on a Node can cause the Leader to map the Node into a new Fleet.

1. Teleport into an Edge Node.
2. Navigate to **Node Settings** then **Distributed Settings**.
3. Enter tags for this Node and select **Save**.

If your Edge Nodes are managed by Cribl.Cloud, you'll need to accept the confirmation modal. Keep in mind that changing the tags on an Edge Node might cause it to be assigned to a different Fleet by the Leader.

You can't change tags for Edge Nodes set up using the `CRIBL_DIST_MASTER_URL` environment variable (instead of the `instance.yml` file). This is because these types of Edge Nodes are typically temporary, so any tag changes would not be saved when the Edge Node restarts. If you need tags that persist, configure your Edge Nodes using the `instance.yml` file.

Troubleshooting the Edge Node List

If you see unexpected results in the **Edge Nodes** list, keep in mind that:

- Edge Nodes that don't maintain their connection to the Leader will eventually disappear from the Edge Nodes page.
- For a newly created Fleet, the **Config Version** column can show an indefinitely spinning progress spinner for that Fleet. This happens because the Edge Nodes are polling for a config bundle that hasn't been deployed. To resolve this, click the **Deploy** option to force a deploy.
- For details on collocating multiple Cribl products, see Cribl Edge and Cribl Stream on the Same Host.
- For details on overriding default ports, see Overriding Default Ports.

8.2.2. Add And Update Edge Nodes

Learn how to add and update Edge Nodes in Cribl Edge

Cribl Edge provides you with the ability to add and update Edge Nodes from the UI. To access this function, select **Edge Nodes** in the sidebar. On the **Edge Nodes** page, select **Add/Update Edge Node**.

Options to add or update an Edge Node

Here, you can update an existing Node with new configurations or add a new Node using the bootstrap script.

Add a New Edge Node with a Bootstrap Script

Using the Cribl Edge UI, you can add Edge Nodes to your existing deployment. To do this, change the environment-specific fields, then copy and paste the resulting bootstrap script into a CLI. The script updates in real-time as you change the fields. The result is a new Edge Node configured with the options you chose.

You can also copy the bootstrap script and modify it instead of manually editing the fields in the UI, as well as concatenate multiple scripts for different use cases.

Host Communication Prerequisites

To enable the Leader to manage the Edge Nodes, you must enable ongoing outbound communication to the Leader's port 4200 on all Edge Nodes hosts.

While the bootstrap script runs, firewalls on each Nodes's host must also allow outbound communication on the following ports:

- Port 443 to `https://cdn.cribl.io`, when **Install package location** is set to `Cribl CDN`.
- Port 443 to a Cribl.Cloud Leader.
- Port 9000 to an on-prem Leader.

Add an Edge Node

1. From the Cribl Edge sidebar, select **Edge Nodes**.

2. On the **Edge Nodes** page, select **Add/Update Edge Node**.
3. Select your OS, then select **Add**.

Linux Windows macOS

1. Fill and modify the deployment option fields:
   - In **Leader or Outpost hostname/IP**, verify or update the Leader URI.
     If you want the Edge Node to connect through an Outpost, provide the protocol, Outpost hostname, and port in this field, typically: `https://<outpostHost>:4200`
   - The **Install package location** defaults to `Cribl CDN`. If desired, change this to `Download URL`.
   - Enter the value of a **Provisioning token**. See Create a New Provisioning Token for information on how to create one.
     Optionally, if your deployment still has an active legacy token, select **Use Legacy Token**. This option is only available for Admin users.
   - As needed, correct the target **Fleet**
   - As needed, correct the **User** and **User Group** to run Cribl as.
   - As needed, correct the **Installation directory**.
2. Optionally, add **Tags** that you can use for filtering and grouping in Cribl Edge. Use a tab or hard return between (arbitrary) tag names.
3. Copy the resulting script to your clipboard.

Finally, to add the Edge Node, paste the script onto the command line of your Edge Node and execute it.

If your script successfully added the Edge Node, you will see it in the **Edge Nodes** list.

Update an Edge Node with a Bootstrap Script

You can use bootstrap scripts to update the configuration of your Edge Node.

Updating adjusts the Leader connection details for the Node, retaining its version. To upgrade the Edge Node - that is, install a newer version of the software - see Upgrading.

Select Update Script Type

When you update a Linux or macOS Node, you must select a **Script type** from the drop-down. Choose between environment variable or CLI to add/update an Edge Node.

With **Environment variable** selected:

1. Hover over the **Script** field and select the copy icon.
2. To allow Edge to update or add Edge Nodes, configure the environment variable with a restart command.

- You can add the restart command to the environment variable in the Linux systemd service unit file, so you don't have to insert the environment variable each time you restart the server:

    1. In the CLI, enter `sudo systemctl edit cribl-edge` on the Edge Node.
    2. Add `ENVIRONMENT="CRIBL_DIST_LEADER_URL=tcp://<authToken>@<leaderHostname>:4200"` to the opened file and save it.
    3. Reload the service with `sudo systemctl restart cribl-edge`.

- Or, you can use `./cribl restart`, but you will have to insert the environment variable each time you restart the server:

```
CRIBL_DIST_LEADER_URL=tcp://<authToken>@<leaderHostname>:4200 ./cribl restart
```

Copy

With **CLI** selected:

1. Hover over the **Script** field and select the copy icon.
2. Paste the copied script into a CLI and run it.

Edge Node Updates Using Fleet Version Settings

The script you generate using the **Add/Update Edge Node** window ensures accurate updates by using the specified Target Software Version for your Fleet, enhancing the reliability and consistency of updates across all supported environments: Docker, Kubernetes, Linux, macOS, and Windows.

For Docker and Kubernetes:

- If you don't specify a target version, the command uses the Leader version's image and version flag respectively, by default.
- If you specify a target version, the command parses the Fleet version and maps it to the appropriate CDN URL or version flag.

For Linux and macOS environments:

- The existing script behavior from the Leader manages the updates unless you specify a target version, in which case the script uses that version.

For Windows:

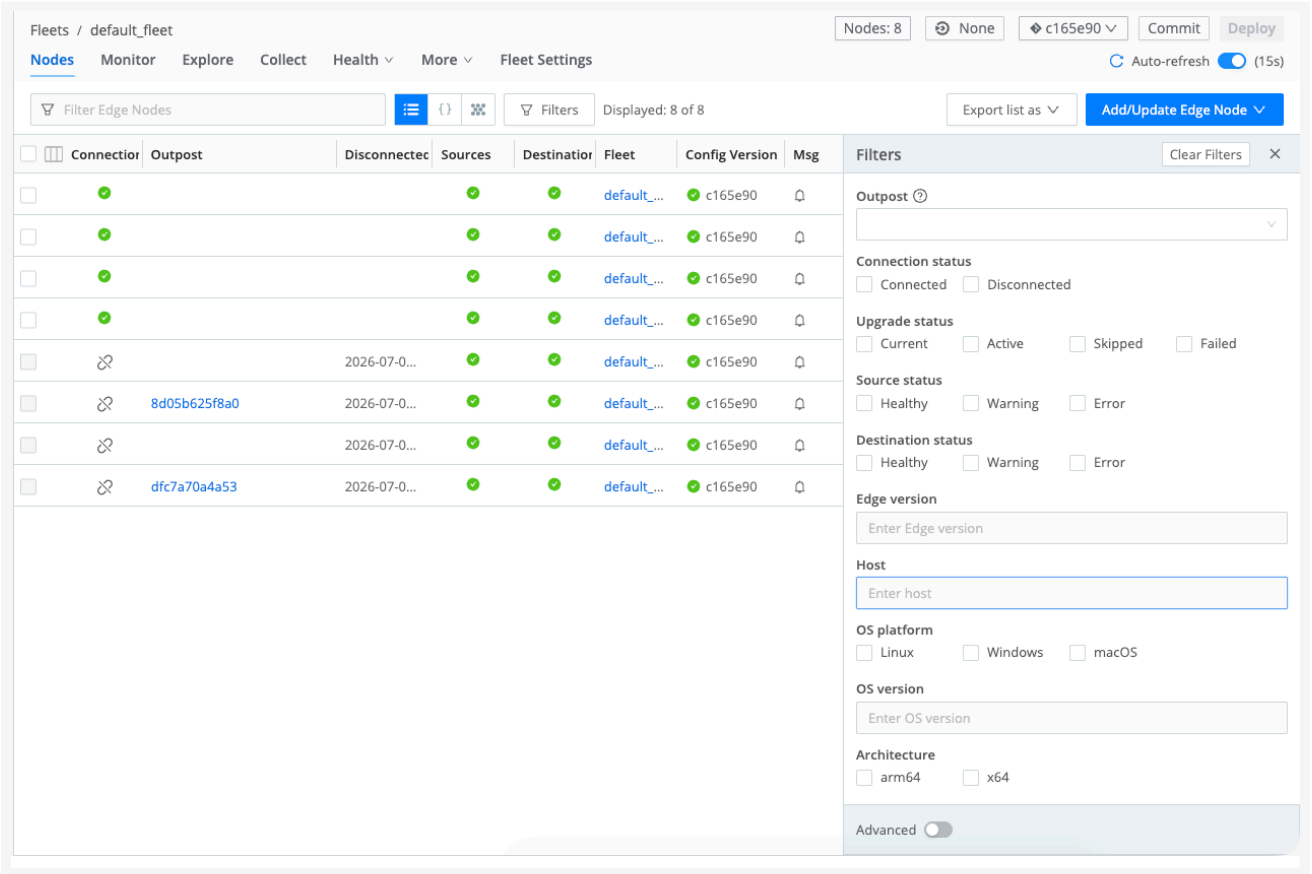
- The default behavior uses the Leader Version from the CDN, while specifying a target version directs the command to parse the Fleet version and map it for MSI download via the CDN.

This mechanism ensures a more consistent and reliable deployment process, maintaining version control and improving update accuracy across all environments.

8.2.3. Filter Edge Nodes

Learn how to filter large lists of Edge Nodes

When your Cribl Edge deployment has a large number of Nodes, you may want to filter your Node list down to a manageable subset of Nodes. This can help you monitor your Edge Nodes and troubleshoot any issues.



For example, you may want to view all of the Edge Nodes that are experiencing upgrade issues. Or, you may need to update the configuration of Nodes that are running a certain operating system version, but you don't know which Fleets they belong to.

The **Filters** option allows you to apply filter criteria to your Node list, so you can quickly find Nodes by OS Platform, IP address, install type, version and more.

Access Node Filters

In Cribl Edge, you can filter Edge Nodes in two places:

- In a specific Fleet in the Edge Nodes list. Navigate to **Fleets**, then select a Fleet.
- On the list of all Edge Nodes. Navigate to **Edge Nodes** from the sidebar.

The Filters option

Filter Modes

You can choose between the default form-based mode and **Advanced** mode when you create a Node filter. Form-based mode contains the preconfigured fields and checkboxes you see when you select **Filters**.

For a table of the options and their definitions, see Form-based Filter Options.

Advanced mode is a JavaScript input field where you can create your own filter, referencing the JSON objects that are associated with an Edge Node.

You can edit the JavaScript by typing in the **Expression** field, but doing so disables the form-based filters unless you undo the changes. To revert back to the form-based filter, select **Undo changes**.

Some filter combinations will never return any results - for example, **OS platform** set to Linux and **Install type** set to MSI, since MSI is only used for Windows installations.

Create an Edge Node Filter

The **Filters** option lets you group a list of Nodes by criteria such as OS platform, IP address, install type, version, and more.

To create an Edge Node filter:

1. Navigate to a list of Edge Nodes, either from the **Nodes** tab in a Fleet or from the **Edge Nodes** sidebar.
2. Select **Filters** to open the Filters panel.
3. Create a filter by selecting from the Node Filter Options, or toggle **Advanced** on to write your own filter using JavaScript.
4. Once you have selected filter criteria, you can use the **Filter Edge Nodes** field to further narrow down the list of visible Nodes.
5. Select **Clear filters** to undo your selections in the Filters panel. This does not clear the **Filter Edge Nodes** field.

Share a Filter

To share a filter with another Cribl user:

1. Select the **Filters** button and create a filter.
2. Select the link icon to copy the filters to your clipboard, or copy the browser URL.
3. Now you can share the link with another user.

Filters are Workspace-specific, so they will only work within the Workspace where you created them.

Form-based Filter Options

You can choose from a set of preconfigured, form-based filter options, and each has an associated JavaScript property. You'll see the JavaScript property in the **Expressions** field when you toggle **Advanced** on.

Field	Description	JavaScript property
Fleet	Find Nodes based on their Fleet assignment. Visible when filtering from the **Edge Nodes** page.	`group=='<fleet>'`
Outpost	Which Outpost the Edge Node is connected to.	`info.outpost.host.toLowerCase().includes(<outpost-host>)`
Connection status	Whether the Edge Node is currently connected to the Leader.	`(disconnected === <true|false>)`
Upgrade status	The upgrade status of the Edge Node. • **Current**: When the Fleet has a Target Version set, this filters Nodes that are running the same version as the Fleet or a newer version. • **Active**: Nodes that are actively upgrading. • **Skipped**: Nodes with a skipped upgrade.	`nodeUpgradeStatus.state`

Field	Description	JavaScript property
	• **Failed**: Nodes that failed to upgrade.	
Source status	The health status for each Source associated with the Nodes.	`(lastMetrics['health.inputs'])`
Destination status	The health status for each Destination associated with the Nodes.	`(lastMetrics['health.outputs'])`
Provisioning Token	Identifier of the token used to provision the Nodes.	`provisioningTokenId`
Edge version	Enter a semantic version of Cribl Edge. For example, 4.1.0.	`info.cribl.version.toLowerCase()`
Host	The host of the Edge Node. You can type in any part of the host string.	`info.hostname.toLowerCase().includes(<host>)`
OS platform	The operating system platform that the Edge Node is running on.	`(info.platform === '<os-platform>')`
OS version	The version of the operating system the Edge Node is running on. For example, Windows 10.	`info.release.toLowerCase().includes('<OS version>')`
Architecture	The processor architecture for the Edge Node.	`(info.architecture === '<architecture>')`

Field	Description	JavaScript property
IP address	The IP address of the Edge Node. Entering a partial value returns all Nodes with matching values. For example, entering `17` will return all Nodes that have `17` somewhere in the address.	`info.conn_ip.toLowerCase().includes('<ip-here>')`
Install type	The installation type for the Node. Select RPM, DEB or Container. Useful for determining which Nodes can't be upgraded by the Leader.	`(info.env.CRIBL_INSTALL_TYPE === '<type>')`

Advanced Filter Options

You can use JavaScript expressions in the Advanced filter to surface more specific, granular search results. You can use any Edge Node properties and types in the **Expression** field.

The JavaScript expression should be in this format, in hierarchical order from parent to child:

```
parent.child.grandchild === 'value'
```

For example:

```
info.aws.type === 't2.medium'.
```

You can also automatically populate the Advanced filter **Expression** field:

1. Select the **JSON view** button.
2. Expand the Node row and select the Node property, then any applicable child properties.
3. Type directly in the **Expression** field to fine-tune the filter.

Filter Edge Nodes in JSON view

Supported Edge Node Properties

You can filter on these Edge Node properties using a JavaScript expression. Remember to separate the parent and child properties using a period `.`.

```
"deployable": "boolean (Whether the Node can be deployed)",
"disconnected": "boolean (Whether the Node is connected to the Leader)",
"workerProcesses": "number (Number of Worker Processes for this Node"),
"id": "string",
"status": "string (Healthy)",
"group": "string (Fleet name)",
"info": {
  "hostname": "string",
  "platform": "string (OS Platform; linux, win32 etc.)",
  "architecture": "string (CPU Architecture; arm64, x64 etc.)",
  "release": "string (OS Kernel release)",
  "cpus": "number (Number of CPU cores)",
  "totalmem": "number (Memory in bytes)",
  "node": "string (NodeJS version)",
  "cribl": {
    "startTime": "number (Unix time in msecs when the process started)",
    "guid": "string (unique instance ID)",
    "installType": "string",
    "tags": "string array (tags configured on the Node)",
    "version": "string (Edge version)"
  },
  "freeDiskSpace": "number (Free disk space in bytes)",
  "totalDiskSpace": "number (Total disk space in bytes)",
  "kube": {
    "source": "string (always cluster)",
    "node": "string (Node name where this Pod is running)",
    "pod": "string (Pod Name)",
    "namespace": "string (namespace, always cribl)",
    "owner": {
      "kind": "string (DaemonSet)",
      "name": "string (cribl-edge)"
    },
  "conn_ip": "string (this is the IP that Cribl Leader sees; different from actual
  "localTime": "number (local Unix time on the Node in msec)"
  },
},
"lastMsgTime": "number (time when Node sent the last message in msec)",
"firstMsgTime": "number (time when Node sent the first message in msec)",
"nodeUpgradeStatus": {
  "timestamp": "number (time when Node entered the state below in msec)",
  "state": "number",
  "skipped": "number (if set, this Node is skipped by thr Leader's automatic upgrad
`
```

```
}
"lastMetrics": {
  "edge.dropped events": "number (events dropped by Node)",
  "health.inputs": "number",
  "health.outputs": "number",
  "total.in_events": "number (total events ingested by Node)",
  "total.out_events": "number (total events sent out by Node)",
  "total.dropped_events": "number (total events dropped by Node)",
  "total.in_bytes": "number (total ingested bytes)",
  "total.out_bytes": "number (bytes Destinations accepted for delivery)"
}
```

Copy

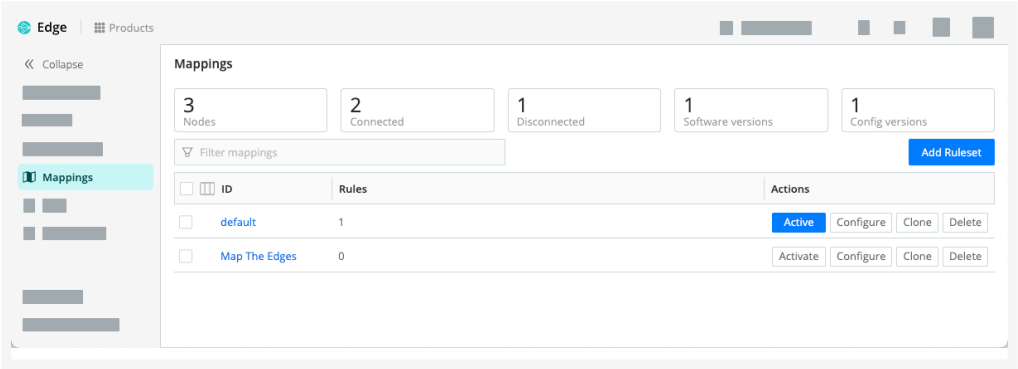
Example Advanced Filter Expressions

You can use these example expressions as a starting point to build your advanced filters.

Edge Nodes with >10 CPUs and >8 GB RAM

Because total memory is reported in bytes, we need to calculate 8GB to bytes before using it in the filter.

```
info.cpus >= 4 && info.totalmem >= 8388608000
```



8.2.4. Map Edge Nodes To Fleets

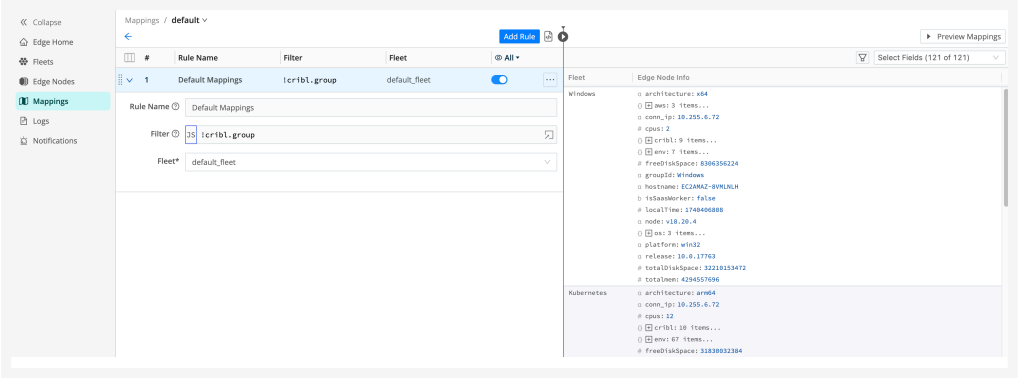
Learn about Fleet Mappings and how to set up a Mapping Ruleset.

Fleet Mappings enable you to assign Edge Nodes to Fleets by applying specific rules defined in Mapping Rulesets. You can map Edge Nodes into Fleets based on geographical location, environment type, operating system, host, and more. This makes centralized configuration management easier for groups of Edge Nodes, and makes it easy for you to add and remove Edge Nodes from Fleets as your deployment scales.

Access Fleet Mappings

Select **Mappings** in the sidebar to display status and controls for the active Mapping Ruleset.

Mappings status/controls



This page displays a maximum of 10,000 results.

Mapping Rulesets

A Distributed deployment of Cribl Edge starts off with a predefined `default` Mapping Ruleset.

Within a Ruleset, a list of rules evaluate Filter expressions on the information that Edge Nodes send to the Leader.

The order of rules in a Ruleset matters. The **Filter** section supports full JS expressions. The Ruleset matching strategy is first-match, and one Edge Node can belong to only one Fleet.

Managing Ruleset page

Only one Mapping Ruleset can be active at any one time, although a ruleset can contain multiple rules. The system should contain at least one defined and present Fleet.

Create a Mapping Ruleset

To create a Mapping Ruleset:

1. In the sidebar, select **Mappings**.
2. Select **Add Ruleset**.
3. Give the **New Ruleset** a unique **ID** and select **Save**.

   The **ID** for a new Ruleset can contain only letters, numbers, underscores, and dashes. Older Ruleset IDs might include other characters.

4. Select **Configure** and start adding rules with **Add Rule**.

As you build and define rules, the Preview pane will display how Edge Nodes will map to Fleets with your defined rules.

You must activate a Ruleset before the Leader can use it. To activate it, go to **Mappings** and select **Activate** on the required Ruleset. You can also **Configure** or **Delete** a ruleset, or **Clone** a Ruleset if you'd like to work on it offline, test different filters, and so on.

Although not required, you can configure Edge Nodes to send a preferred Fleet name with their payload (found in payload's `cribl.group` key). See Mapping Order of Priority for how this ranks in mapping priority.

Mapping Rule Examples

See some common Mapping Rule examples.

Map Edge Nodes Based on OS

Fleets are not aware of the operating systems their Edge Nodes run on, so they can't take into account limitations such as platform-specific Sources and Destinations.

When you manage Edge Nodes on different systems, Cribl recommends creating OS-specific Fleets.

To map Edge Nodes to Fleets based on their OS, use the `platform` filter.

OS	Filter
Linux	`platform === "linux"`
Windows	`platform === "win32"`
macOS	`platform === "darwin"`

Map Edge Nodes Connected to an Outpost

To map Edge Nodes that connect to an Outpost in a specific Outpost Group, filter on the `outpost.groupname` field, for example:

Filter: `outpost.groupname === 'EU_2'`.

You can also map Edge Nodes by the specific Outpost they connect to by filtering on the `outpost.guid` or `outpost.host` fields, for example:

Filter: `outpost.host === '5ab6c676be6a'`.

Map Edge Nodes Based on Tags

You can use tags assigned to Edge Nodes to map specific Nodes to a Fleet.

To map Edge Nodes that have a specific tag to a Fleet, filter on the `cribl.tags` field, for example:

Filter: `cribl.tags.includes("WinLaptop")`

Find Edge Nodes Running in a Container

Edge Nodes running in a container report additional metadata about the container to the Leader. This helps you quickly identify which of your Edge Nodes are running in a container from the Leader UI and map them to the appropriate Fleets.

When Cribl Edge is running in a container, you will see the `hostOs` property in events collected by the System State Source. This object will contain properties about the container when they're available, such as:

- `arch`
- `cpu_count`

- `cpu_speed_mhz`
- `cpu_type`
- `interfaces`
- `memory`
- `platform`
- `release`
- `hostname`
- `timezone`

From the **Mappings** menu, you will also see the `hostOs` property in the **Edge Node info** panel. This object will include the `id`, `addresses`, and `version` of the container when available.

`interfaces` is a set of key-value pairs that contain an array of CIDR values.

Complex Edge Node Mappings

The mapping filter supports JS expressions and lets you string together more complex filters.

For example, let's assume that you want to define a rule for all hosts that satisfy this set of conditions:

- IP address starts with `10.10.42`, AND Edge Node has more than 6 CPUs, OR:
- `CRIBL_HOME` environment variable contains `DMZ`.

Filter: `(conn_ip.startsWith('10.10.42.') && cpus > 6) || env.CRIBL_HOME.match('DMZ')`.

Collect AWS EC2 Instance Tag Metadata

If Cribl Edge is connected to an AWS EC2 instance, you will see metadata for AWS instance tags in the **Mappings** tab. You can use tags to map EC2 Nodes to the correct Fleet.

For Cribl Edge to obtain tags, you **must** allow access to tags in the EC2 instance metadata.

Mapping Order of Priority

Priority for mapping to a Fleet is as follows: Mapping Rules > Fleet (`cribl.group`) sent by Edge Node > `default_fleet` Fleet.

- If a Filter matches, use that Fleet.
- Else, if an Edge Node has a Fleet defined, use that

9. Workspaces

Workspaces offer a multi-tenancy capability, enabling you to create multiple isolated instances in your Cribl.Cloud Organization. This lets you strengthen your security, and fulfill compliance and isolation requirements.

Each Workspace offers a dedicated virtual private cloud (VPC) that acts as a separate environment within your Organization. Workspaces do not share product configurations, resources, or data flows, and each has a separate Leader Node. They do share a layer of access control (Organization-level Permissions and SSO configuration), as well as API credentials, licenses, and billing.

A centralized interface allows you to manage all your Workspaces and control access for Members and Teams to individual Workspaces.

Multiple Workspaces require a Cribl.Cloud Enterprise plan.

An example use case scenario for creating multiple Workspaces is setting up separate environments for different business units in an enterprise. Data management, security, development, and any other units can have their own federated Workspaces, with completely separate Members and Permissions lists. This way, they can work in isolation without risk of interference and with increased focus.

Limitations

The number of included Workspaces depends on your Cribl.Cloud plan:

Plan	Included Workspaces	Additional Workspaces you can add
Standard	1 (the Main Workspace)	N/A
Enterprise	3	Up to 2, at 250 credits each per month

On an Enterprise plan, Organization Owners and Admins can add Workspaces beyond the included allowance. When you have used the 3 included Workspaces, you can add up to two more on the **Manage Workspaces** page for 250 credits each per month.

When you select **Add Workspace**, Cribl.Cloud opens **Accept additional cost?** Select **Accept** to continue, or **Cancel**. The confirmation states that each Workspace you add costs an additional 250 credits per month, reflected in your next billing cycle.

Charges for additional Workspaces appear on your invoice under **Infrastructure**. See Understand Your Monthly Invoice.

In Cribl.Cloud, one credit equals one US dollar. An additional Workspace therefore costs $250 per month, prorated daily. See How Is Cost Calculated?.

Switch Workspaces

When you have access to multiple Workspaces in your Cribl.Cloud Organization, you can switch between them from the top bar in any Cribl product:

1. On the top bar, select your current Workspace name.
2. In the drop-down, select the Workspace you want to switch to.

The drop-down lists **Manage Workspaces** first. Select it to open the Workspace management modal, where you can add, edit, or delete Workspaces.

Below **Manage Workspaces**, the drop-down lists your Workspaces with the current Workspace first, followed by other Workspaces in alphabetical order.

If your Organization has only one Workspace, selecting the Workspace name on the top bar opens the Workspace management modal directly.

Manage Workspaces

To list the Workspaces in the Organization, in the sidebar, select **Workspace** or **Organization** and then **Manage Workspaces**. The list includes the name, ID, description, Cribl Insights retention status, tags, Cribl version number, release channel, and current state for each Workspace in the Organization.

Select a Workspace name or the ellipsis (**. . .**) in the **Actions** column to edit the Workspace name, description, and tags or delete the Workspace.

Release Channels

In Cribl.Cloud, Enterprise customers can assign each Workspace to the Fast, Regular, or Slow release channel.

The Fast release channel publishes new features and services approximately weekly. The Regular release channel (default) follows the standard monthly release cadence. The Slow release channel also updates on a monthly basis but is one version behind the Regular release channel. Cribl sends monthly notifications describing the versions published to each release channel.

Release channels give you self-service control over the upgrade cadence for each Workspace and allow you to validate new Cribl versions in pre-production Workspaces before deploying them to production environments. Release channel selection does not affect your support or product lifecycle.

Release channels determine when Cribl publishes feature and maintenance releases to Workspaces:

- **Fast**: Cribl publishes new features and services to the Fast release channel approximately weekly. Use Fast to preview upcoming functionality and provide feedback before features become available on the Regular release channel.

  > The **Fast** release channel is only available in commercial Cribl.Cloud, not in Cribl.Cloud Government.

- **Regular** (default): Cribl publishes new feature and maintenance releases to the Regular release channel monthly.
- **Slow**: Cribl publishes new feature and maintenance releases to the Slow release channel one month after the corresponding Regular release enters production.

If Cribl publishes a hotfix to the Regular release channel within the previous two weeks, Cribl delays the Slow release channel update until the following month.

Cribl does not update the Slow release channel in November or December.

Cribl might deliver critical security and other emergency updates outside the normal release channel schedule. In these cases, to protect customer environments, Cribl might update Workspaces assigned to the Slow release channel to the same version as Workspaces assigned to the Regular release channel.

Change the Release Channel for an Existing Workspace

To change the release channel for an existing Workspace:

1. On the top bar, select the current Workspace name, then select **Manage Workspaces**.
2. Next to the Workspace that you want to update, select **Settings** in the **Actions** column.
3. On the **Details** page, select the **Release Channels** tab.
4. Select **Fast**, **Regular**, or **Slow**.
5. Select **Save**.

Cribl does not immediately change the Workspace version when you change its release channel. The Workspace stays on its current version until the next scheduled upgrade cycle.

Cribl does not downgrade a Workspace when you change it to the Slow release channel. Cribl does not support rolling back Workspaces to older versions.

For hybrid deployments, do not upgrade Worker Nodes in a customer-managed Worker Group or Edge Nodes to a version newer than the Leader Node version. For version compatibility requirements, see Supported Version Differences Between Leader and Workers and Supported Version Differences Between Leader and Edge Nodes.

View Workspace Details

Workspaces provide a set of information that you can use when configuring data flow through their Edge Nodes.

View Access Details

To view detailed access information of your Workspace, in the sidebar, select **Workspace** and then **Access**.

This page presents a summary of information about your Cribl.Cloud Organization, as well as the **Cribl.Cloud URL** for the current Workspace.

Cribl.Cloud URL

Cribl.Cloud URL is a static address associated with the load balancer that is in front of the Leader. Customer-managed (hybrid) Edge Nodes will connect to this address on port 4200, while the Leader UI is served from this address on port 443.

You can use this URL for certain API calls and certain Collection operations coordinated by the Leader.

Static External IPs for the Leader

The **Leader NLB IPs** field in **Workspace** > **Access** lists the IPs for the Leader Network Load Balancers associated with the Workspace.

Typically, only 2 of the 3 addresses will be active (returned by DNS) at any time, while the inactive address is swapped in during infrastructure maintenance events.

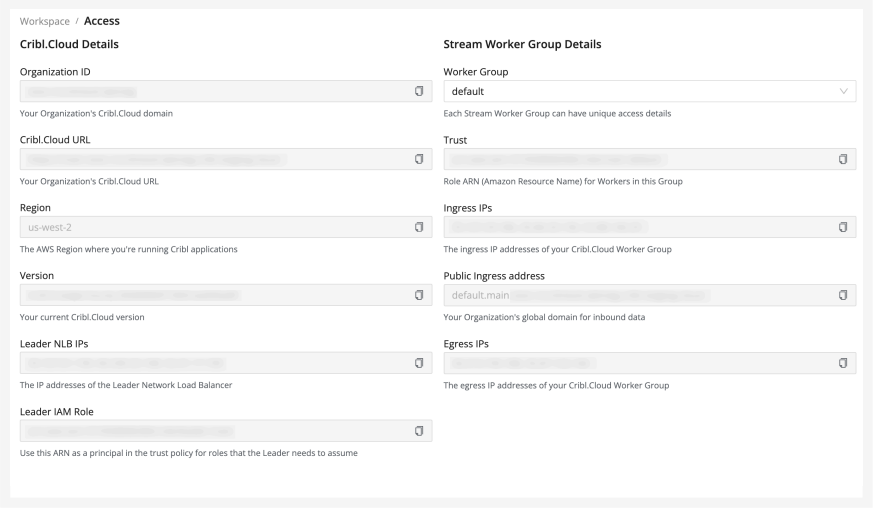
You can add all those IPs to your firewall allowlist to ensure that the load balancers are accessible across your hybrid deployment.

Stream Worker Group Details

Stream Worker Group Details provides information about Cribl-managed Worker Groups in Cribl.Cloud, if any are provisioned.

If no Worker Group is provisioned, you can select **Provision Now** to provision infrastructure for the Group. After a lag, the Group will be ready to process data, and this modal's remaining fields will populate.

For a provisioned Worker Group, you see the following information:



Field	Description
Trust	AWS IAM role ARN for Cribl-managed Workers in this Worker Group. On an AWS-based Worker Group, use this ARN as the principal in AWS trust policies when configuring cross-account access. Azure-based Worker Groups also display an ARN but do not have AWS credentials. The ARN in the **Trust** field is not usable in your AWS account.

Field	Description
Ingress IPs	The IPv4 addresses of Worker Groups' load balancers, also used when receiving data from Push Sources. These addresses will remain constant, so you can build firewall rules around them. Three Ingress IPs are provided for each Worker Group, one on each Availability Zone, assuming the Group has at least three Workers. In a Worker Group of fewer than three Workers, one of the IPs will be inactive.
Public Ingress address	Each Group's domain for inbound data. This address prepends the Group name to the Organization's global domain name. It does not append ports per data type - you can obtain these from the Data Sources tab.
Egress IPs	The public IP addresses of your Cribl.Cloud Organization. These addresses are Group-specific. By default they are dynamic: Cribl will occasionally update them when we need to rescale core infrastructure. If you enable static egress for the region, these addresses stay stable so you can add them to firewall and Destination allowlists.

Public Ingress address and **Egress IPs** are used for both outbound connections from the Workers and Pull Sources.

Because individual **Ingress IPs** can become inactive, Cribl recommends that you send your data to the **Public Ingress address** instead of directly to IPs.

By default, egress IPs are not static. To keep outbound traffic in a region on a stable set of IPs for Destination and firewall allowlists, enable Static Egress IP on **Workspace** > **Connections**.

Access Details modal for a provisioned Group

Configuring Stream Groups (beyond the `default` Group) requires a certain plan. For details, see Pricing. For details about creating and provisioning Groups, see Cribl.Cloud Worker Groups.

View Data Sources

To view detailed access information about a Workspace's Data Sources, in the sidebar, select **Workspace** and then **Data Sources**.

The **Data Sources** page lists ports, protocols, and data ingestion inputs that are open and available to use, including pre-enabled Sources. Use the **Group** drop-down to filter these details per Cribl-managed Worker Group in Cribl.Cloud. For details, see Available Ports and TLS Configurations.

For each existing Source listed here, Cribl recommends using the preconfigured endpoint and port to send data into Cribl Stream.

Get ARN

To get the Worker role ARN for a Workspace, in the sidebar, select **Workspace**. In the **Stream Worker Group Details** section, select a Worker Group and copy the value of the **Trust** field.

You can use this **Worker ARN** as the principal in the trust policy for an AWS account IAM role that Cribl Workers will assume. Attaching this trust relationship enables the `AssumeRole` action, providing cross-account access. For usage details, see the AWS Cross-Account Data Collection topic, **Account B Configuration** section.

This option applies only to AWS-based Cloud Workers. You cannot use this technique to enable access for Azure-based Worker Groups or to customer-managed hybrid Workers.

Set Up ACL

To set up Access Control List (ACL) Rules, in the sidebar, select **Workspace** and then **Access Control List**.

ACL Rules (IPv4 CIDR ranges) let you restrict data sent to your data sources. The Rules you define here are global to all Cribl-managed Worker Groups in Cribl.Cloud in the current Workspace. You can set up a maximum of 9 ACL Rules.

The default `0.0.0.0/0` rule (modifiable) imposes no limits. End a rule with `/32` to specify a single IP address, or with `/24` to enable a whole CIDR block from `x.x.x.0` to `x.x.x.255`.

Select **Save** after adding, modifying, or removing rules. Each change takes up to 5 minutes to propagate. During this time, rule editing is temporarily disabled to prevent conflicts. A successful update proceeds silently - you will not see a confirmation message.

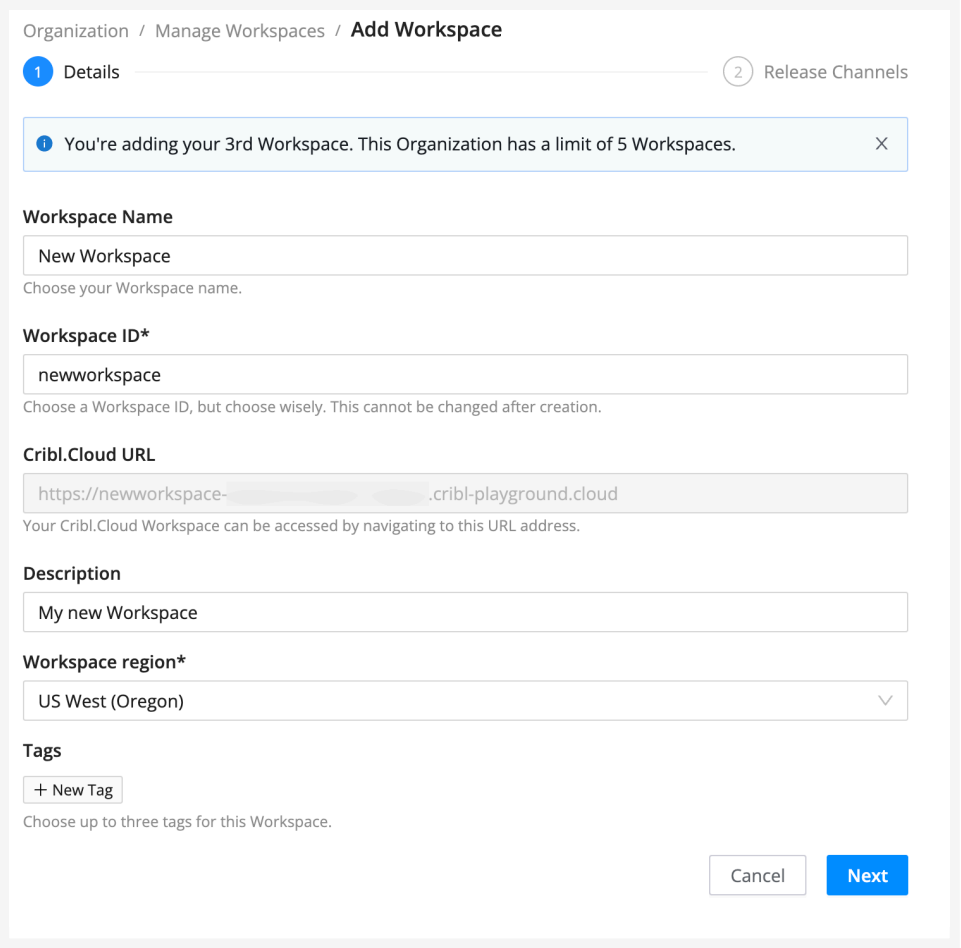
- The **ACL** options apply only to Cribl-managed Workers. You cannot use them to set access rules on customer-managed hybrid Workers.

- If you delete the default `0.0.0.0/0` rule and do not configure any other ACL rules, all inbound data to Cribl-managed Worker Groups in this Workspace will be blocked until you add an allow rule.

9.1. Configure Workspaces

Learn how to configure Workspaces in your Cribl.Cloud deployment.

Before You Begin



When you create a new Workspace in Cribl.Cloud, Cribl automatically provisions Cribl-managed Worker Nodes in the `default` Worker Group. **These Worker Nodes consume infrastructure credits**, but you can deprovision the `default` Worker Group from Worker Group settings. See Manage Cribl.Cloud Worker Groups for steps.

Add New Workspace

To create a new Workspace:

1. On the top bar, select the name of the current Workspace and then **Manage Workspaces**. This opens a modal with a list of all Workspaces to which you have access.
2. Select **Add Workspace**. Only Organization Owners and Organization Admins can add a Workspace.
    - If the Organization has used its included three Workspaces, Cribl.Cloud opens **Accept additional cost?** Select **Accept** to continue, or **Cancel**. See Workspace Limitations.
    - The confirmation states that you have reached your current Workspace limit, that each Workspace you add costs an additional 250 credits per month, and that the charge will appear in your next billing cycle.
3. Enter the following information:
    - **Workspace Name**: Human-readable name for the Workspace.
    - **Workspace ID**: Internal ID for the Workspace. This ID will be part of the Cribl.Cloud URL. **Cannot be changed** once the Workspace is created.
    - **Description**: Brief description for the Workspace (optional).
    - **Workspace region**: AWS Region where you want to deploy the Workspace. **Cannot be changed** once the Workspace is created.
    - **Tags**: Up to three tags that you can use to filter Workspaces (optional).

    If this Workspace is beyond the included allowance, the **Details** step shows that the Workspace will cost 250 credits per month, reflected in your next billing cycle.
4. Select **Next**.

Creating a new Workspace

5. Optionally select a data retention tier for Insights for the Workspace, then select **Next**.
6. Select the release channel to use for the Workspace.
    - **Fast**: Get early access to new features and services, released approximately weekly. Allows you to preview upcoming functionality and provide feedback before features become available on the Regular release channel. Available only in commercial Cribl.Cloud, not in Cribl.Cloud Government.
    - **Regular** (default): Get new feature and maintenance releases every month.
    - **Slow**: Get new feature and maintenance releases 1 month after the Regular release channel goes into production. If the Regular release channel has a hotfix in the previous 2 weeks, the Slow release channel is delayed until the following month. No releases in November or December. If needed, critical security upgrades may also ship on the Slow release channel.
7. Select **Save**.

The Workspace can take up to several minutes to spin up. While the process continues, you can navigate away and keep working with your Cribl.Cloud instance as usual.

Workspace Regions

When you add a new Workspace, you can select the AWS Region where you want to deploy it. The default Workspace `main` is always deployed in the same Region as the Organization, but you can deploy additional

Workspaces in any of the following AWS Regions:

AWS Region Name	AWS Region Code
Asia Pacific (Singapore)	`ap-southeast-1`
Asia Pacific (Sydney)	`ap-southeast-2`
Asia Pacific (Tokyo)	`ap-northeast-1`
Canada (Central)	`ca-central-1`
Europe (Frankfurt)	`eu-central-1`
Europe (Ireland)	`eu-west-1`
Europe (London)	`eu-west-2`
Europe (Paris)	`eu-west-3`
Europe (Zurich)	`eu-central-2`
South America (São Paulo)	`sa-east-1`
US East (N. Virginia)	`us-east-1`
US East (Ohio)	`us-east-2`
US West (Oregon)	`us-west-2`

Cribl.Cloud Government supports Workspace deployment exclusively in the AWS US East/West Regions.

Edit or Delete a Workspace

To edit a Workspace:

1. On the top bar, select your current Workspace name. This opens a modal with a list of all Workspaces you have access to.
2. Next to the Workspace you want to edit, select **Settings** in the **Actions** column to open the **Details** page for the Workspace.
3. On the **Details** page, you can change the name of the Workspace, description, and tags. However, you can't change the Workspace ID after it has been created.
4. Select **Save**.

For all Workspaces except `main`, you can select **Delete Workspace** on the **Details** page to delete it. You will need to manually type the name of the Workspace as a security measure.

It is not possible to delete the `main` Workspace.

Only **Organization Owners** or **Organization Admins** can add and delete Workspaces.

9.2. Enable Static Egress IPs For Cribl.Cloud

Use static egress when a Destination, firewall, or API will accept Cribl.Cloud traffic only from a known source IP. By default, Cribl.Cloud uses public egress, and those outbound addresses can change when Cribl rescales infrastructure. Static egress keeps the outbound traffic in a region on a stable set of IPs that you can add to an allowlist once.

Typical cases, when Cribl.Cloud makes the outbound connection:

- A SaaS Destination such as Splunk Cloud that requires an IP allowlist and does not accept FQDN-based rules.
- An on-prem firewall or security group that can allow only specific source addresses.
- A self-hosted HashiCorp Vault server whose allowlist must include the Cribl.Cloud Leader. See Self-Hosted HashiCorp Vault and IP Allowlists.

Static egress still sends traffic over the public internet. If the Destination can use a private path, you might prefer to use Private Link instead. You should enable static egress per region only where you need a stable source IP.

Enable or Disable Static Egress

You can configure static egress in the Cribl.Cloud portal. You need the **Admin** or **Owner** Permission on the Workspace.

1. In the sidebar, select **Workspace**, then **Connections**.
2. Select the **Static Egress IP** tab.
3. Select one or more regions that share the same **Status**. You can't enable and disable regions in the same action.
4. Select **Enable Static Egress IP** or **Disable Static Egress IP**.
5. Review the region list in the confirmation dialog, then select **Enable** or **Disable**.

When you enable or disable static egress, you can't access the Workspace UI for approximately 15 minutes. Data will continue to flow through the Workspace during that window.

After you enable a region, the **Status** changes to **Enabled** before addresses appear. Wait until the **Static Egress IP** column lists IP addresses, then copy every address into your Destination or firewall allowlist. Do not allowlist the region while the column still shows **Provisioning static IP addresses...**.

After you disable a region, those IPs are no longer used. Update downstream allowlists so they no longer depend on the removed addresses, or traffic to those Destinations can fail.

Static egress IPs are not the same as **Leader NLB IPs** on **Workspace** > **Access**. Leader NLB IPs are inbound addresses for hybrid connectivity to the Leader. Static egress IPs are outbound addresses for traffic that Cribl.Cloud sends to Destinations, Collectors, and similar pull paths.

10. Administration

Consult the following topics to learn how to manage and configure your Cribl Edge deployment.

- Configuration Management
- Upgrade Cribl Edge
- Notifications
- Uninstall Cribl Edge from Linux
- Uninstall Cribl Edge from Windows
- Uninstall Cribl Edge from macOS
- Customize the Interface
- Scripts

10.1. Upgrade Cribl Edge

Learn about the ways you can upgrade Cribl Edge, as well as general and version-specific upgrade considerations.

When upgrading a Cribl Edge deployment, the general order of steps is:

1. Upgrade the Leader Node.
2. Upgrade Outpost Nodes, if present.
3. Upgrade Edge Nodes.
4. Commit and deploy the changes on the Leader.

If your deployment uses a second Leader, refer to Upgrading with a Second Leader.

Prepare for an Upgrade

Before upgrading the Leader, plan your whole upgrade strategy, in particular whether you want to upgrade all your Edge Nodes at the same time. Edge Nodes will not upgrade automatically when you upgrade the Leader. In particular:

- Revise Better Practices for things to consider before starting the upgrade.
- Ensure you have configured your deployment for rollbacks.
- If you are upgrading older Cribl Edge versions, pay attention to the special cases described in Troubleshooting Edge Upgrades.

Supported Version Differences Between Leader and Edge Nodes

Cribl strongly recommends keeping Leader Nodes and Edge Nodes on the same version for the best experience and to ensure access to all features.

If you need to keep Edge Nodes on a different version than the Leader, for example during a phased upgrade, make sure they do not stay on a significantly older version.

Do not upgrade Edge Nodes to a newer version than the Leader Node.

Notice: End of Support for Edge Nodes Running Version 3.x

Cribl is ending support and testing for Edge Nodes running version 3.x that connect to the Leader. To ensure a smooth transition for legacy environments, modern Leaders will not actively block inbound connections from Edge Nodes running version 3.x at this time. However, backward compatibility is no longer actively maintained or tested.

> If you have legacy Edge Nodes running version 3.x remaining in your Fleet, we strongly recommend upgrading them to a currently supported release. This guarantees uninterrupted configuration management and telemetry collection.

Upgrade from Non-GA Versions

Cribl Edge does **not** support direct upgrades from any pre-GA version (such as a Cribl-provided test candidate) to a GA version. To get the GA version running, you must perform a new install.

10.1.1. Upgrade Leader Node

Upgrade the Leader Node of your Distributed deployment of Cribl Edge.

The Leader Node, which controls both Edge Nodes and Stream Workers, upgrades differently depending on your environment:

- In Cribl.Cloud, your Leader Node will be upgraded automatically as Cribl releases new product versions.
- In an on-prem deployment, you select when you want to upgrade your Leader Node.

There are two ways to upgrade the Leader Node in an on-prem deployment: directly from the UI, and manually from the command line.

Before you start upgrading your Leader Node, make sure to read Prepare for an Upgrade.

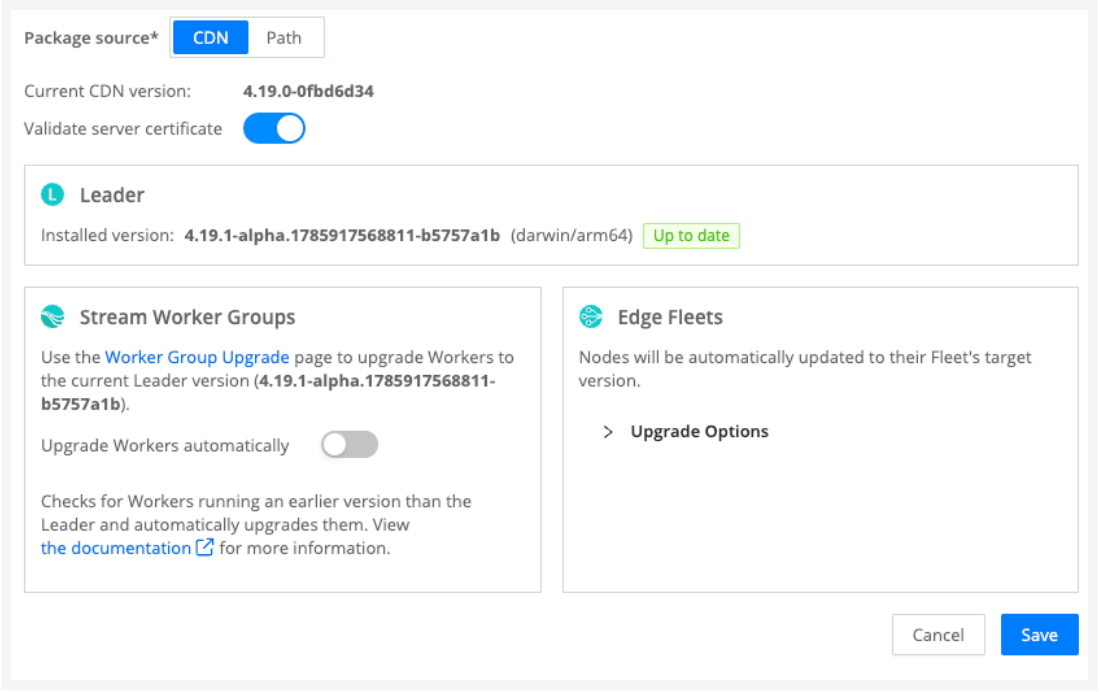
If your deployment uses a second Leader configured for failover, refer to Upgrade with a Standby Leader.

Upgrade Leader from the UI

To upgrade an on-prem Leader Node directly from the UI, go to **Settings** > **Global** > **System** > **Upgrade**.

You can choose to either use upgrade packages from the Cribl content delivery network (CDN), or point to packages located in a specified remote or filesystem location:

Package Source	Description
CDN	Downloads an installation package directly from the Cribl content delivery network. The Leader will always upgrade to the current CDN version when you select **Upgrade**.
Path	Uses an installation package from the filesystem or a remote URL. You must provide the correct path for your Leader platform and architecture.



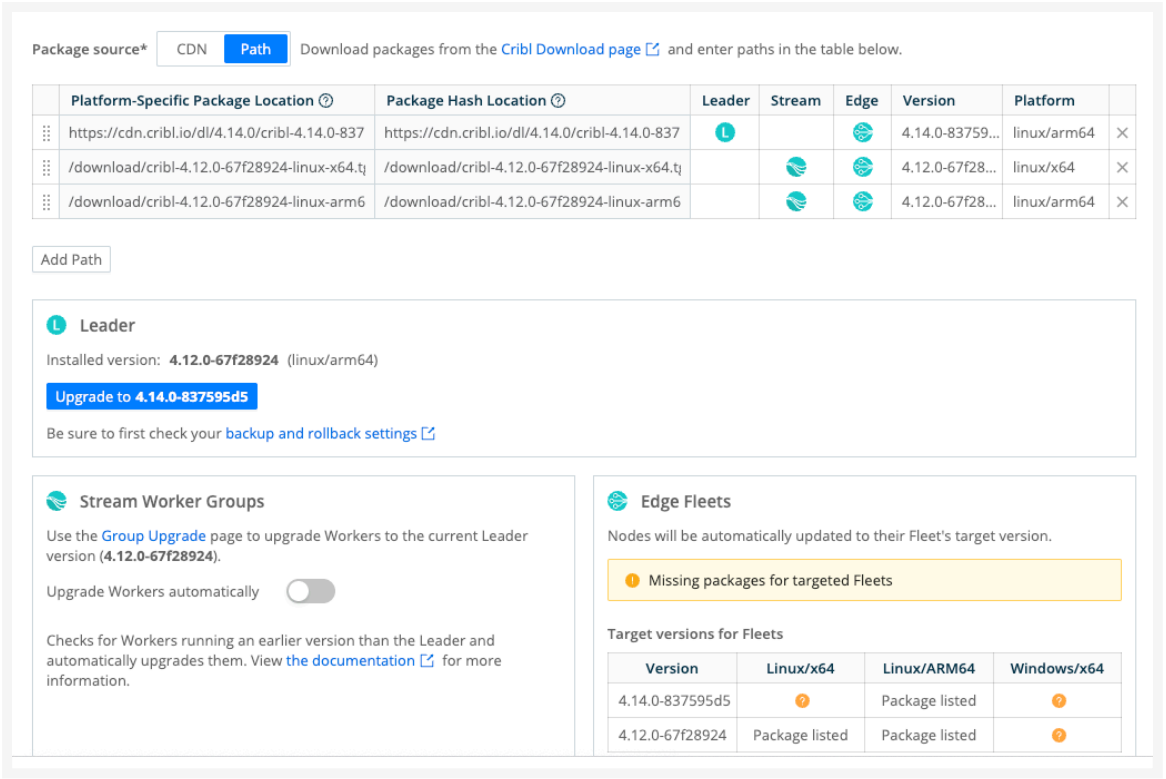
If your Leader controls Stream Workers, upgrading it can cause Workers to upgrade automatically, depending on configuration. Refer to Automatic Upgrades for more information.

Upgrade Leader from CDN

To upgrade a Leader Node using packages hosted in Cribl CDN:

1. Go to **Settings** > **Global** > **System** > **Upgrade**.
2. Select **CDN** in **Package source**.

Upgrade the Leader using CDN



If your Leader is running an older version, you will see the latest version of the Cribl package that is available on the CDN.

3. Do not toggle **Validate server certificate** off, unless you are using a trusted TLS-inspecting proxy.
4. Upgrade the Leader by selecting **Upgrade to <version>**.

Upgrade Leader from a Path

To upgrade a Leader Node using specified packages:

1. Go to **Settings** > **Global** > **System** > **Upgrade**.
2. Select **Path** in **Package source**.

Upgrade the Leader using Path

3. Provide the Location of a Cribl package in **Platform-Specific Package Location**. You can either:
   - Point to an HTTP URL that houses the package, for example `https://cdn.cribl.io/dl/4.14.0/cribl-4.14.0-837595d5-linux-x64.tgz`, or:
   - Download the package from the Cribl download page and point to local filesystem path, for example `/download/cribl-4.14.0-837595d5-linux-x64.tgz`. In the second case, the Leader must have access to the local filesystem location. When you stage these packages on your own servers, preserve the original file names.

Make sure you download the correct package for your platform and architecture.

4. Download the package's SHA or MD5 hash, or point to its URL in **Package Hash Location**. For a CDN location, you can append `.sha256` to the contents of the **Platform-Specific Package Location** field. The **Leader** column in the table will confirm with an icon when the package will be used to upgrade the Leader.

When Cribl Edge is running in FIPS mode, MD5 is not an acceptable hashing algorithm.

5. When you have added the correct package for the Leader, select **Save**.
6. Select **Upgrade to <version>** in the **Leader** section.

Additional Packages for Node Upgrades

You can use the **Platform-Specific Package Location** table to specify packages for different versions and platforms/architectures for use when upgrading Stream Workers and Edge Nodes.

The **Stream** and **Edge** columns in the table will indicate which packages will be used to upgrade which Nodes in your deployment.

Missing Package Links

When you see a warning about "Missing packages", it means there are Worker Groups or Edge Fleets that can't be upgraded due to a missing package path.

To add package links:

1. Select the **Copy** icon to add the link to your clipboard.
2. Paste the copied package link into a new **Platform-specific package location** field.
3. Add the appropriate path directory to the beginning of the installation package path (where your Cribl upgrade packages are located).
   For example: `/download/cribl-4.14.0-837595d5-linux-x64.tgz`
4. Select **Save** to add the upgrade package path and resolve the warning.

Upgrade Leader Manually

Besides upgrading from the UI, you can also upgrade your Leader Node manually, using the CLI. This might be desired in, for example, airgapped deployments, or when you want to select a Leader version lower than the latest available.

To upgrade the Leader Node manually:

1. Download the Cribl package in your target version, platform, and architecture from the Cribl download page.
2. Commit and deploy your current Leader configuration.
   Optionally, `git push` to your configured remote repo.
3. Stop the Leader.
   - Optional but recommended: Back up the entire `$CRIBL_HOME` directory.
   - Optional: Check that the Workers and Edge Nodes are still functioning as expected. In the absence of the Leader Node, they should continue to work with their last deployed configurations.
4. Uncompress the new Cribl package on top of the old one.
5. Change ownership of the `cribl` directory as needed:

```
sudo chown -R cribl:cribl $CRIBL_HOME
```

Copy

6. Restart the Leader and log back in.
7. Wait for all the Workers and Edge Nodes to report to the Leader, and ensure that they are correctly reporting the last committed configuration version.

Leader Upgrades and Edge Nodes

Edge Nodes will not upgrade automatically when you upgrade the Leader, even if set to current Leader version. See Upgrade Edge Nodes in a Fleet to learn how to upgrade all Edge Nodes in a Fleet.

Upgrade with a Standby Leader

For deployments with a standby Leader configured for failover, follow this upgrade order:

1. Stop the standby Leader first.

10.1.2. Upgrade Outpost

Use Outpost Group configuration to automatically upgrade Outposts.

Required Permission: **Admin/Owner**

Outposts are upgraded in bulk by setting the desired target version for the Outpost Group they belong to.

To automatically upgrade Outposts in a group:

1. In the sidebar, select **Outposts**.
2. In the row for the Outpost Group you want to upgrade, select the button in the **Target Software Version** column.
3. In the **Target Version** modal, select a version from the **Upgrade target version** dropdown. You have two options:
    - **None** - when set to None, the Outposts in the group will never upgrade automatically.
    - **<version> (current leader version)** - when set to this option, the Outposts will be upgraded to match the software version of the currently running Leader Node.
4. Confirm with **Save**.

The next time the Outpost in the selected group connects to the Leader, it will upgrade to the selected version.

Outposts in the selected group will not upgrade to any future version until you change the target software version in the drop-down (even if you upgrade the Leader).

The **Add/Update Outpost Node** command uses the **Target Software Version** for your Outpost Group when constructing the script for upgrading your Outposts.

See Add an Outpost with a Bootstrap Script for more details about the command.

10.1.3. Edge Node Upgrades

Upgrade Edge Nodes automatically or manually.

There are two ways to upgrade Edge Nodes: in bulk together with the whole Fleet, and manually, per Edge Node.

Edge Nodes in containers undergo a different upgrade process. Refer to Upgrading Containers for more information.

Fleet Upgrades

Upgrading Edge Nodes in bulk with their Fleet is the more straightforward of the two upgrade options, and manageable completely from the Leader Node UI. With this method, you set the desired target version for all Edge Nodes in a given Fleet. All Edge Nodes will then upgrade automatically to the target version.

See Upgrade Edge Nodes in a Fleet for more details.

Upgrading Edge Nodes from the Leader is available on certain plan/license tiers. For details, see Pricing.

Automatic Edge Node upgrades have the following limitations:

- You can't automatically upgrade Edge Nodes installed via RPM or from a .deb package. Refer to Upgrade RPM Installations and Upgrade .deb Installations for the manual upgrade process for those Nodes.
- You can't automatically upgrade Edge Nodes on Windows running version 4.3.0 or older. Use manual upgrade instead.
- Upgrading a Single-instance deployment requires a manual upgrade.

Manual Upgrades

Upgrading Edge Nodes manually requires running the upgrade process on the CLI for each Node.

Manual upgrades let you pause and resume upgrades as needed, which gives you more granular control over the process. You can also upgrade individual Nodes separately. This is useful when you're testing upgrades on a subset of Nodes before rolling out to the entire deployment.

Consider upgrading via CLI when your deployment is airgapped for security or compliance reasons and can't download new packaged from the internet.

See Upgrade Edge Nodes Manually for more details.

When upgrading Edge Nodes on Windows, consult Debugging Cribl Edge on Windows.

10.1.3.1. Upgrade Edge Nodes In A Fleet

Upgrade a whole Fleet of Edge Nodes by defining a target version.

To automatically upgrade Edge Nodes in one Fleet, you can set the desired target version for the Fleet through the UI.

Upgrading Edge Nodes from the Leader is available on certain plan/license tiers. For details, see Pricing.

Automatic Fleet upgrades have the following limitations:

- You can't automatically upgrade Edge Nodes installed via RPM. Refer to Upgrade RPM Installations for the manual upgrade process for those Nodes.
- You can't automatically upgrade Edge Nodes on Windows running version 4.3.0 or older. Use manual upgrade instead.
- Automatic upgrades on Edge Nodes on Windows require specific configuration of service accounts. See Service Accounts and Edge Node Upgrades for more information.
- Upgrading a Single-instance deployment requires a manual upgrade.

Upgrade Edge Nodes

To automatically upgrade Edge Nodes in a Fleet:

1. In the sidebar, select **Fleets**.
2. In the row for the Fleet you want to upgrade, select the button in the **Target Software Version** column.
3. In the **Target Version** modal, select a version from the **Upgrade target version** dropdown. You have two options:
    - **None** - when set to None, the Nodes in the Fleet will never upgrade automatically. Choose this option for highly critical Edge Nodes or Nodes managed by other departments that require strict control over upgrades.
    - **<version> (current leader version)** - when set to this option, the Nodes will be upgraded to match the software version of the currently running Leader Node.
4. Confirm with **Save**.

The next time the Node in the selected Fleet connects to the Leader, it will upgrade to the selected version.

Nodes in the selected Fleet will not upgrade to any future version until you change the target software version in the drop-down (even if you upgrade the Leader).

The **Add/Update Edge Node** command uses the **Target Software Version** for your Fleet when constructing the script for upgrading your Edge Nodes. For details, see Edge Node Updates Using Fleet Version Settings.

Subfleet Target Version

Subfleets do not inherit the **Target software version** from their parent Fleet, but you can set the target software version for each Subfleet using the same steps you used in the parent Fleet.

Package Sources for Offline Upgrades

Automatic Edge Node upgrade in Fleets will download packages from the Cribl CDN. For offline use in an on-prem deployment, you can also pre-download packages for specific platforms and architectures. Make sure you place the packages in a location that the Leader Node can access. To indicate that the system should use those packages:

1. Go to **Settings** > **Global** > **System** > **Upgrade**.
2. Select **Path** in **Package source**.
3. In **Platform-Specific Package Location**, enter the path to your locally downloaded package. You can add multiple paths to target different platforms or target Cribl Edge versions.
4. In **Package Hash Location**, point to the SHA or MD5 hash file for each of the packages.
5. Select **Save**.

When the Fleet next upgrades, it will use those downloaded packages instead of CDN.

Enable Legacy Edge Upgrades (Deprecated)

While this functionality still exists, it is deprecated and we do not recommend using it.

Enabling legacy upgrades removes the ability to automatically upgrade Nodes on a per-Fleet basis.

If you experience issues with the Fleet upgrade functionality, this option lets you use the job-based upgrade framework and manually upgrade Fleets via the Fleet Upgrade UI and **Upgrade** button.

To enable legacy upgrades, go to **Settings** > **Global** > **System** > **Upgrade**, and in **Edge Fleets**, under **Upgrade Options**, select **Enable Legacy Edge upgrades**. You'll also need to toggle **Disable Jobs/Tasks** off. See Jobs.

10.1.3.2. Upgrade Edge Nodes Manually

Upgrade individual Edge Nodes using CLI.

Upgrading individual Edge Nodes manually via the CLI gives you more control over the process than automatic Fleet upgrade, letting you pause and resume upgrades as needed and select specific versions to upgrade to.

To upgrade an individual Edge Node manually:

Prepare the Installation

1. Download the Cribl package from the Cribl download page. Pay attention to select the correct package for your platform and processor type. If the Leader is on a prior release, see Cribl Past Releases section at the bottom of the page for older packages.
2. Stop the Edge Node.

Install the New Edge Node

Linux Windows macOS

1. Uncompress the new Edge version on top of the old one, for example in the `/opt/cribl-edge` directory:

```
tar xvzf cribl-<version>-<build>-<arch>.tgz
```

Copy

Finalize Installation

To finalize the installation:

1. Restart Cribl Edge.
2. Ensure that newly upgraded Edge Nodes report to the Leader with their new software version.
3. Commit and deploy the newly updated configuration **only after all** Edge Nodes have upgraded.

Your Edge Node upgrade is now complete.

Upgrade RPM Installations

Manual upgrade is the only possible way of upgrading Edge Nodes install using RPM packages.

To upgrade an RPM installation:

1. Download the new Cribl Edge RPM package for your desired version.
2. Use your system's package manager (such as `yum` or `apt-get`) to upgrade the existing Edge Node:

```
sudo yum update <path-to-RPM-package>
```

Copy

3. If you are upgrading the Edge Node from an older version to 4.16.0 or later, set optional Linux capabilities in the Cribl Edge service file located at `/etc/systemd/system/cribl-edge.service` or `/lib/systemd/system/cribl-edge.service`:

```
[Service]
AmbientCapabilities=CAP_DAC_READ_SEARCH CAP_SYS_PTRACE
```

Copy

The upgrade retains all changes you make to environment variables.

For large organizations, Cribl recommends establishing an internal repository for RPM packages. This centralized approach streamlines upgrades by eliminating the need to download individual RPMs to each node, improving efficiency and consistency.

Upgrade .deb Installations

Manual upgrade is the only possible way of upgrading Edge Nodes installed using .deb packages.

To upgrade a .deb installation:

1. Download the new Cribl Edge .deb package for your desired version.
2. Use the apt package manager to upgrade the existing Edge Node:

```
sudo apt install <path-to-new-deb-package>
```

Copy

The upgrade retains all changes you make to environment variables.

10.1.4. Upgrade Containers

Learn how to upgrade Edge Nodes on Containers.

Upgrading Cribl Edge Containers

If you're asking, "Why didn't my Kubernetes Node upgrade?" or perhaps, "Why *did* my Docker Node upgrade?", then you're in the right place.

Cribl Edge handles upgrades for containerized Nodes (4.5.0 and newer) differently than standalone or on-prem Nodes. Leader Nodes don't upgrade Edge Nodes that are running in a container (such as containerd, Docker, or Kubernetes), because Edge Nodes revert back to their Helm chart image after a Pod restarts. Instead, upgrade containerized Nodes manually.

Upgrades for containerized Nodes also work a little differently in 4.5.0 and newer compared to 4.4 and older. Consider these upgrade scenarios:

Scenario	Do the Nodes Upgrade?	Logic Explanation
A Fleet contains **Kubernetes / containerized** Nodes running version v.4.5.0. The Fleet has a set **Target Software Version** of 4.5.2.	No	• The Nodes are running in a container. Containerized (Docker, Kubernetes, etc) Nodes will not be upgraded automatically. • Nodes on version 4.5.0 and newer inform the Leader that they are containerized Nodes.
A Fleet contains **Kubernetes / containerized** Nodes running v.4.4. The Fleet has a set **Target Software Version** of 4.5.0.	Yes	• Nodes on v.4.4 and older do not have the ability to inform the Leader that they're containerized.

Specific Considerations for Upgrading Containers

When upgrading, you must consider the initial install method for Edge Nodes relevant to containerized deployments.

Considerations for Kubernetes (Helm Charts)

Recommended method: If you initially deployed these Edge Nodes using Helm Charts, it's recommended to maintain consistency and upgrade them using the same method.

Process: Update the Helm Chart version to the desired Cribl Edge version in your Helm repository.

Deploy the updated Helm Chart to your Kubernetes cluster. Kubernetes will manage the upgrade process and ensure no downtime due to restarts.

Upgrading Edge Nodes manually within containers is highly discouraged. It can interfere with Kubernetes' resource management and lead to unexpected behavior.

For details on managing your Kubernetes Deployment, see Deploying via Kubernetes.

Considerations for Docker Containers

Cribl Edge upgrades won't be applied if your Node Info indicates `env.CRIBL_INSTALL_TYPE` is set to `CONTAINER`. This is because upgrades are designed for installations on physical or virtual machines, and containerized deployments manage updates differently.

Upgrading Kubernetes Edge Nodes

Edge Nodes deployed in Kubernetes can't be upgraded via the Leader. Instead, use our Helm charts to upgrade the Edge Nodes deployed in your Kubernetes cluster:

```
helm upgrade --install
```

Copy

For details on common challenges, see edge-via-kubernetes.

Updating the Docker Image

Cribl recommends that you always use our latest stable container image wherever possible. This will provide bug fixes and security patches for any vulnerabilities that Cribl has discovered when scanning the base image OS, dependencies, and our own software.

You can explicitly pull the latest stable image with this CLI command:

```
docker pull cribl/cribl:latest
```

Copy

Updating the Packaged OS

Cribl strongly recommends that you monitor and patch vulnerabilities in the packaged OS. The base OS might have been updated with fixes for new vulnerabilities discovered after Cribl published its container images. This is especially important if you choose to keep an earlier Cribl image in production.

You can update the base OS image by updating the package, as shown in the following `Dockerfile`. This example assumes you're updating Cribl's `latest` image:

```
FROM cribl/cribl:latest
RUN apt-get update && \
    apt-get -y upgrade dpkg
```

Copy

Cribl Edge supports both Docker and `containerd` runtimes.

10.1.5. Better Practices For Upgrading Cribl Edge

Streamlining the Upgrade Process.

While Cribl Edge is designed to provide an easy way to upgrade the version of Cribl Edge on your nodes, we recognize that everyone's environment and requirements are different. Here are some recommendations for planning upgrades in your environment either through our Fleet-level upgrades, or when using other deployment tools.

Plan Your Upgrade

A successful Cribl Edge upgrade requires careful planning. Consider these steps to ensure a smooth transition.

For your Environment

- Identify your current Cribl Edge version. Determine your Cribl Edge version by running the command `./cribl version` in your terminal or by checking the upper right corner of the Cribl Edge UI landing page.
- Evaluate changes or updates in your OS that could interfere with the upgrade, such as any software that might block connections. Ensure the Cribl process is allowlisted and allowed to execute without limitations to facilitate a smooth installation.
- Coordinate with your Security/IT team. Before deploying Cribl Edge on Nodes, consult with your security or IT department. They can advise on any necessary approvals or specific deployment guidelines you need to follow.

For your Deployment

- Review Supported Version Differences Between Leader and Edge Nodes.
- Review the Release Notes for the version you want to upgrade to and any previous versions you might have skipped.
- Check the Known Issues page for anything might impact your environment, including compatibility issues with your OS, third-party applications, or configurations. Additionally, assess potential issues with Sources, Destinations, and other configurations.
- If you initially installed Cribl Edge using containers, refer to the Upgrading Containers documentation for details.

Decide on an Upgrade Strategy

For organizations using Leader-initiated updates, Fleets offer a valuable tool for managing upgrades. By categorizing Edge Nodes into different Fleets based on upgrade schedules or risk tolerance, you can control the

upgrade process with greater precision. If you are using other upgrade management tools, using Fleets this way can still be beneficial, but their impact might be less pronounced.

Consider organized your Fleets into:

- **Mission-critical Edge Nodes**: To prioritize software stability and minimize downtime for these critical Edge Nodes, organize them into Fleets that will follow a longer upgrade cycle.
- **Non-critical Edge Nodes**: Organize non-critical Edge Nodes into Fleets that will have a more frequent upgrade cycle (every two to three months, for example), to balance feature adoption and system stability.
- **Early-Adopter Edge Nodes**: To evaluate new releases, consider creating dedicated test Fleets comprised of Edge Nodes suitable for testing. These Fleets can be upgraded frequently.

Configure Fleets to match your desired upgrade approach. See Upgrade Edge Nodes in a Fleet for details.

Establish an Appropriate Window For Upgrades and Maintenance

Consider acceptable downtime and maintenance windows:

- Edge Node upgrades will require a restart of the Edge process. Consider organizing Fleets in a way that accounts for rolling upgrades and avoid potentially concurrent downtime.
- Note that Edge Node upgrades occur in batches of 500, so large Fleets may require longer upgrade times.
- Coordinate with Edge Node owners to schedule upgrades that minimize service interruptions, taking into account time zone variations.

Roll Out Fleet-Level Upgrades for Large Deployments

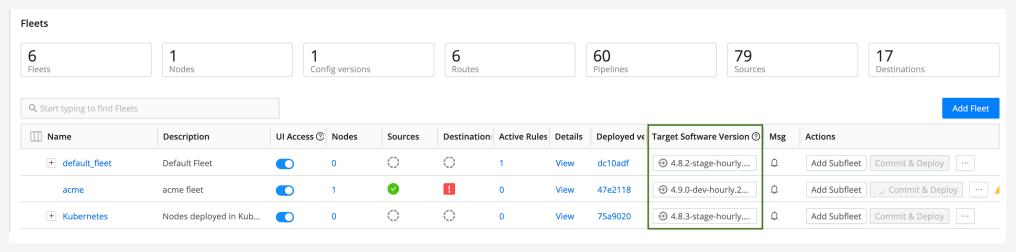
Fleet-level upgrades involve updating multiple Edge Nodes simultaneously. This approach is ideal for larger deployments where managing individual upgrades would be impractical.

Steps for Fleet-Level Upgrades

- **Staged rollout**: Start your Cribl Edge upgrade in a designated test Fleet or SubFleet (as a pilot group) to minimize risk and identify issues before impacting production. Or consider separating your dev/testing environment from your production.
- **Asynchronous upgrades**: Use the upgrading framework to allow Nodes to request upgrade packages from the Leader in batches, reducing load on the Leader.
    - Nodes communicate to the Leader via heartbeat every 60 seconds.
    - Upgrade packages are requested in batches of 500.

- **Error handling**: Look for informative error messages in logs such as `msiexec`, the Windows Event Log, and `cribl.log`. Log files are located in the `$CRIBL_HOME/log/` directory:
    - Server/API (Leader logs): `C:\ProgramData\Cribl\log\cribl.log`: Server/API (Leader)
    - Edge Node logs: `C:\ProgramData\Cribl\log\worker\0\cribl.log`

Monitor the Upgrade Status



For details, see Fleet Upgrade Information.

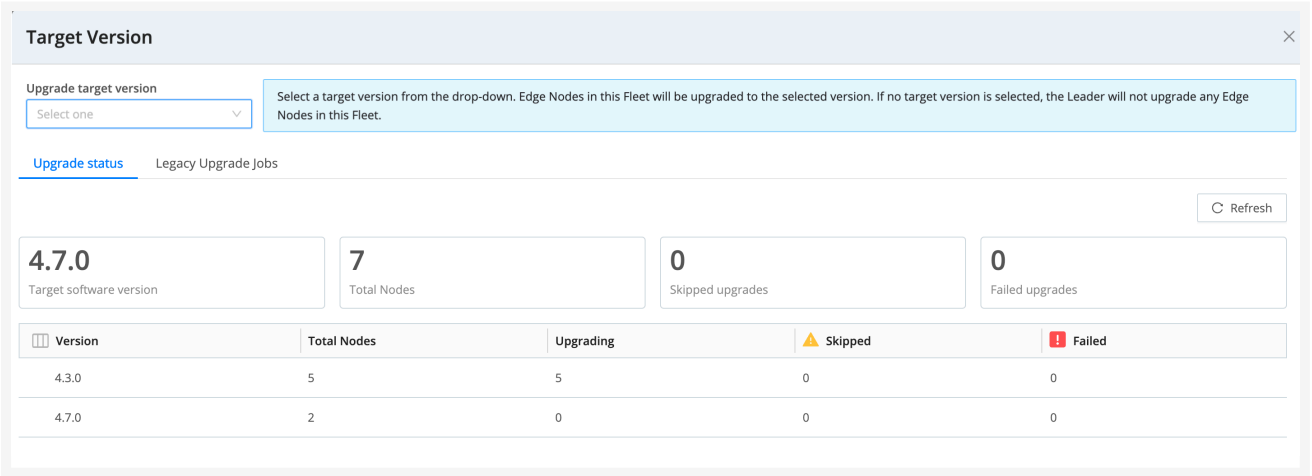
10.1.6. Monitor Node Upgrade Status

Learn how to monitor the upgrading status via the UI.

To view the upgrade status of eligible Edge Nodes in a Fleet, select the **Target version** button.

You can find this button on the **Fleets** page (**Manage > Fleets**) or in the top bar of a selected Fleet.

Target version button on **Manage > Fleets**



Target version button at the top of a selected Fleet

When you select this button, the **Target Version** window will open.

Explore the Target Version Window

The **Target Version** window provides information about Edge Node upgrades and allows you to select an upgrade target version for your Edge Fleets.

A popup window titled “Target Version” that shows the upgrade status of Edge Nodes in a Fleet

View the Status of Fleet Upgrades

The **Upgrade status** tab shows an overview of the Edge Nodes in this Fleet and the upgrade status for each Node version. The Nodes are organized by version, and the status columns display how many Nodes are in each status.

In this tab, you can view:

Status	Description
Version	Version for the Edge Nodes in this Fleet.
Total Nodes	Total number of Nodes in this Fleet running this version.
Upgrading	Nodes that are actively upgrading.
Skipped	Number of Nodes that were not upgraded due to one of these reasons: • The Fleet target version is not set. • No suitable upgrade package was found. You should use the **Path** package upgrade to add the specific upgrade package. • The Edge Node version is too old to receive an upgrade: ◦ Version 4.3.0 and older for Windows Nodes ◦ CentOS 6.x Nodes • The Leader couldn't download the upgrade package from the CDN.
Failed	The Node was not upgraded due to an error. The Node will retry the upgrade in the next hour.

View Upgrades for Legacy Edge Nodes

The **Legacy Upgrade Jobs** tab shows Leader-scheduled jobs that will upgrade Edge Nodes running versions 4.4.4 or older. If there are no legacy upgrade jobs, this tab will not show.

In this view, you can view the status the upgrade job per Edge Node.

- You can use the **Actions** icons to perform actions on the upgrade job: pause, stop, copy the link, delete, and view logs. If you cancel a job, you can view its artifacts.
- Click the **ID** to view job stats, settings, a live view, and logs.

10.1.7. Fleet Upgrading Use Case

An example upgrading use case, starring fictional solar energy company Greatgreen Goats.

Greatgreen Goats: A Fleet Upgrading Use Case

To help you conceptualize automatic Fleet upgrades, this use case walks you through how the fictitious company Greatgreen Goats upgrades Nodes in their two Fleets.

Greatgreen Goats is a small but rapidly growing company focused on installing and maintaining solar energy systems at goat farms around the country.

They use an on-prem Cribl Edge deployment to manage data on their Edge Nodes, divided into two distinct Fleets:

- **Fleet 1: Linux Operations.** This Fleet contains 20 Nodes, all running Edge 4.13.3. When the IT admin upgrades the Leader of Fleet 1 to 4.14.0, and they set the target upgrade version in the drop-down to **None**. Therefore, Nodes in Fleet 1 are never upgraded. They continue to remain at their current version, 4.13.3.
- **Fleet 2: Windows Monitoring.** This Fleet contains 15 Nodes. In this Fleet, the IT admin selects the current Leader version (in this case, 4.14.0) in the **Target upgrade version** drop-down. Now, when Nodes connect to the Leader, they pull down version 4.14.0 and upgrade to that version.

Fast forward four weeks: Cribl Edge has released a new version: 4.14.1. The IT admin upgrades the Leader to version 4.14.1.

Since Fleet 1 does not have a target version selected, Nodes in Fleet 1 remain at their current version, 4.13.3. If the IT admin decides to change the **Target upgrade version** to match the Leader in Fleet 1, the Nodes in Fleet 1 will be upgraded to 4.14.1.

Nodes in Fleet 2 will remain on version 4.14.0, which was the Leader's previous version, until the admin selects the next **Target upgrade version** (4.14.1, the Leader's new version). Then, Nodes will request the new version the next time they connect to the Leader and automatically upgrade.

This approach gives the IT admin at Greatgreen the flexibility to upgrade Nodes in Fleets independently from the Leader. Greatgreen can now scale and upgrade their Fleets with more reliability, since Nodes are pulling the release down from the Leader (instead of the Leader creating an overwhelming number of upgrade jobs).

10.1.8. Roll Back Cribl Edge

Roll back a Cribl Edge deployment to an older version.

You can roll back a Cribl Edge deployment or individual Edge Nodes to an older version either to mitigate a failed upgrade, or manually, at will.

Automatically Roll Back Failed Upgrades

When you initiate an upgrade through the UI, Cribl first stores a backup of your current stable deployment. Should the upgrade fail, Cribl will automatically roll back to the older version using this backup.

In Cribl.Cloud, the backup and rollback happen automatically. In an on-prem deployment, this behavior is also enabled by default, but you can configure it in detail (or disable it) using the following settings located in **Settings** > **Global Settings** > **System** > **General Settings** > **Upgrade & Share Settings**:

- **Enable automatic rollback**: Toggle off to disable the automatic rollback of a failed upgrade.
- **Rollback timeout (ms)**: Time to wait, after an upgrade, before checking each Node's health to determine whether to perform the rollback. Defaults to `30000` milliseconds (30 seconds).
- **Rollback condition retries**: Number of times to retry the health check before performing a rollback. Defaults to `5` attempts.
- **Check interval (ms)**: Time to wait between health-check retries. Defaults to `1000` milliseconds (1 second).
- **Backups directory**: Specify where to store backups. Defaults to `$CRIBL_HOME/state/backups`.
- **Backup persistence**: A relative time expression specifying how long to keep backups after each upgrade. Defaults to `24h`.

Manual Rollback

If you need to roll back an Edge Node or a whole on-prem deployment to an older version, or if an automatic rollback fails, you can attempt a manual rollback. However, Cribl recommends first considering other options - an upgrade, or working with Cribl Support - before performing a manual rollback.

You can't roll back a Cribl.Cloud Leader.

Do not manually roll back any Cribl Edge instance running in a container. Instead, locate, download, and launch a container image hosting the earlier version you want.

Before running a manual rollback, especially if you are also rolling back the Leader, we recommend backing up all your configurations.

1. Ideally, link your deployment to a Git remote repo, and commit and push your Leader's configuration to that remote. The repo will provide a stable location from which to restore your config, if necessary. Refer to Connect to External Git Repositories for more information.
2. Stop the Leader instance. (From `$CRIBL_HOME/bin/`, execute `./cribl stop`. If you are running the Leader using systemd, use `sudo systemctl stop cribl`.)
3. Create a local backup of your Leader's whole `$CRIBL_HOME` directory. This backup is crucial if you are rolling back from a version that included configuration schema changes.

Once the backup is ready, you can proceed to roll back each Node (Edge Nodes and Leader) individually. Make sure that Edge Nodes do not run a newer version than the Leader Node.

1. Download the package for your desired version. Navigate to https://cribl.io/download/, scroll down to the **Cribl Past Releases** section, and locate the version that you want to roll back to.
2. Select the proper release version for your environment and copy the link to the release binary.
3. Stop the Edge Node. (From `$CRIBL_HOME/bin/`, execute `./cribl stop`. If you are running the Node using systemd, use `sudo systemctl stop cribl-edge`.)
4. In your Node's host, in the parent of your `$CRIBL_HOME` directory, run the install command for this version. For example, on a Linux host, run:

```
sudo curl -Lso - https://cdn.cribl.io/dl/4.18.0/cribl-4.18.0-dfc74421-linux-x64.
```

Copy

5. If the version you are rolling back from included configuration schema changes, restore your configuration from the backed-up `$CRIBL_HOME` directory.

Once the rollback is complete, repeat the same steps for all Nodes you want to return to an older version.

10.1.9. Troubleshoot Edge Upgrades

Find solutions to common issues you can encounter when upgrading Cribl Edge.

While we expect you'll have an easy time upgrading Cribl Edge, here is the troubleshooting information we've curated in case you do experience a hiccup:

Direct Upgrades

Cribl Edge does **not** support direct upgrades from any pre-GA version (such as a Cribl-provided test candidate) to a GA version. To get the GA version running, you must perform a new install.

Service Timeout for Leader Upgrades

If your Leader is managed by a service manager (such as systemd, openRC, or Upstart), the default `TimeoutSec=60` might be insufficient for complex environments.

The cumulative time required to parse dozens of Fleets, or environments with a high density of Sources, Destinations, and Routes, can easily exceed the 60-second window. If this threshold is hit, `systemd` will end the process mid-migration, causing the upgrade to fail.

To prevent this, temporarily increase the timeout:

1. Open the service configuration (or use an override): `systemctl edit cribl.service`
2. Set a higher limit, for example: `TimeoutSec=600`
3. Reload the configuration: `systemctl daemon-reload`
4. Retry the upgrade.

Once the upgrade completes, repeat these steps to revert to the default value, `TimeoutSec=60`. This keeps your stop/restart cycles fast by allowing `systemd` to intervene quickly if the process becomes unresponsive.

For more background on timeouts during larger data migrations, see details in Addressing HA Migration Timeouts.

Limited Feature Functionality After Leader Upgrade

Upgrading a Leader Node to a newer version may surface configuration options in the UI that will not be functional until you upgrade the connected Edge Nodes to the same version.

Cribl strongly recommends keeping Leader Nodes and Edge Nodes on the same version for the best experience and to ensure access to all features.

Error on Windows Edge Node Upgrades

When performing a Leader-initiated upgrade of Windows Edge Nodes in a Fleet, you can encounter an "Edge must be run as administrator to upgrade itself" error logged in `cribl.log`.

This error indicates that the service account under which the Cribl Edge service runs does not have proper permissions.

See Service Accounts and Edge Node Upgrades for information on how to configure service accounts to run Node upgrades in a Fleet.

Upgrade to Older Versions

Take a look at the following information if your Edge Nodes are running older software versions.

Upgrade to 4.2.x

Leaders on 4.2.x are compatible with Edge Nodes on 4.1.2, 4.1.3, and later. Due to a security update, Edge Nodes running on 4.0.4 cannot receive configurations from 4.2.x Leaders.

Upgrade to 4.1.x or Newer

Cribl Edge 4.1 and newer encrypts TLS certificate private key files when you add or modify them. See instructions for backing up your keys from earlier versions.

Upgrade to 4.0.x or Newer

Before upgrading your Leader to 4.0 and newer, see Persisting Socket Connections to prepare the host to keep communications open from Edge Nodes.

Safeguard Unencrypted Private Keys for Rollback

Cribl Edge 4.1 and newer encrypt TLS certificate private key files when you add or modify them.

Before upgrading from a version older than 4.1, make a backup copy of all unencrypted TLS certificate private key files. Having access to the unencrypted files is essential if you later find that you need to roll back to your previous version.

To safeguard your unencrypted private keys, make a full backup of all Cribl config files. Files in the `auth/certs` directory are particularly important, such as those in:

- `groups/default/local/cribl/auth/certs/`
- `groups/<groupname>/local/cribl/auth/certs/`

- `cribl/local/cribl/auth/certs/`
- Etc.

Take appropriate precautions to prevent unauthorized access to these unencrypted private key files. If you need to roll back to a version older than 4.1, see Restoring Unencrypted Private Keys.

10.2. Notifications

With Notifications, you can set up alerts to notify Cribl Edge system administrators about events that require their immediate attention.

For example, you could set up a Notification to alert you when a Source stops sending data to a given Fleet, or when the volume of data sent to a Destination from the Fleet exceeds a threshold.

Notifications require certain plan or license tiers. Without an appropriate license, the configuration options described here will be hidden or disabled in Cribl Edge. For more information on license types, and a feature comparison, see Pricing.

How to Get Notifications

You can get notifications through:

- **Internal logs:** Cribl Edge stores these application-wide logs in the `notifications.log` file on the Leader Node, which also handles sending all Notifications. See Internal Logs for more information about logs.
- **Events in the UI:** Displays events in the Monitoring page. See Monitoring for more information about UI notifications.
- **Custom targets:** You can configure Notification targets to send alerts through email, pagers, Slack messages, and more. See Notification Targets for information about available targets and setup instructions.

Network connectivity for external targets: For any external Notification targets (email, PagerDuty, Slack, webhooks, AWS SNS, and similar), the Leader Node must be able to establish outbound connections to the corresponding service endpoints over the ports and protocols those services require (often HTTPS/443, or SMTP ports for email). On-prem deployments may need explicit firewall rules to allow this outbound traffic from the Leader.

Types of Notifications

Type	Available Notifications	For more info
Sources	• High Data Volume • Low Data Volume • No Data • Source Persistent Queue Usage	Add a Notification for a Source

Type	Available Notifications	For more info
Destinations	• Destination Backpressure Activated • Destination Persistent Queue Usage • Unhealthy Destinations	Add a Notification for a Destination
Licenses	• Pending expiration of license	Add a Notification about License Expiration

You can also configure Cribl Stream to relay Notifications generated by other Cribl products. For an example, see the Cribl Search topic Notifications via Cribl Stream.

Notification Permissions

Notifications work with Cribl Edge role-based access control (RBAC). For users with non-administrative permissions, their assigned Roles and Policies determine the Fleets on which they can view Notification messages, configure Notifications, and configure targets.

Add a Notification for a Source

To create alerts for a Source or Collector:

1. Navigate to your Fleet. Then select **More** > **Sources**.
2. Select the Source type to display the table of its configured Sources. For example, select **Syslog** to set up notifications for a Syslog Source.
3. Select the **Notifications** button in the row for the Source you want to configure.
4. In the **Notification** modal, configure the following settings under **General**:
    - **ID**: Provide a unique ID for the Notification in this section.
    - **Enabled**: Toggle on (default) if you want Cribl Edge to enable the Notification. Toggle off to turn off the Notification.
5. In the **Configuration** section in the **When...** field, select the condition that will trigger the Notification and then configure the settings for that trigger condition. See Source Settings for more information about the trigger condition settings. The available Source Notification trigger conditions:
    - **High Data Volume**: Incoming data is above the data volume threshold for your configured time window.
    - **Low Data Volume**: Incoming data is below the data volume threshold for your configured time window.
    - **No Data Received**: The Source or Collector ingests zero data over your configured time window.

- **Persistent Queue Usage**: The Source persistent queue accumulates files past the threshold percentage of storage capacity. See Optimize Source Persistent Queues for more information about working with Source persistent queues to manage backpressure.

6. In the **Configuration** section, set the **Only notify on start and resolution** toggle. When toggled on, Cribl Edge will send a Notification when the triggering condition begins and then a second Notification to report when the condition has ended.
7. Configure the **Send Notification to** setting to set the Notification target(s). If you don't have a Notification target, the **Messages** icon will indicate you have a new Notification. See Notification Targets for more information about available targets and adding new targets.
    - Select **Add Target** to add an existing target.
    - Select **Create Target** to add a new target.
8. Save the Notification.

Your Notification will now appear on the **Events** tab within the configuration window for this Source. To view all Notification events and targets, select **Notifications** in the sidebar.

Consider testing the condition to determine if you configured the Notification properly by deliberately triggering the Notification trigger.

Source Notification Settings

The function of the **Data volume** and **Time window** settings change depending on which Notification trigger you selected:

Notification Trigger	Settings
High Data Volume	Triggers an alert if the total data ingested within the configured **Time window** exceeds the specified **Data volume** threshold.
Low Data Volume	Triggers an alert if the total data ingested within the configured **Time window** falls below the specified **Data volume** threshold.
No Data Received	Triggers an alert if a Source or Collector fails to ingest any data for the duration of the configured **Time window**.
Persistent Queue Usage	Triggers an alert when persistent queue disk usage exceeds the specified **Usage threshold**. The **Time window** determines how often this condition is checked.

Source name: This field locks to the Source for this Notification and cannot be edited.

Time window: This field's value sets the threshold period before the Notification will trigger. The default `60s` will generate a Notification when the Source has reported the trigger condition over the past 60 seconds. To enter alternative numeric values, append units of `s` for seconds, `m` for minutes, `h` for hours, and so forth.

See Source Notifications Best Practices for information about avoiding false notifications when configuring the **Time window** setting for Collectors that run on a schedule.

Data volume: Enter the threshold above which a Notification will trigger. Accepts numerals with units like `KB`, `MB`, and so forth. For example: `4GB`. If you want the unit to be bytes, enter the numeral only, without a unit designator.

Usage threshold: The percentage of full or used storage disk capacity. Cribl Edge generates a `Persistent Queue usage has surpassed <threshold>%` Notification when the Source persistent queue storage disk capacity is past the specified **Usage threshold** percentage. This field appears only when you configure a Notification for **Persistent Queue Usage**.

Metadata: User-defined fields included in the Notification payload. All Notification types can contain metadata. To add custom metadata fields, select **Add field** and add the fields as key-value pairs:

- **Name**: Enter a name for the custom field.
- **Value**: Enter a JavaScript expression that defines this field's value, enclosed in quotes or backticks. This can evaluate to a constant if needed.

Source Notification Best Practices

To ensure your Source Notifications are reliable and easy to manage, follow these best practices:

- For Collectors that run on a schedule, always set the **No Data Received** Notification time window to a duration that is longer than the time between scheduled runs. Because there is no data flow between runs, a shorter time window will trigger false alarms.
- When cloning a Source, remember to manually recreate any Notifications you need on the new Source. Cloning a Source does **not** copy its associated Notifications.

Add a Notification for a Destination

To create alerts for a Destination:

1. Navigate to your Fleet. Then select **More** > **Destinations**.
2. Select the Destination type to display the table of its configured Sources. For example, select **Syslog** to set up notifications for a Syslog Destination.
3. Select the **Notifications** button in the row for the Destination you want to configure.
4. In the **Notification** modal, configure the following settings under **General**:
    - **ID**: Provide a unique ID for the Notification in this section.
    - **Enabled**: Toggle on (default) if you want Cribl Edge to enable the Notification. Toggle off to turn off the Notification.

5. In the **Configuration** section in the **When...** field, select the condition that will trigger the Notification and then configure the settings for that trigger condition. See Destination Settings for more information about the trigger condition settings. The available Destination Notification trigger conditions:
    - **Destination Backpressure Activated**: The Destination has engaged its backpressure behavior, such as when a downstream Destination receiver is unreachable or slow to respond. This notification indicates that Cribl Edge detected blocked or dropped delivery during at least 5% of the trailing time window. It does not confirm that persistent queue has successfully engaged. The triggering conditions:
        - The Destination's **Backpressure behavior** is set to `Block` or `Drop`, and backpressure causes outgoing events to block or drop.
        - The Destination's **Backpressure behavior** is set to Persistent Queue and its **Queue-full behavior** is set to either `Block` or `Drop new data`. When the queue is full, it causes the Destination to block or drop outgoing events.
    - **Persistent Queue Usage**: The Destination persistent queue accumulates files past the threshold percentage of storage capacity. See Optimize Destination Persistent Queues for more information about working with Destination persistent queues to manage backpressure.
    - **Unhealthy Destination**: The health of the Destination has been in red status (as indicated on the Monitoring page) over the configured time window.
6. In the **Configuration** section, set the **Only notify on start and resolution** toggle. When toggled on, Cribl Edge will send a Notification when the triggering condition begins and then a second Notification to report when the condition has ended.
7. Configure the **Send Notification to** setting to set the Notification target(s). If you don't have a Notification target, the **Messages** icon will indicate you have a new Notification. See Notification Targets for more information about available targets and adding new targets.
    - Select **Add Target** to add an existing target.
    - Select **Create Target** to add a new target.
8. Save the Notification.

Your Notification will now appear on the **Events** tab within the configuration window for this Destination. To view all Notification events and targets, select **Notifications** in the sidebar.

Destination Notification Settings

The function of the **Time Window** settings change depending on which Notification trigger you selected:

Notification Trigger	Settings
Destination Backpressure Activated	The threshold for the Notification to trigger is: Cribl Edge detected a blocked or dropped state during ≥ 5% of the trailing **Time window**

Notification Trigger	Settings
Persistent Queue Usage	The **Time Window** determines how frequently the Notifications repeat.
Unhealthy Destination	The **Time Window** determines how frequently the Notifications repeat.

Destination name: This field locks to the Destination for this Notification.

Time window: This field's value sets the threshold period before the Notification will trigger. The default `60s` will generate a Notification when the Destination has reported the trigger condition over the past 60 seconds. To enter alternative numeric values, append units of `s` for seconds, `m` for minutes, `h` for hours, and so forth.

Usage threshold: The percentage of full or used storage disk capacity. Cribl Edge generates a `Persistent Queue usage has surpassed <threshold>%` Notification when the Destination persistent queue storage disk capacity is past the specified **Usage threshold** percentage. This field appears only when you configure a Notification for **Persistent Queue Usage**.

Metadata: User-defined fields included in the Notification payload. All Notification types can contain metadata. To add custom metadata fields, select **Add field** and add the fields as key-value pairs:

- **Name**: Enter a name for the custom field.
- **Value**: Enter a JavaScript expression that defines this field's value, enclosed in quotes or backticks. This can evaluate to a constant if needed.

Destination Notification Best Practices

When cloning a Destination, remember to manually recreate any Notifications you need on the new Destination. Cloning a Destination does **not** copy its associated Notifications.

Add a Notification About License Expiration

To create a license-expiration alert:

1. Navigate to **Settings** > **Global** > **Licensing**. Then select **Add Expiration Notification**.
2. In the **Notification** modal, configure the following settings under **General**:
    - **ID**: Provide a unique ID for the Notification in this section.
    - **Enabled**: Toggle on (default) if you want Cribl Edge to enable the Notification. Toggle off to turn off the Notification.
3. Optional: Add or create a Notification target. See Notification Targets for more information. If you don't have a Notification target, the **Messages** icon will indicate you have a new Notification.
4. Save the Notification.

To view all Notification events and targets, select **Notifications** in the sidebar. You can also reach this page by selecting **Settings** > **Global** > **Licensing**.

Consider testing the condition to determine if you configured the Notification properly by deliberately triggering the Notification trigger.

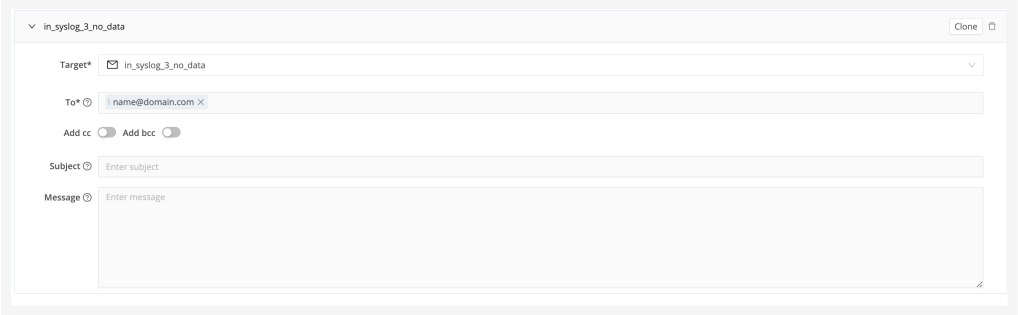
Edit Notifications

To edit a Notification:

1. Select **Notifications** in the sidebar. You can also reach this page by selecting an existing Notification in a Source or Destination modal. This page lists all Notifications.
2. Select anywhere on the row the Notification you want to edit.
3. To edit a Notification target (the delivery method for the Notification), use the **Targets** tab on this screen. See Notification Targets for additional details.

10.2.1. Email Notifications

If you're a Cribl Edge admin, email notifications make it easy to receive alerts about any operational issues that require your attention, such as a particular Source or Destination condition or a pending license expiration.



An email Notification requires two things – a configured Notification and an email Notification target. Cribl.Cloud Organizations using certain plan/license tiers also have access to a preconfigured email Notification target.

Email Notifications do not have an unsubscribe option. Recipients who do not want to receive particular email Notifications should contact their Cribl Edge admins.

Email Notifications are sent on a no-reply basis.

Configure Email Notifications

When you create a Notification for an email target, specify the recipients of the message, the subject line, and the contents of the message.

Email Notification with target selected

Target: The ID of the email target to which you want to send the Notification.

Select **Add target** to add an existing target.

Select **Create target** to create a new target. For information on configuring email Notification targets, see Email Notification Targets.

If the Notification already has a designated target, you can change the selection by selecting the drop-down.

When an email Notification target is selected, the following additional fields appear:

To: The email address of the recipient.

Add cc: When enabled, reveals a field where you can enter the addresses of additional recipients.

Add bcc: When enabled, reveals a field where you can enter the addresses of additional recipients that do not appear in the Notification email.

Cribl Edge does not limit the total number of recipients for a Notification, but your email service might set a limit.

Subject: The subject line of the email Notification. You can use variables in the subject line.

Message: The content of an email Notification. You can use variables in the body of the email message.

Email Notification Variables

Email variables are placeholders in the email template that get replaced with actual values when the email is sent. These variables can be:

- General-use variables, like `condition`, `worker_group`, or `timestamp`
- Special-purpose variables

You can use a variety of general-use and special-purpose variables in the subject or message body of an email Notification. Insert a variable name between two braces preceded by a `$`. For example: `${cribl_notification}`.

General-Use Email Variables

Variable	Description
`workspace`	Workspace name (Cribl.Cloud only).
`organization`	Organization ID (Cribl.Cloud only).
`timestamp`	Timestamp when the email is sent. For example: `2019-08-04 18:22:24 UTC`.
`cribl_notification`	User-defined notification ID.

Special-Purpose Email Variables

Variable	Usage	Notification type	Example
`_raw`	The `_raw` field of the Event triggering the Notification.	• License expiration • Cribl Search	`Your Cribl license expires in 3 days on 2019-08-04 18:22:24 UTC. Please update your license to continue processing data after 2019-08-04 18:22:24 UTC.`
`__worker_group`	Name of the Worker Group	• Destination Backpressure	`default`

Variable	Usage	Notification type	Example
	triggering the Notification.	• High data volume • Low data volume • No data • Persistent Queue Usage • Unhealthy Destination	
`timewindow`	Metric evaluation period used for Notification.	• Destination Backpressure • High data volume • Low data volume • No data • Persistent Queue Usage • Unhealthy Destination	`60s`
`status`	Status of the Notification Status of backpressure engagement.	• Destination Backpressure • High data volume • Low data volume • No data • Persistent Queue Usage • Unhealthy Destination	`OK`, `ALARM` `DISENGAGED`, `BLOCKING` or `DROPPING`
`input`	Type and name of a Source or Collector.	• High data volume • Low data volume • No data	`syslog:in_syslog_1`
`output`	Type and name of a Destination.	• Destination Backpressure • Persistent Queue Usage • Unhealthy Destination	`webhook:out_webhook_1`

Variable	Usage	Notification type	Example
`bytes`	Quantity of data triggering the specified Notification.	• High data volume • Low data volume • No data	`0`
`dataVolume`	Data volume which triggered the Notification. Accepts numerals with units like KB, MB, and so on.	• High data volume • Low data volume	`1G`
`health`	Health metric of the specified Source or Destination.	• Unhealthy Destination	`0`
`queue_usage`	Percentage of capacity set in the **Usage threshold** field.	• Persistent Queue Usage	`90`
`usage`	The actual usage, in percent.	• Persistent Queue Usage	`50`
`usageThreshold`	The usage threshold, in percent.	• Persistent Queue Usage	`50`

Troubleshoot Email Notifications

The section details the troubleshooting steps you can take if an email Notification fails to reach its intended recipient.

Test the Email Notification Target

An email Notification can fail if the target is misconfigured. You can test your email Notification target by following this procedure:

1. Open the target (in **Notifications** > **Targets**).
2. Select **Test Target**.
3. Add one or more email addresses to the **Test Target** modal and select **Send Test Email**.

4. Check the designated inbox to verify receipt of the test message. If it does not arrive in the designated inbox, review the target configuration.

Check Notification Service Logs

A failed email Notification leaves a log entry. You can examine logs by following this procedure:

1. Select **Monitoring** > **Logs**.
2. In the drop-down on the left, select **Leader** > **Notifications Service**.
3. Examine any logs that have errors.

Check Notifications

Cribl Edge stores Notifications. You can check them by following this procedure:

10.2.2. Notification Targets

A Notification target allows you to receive alerts using your preferred channel or alert delivery method. Every Notification requires one or more targets.

Available target types include:

- Webhook
- PagerDuty integration
- Slack
- AWS SNS
- Email
- System Messages (default)

When you create a new Notification, its default target type will be **System Messages**. When an event occurs in Cribl Edge to trigger a Notification condition, you will see an indicator in the **Messages** icon. Select the icon to open the **Messages** drawer and view the Notification details.

Add a Notification Target

To add a new Notification target:

1. In the Cribl Edge sidebar, select **Notifications**, and then select the **Targets** tab.
2. Select **Add Target** to open the **New Target** modal.
3. Give this target a unique **Target ID**.
4. Select the desired **Target type**.

Then configure the target as described in the appropriate page:

- Webhook
- PagerDuty
- Slack
- AWS SNS
- Email

Network requirement: Before you rely on a Notification target, confirm that the Leader Node can reach the target endpoint over the correct outbound ports (for example, HTTPS/443 for most SaaS integrations or SMTP ports for email gateways).

When you create a Notification target in Cribl Stream, Edge, or Search, it will also be available to you in the other products. For example, if you create a Notification target in Cribl Stream, you can also access it in Cribl Edge and Cribl Search.

Notifications require certain plan/license tiers. Without an appropriate license, target configuration options will be hidden or disabled in Cribl Edge's UI.

Manage Notification Targets

You can manage targets by selecting **Notifications** > **Targets**.

Select any existing Notification target to open a modal where you can manage the target, using buttons at the bottom of the page.

Select **Delete Target** to delete an existing Notification target. You can also select multiple targets for deletion, using the check boxes on the left side of the modal.

Select **Clone Target** to copy an existing target. A modal will open so you can modify the configuration of the target you started with.

To edit any target's definition in a JSON text editor, select **Manage as JSON** at the bottom of the **Notifications** > **Targets** modal. You can directly edit multiple values, and you can use the **Import** and **Export** buttons to copy and modify existing target configurations as `.json` files.

Some targets have additional controls for target configuration. See the documentation for the target of interest for more information.

10.2.2.1. Webhook Notification Targets

With this option, you can send Cribl Edge Notifications to an arbitrary webhook. Select **Webhook** in the **New Target** modal to expose multiple left tabs, with the following configuration options:

General Settings

Target ID: Enter a unique ID used to identify the target. This will show in the **Target ID** column of the **Targets** tab. You can't change it later, so make sure you like it.

Configuration

The added options that appear on this first left tab are:

URL: The endpoint that should receive Cribl Edge Notification events.

To proxy outbound HTTP/S requests, see System Proxy Configuration.

Method: Select the appropriate HTTP verb for requests: `POST` (the default), `PUT`, or `PATCH`.

Format: Specifies how to format Notification events before sending them to the endpoint. Select one of the following:

- `NDJSON` (newline-delimited JSON, the default).
- `JSON Array`.
- `Custom`, which exposes these additional fields:
    - **Source expression**: JavaScript expression whose evaluation shapes the event that Cribl Edge sends to the endpoint - for example: `notification=${_raw}`. For other fields you can use, see Expression Fields. If empty, Cribl Edge will send the full Notification event as stringified JSON.
    - **Drop when null**: Toggle on if you want to drop events where the above **Source expression** evaluates to `null`.
    - **Event delimiter**: Delimiter string to insert between individual events. Defaults to newline character (`\n`).
    - **Content type**: Defaults to `application/x-ndjson`. You can substitute a different content type for requests sent to the endpoint. This entry will be overridden by any content types set in this modal's **Advanced Settings** tab > **Extra HTTP Headers** section.
    - **Batch expression**: Expression specifying how to format the payload for each batch. Defines a wrapper object in which to include the formatted events, such as a JSON document. This enables requests to APIs that require such objects. To reference the events to send, use the `${events}`

variable. An example expression to send the batch inside a JSON object would be: `{"items" : [${events}] }`.

Expression Fields

When building the Source expression, you can use the following fields:

Fields Common to All Notification Types

- `starttime`: Beginning of the time bucket where this condition was reported. All Notifications have this field.
- `endtime`: End of the time bucket where this condition was reported. All Notifications have this field.
- `_time`: Timestamp when this Notification was created. All Notifications have this.
- `cribl_host`: Hostname of the (physical or virtual) machine on which this Notification was created. All Destination and Source Notifications have this.
- `cribl_notification`: Configured name/ID of this Notification. All Destination and Source Notifications have this.
- `origin_metadata`: Object containing metadata about the Notification's origin, with the following fields for all Destination Notifications:
  - `type`: "output".
  - `id`: ID of the affected Destination.
  - `subType`: Destination's type (where applicable).
- `origin_metadata`: Object containing metadata about the Notification's origin, with the following fields for all Source Notifications:
  - `type`: "input".
  - `id`: ID of the affected Source.
  - `subType`: Source's type (where applicable).

Unhealthy Destination

- `health`: Numeric value where `0`=green, `1`=yellow, `2`=red.
- `output`: Output ID of the affected Destination.
- `_raw`: "Destination `${output}` [in group `${__worker_group}`] is unhealthy".
- `_metric`: "health.outputs".

Destination Persistent Queue Usage

- `output`: Output ID of the affected Destination.
- `timeWindow`: The interval at which Notifications will be repeated.
- `usageThreshold`: The minimum persistent queue utilization (stated as a percentage) that will trigger Notifications.
- `_metric`: "system.pq_used".
- `usage`: The persistent queue utilization (stated as a percentage) that triggered the Notification.

Destination Backpressure Activated

- `backpressure_type`: `1` for Block, `2` for Drop.
- `output`: Output ID of the affected Destination.
- `_raw`: "Backpressure ([dropping|blocking]) is engaged for destination `${output}` [in group `${__worker_group}`]".
- `_metric`: "backpressure.outputs".

Source High Data Volume

- `health`: Numeric value where `0`=green, `1`=yellow, `2`=red.
- `bytes`: Number of bytes received in the time bucket.
- `input`: Input ID of the affected Source.
- `_raw`: "Source `${input}` [in group `${__worker_group}`] traffic volume greater than `${dataVolume}` in `${timeWindow}`".
- `_metric`: "total.in_bytes".

Source Low Data Volume

- `health`: Numeric value where `0`=green, `1`=yellow, `2`=red.
- `bytes`: Number of bytes received in the time bucket.
- `input`: Input ID of the affected Source.
- `_raw`: "Source `${input}` [in group `${__worker_group}`] traffic volume less than `${dataVolume}` in `${timeWindow}`".
- `_metric`: "total.in_bytes".

Source No Data Received

- `health`: Numeric value where `0`=green, `1`=yellow, `2`=red.

- `_time`: Timestamp when this Notification was created.
- `input`: Input ID of the affected Source.
- `_raw`: "Source `${input}` [in group `${__worker_group}`] had no data for `${timeWindow}`".
- `_metric`: "total.in_bytes"

License Expiration

- `severity`: One of "warn" or "fatal".
- `title`: One of: "License expiring soon, data will stop flowing." Or: "License has expired. Data flow has been stopped.".
- `text`: One of: "License will expire on `${expirationDate}`, no external inputs will be read" after that time. Please contact sales@cribl.io to renew your license." Or: "License has expired."

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header.
- **Basic**: In the resulting **Username** and **Password** fields, enter HTTP Basic authentication credentials.

Post-Processing Settings

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` - Cribl Edge Node that processed the event.
- `cribl_input` - Cribl Edge Source that processed the event.
- `cribl_output` - Cribl Edge Destination that processed the event.
- `cribl_route` - Cribl Edge Route (or QuickConnect) that processed the event.
- `cribl_wp` - Cribl Edge Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Edge limits the delay to 180 seconds even if the `Retry-After` header

specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Edge applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Edge continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3

minutes).

Advanced Settings

Validate server certs: Reject certificates not authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA). Defaults to toggled on.

Round-robin DNS: Toggle on to enable round-robin DNS lookup across multiple IP addresses, IPv4 and IPv6. When a DNS server resolves a Fully Qualified Domain Name (FQDN) to multiple IP addresses, Cribl Edge will sequentially use each address in the order they are returned by the DNS server for subsequent connection attempts.

Compress: Toggle on (default) to compress the payload body before sending.

Keep alive: By default, Cribl Edge sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Edge to close the connection immediately after sending a request.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Edge hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `4096` KB, but you can set this limit to as high as 500 MB (512000 KB).

High values can cause high memory usage per Edge Node, especially if a dynamically constructed URL causes this target to send events to more than one URL. The actual request body size might exceed the specified value because the target adds bytes when it writes to the downstream receiver. Therefore, we recommend that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Events-per-request limit: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass to all events as additional HTTP headers. Values will be sent encrypted. You can also add headers dynamically on a per-event basis in the `__headers` field; headers added by this method take precedence over headers defined in the **Extra HTTP headers** table.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Edge will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Used to declare headers that are safe to log as plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

10.2.2.2. PagerDuty Notification Targets

This option sends Cribl Edge Notifications to PagerDuty, a real-time incident response platform, using Cribl Edge's native integration with the PagerDuty API. Select **PagerDuty** in the **New Target** modal to expose the following additional options on the modal's (single) **General Settings** left tab:

General Settings

Target ID: Enter a unique ID used to identify the target. This will show in the **Target ID** column of the **Targets** tab. It can't be changed later, so make sure you like it.

Configuration

Routing key: Enter your 32-character Integration key on a PagerDuty service or global ruleset.

Group: Optionally, specify a PagerDuty default group to assign to Cribl Edge Notifications.

Class: Optionally, specify a PagerDuty default class to assign to Cribl Edge Notifications.

Component: Optionally, a PagerDuty default component value to assign to Cribl Edge Notification. (This field is prefilled with `logstream`.)

Severity: Set the default message severity for events sent to PagerDuty. Defaults to `info`; you can instead select `error`, `warning`, or `critical`. (Will be overridden by the `__severity` value, if set.)

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Edge applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Edge continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

10.2.2.3. Slack Notification Targets

You can send Notifications to a Slack channel, using Slack's Incoming Webhooks.

You can also use a Webhook Destination to send specific event data to Slack for a team's attention. For more information, see our Slack/Webhook integration topic.

First, in your Slack workspace, use a Slack app to enable incoming webhooks.

Then, in the **New Target** modal, click **Slack** to expose the following additional options on the modal's (single) **General Settings** left tab:

General Settings

Target ID: Enter a unique ID used to identify the target. This will show in the **Target ID** column of the **Targets** tab. You can't change it later, so make sure you like it.

Configuration

Webhook URL: Add the full URL of your Slack Incoming Webhook. For example: `https://hooks.slack.com/services/T00000000/B00000000/XXXXXXXXXXXXXXXXXXXXXXXX`.

Retries

Honor Retry-After header: When toggled on and the `retry-after` header is present, Cribl Edge honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. Cribl Edge always ignores `retry-after` headers that specify a delay longer than 20 seconds.

Cribl Edge will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).

When toggled off (default), Cribl Edge ignores all `retry-after` headers.

Settings for failed HTTP requests: Automatically retries after unsuccessful response status codes, such as `429` (Too Many Requests) or `503` (Service Unavailable). Clicking **Add Setting** reveals a table where you can add retry parameters for individual failed HTTP requests. These include:

- **HTTP status code**: The individual status code for which the retry parameters apply.
- **Pre-backoff interval (ms)**: How long, in milliseconds, Cribl Edge should wait before initiating backoff. The maximum interval is 600,000 ms (10 minutes).
- **Backoff multiplier**: Base for exponential backoff. A value of `2` (default) means Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so forth.

- **Backoff limit (ms)**: The maximum backoff interval, in milliseconds, Cribl Edge should apply. Default (and minimum) is 10,000 ms (10 seconds); maximum is 180,000 ms (180 seconds).

Retry timed-out HTTP requests: When toggled on, Cribl Edge to automatically retries HTTP requests that have timed out. Default is toggled off. Enabling this option exposes the following settings:

- **Pre-backoff interval (ms)**: How long, in milliseconds, Cribl Edge should wait before initiating backoff. Maximum interval is `600,000 ms` (10 minutes).
- **Backoff multiplier**: Base for exponential backoff. A value of `2` (default) means Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so forth.
- **Backoff limit (ms)**: The maximum backoff interval, in milliseconds, Cribl Edge should apply. Default (and minimum) is 10,000 ms (10 seconds); maximum is 180,000 ms (180 seconds).

10.2.2.4. AWS SNS Notification Targets

You can send Notifications to an Amazon Simple Notification Service (SNS) topic. This gives you access to a broad array of Notification destinations, such as various AWS services, mobile push notifications, or text messages.

To add an Amazon SNS Notification target in Cribl Edge, select **Notifications** in the sidebar, and then select **Targets** > **Add Target** > **AWS SNS**.

General Settings

Target ID: Enter a unique ID used to identify the target. This will show in the **Target ID** column of the **Targets** tab. It can't be changed later, so make sure you like it.

Configuration

Destination type: Defaults to **Topic ARN**. The SMS section explains the **Phone number** option.

Default Topic ARN: The default Amazon Resource Name (ARN) of the Amazon SNS topic to which you want to send Notifications. Enter the ARN in the following format:

```
arn:aws:sns:region:account-id:MyTopic

// for example:
// arn:aws:sns:us-west-2:000000000000:my-topic
```

Copy

If you use a non-AWS URL, the format must be:

```
{url}/myQueueName

// for example:
// https://host:port/myQueueName
```

Copy

The default topic ARN must be a JavaScript expression (which can evaluate to a constant value), enclosed in quotes or backticks. Can be evaluated only at initialization time. For example, if you're referencing a Global Variable: `` `https://host:port/myQueue-${C.vars.myVar}` ``. This value can be overridden by the Notification event `__topicArn` field.

Topic type: The type of the topic selected in AWS SNS. Can be **Standard** or **FIFO**.

Message group ID: The tag that specifies that a message belongs to a specific message group. Messages that belong to the same message group are processed in a first in, first out (FIFO) manner. Must be a JavaScript expression (which can evaluate to a constant value), enclosed in quotes or backticks. Can be evaluated only at initialization time. For example, referencing a global variable: `` `https://host:port/myQueue-${C.vars.myVar}` ``.

Region: Select the Region associated with the Amazon S3 bucket.

Phone number allowlist: A wildcard list of phone numbers that are allowed to receive SMS notifications. This is used when **Destination type** is set to **Phone number**.

Authentication

Auto: This default option uses the AWS instance's metadata service to automatically obtain short-lived credentials from the IAM role attached to an EC2 instance, local credentials, sidecar, or other source. The attached IAM role grants Cribl access to authorized AWS resources. Can also use the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. Works only when running on AWS.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Edge Nodes not in an AWS VPC, like those running a private cloud.

The **Manual** option exposes these additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

The values for **Access key** and **Secret key** can be a constant or a JavaScript expression enclosed in quotes or backticks. Store credentials as secrets and reference them with `C.Secret()`: use `` `${C.Secret('myKeyPair', 'keypair').apiKey}` `` for the access key and `` `${C.Secret('myKeyPair', 'keypair').secretKey}` `` for the secret key.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The Secret option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Edge's secrets manager. To store a new, reusable secret, select **Create**.

Assume Role

Enable for SNS: Toggle on to define an IAM Role to use, instead of automatically detecting one locally.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Post-Processing

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` - Cribl Edge Node that processed the event.
- `cribl_input` - Cribl Edge Source that processed the event.
- `cribl_output` - Cribl Edge Destination that processed the event.
- `cribl_route` - Cribl Edge Route (or QuickConnect) that processed the event.
- `cribl_wp` - Cribl Edge Worker Process that processed the event.

Advanced Settings

Maximum number of retries: The maximum number of retries before the output returns an error. The retries use an exponential backoff policy.

Endpoint: The SNS service endpoint. If empty, defaults to AWS' Region-specific endpoint. Otherwise, it must point to an SNS-compatible endpoint.

Signature version: Signature version to use for signing SNS requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. Toggling on (default) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to toggled on.

SMS Notifications

You can use an Amazon SNS Notification target to send text messages (SMS) to a list of phone numbers. To do this, you'll need to set up a allowlist of phone numbers that are permitted to receive Notifications.

1. Select **Notifications** in the sidebar, and then select **Targets** > **Add Target**.
2. Enter a unique **Target ID**.

3. Set the **Target type** to **AWS SNS**.
4. Set **Destination type** to **Phone number**.
5. Set **Region** to the Region of the Amazon S3 bucket.
6. In **Default Phone number**, enter a comma-separated list of phone numbers that are allowed to receive Notifications. This value can be overridden by the Notification event `__phoneNumber` field. You can use `*` as the wildcard character.
   For example: `+15555550123, +15555551***`.
7. If desired, use **Phone number allowlist** to specify a wildcard list of allowed phone numbers.
8. Configure the remaining sections of the AWS SNS Notification target as described earlier.
9. Select **Save**.

Now, when you set up Notifications, you can select the new Amazon SNS target and specify any phone number that matches the configured allowlist.

10.2.2.5. Email Notification Targets

You can send notifications by email, using an SMTP server of your choice. Once you have configured the email notification target, you can specify the recipients and customize the subject line and message content. See Email Notifications for details on configuring an email Notification.

To add an email Notification target in Cribl Edge, select **Notifications** in the sidebar, and then select **Targets** > **Add Target** > **Email**.

General Settings

Target ID: Enter a unique name to identify this email Notification target.

Configuration

Address: Identify the SMTP server by its hostname or IP address.

Port: Set the SMTP port. Use port `587` for SMTP Secure (SMTPS). Use `465` when SSL/TLS is enabled. You can also use port `2525` if your email service provider supports this port as a backup when other ports are blocked by a network provider or a firewall.

In Cribl.Cloud, Organizations on an Enterprise plan can use the default email notification target - `system_email` - and avoid configuring an SMTP server. If you **do** wish to configure an SMTP server in Cribl.Cloud, use any port other than port `25`.

Encryption type: Specify the encryption type used to secure SMTP communication. Options include:

- **STARTTLS**: Select this option to start the connection as plaintext, then upgrade it to a TLS-encrypted one if the server supports it. If the server doesn't support it, the connection remains plaintext.

  STARTTLS upgrades the connection to be encrypted but does not authenticate the server. Take additional steps to prevent man-in-the-middle attacks.

- **Require STARTTLS**: Select this option to require TLS. If the server doesn't support a secure connection, the connection will be dropped.
- **TLS (SMTPS)**: Select this option to use an encrypted connection from the start without requiring a subsequent connection upgrade.
- **None**: Select this option to use a plaintext connection.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Validate server certs: Toggle on to reject certificates that are **not** authorized by a CA in the **CA certificate path** or by another trusted CA (such as the system's CA).

From: Identify the email address of the sender.

Authentication

Username: The authentication principal (if required).

Password: The authentication credential (if required).

Test Email Notification Targets

When you finish configuring your email Notification target, you can manage it, using the following options.

Click **Save & Test Target** to save your target and open a modal where you can enter an email to test your email Notification target. After configuration, the button text changes to **Test Target**.

Default Email Notification Target for Cribl.Cloud Enterprise Orgs

For Cribl.Cloud Enterprise orgs, a default email Notification target is available for Cribl Stream, Edge, Search, and Insights. You can use this target to route any email Notification to any valid email address.

This target appears on the **Notifications** > **Target** page as `system_email`. You cannot modify or remove this target.

The `system_email` Notification target is managed by Cribl. It will be disabled in the unlikely event of abuse. If this target is disabled for a workspace, a log entry will appear in the Notifications Service logs. Select **Monitoring** > **Logs** > **Notifications Service** to view this log.

The `system_email` email Notification target is available only for Cribl.Cloud Enterprise organizations.

Send Domain for Cribl.Cloud Email Notifications

Every Cribl.Cloud workspace and organization has a unique address for its email Notification target. Messages sent using this target will have a sender's address in the form `do-not-reply@<workspaceName>-<organizationId>.criblcloud.email`. To ensure delivery, recipients should add the `criblcloud.email` domain to their email allowlists.

10.3. Configuration Management

Configuration management is the practice of maintaining your deployment's settings in a known, consistent, and versioned state. For Cribl Edge, this means ensuring that you have a clear strategy for developing, maintaining, versioning, and deploying your configuration content at scale.

There are three basic categories of configuration content that you typically need to manage in your Cribl deployment:

- **Data Flow Integrations:** The configurations for integrations (Sources, Collectors (Cribl Stream only), and Destinations) that connect Cribl to your upstream data sources and downstream data destinations.
- **Processing Logic:** The configurations for Routes, Pipelines, and Functions contain the rules and logic that filter and transform your data.
- **Supporting Knowledge Objects:** These are the reusable assets that apply context and structure to your raw data, including Event Breakers, lookup files, HMAC Functions, and more.

See Reference Architecture: Configuration Management for a general introduction to configuration management goals and an overview of configuration management strategies and approaches.

10.3.1. Commit And Deploy Changes

In Cribl Edge, you use the commit and deploy workflow to push configuration changes from the Leader Node (the control plane) to your Fleets (the data plane). See The Cribl Three-Plane Model for an explanation of the Cribl architectural model if needed.

The commit and deploy workflow ensures that changes are versioned, auditable, and synchronized. It also allows you to revert and roll back changes as needed.

Only users with **Admin** or **Editor** permissions have the ability to view and commit configuration changes. See Permissions for more information about roles and abilities.

The Commit and Deploy Lifecycle

The Leader Node acts as the central configuration management hub and is the single authority for all configurations. When you deploy changes from Cribl Edge, it uses a local Git repository to track and version control all configuration changes for that Leader.

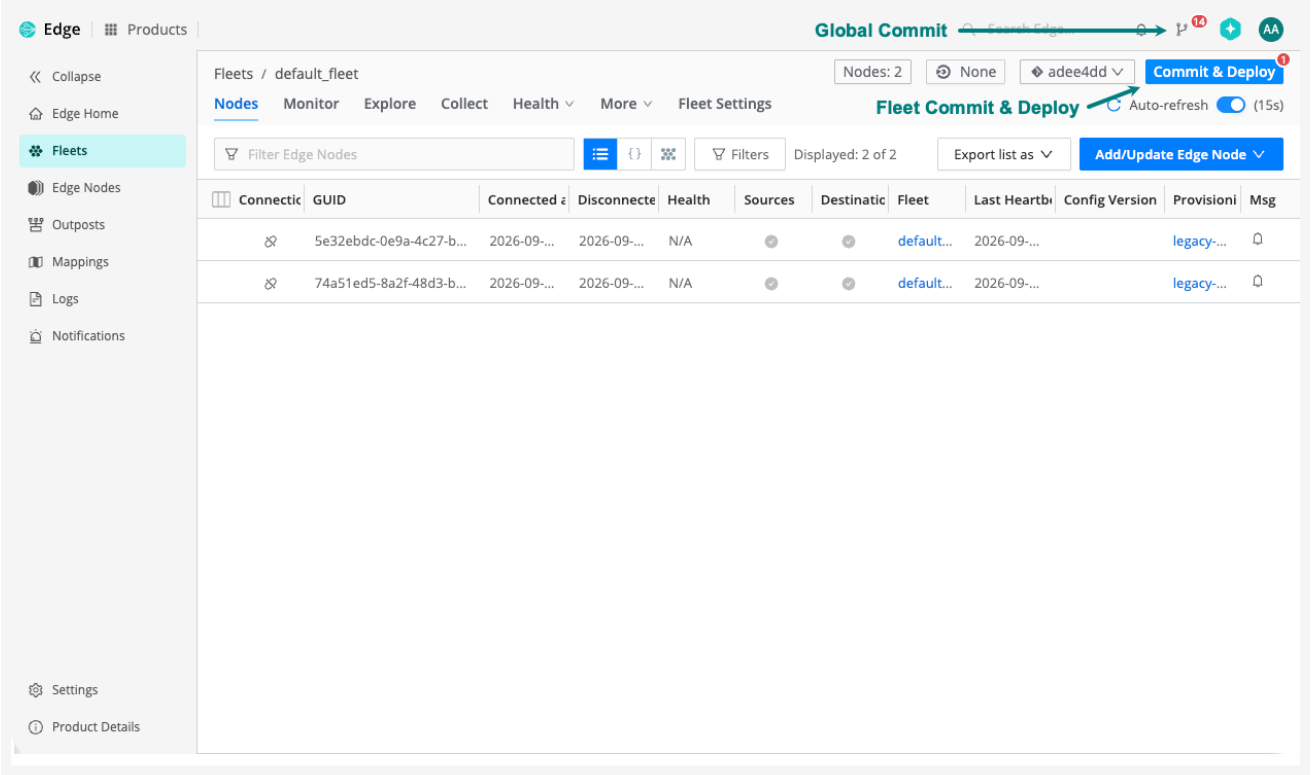
The lifecycle of a configuration change follows a specific order of operations:

1. **Version Control:** Every time you commit in the UI, Cribl Edge performs a Git commit to the local repository on the Leader. This captures a point-in-time snapshot of your settings, including the user who made the change and a description of the update.
2. **Edge Node Notification:** When you deploy, the Leader increments the configuration version and notifies all Edge Nodes in the targeted Fleet that a new version is ready.
3. **Pull Mechanism:** Edge Nodes do not have configurations pushed to them. Instead, they pull the latest bundle from the Leader over the management channel. This ensures that even Edge Nodes with intermittent connectivity eventually synchronize to the source of truth: the Leader.

See How Worker Nodes and the Leader Node Work Together (Stream) and Leader/Edge Node Communication (Edge) for a more detailed technical explanation of the architecture.

Global Commit vs. Fleet Commit

Distributed mode includes Fleet-specific **Commit** and **Deploy** controls. These controls function differently from the global **Commit** button because they have a different scope.



The global **Version Control** button:

- **Scope:** Commits changes for the Leader Node and all Stream Worker Groups, Edge Fleets, Outpost Group, as well as Search configurations simultaneously.
- **Result:** Changes are versioned but not deployed.

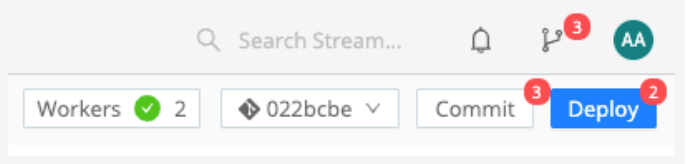
The Fleet **Commit** and **Deploy** buttons:

- **Scope:** Commits and deploys changes for only the currently selected Fleet.
- **Result:** Allows for a single-click Commit and Deploy, making changes live for that specific group immediately.

These controls will appear slightly differently depending on whether you have changes committed but not yet deployed, and on whether you've enabled the Collapse actions setting.

Commit and Deploy controls for an Edge Fleet

Commit and Deploy Changes

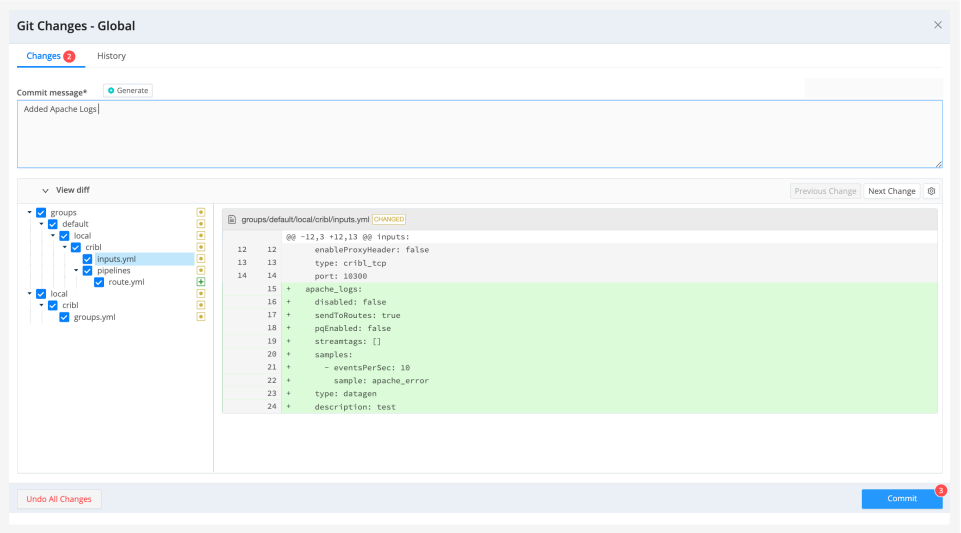


You make configuration changes directly through the Cribl UI or using direct API calls to the Leader Node. The Leader distributes the configuration bundle to Worker Groups, Fleets, Outpost Groups, and other entities upon a manual commit and deploy.

You can also use the Cribl API to automate commit and deploy commands. Read Commit and Deploy Changes in the API documentation for more information.

To commit and deploy configuration changes in the UI:

1. Check the top bar to determine if you have any pending changes to commit. Pending commits have a red dot indicator.



Changes pending commit

2. Select **Commit** to commit pending changes.

> Ensure you select the correct button for your intended scope: either the specific Fleet or the Global (all Groups/Fleets and Leader) level. See Global Commit vs. Fleet Commit for an explanation of the differences in scope and which buttons to use.

3. In the **Git Changes** modal, verify the configuration changes. Optionally, clear the check boxes for individual files or folders to exclude them from the commit. If needed, select **Undo All Changes** to reverse the changes instead of committing them.

Review the pending commit

The **View diff** pane presents the following configuration changes:

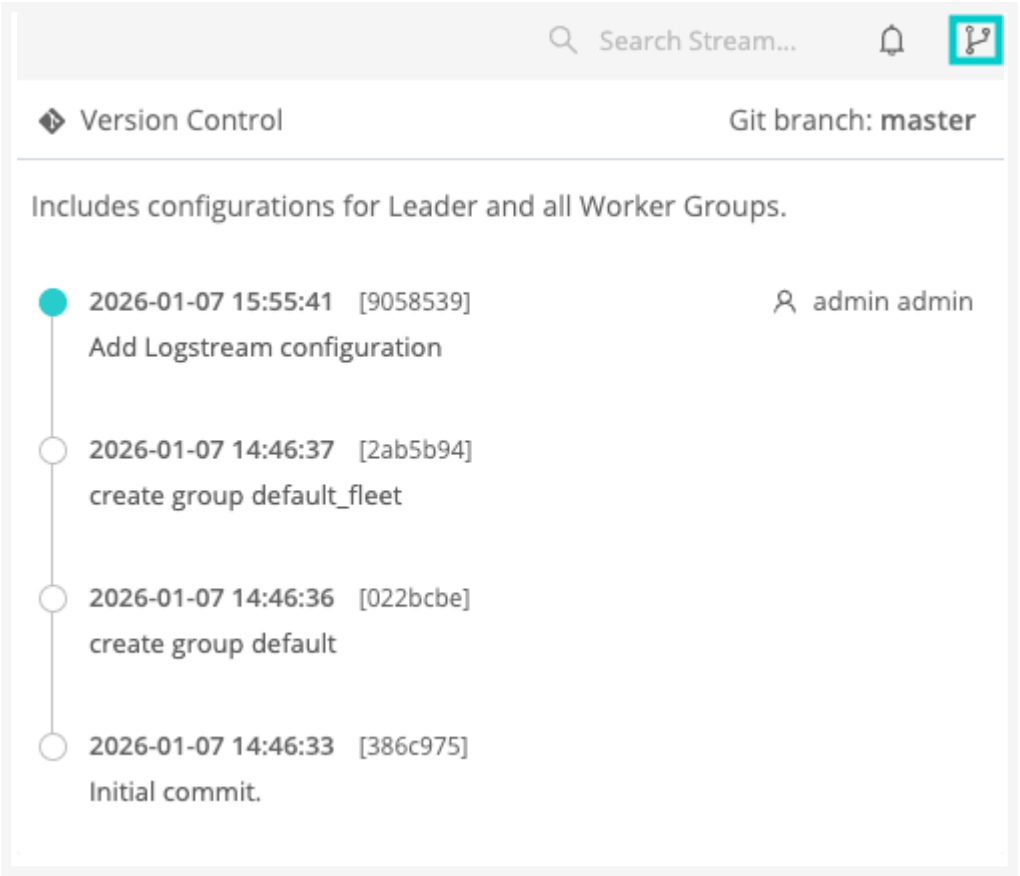
- Leader-related configurations are located in the diff under the `local` entry.
- Definitions of Stream Worker Groups, Edge Fleets, and Outpost Groups reside in `local/cribl/groups.yml`.
- Configuration changes related to specific Stream Worker Groups, Edge Fleets, Outpost Groups, and to Search, are located under the `groups` entry, with specific entries for each group.

See Configurations files for more information about what content the specific files and folders shown in the **View diff** pane represent.

4. Enter a commit message, or select **Generate** to have Cribl AI create a message for you, if a model is configured.
5. Commit your changes, depending on your scope:

Button	Scope	Result
Commit	Global: Commits changes for **all** Stream Worker Groups, Edge Fleets, Outpost Group, as well as Search configurations and the Leader Node simultaneously.	Changes are versioned but not deployed.
Commit Only	Fleet: Commits configurations for the currently selected Fleet and its Subfleets, if **Deploy Subfleets** is selected.	Changes are versioned but not deployed.
Commit & Deploy	Fleet: Commits configurations for the currently selected Fleet and its Subfleets, if **Deploy Subfleets** is selected.	Commits and deploys configuration for the currently selected Fleet and its Subfleets, if **Deploy Subfleets** is selected.

If the commit was successful, you will see a **Commit successful** confirmation message.

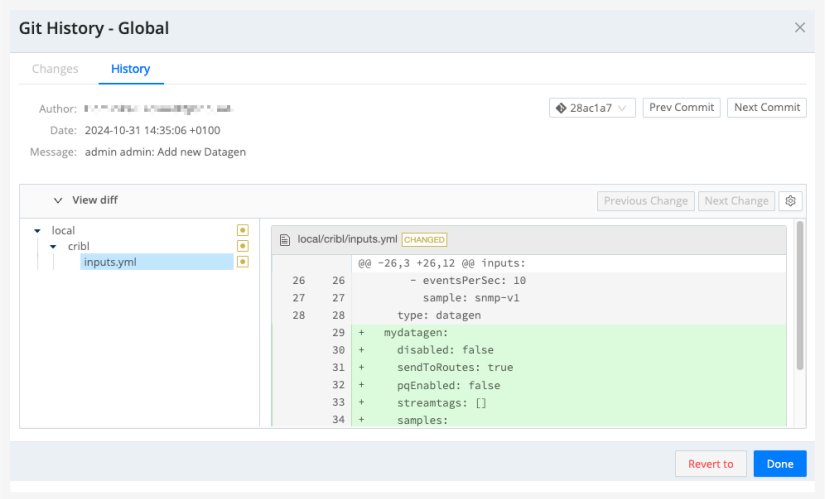


Make sure to commit and deploy changes on all Subfleets before committing or deploying anything on the their parent Fleets to avoid necessary configurations changes being omitted from the commit.

View and Revert Committed Changes

To view committed changes in the UI:

- **Fleets:** Select **Commit** from the top bar and select the **History** tab in the **Git Changes** modal to cycle through the most recent commits.
- **Global:** Select the global **Version Control** icon from the top bar to see a list of the most recent changes. Select a change to view it in the **Git History** modal.



View commits for a Worker Group using the Version Control icon in the top bar

Revert Commits in the UI

Reverting a commit in the UI proceeds slightly differently for Single-instance and for Distributed deployments. In a Distributed deployment, you revert commits for each Fleet separately.

To revert a commit in the UI:

1. If you are on a Distributed deployment, in the sidebar, select **Fleets**, then select the Fleet you want to revert the commit for.
2. Select the commit you want to revert.
3. In the resulting **Git History** modal, verify the diffs in the configuration changes and select **Revert to**.

10.3.2. Connect To External Git Repositories

In on-prem deployments, Cribl supports Git remote repositories so you can implement version control for all configuration changes. Connecting to Git is not required.

This feature requires an Enterprise Cribl license. For details, see Pricing.

You can configure a Leader Node with Git remote push capabilities through the Cribl Edge CLI, or through the Cribl Edge user interface. From Settings, select the **Global** tab, then select **System** > **Git Settings**.

To create a repo, see these tutorials:

- Setting Up a Repository (CLI instructions, host-agnostic, from Atlassian).
- Creating a New Repository (specific to the GitHub Web UI).
- Create a Repo (longer GitHub-specific tutorial, also covers committing changes).

Remote Formats Supported

Remote URI schema patterns should match this regex: `(?:git|ssh|ftps?|file|https?|git@[-\w.]+):(\/\/)?(.*?)(\.git\/?)?$`

You can find a list of supported formats in this external article: What are the supported git url formats?

For example:

- GitHub or other providers: `<protocol>://git@example.com/<username>/<reponame>.git`
- Local Git servers: `git://<host.xyz>:<port>/<user>/path/to/repo.git`

Secure Local Configuration and Remote Repos

Make a local backup of your whole `$CRIBL_HOME` directory before you set a remote repo. This safeguards your Cribl Edge configuration against being overwritten by a misconfigured remote.

Create each new remote as an empty repo, with no README file and no commit history. (See the following GitHub and GitLab examples.)

Some files that are used by Cribl Edge (both Leader and Fleets) contain sensitive keys; examples are `cribl.secret` and `...auth/ssh/git.key`. These will be pushed to the remote repo as part of the entire directory structure under version control. Ensure that this repo is secured appropriately.

Connect to a Remote Repo over HTTPS (Recommended)

Cribl recommends connecting to a remote repo over HTTPS, using **Basic** authentication with a personal access token. Enter the token in the **Password** field rather than embedding it in the **Remote URL**. Cribl Edge encrypts the **Password** field in `cribl.yml` and redacts it from the Git settings API, so the token does not travel with your configuration.

Do not embed a token in the Remote URL

Avoid an **Authentication type** of **None** with the token embedded in the **Remote URL**, as in `https://<username>:<token>@github.com/<owner>/<repository>.git`. Cribl Edge stores that URL verbatim in `cribl.yml` and returns it unchanged from the Git settings API, leaving the token in plaintext in both places. Because Cribl Edge commits and pushes `cribl.yml` itself, the token also lands in the commit history of your remote repo, where secret scanners flag it.

If you already configured a remote this way, revoke the token on your Git provider, then reconfigure the remote with **Basic** authentication and a new token. Revoking is necessary because rotating the token does not remove the exposed one from the commit history.

Example: Connect to GitHub over HTTPS with a Personal Access Token

1. Create a new GitHub repository.
   For best results, create a new empty repo, with no README file and no commit history. (This will prevent `git push` errors.) Note the username and email associated with your login on the repo provider.
2. Create a classic personal access token with **repo** scope. GitHub also offers fine-grained personal access tokens, but these do not work with Cribl Git operations.
3. Copy the token to your clipboard.
4. In Cribl Edge, from Settings, select the **Global** tab, then select **System** > **Git Settings**.
5. In the **Remote** tab, select **Authentication type**: **Basic**.
6. Fill in the **Remote URL** field with your repo name, and no credentials. Use this format:
   `https://github.com/<owner>/<repository>.git`
7. In **User**, enter your username on the repo provider.
8. In **Password**, paste the personal access token.

For additional details, see the GitHub Creating a Personal Access Token tutorial.

For GitHub repos specifically, use a classic personal access token as the **Password** value. GitHub announced its end of support for plaintext account passwords on Git operations as of August 13, 2021.

Example: Connect to a Remote over HTTPS with a Username and Password

Use this method only for a Git host that still accepts account passwords on Git operations. Most hosted providers, including GitHub, now require a token instead. Where a provider issues a token, follow the personal access token example and treat the token as the password.

1. Create a new **empty** repo, with no README file and no commit history. (This will prevent `git push` errors.) Note the username and email associated with your login on the repo provider.
2. In Cribl Edge, from Settings, select the **Global** tab, then select **System** > **Git Settings**.
3. In the **Remote** tab, select **Authentication type**: **Basic**.
4. Enter your credentials in the **User** and **Password** fields.

Neither the **User** nor the **Password** value can contain a colon (`:`) or an at sign (`@`), because Cribl Edge assembles them into a URL. Personal access tokens use characters that are safe in the **User** and **Password** values, but an account password might not.

What Basic Authentication Protects

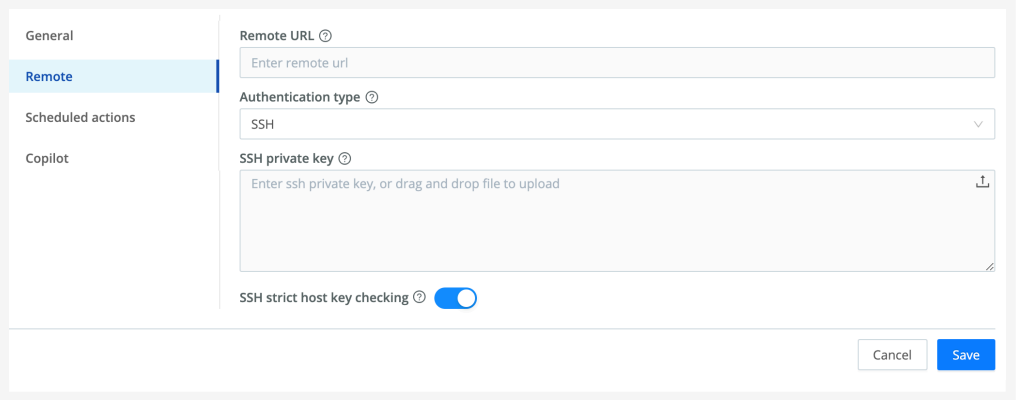
Basic authentication keeps the credential out of `cribl.yml`, and therefore out of the configuration that Cribl Edge commits and pushes. It is not full encryption at rest. Two limits are worth planning around:

- When Cribl Edge authenticates to the remote, it decrypts the password and writes it into `$CRIBL_HOME/.git/config` as part of the `remote.origin.url` value. Git does not commit the `.git` directory, so this credential does not reach the remote, but it is readable by anyone with filesystem access to the Leader.
- SSH private keys are stored in plaintext as well, in `$CRIBL_HOME/local/cribl/auth/ssh/git.key`. Cribl Edge keeps this file outside `cribl.yml` and restricts access to the file owner. See also the warning about sensitive files reaching your remote repo.

Restrict filesystem access to `$CRIBL_HOME` on the Leader accordingly, and scope each token to the narrowest permissions your workflow needs.

Connect to a Remote with SSH

You can set up SSH keys from the CLI, or upload keys via the UI. If you have a passphrase set, this functionality is available only through the CLI. The example below outlines the UI steps.



Example: Connect to GitHub with SSH

1. Create a new GitHub repository.
   For best results, create a new **empty** repo, with no readme file and no commit history. (This will prevent `git push` errors.) Note the user name and email associated with your login to the repo provider.
2. Add an SSH public key to your GitHub account.
3. In Cribl Edge, from Settings, select the **Global** tab, then select **System** > **Git Settings**.
4. In the **Remote** tab, fill in the **Remote [repo] URL**. In the generic example below, replace `<username>` with your username on the repo provider:
   - **Remote URL**: `<protocol>://[user@]server[:port][/path/to/repo.git]` (For example: `ssh://user@server/project/path.git`)
   - For GitHub specifically, the URL/protocol format must be: `ssh://user@server/project/path.git`
   - A specific (fictitious) GitHub example: `ssh://myuser@git.example.com/repos/myproject.git`

   > The Remote Host (or SSH Remote) field currently requires a full `SSH` URL, including the `ssh://` prefix. While the `[user@]server:project.git` (Git-style) format is more common, it is not yet supported. Translate Git-style URLs to SSH-style: for example, `user@server:project/path.git` becomes `ssh://user@server/project/path.git`.
5. Paste in the **SSH private key**.

   > The key will paste in with an appended newline below it. Do not delete this newline before you save the Remote Settings, or else you will trigger an error of the form: `fatal: Could not read from remote repository.`
6. As the user running Cribl Edge, run this command to add the GitHub keys to `known_hosts`:
   `ssh-keyscan -H github.com >> ~/.ssh/known_hosts`

For additional details, see the GitHub Connecting to GitHub with SSH tutorial.

Cribl Edge Git settings

GitLab Notes

For repos hosted on GitLab, we recommend that you:

- Create a new empty (blank) project, with no README file and no commit history. (Clear the **Initialize repository with a README** check box.)

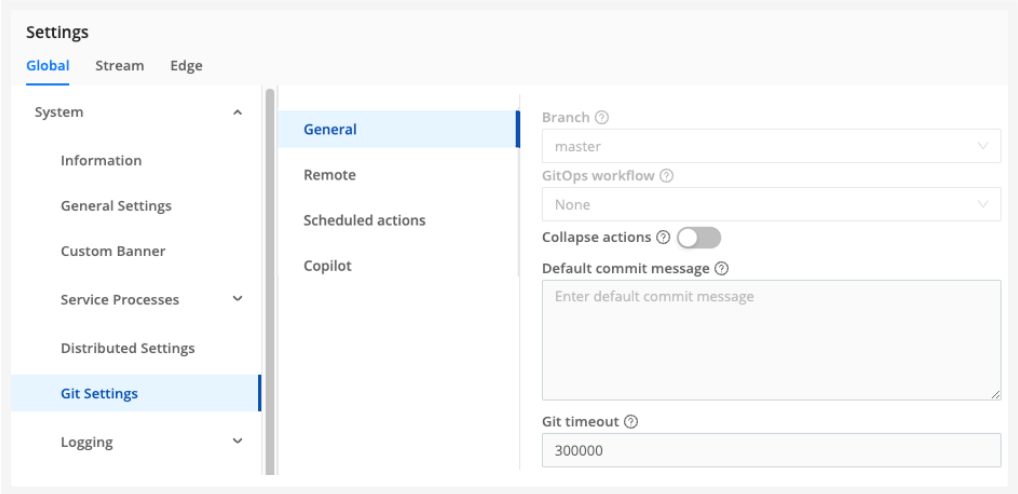
  This will prevent `git push` errors by creating a project with no branch, not even `main`. When you later push the Cribl Edge `master` branch, that will create a corresponding `master` branch on the GitLab remote with no conflicts.

- Create a GitLab project access token for authentication. See the GitLab documentation, which also covers project bot conventions.
- With project bots, the username for the first token is set to `project_{project_id}_bot`. The password is the alphanumeric token.
- Create the token with `write_repository` scope.
- Specify a remote URL in HTTPS format, with no embedded credentials. For example: `https://localgitlab.<yourdomain.ext>/<yourusername>/cribl.git`
- Select **Authentication type**: **Basic**, then enter the bot username in **User** and the project access token in **Password**.
- If you do see a `main` branch in the Cribl Edge UI, do not select it. Leave the branch at `master`, then use the **Commit** and **Push** commands in the Edge UI. This will create the desired `master` branch on the GitLab remote.

The GitLab **Repository Settings** > **Push Rules** section includes these two settings of interest:

- As needed, enable **Check whether author is a GitLab user**.
- Understand the consequences of enabling **Prevent committing secrets to Git**. This blocks commits of `.pem` and `.key` files. If you have certificates or SSH keys configured, this will break commits from Cribl Edge, throwing only a generic `API Error` in the UI. Check your `git` CLI client for more-specific diagnostics.

Additional Git Settings

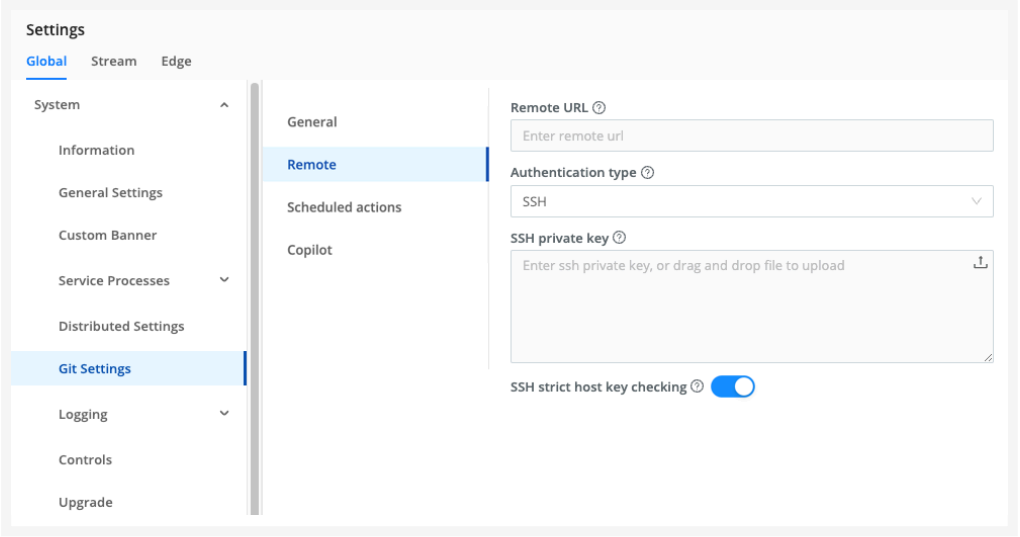


These settings are on-prem only. Cribl.Cloud users will only see the default commit message.

From Settings, select the **Global** tab, then select **System** > **Git Settings**. Select the **General** tab to modify the following additional Git configurations, all of which are optional:

- **Branch**, **GitOps workflow**: These drop-downs are available to configure GitOps in Cribl Stream.

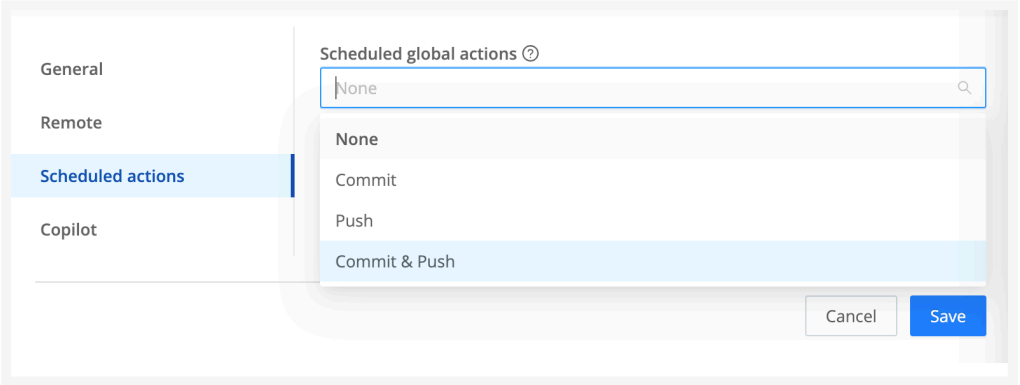
See the GitOps documentation for details and precautions.



- **Collapse actions**: Combine multiple Git buttons to one, to reduce repetitive clicks. See Collapse Actions below.
- **Default commit message**: Enter a placeholder message to apply to all commits from Cribl Edge. This also reduces clicks.
- **Git timeout**: Maximum time (in milliseconds) to wait for Git processes to complete before killing them. If a Leader instance hangs, try lowering this value from the default `600000` (600 seconds = 10 minutes). However, avoid very low values (like `1000` ms), which might time out even when Git processes are working properly. Enter `0` to wait indefinitely.

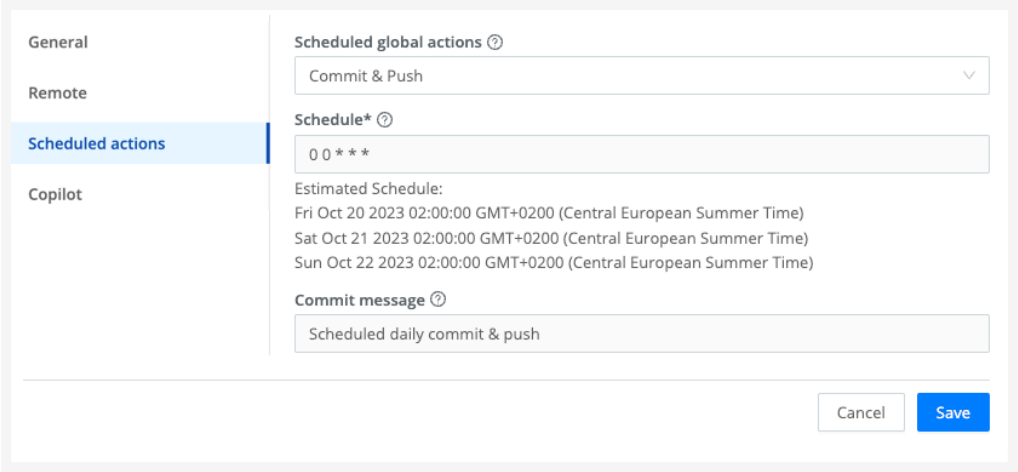
Git Authentication Type settings

On the **Git Settings** > **Remote** tab, you can change the **Authentication Type** from its **SSH** default to **Basic** authentication. This displays two additional fields:



- **User**: Username on the repo.
- **Password**: Authentication password, or a personal access token. Cribl Edge encrypts this field in `cribl.yml` and redacts it from the Git settings API.

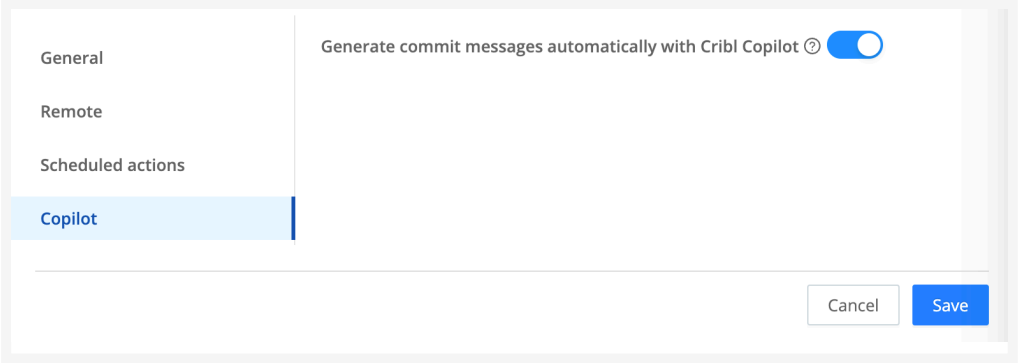
Git Authentication Type settings



With GitHub, use a classic personal access token as the **Password** value. GitHub no longer accepts account passwords on Git operations, but it does accept a token in this field. For details, see Connect to a Remote Repo over HTTPS.

On the **Git Settings** > **Scheduled Actions** tab, you can schedule a **Commit**, **Push**, or **Commit & Push** action to occur on a predefined interval.

Git Scheduled Actions selection



For the selected action type, you can define a cron schedule, and a commit message distinct from the **Default commit message** on the **General** tab. Then select **Save**.

Saving a Git Scheduled Action

You can schedule only one type of action. To swap to a different type, select it from the **Scheduled global actions** drop-down, and resave. To turn off scheduled Git commands, select **None** from the drop-down, and resave.

On the **Git Settings** > **Billy** tab, you can toggle the **Generate commit messages automatically with Billy** option on to have Billy auto-generate every commit message for you. AI-generated messages override any default commit message you may have set.

Enabling AI-generated commit messages

Push Configs to a Remote Repo

Once you've configured a remote, a **Git Push** button appears in the **Global Config** dialog. You can use this to copy committed configuration changes to your remote.

The branch indicator will normally read `master`, as shown above, unless you have enabled GitOps (Cribl Stream only) with an appropriate license.

Collapse Actions

If you enabled the **Git Settings** > **Collapse Actions** option, you will be offered a combined **Commit & Push** button in the **Global Config** dialog.

At the Fleet level, enabling **Collapse Actions** adds a combined **Commit & Deploy** option to the modal you see after clicking **Commit** for the Fleet config.

Enabling **Collapse Actions** with a remote repo simplifies the **Git Changes** confirmation dialog. It substitutes just a commit **Message** text box, with **OK** and **Cancel** buttons - omitting the diff view. Don't enable this option if you prefer to inspect configuration changes before committing.

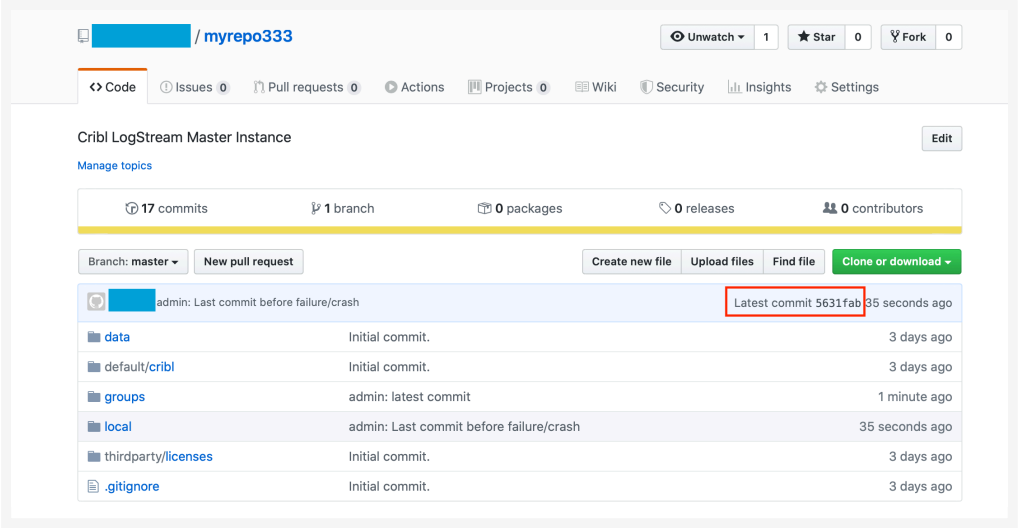
Back Up Configs Out of Band

Once you've configured your remote repo, changes to all Cribl Edge config files under the `$CRIBL_HOME` directory will normally be backed up to your remote whenever you select the above **Git Push** or **Commit & Push** UI buttons. The exceptions are:

- Any configuration files you've chosen to store outside `$CRIBL_HOME`.
- Any configuration files residing in paths you've added to the `.gitignore` file.

To back up these files to your remote, you'll need to either:

- Change the above paths/settings, or
- Use an external `git` client to manually push them.



Troubleshooting Push Errors

To resolve errors commonly encountered when pushing to a remote repo, see:

- Git Push Errors
- Git Remote Repos & Trusted CAs

Restore Leader from a Remote Repo

If a remote repo is configured and has the latest known good Leader configuration, this section outlines the general steps to restore the config from that repo.

Restoring from remote repo

Let's assume that either the entire `$CRIBL_HOME` directory of the Leader is corrupted, or you're replicating the config of the remote repo onto a fresh instance. Let's also assume that the remote repo has the form: `git@github.com:<username>/<reponame>.git`.

1. **Important**: In a directory of choice, untar the **same Cribl Edge version** that you're trying to restore, but do not start it.

Make sure you download the **matching** Cribl Edge version. The Cribl Download page foregrounds current version of Cribl Edge, but provides a link to this archive of prior releases.

2. Change directory into `$CRIBL_HOME` and initialize `git`:

```
# git init
```

Copy

3. If you are using SSH key authentication, specify the key using the following command:

```
GIT_SSH_COMMAND='ssh -i </path/to/github/repo>.key -o IdentitiesOnly=yes'
```

Copy

As an alternative to executing `GIT_SSH_COMMAND` on the fly, you can set your key in `$CRIBL_HOME/.git/config` with: `git config core.sshCommand "ssh -i /path/to/key"`

Or set it globally with: `git config --global core.sshCommand "ssh -i /path/to/key"`

4. Ensure that you have proper access to the remote repo:

```
# git ls-remote git@github.com:<username>/<reponame>.git
56331fabb4822eaec4ca0ffd008d6e9974c1e419f        HEAD
5631fabb4822eaec4ca0ffd008d6e9974c1e419f         refs/heads/master
```

Copy

5. Next, add/configure the remote:

```
# git remote add origin git@github.com:<username>/<reponame>.git
```

Copy

6. Now set up your local branch to exactly match the remote branch:

```
# git fetch origin
# git reset --hard origin/master
```

Copy

7. Finally, to confirm that the commits match, run this command while in `$CRIBL_HOME`:

```
# git show --abbrev-commit
```

Copy

You should see output indicating that `HEAD` points to both `master` and `origin/master`, as in this example:

```
commit 5631fab (HEAD -> master, origin/master)
Author: First Last <email@example.com>
Date:   Fri Jan 31 10:16:07 2020 -0500

    admin: Last commit before failure/crash
......
```

Copy

Step 6 above pulls in all the latest configs from the remote repo. Step 7 confirms the local repo matches the remote. You should now be able to start the Leader as normal. Once up and running, Edge Nodes should start

checking in after about 60 seconds.

Verify cribl.secret

The `cribl.secret` file - located at `$CRIBL_HOME/local/cribl/auth/cribl.secret` - contains the secret key that is used to encrypt sensitive settings on configuration files (for example, AWS Secret Access Key). Make sure this file is properly restored on the new Leader, because it is required to make encrypted conf file settings usable again.

`.gitignore` File

A `.gitignore` file specifies files that Git should ignore when tracking changes. Each line specifies a pattern that matches a file path to ignore.

Cribl Edge maintains a `.gitignore` file with two sections:

- `CRIBL SECTION`: Default ignore patterns that Cribl Edge manages. On Leader start or restart, Cribl Edge synchronizes the `CRIBL SECTION` with the ignore patterns for that Cribl version.
- `CUSTOM SECTION`: Ignore patterns that you add. Cribl Edge does not modify this section. See Handle Customer-Defined .gitignore Exclusions for details.

The following example shows the required section structure in the `.gitignore` file. It does not include a complete list of Cribl-managed patterns because those patterns can change by Cribl version. Treat `$CRIBL_HOME/.gitignore` on the Leader as the authoritative list for your deployment.

.gitignore

10.3.3. Configure Fleet Settings

Configure teleporting, throughput throttling, logging, and security at the Edge Fleet level.

Required Permission: **Admin**

In Cribl Edge, you can use **Fleet Settings** to configure Node teleporting, throughput throttling, logging, upgrading, and security at the Fleet level.

To edit Fleet Settings:

1. Select the Fleet, then select **Fleet Settings**.
2. Configure the following settings per Fleet.

General Settings

Fleet Configuration

You can configure the following general Fleet options on the **Overview** tab:

Fleet Configuration Setting	Description
Enable teleporting to Nodes	Check to enable authenticated access to the Edge Node UI from the Leader. For more information about teleporting, see Teleport into an Edge Node.
Description	Optionally, add or edit the Fleet description.
Tags	Use tags to organize Fleets into logical categories. Then, you can search by tags on the **View all Fleets** interface. This search filters the list of Fleets, showing only those with the tag you entered.
Time to keep disconnected Nodes	Configure how long the Fleet should retain information about a Node that disconnects from the Leader. Format examples: 8h, 5d, 1w (format defaults to days if you only specify a number). Default: 1 day.
Inherited configuration	Optionally, select an existing Fleet that this Fleet will inherit configurations from.

Settings configured on the **Overview** tab are not inherited by Subfleets.

API Server Settings

General

You can set the following options for the API server:

API Server Setting	Description
Host	The hostname or IP address you want to bind the API server to. • Defaults to `127.0.0.1` for standalone Edge Nodes and Edge Fleets. • You can override the value with the `CRIBL_API_HOST` environment variable.
Port	API port to listen to. • Defaults to `9420` for standalone Edge Nodes and Edge Fleets. • You can override the value with the `CRIBL_API_PORT` environment variable.

TLS

For information on TLS options, see the documentation for any Source or Destination that supports TLS.

Advanced

You can set the following advanced options for the API server:

API Advanced Server Setting	Description
Retry count	The number of times to retry binding to the API port. Default is `120`.
Retry period	The period between consecutive retries for API port binding, in seconds. Default is `5`.
URL base path	The URL base path from which to serve all assets. Setting a URL base path may be useful when operating behind a proxy server.
Listen on port	Toggle on (default) to expose the API service to the network on the configured API port. When toggled off, Cribl Edge doesn't listen on the port (`9420` by default).
Local UI access	Toggle on (default) to allow direct browser access to the UI for Edge Nodes.
Logout on roles change	If role-based access control is enabled, toggle on to automatically log out users when their assigned Roles change. Default is toggled on.

API Advanced Server Setting	Description
Auth token TTL	Authentication tokens' valid lifetime, in seconds. Default is `3600` (60 minutes = 1 hour); minimum is `1`.
Session idle time limit	How long to observe no user interaction before invalidating users' session tokens, in seconds. Default is `3600` (60 minutes = 1 hour); minimum is `60`.
Login rate limit	Deprecated in advanced settings. Configure at **Limits > API**.
SSO/SLO callback rate limit	Deprecated in advanced settings. Configure at **Limits > API**.
HTTP headers	One or more custom HTTP headers to send with every response.
Enable API cache	Toggle on to enable browser caching of frequent API requests. Default is toggled on. Toggling off can slow the UI response time.

Default TLS Settings

See the System-wide TLS Settings Including Ciphers.

Limits

The **Limits** tab provides access to controls for metrics, storage, metadata, jobs, the Redis cache and connections to it, and CPU settings.

Metrics

You can configure the following options for metrics. For more information, see Controlling Metrics Volume.

Metrics Field	Description
Metrics worker tracking	Define which metrics are not assigned a Node ID dimension, which means they will not be split by Edge Node.
Number of metrics allowed	The total number of metrics series allowed.
Metrics cardinality limit	The maximum allowed number of unique combinations of metrics names and their dimensions.
Metrics GC period	The metrics garbage collector (GC) runs when the total number of stored metrics exceeds the **Number of metrics allowed**.
Metrics never-drop list	A list of internal metrics that the Cribl Edge Node will always send to the Leader.
Disable field metrics	A list of metrics that you don't want to collect.

Metrics Field	Description
Metrics to send from Edge Node	Set of metrics to send from the Edge Nodes to the Leader.

Metrics to send from Edge Node allows the following settings:

Metrics to send from Edge Node	Description
Minimal	Sends metrics for events and bytes in and out. Recommended for high-cardinality deployments. Sent as aggregate totals per Fleet: • `total.in_events` • `total.out_events` • `total.in_bytes` • `total.out_bytes` Excludes metrics that are coming directly from Sources or Destinations.

Basic (default)	Contains all the metrics in the minimal set, and more. Sends metrics required to display all monitoring data available in the Edge UI. Sent as aggregate totals per Source/Destination:
	`total.in_events`, `total.out_events`, `total.in_bytes`, `total.out_bytes`.
	Also, Sent as aggregate totals per Source:
	`health.inputs`
	Sent as aggregate totals per Destination:
	`health.outputs`
	Sent as aggregate totals per Route:
	`route.in_events`, `route.in_bytes`, `route.out_events`, `route.out_bytes`, `route.dropped_events`
	Sent as aggregate totals per Pipeline:
	`pipe.in_events`, `pipe.out_events`, `pipe.dropped_events`
	Sent as aggregate totals per Pack:
	`pack.in_events`, `pack.out_events`, `pack.err_events`, `pack.dropped_events`

Metrics to send from Edge Node	Description
All	Send all metrics with no filtering. All metrics without filtering, including **Basic**, plus Worker/Edge Node Resource Metrics, Persistent Queue Metrics, and Other Internal Metrics.
Custom	Send a customized set of metrics. All metrics that match a JavaScript expression that you define, plus the metrics in the **Minimal** set.

Storage

You can configure the following options for storage:

Storage Setting	Description
Sample size limit	Maximum file size, in binary units (`KB`, `MB`), for sample data files. Maximum: `3 MB`. Default: `256 KB`.
Min free disk space	The minimum amount of disk space on the host before various features take measures to prevent disk usage (KB, MB, and so on). Default: `5 GB`. To avoid the "Unable to write to the filesystem, disk space low" error, ensure that the available disk space remains above this threshold by monitoring disk usage and configuring alerts.
Worker Process PQ size limit	Highest accepted value for the **Queue size limit** option used in individual Sources' and Destinations' persistent queues. Default: `1 TB`. Consult Cribl Support before increasing beyond this value.

Metadata

Event metadata sources: List of event metadata sources to enable. Available sources: `os`, `cribl`, `aws`, `azure`, `env`, and `kube`. `os`, `cribl`, `aws`, `env`, and `kube` sources are enabled by default.

Jobs

Job Limits Setting	Description
Disable jobs/tasks	When enabled, the Edge Nodes won't poll the Leader for jobs/tasks. The job limits settings below will not affect Edge Nodes on version 4.5.0 and newer. Edge Nodes running 4.4.4 and older still use these jobs settings even if jobs/tasks are disabled here.
Concurrent job limit	The total number of jobs that can run concurrently. Defaults to `10`.
Concurrent system job limit	The total number of **system** jobs that can run concurrently. Defaults to `10`. Minimum `1`.

Job Limits Setting	Description
Concurrent scheduled job limit	The total number of **scheduled** jobs that can run concurrently. This limit is set as an offset relative to the **Concurrent job limit**. Defaults to `-2`. Skipped jobs indicate that a Fleet's **Concurrent job limit** has been reached or exceeded. Increase this limit to reduce the number of skippable jobs. For resource-intensive jobs, this might require deploying more Edge Nodes.
Concurrent task limit	The total number of tasks that a Worker Process can run concurrently. Defaults to `2`. Minimum `1`.
Concurrent system task limit	The number of system tasks that a Worker Process can run concurrently. Defaults to `1`. Minimum `1`.
Task usage percentage limit	Value, between `0` and `1`, representing the percentage of total tasks on a Worker Process that any single job may consume. Defaults to `0.5` (50%).
Task poll timeout	The number of milliseconds that a Worker's task handler will wait to receive a task, before retrying a request for a task. Defaults to `60000` (60 seconds). Minimum `10000` (10 seconds).
Max replay slots	Maximum number of missed cron slots to replay synchronously on restart for non-skippable jobs with `resumeMissed` enabled. Beyond this cap, iterators jump forward to prevent unbounded memory usage. Default is `1000`.

API

You can configure the following options for API limits.

Metrics Field	Description
Login rate limit	The number of login attempts allowed over the specified interval. For example, to limit login attempts to 50 per minute, set the **Rate** at `50` and select `minute` as the **Interval**. Supported intervals are `second`, `minute`, `hour`, and `day`. Default is 2 seconds.
SSO/SLO callback rate limit	The number of requests to SSO and SLO callback endpoints allowed over the specified interval. For example, to limit requests to 10 per minute, set the **Rate** at `10` and select `minute` as the **Interval**. Supported intervals are `second`, `minute`, `hour`, and `day`.

Completion Limits

Completion Limits Setting	Description
Artifact reaper period	Interval on which Cribl Edge attempts to reap jobs' stale disk artifacts. Defaults to `30m`.
Finished job artifacts limit	Maximum number of finished job artifacts to keep on disk. Defaults to `100`. Minimum `0`.
Finished task artifacts limit	Maximum number of finished task artifacts to keep on disk, per job, on each Edge Node. Defaults to `500`. Minimum `0`.

Task Manifest and Buffering Limits

Task Manifest and Buffering Setting	Description
Manifest flush period	The rate (in milliseconds) at which to refresh the task manifest of a job. Defaults to `100` ms. Minimum `100`, maximum `10000`.
Manifest buffer size limit	The maximum number of tasks that the task manifest can hold in memory before flushing to disk. Defaults to `1000`. Minimum `100`, maximum `10000`.
Manifest reader buffer size	The number of bytes that the task manifest reader should pull from disk. Defaults to `4kb`.
Job dispatching	The method by which tasks are assigned to Worker Processes. Defaults to `Least In-Flight Tasks`, to optimize available capacity. `Round Robin` is also available.
Job timeout	Maximum time a job is allowed to run. Defaults to `0`, for unlimited time. Units are seconds if not specified. Sample entries: `30`, `45s`, `15m`.
Task heartbeat period	The heartbeat period (in seconds) for tasks to report back to the Leader/API. Defaults to `60` seconds. Minimum `60`.
Orphaned job TTL	Time to keep orphaned job artifacts on disk. Orphaned jobs without a done file are reaped after this period. Units are seconds, minutes, hours, or days. Sample entries: `30s`, `15m`, `24h`, `7d`. Defaults to `7d`.

Redis

Cache

Redis Cache Setting	Description
Key TTL in seconds	Maximum time to live of a key in the cache (seconds). `0` indicates no limit. Defaults to `10 minutes`.
Key limit	Maximum number of keys to retain in the cache. `0` indicates no limit. Defaults to `0`.
Cache size limit (bytes)	Maximum number of bytes to retain in the cache. `0` indicates no limit. Defaults to `0`.
Service period (seconds)	Frequency of cache limit enforcement. Defaults to every `30 seconds`.
Server assisted	Default is toggled off. When toggled on, the following control appears.
Client tracking mechanism	Mechanism for invalidation message delivery. In default mode, the server remembers which keys a client has requested and only sends invalidations for those, using more Redis server memory. In broadcast mode, it sends all invalidations, requiring more processing by Cribl Edge.

Connections

Redis Connections Setting	Description
Reuse Redis connections	Toggle on if you want Cribl Edge to try to reuse Redis connections when multiple Redis Functions (or references to them) are present. When enabled, displays the following additional control: • **Connection limit**: The maximum number of identical connections allowed before Cribl Edge tries to reuse connections. Defaults to `0`, meaning unlimited connections are allowed (equivalent to leaving **Reuse Redis connections** toggled off). Setting a non-zero integer value forces Cribl Edge to try to reuse connections for each individual Worker Process (**not** to reuse connections **among** Worker Processes).

To understand why and when to employ these controls, see Managing Redis Connections.

Lookups

Lookup Setting	Description
Lookup file max size	Maximum allowed disk space for persisting a single lookup data file. Defaults to `500 MB`. If you use very large lookup files, increase this limit. A larger limit can consume more disk space and memory on Edge Nodes, potentially impacting performance.

Lookup Setting	Description
Lookup files disk limit	Maximum allowed disk space for persisting lookup data and metadata files. Defaults to `2 GB`. This aggregate limit applies to the sum of all lookup files managed by that Node.
Allowed lookup file paths	Additional directories where lookup files can reside, beyond the default lookup directories under `$CRIBL_HOME`. Enter each directory path separately. Environment variables such as `$CRIBL_HOME` are expanded, and relative paths resolve against `$CRIBL_HOME`. A lookup file is permitted when it resides in a listed directory. Leave this empty to restrict lookups to the default lookup directories.

Other

Other Setting	Description
CPU profile TTL	The time-to-live for collected CPU profiles.
Default managed node heartbeat period	How many seconds a managed Node will wait to send back a heartbeat to the Cribl control plane.
Config bundle download timeout	How many seconds an Edge Node will wait for a successful Leader connection before canceling a download of a new configuration bundle. This timeout helps prevent Nodes from hanging indefinitely when there are network issues or other delays during the download process. A `0` value means wait indefinitely, which could cause Nodes to hang.
Minimum reconnect interval	The minimum time to wait before attempting to reconnect to the Leader after being disconnected or when the Leader is not available. The interval is doubled with each failed reconnect attempt until the maximum limit is reached.
Maximum reconnect interval	The maximum time to wait before attempting to reconnect to the Leader after being disconnected or when the Leader is not available.
Random reconnect interval	Upper limit on the random time added to each reconnect interval. Set this to a value other than zero to randomly spread out reconnection attempts. This can prevent the Leader being overwhelmed by reconnection attempts by a large number of Edge Nodes.
Use Windows tools to collect process info	Enable PowerShell to collect process information instead of using the native API. This legacy setting will be removed in a future release. We highly recommend keeping this option disabled and using the newer native capabilities which are faster and more reliable.
Disable metrics accessor cache	Consult Cribl Support before adjusting this advanced setting. Disables the metrics accessor cache.

When using PowerShell to collect process information, the environment variables displayed in the Explore > Processes tab might be inaccurate. They will reflect the environment of the PowerShell process itself, not the actual environment of the process being viewed.

Proxy Settings

Proxy Setting	Description
Use proxy env vars	Honors the `HTTP_PROXY/HTTPS_PROXY` environment variables. Defaults to toggled on. Cribl prioritizes environment variables for proxy settings in this order: Process, User, and System. If your Cribl service is managed by a service manager other than systemd (such as upstart or init), the `Use proxy env vars` toggle might not behave as expected because Cribl might prioritize environment variables set by the service manager instead of using the proxy settings you intended.

Shutdown Settings

Shutdown Setting	Description
Drain timeout (sec)	Determines how long a Cribl server will wait for writes to complete before the server shuts down on individual Worker Processes. If you notice that Workers are under-ingesting available data upon shutdown or restart, increase the `10`-second default. Acceptable range of values: minimum `1` second, maximum `600` seconds (10 minutes).

SNI

SNI Setting	Description
Disable SNI-based connection routing	This setting affects how the Cribl Edge control plane routes connections.

Do not change this setting without consulting Support first.

Support

Support Setting	Description
Feature Flag Overrides	Cribl thoroughly tests all releases in Cribl.Cloud environments to ensure stability and reliability. However, new features can sometimes behave unpredictably in customer-managed data environments. The scale of some environments and the complexity of many possible configurations make it difficult to test for every possible scenario, occasionally leading to unforeseen issues. To ensure the stability of your production environment, Cribl Edge includes a safety mechanism that makes it possible to disable specific new features if they are causing unexpected issues. This is a customer-first tool designed to minimize impact and avoid the need to roll back upgrades or wait for a full patch release. If you suspect that a new feature is impacting your environment, please contact the Support team for assistance. This process ensures that Cribl can quickly stabilize your environment while also collecting the necessary information to improve Cribl Edge for everyone. **Do not change this setting without consulting Support first.**
Log file max size	Maximum size of each log file before rotation. Enter a numeral with units of KB or MB (for example, `5 MB`, `1024 KB`). Default: `5 MB`. Minimum: `1 MB`.
Number of log files to keep	Number of rotated log files to keep before purging. Default: `5`. Range: `1–100`. Only new rotations use this limit. Existing files above the previous limit are not removed.

Worker Processes

Worker Processes Setting	Description
Process count	**This setting only applies to the** Kubernetes Logs **and** File Monitor **Sources**. Indicates the number of Worker Processes to spawn. Positive numbers specify an absolute number of Workers. Negative numbers specify a number of Workers relative to the number of CPUs in the system, for example: {<`number of CPUs available`> minus <`this setting`>}. The default in Cribl Edge is 1. • You can use **Process count** to adjust the number of Worker Processes **only for the Kubernetes Logs and File Monitor Sources**. This is necessary when running the Kubernetes Logs/File Monitor Source with load balancing enabled. Load balancing increases performance when you have a higher event ingest volume than one Worker Process can handle. • Cribl Edge will provision at least the **Minimum process count** set below, but no more than the number of CPUs the host has available.
Minimum process count	Indicates the minimum number of Worker Processes to spawn. Overrides the lowest Process count result. Cribl Edge interprets a 0 entry as "default," which here yields 1 Process.
Memory (MB)	Amount of heap memory available to each Worker Process, in MB. The OS allocates heap memory dynamically as the Process requests it up to the amount dictated by this setting. The Memory (MB) setting does not govern external (ext) memory.
Enable heap snapshots	Default is toggled off. Toggle on for Cribl Edge to automatically create memory snapshots for Worker Processes when they approach or exceed memory limits. Only the two most recent heap snapshots are retained. Older snapshots are automatically deleted. This behavior cannot be modified. **Enable heap snapshots** is available for hybrid or on-prem deployments only. This setting should only be enabled if recommended by support or if you are experiencing out-of-memory issues. Be aware that enabling this setting may impact system performance and storage usage.
Restart unresponsive Worker Processes	Default is toggled on. Cribl Edge automatically restarts Worker Processes that are unresponsive and unable to send timely heartbeats to the API Process. Toggle off to disable automatic restarts.
Worker Process reload timeout (secs)	Maximum time to wait for a Worker Process to reload configuration before restarting it. Defaults to `60` seconds. Acceptable range: `10`–`600` seconds. Consult Cribl Support before changing this setting.
Worker Process config update	Fraction of Worker Processes to reload or restart at each step during

10.4. Uninstall Cribl Edge From Linux

Removing a Cribl Edge installation from Linux, whether for a clean reinstall or permanently.

Uninstalling a Single Edge Node

- (Optional) To prevent systemd from trying to start Cribl Edge at boot time, run the following command: `sudo $CRIBL_HOME/bin/cribl boot-start disable`
  If you're running both Cribl Edge and Cribl Stream on the same host, be sure to execute this command in the same mode (Edge or Stream) and the same directory in which you originally ran `cribl boot-start enable`.
- Stop Cribl Edge (stopping the main process).
- Back up any necessary configurations/data.
- Delete the `cribl` user: `userdel cribl`
- Delete the user group: `groupdel cribl`
- Remove the directory where Cribl Edge is installed.
- Directly delete any local files that Cribl Edge added while running, such as the `.dat` file and other local configs.
- Remove any leftover files in the system's temporary directory. On Linux, this is `/tmp` by default.
- Remove any related configuration files and scripts, and disable the Cribl service if using a service manager.

In a Distributed deployment, repeat the above steps for the Leader instance and all Edge Node instances.

Uninstalling a Distributed Deployment

In a distributed deployment, repeat the above steps on:

- The Leader instance.
- All Edge Node instances.

10.5. Uninstall Cribl Edge From Windows

Cleanly remove a Cribl Edge instance from Windows.

You can uninstall Cribl Edge - whether for a clean reinstall or permanently - either via the Windows UI or via your command prompt.

Using the Windows UI

To uninstall Cribl Edge using Windows' graphical UI:

1. On your Windows Server, search for **Add or remove programs**.
2. In the **Apps & features** list, scroll to **Cribl Edge**, and click **Uninstall**.
3. In the confirmation dialog, click **Yes**.

A success message will confirm removal.

This uninstall process does not automatically delete the `local`, `log`, `pid`, and `state` directories, because those folders include contents generated after the original installation completed. To completely remove the application, you must explicitly delete the folders from the filesystem.

Using the Command Prompt

If you installed Cribl Edge using the command line, you can uninstall it by running the following at a command prompt:

```
msiexec /x cribl-<version>-<build>-<arch>.msi
```

Copy

10.6. Uninstall Cribl Edge From MacOS

Cleanly remove a Cribl Edge instance from macOS.

To cleanly remove a Cribl Edge instance from macOS:

1. Stop the service:

```
sudo launchctl unload /Library/LaunchDaemons/io.cribl.plist
```

Copy

2. Remove the installed Edge Node:

```
sudo rm -rf /Library/LaunchDaemons/io.cribl.plist /opt/cribl
sudo pkgutil --forget io.cribl.pkg.edge
```

Copy

10.7. Customize The Interface

You can customize the Cribl Edge interface to adapt it to your needs by adding:

- A custom login page with a selected logo and additional explanatory text.
- Custom banners to serve information, warnings, or news to users.

10.7.1. Custom Banners

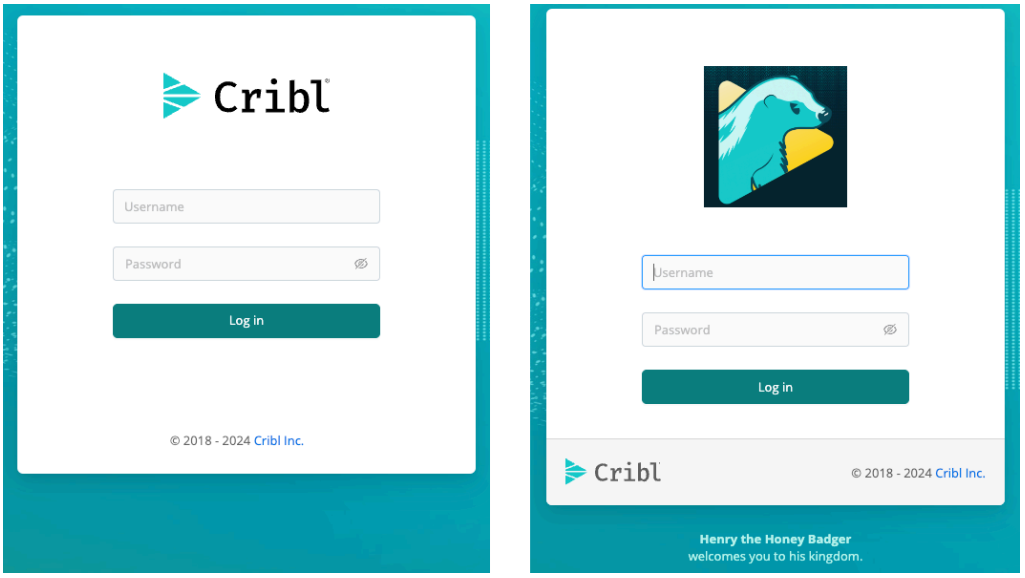
Cribl admins can define a custom banner from the Leader. This will be displayed at the top of your Cribl Organization, above all Cribl apps. You can display one banner at a time.

Your banner can display warnings, requirements, neutral updates, or good news about new features or options. It can contain a mixture of text, a raw URL, or a URL with a friendly/short label. The banner does not appear unless you enable and configure it, as described here.

1. In the sidebar, select **Settings** > **Global**.
2. Select **System** > **Custom Banner**.
3. Toggle **Enable banner** on to expose the configuration options.
4. From the **Background color** dropdown, select a background color for your banner. You can also pick a custom color by selecting **+Add color** in the dropdown.
5. Optionally, toggle **Invert front color** to **Yes** to make the text on the banner white instead of black (typically, for darker custom banner colors).
6. In the **Banner message** field, enter a single-line message of up to 100 characters. The displayed banner will truncate characters that cannot fit across one line of a given viewport.
    - You can use emojis and special characters in the banner message. To open the menu of supported options, place the cursor in the **Banner message** field and press **Ctrl+Cmd+Space** (macOS) or **Windows key + semicolon** (Windows).
7. In the **Link URL** field, optionally enter a hyperlink to append to the message.
8. In the **Link display** field, optionally give your **Link URL** a text label. This can include up to 100 characters, but a long label can force-truncate the **Banner message**. A short label helps everything fit.
9. Select **Save** to display your banner.
10. Commit your changes from the Leader.

To hide the banner, toggle the **Enable banner** off, and again **Save** and commit your changes. Your banner's configuration will remain intact, ready to re-enable and/or revise when you're ready.

10.7.2. Custom Login Page



You can customize the look of the login page for all Cribl apps.

Custom login pages are available only in on-prem installations.

Configure Custom Login Page

To configure a custom login page:

1. In the Cribl Edge sidebar, select **Settings**, then **Global**.
2. Under **System**, select **General settings**.
3. Go to **Custom login page** and toggle **Enabled** on.
4. In **Logo file**, select an image file that will serve as a logo. The image must be no larger than 350x350px, under 2MB, and in .png, .jpg, or .jpeg format.
5. In **Content**, edit the provided HTML to modify the text block displayed under the login box.

Built-in and customized login pages

10.8. Scripts

Scripts are available only in on-prem deployments, not in Cribl.Cloud.

Admins can run scripts (for example, shell scripts) from within Cribl Edge by configuring and executing them at **Settings** > **Global** > **Scripts**. Scripts are typically used to call custom automation jobs or, more generally, to trigger tasks on demand. For example, you can use Scripts to run an Ansible job, or to place a call to another automation system, when Cribl Stream configs are updated.

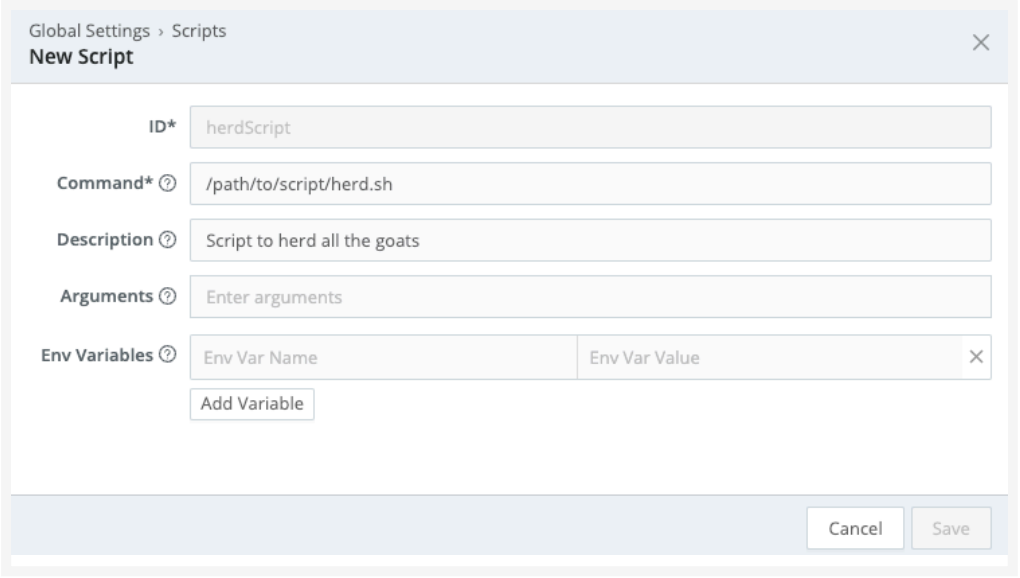
With Great Power Comes Great Responsibility!

Scripts will allow you to execute almost anything on the system where Cribl Edge is running. Make sure you understand the impact of what you're executing before you do so!

Enable Scripts

For security reasons, using scripts is disabled by default on all new deployments. You can re-enable them by using the `limits` command (available since Cribl Edge 4.8.2).

To control script availability, run:



```
# Enable scripts
./cribl limits -s true
# Disable scripts
./cribl limits -s false
```

Copy

When you enable or disable scripts, you need to restart the instance for the changes to take effect.

Add Scripts

To add a new script, select **Add Script** on the scripts settings page.

Settings > Scripts page

The **New Script** modal provides the following fields:

- **ID**: Unique ID for this script.
- **Command**: Command to execute for this script.
- **Description**: Brief description about this script. Optional.
- **Arguments**: Arguments to pass when executing this script.
- **Env variables**: Extra environment variables to set when executing script.

Scripts in Distributed Deployments

- Scripts can be deployed from the Leader Node, but can be **run** only locally from each Worker Node.
- If the Script command is referencing a file (for example, `herd.sh`), that file must exist on the Cribl

11. Secure Your Deployment

Secure your Cribl Edge deployment, whether hosted on Cribl.Cloud, hybrid or on-prem, by following these guides:

- Secure your Cribl.Cloud Deployment
- Cribl.Cloud Security Practices
- Secure your On-Prem/Hybrid Deployment
- Configure TLS
- Create and Manage Legacy Secrets
- Configure KMS Providers
- Create and Manage Encryption Keys
- Compliance

11.1. Secure Your Cribl.Cloud Deployment

Cribl.Cloud is SOC 2 Type II-certified and GDPR-compliant, simplifying compliance with industry standards and regulatory requirements. For Cribl.Cloud security architecture details, see Cribl.Cloud Security Practices.

For formal compliance reports and penetration test executive summaries, see Request Access to TrustCloud.

To secure your Cribl.Cloud deployment, consider implementing the following.

Secure Your Cribl.Cloud Account

Create a strong password during your initial setup.

To create a secure password, ensure it is at least 12 characters long and includes a combination of lowercase letters, uppercase letters, numbers, and special characters (!@#$%^&*). Follow the on-screen instructions carefully to meet these requirements.

(For Cribl.Cloud setup instructions, see Initial Cribl.Cloud Setup).

Review Your Network Settings

When you log into your Cribl.Cloud Organization, navigate to the **Workspace** link. Here you can check and manage connectivity details - Data Sources, Access Control, and Trust relationships - for your Cribl-managed Workers in Cribl.Cloud.

On the **Data Sources** tab, you can review the available ports and TLS configurations.

Note that TLS encryption is pre-enabled for you on some, but not all Sources. For more information, see TLS in Cribl.Cloud.

Configure TLS Mutual Authentication on Cribl.Cloud

Within Cribl.Cloud, enabling mutual TLS authentication for individual data sources requires a trusted Certificate Authority (CA) certificate chain. This CA certificate verifies the legitimacy of the client certificate presented by the source during connection. For details, see TLS Mutual Authentication in Cribl.Cloud.

Set Up Role-Based Access Control for Members

Cribl.Cloud offers detailed role-based access control (RBAC) to ensure appropriate permissions and security. For details on how to invite and manage the roles for Members of your Organization, see Members.

Set Up Your Preferred Authentication Method

When your Cribl.Cloud Organization uses a certain plan, you have a range of secure and convenient login options to fit your Organization's needs, including:

- Local Accounts - Create traditional usernames and passwords for direct login. For details, see Local Authentication.
- Federated Authentication (OIDC and SAML): Integrate with existing identity providers (IdPs) like Okta or Entra ID for centralized user management and single sign-on (SSO). For details, see Cribl.Cloud SSO Setup.

Data at Rest

Cribl.Cloud provides built-in encryption for data at rest, ensuring that your information remains secure within its infrastructure.

Secure Data in Motion

For an extra layer of protection, you can enrypt individual fields within events. For details, see Encryption of Data in Motion.

Currently, Cribl Edge supports decryption only when Splunk is the end system. For details, see Decryption of Data in Splunk.

For a comprehensive solution, we recommend configuring TLS. TLS encrypts the entire data stream, including all event fields, regardless of Source or Destination type. This provides a more robust security posture for your data in motion. For details, see Secure Sources and Destinations with TLS and mTLS.

Configure a Key Management Service (KMS)

A Cribl.Cloud Organization on a certain plan offers a Key Management Service (KMS) that strengthens the security of your data. KMS securely manages the encryption keys used to protect sensitive information on Worker Groups and Nodes within Cribl. For details on how to activate and configure KMS, see KMS Configuration.

(Optional) Segment Your Organization with Workspaces

Segment your organization's data and user access using Workspaces. This multi-tenancy feature allows you to create isolated instances within your Cribl.Cloud Organization, addressing critical security, compliance, and data isolation requirements tailored for diverse business units.

Each Workspace boasts a dedicated virtual private cloud (VPC). This essentially creates a separate environment within your Organization for each Workspace, ensuring the complete isolation of data and users in different Workspaces.

For details, see Configuring Workspaces.

(Optional) Create Isolated Data Environments Using Stream Projects

Within Cribl Stream, Projects offer a more granular level of isolation allowing teams and users to manage and share data flows without impacting others. Projects enable you to define the data that the Project's users can consume, where that data can be sent, and who has access to the Project.

Projects are ideal for teams and users who need to share and manage specific data, with accelerated access to relevant data and minimal configuration requirements. Data can be forked into full-fidelity versus redacted views to match the authorzation requirements and needs of different teams or users.

For details, see Configuring Projects.

11.2. Secure Your On-Prem/Hybrid Deployment

This document outlines essential security considerations to safeguard your on-prem/hybrid Cribl deployment.

Secure Your Installation

Secure your Cribl Edge deployment by ensuring the following during installation.

Choose a Secure Environment

Protect your Cribl deployment by:

- **Isolating your deployment** - deploy Cribl Edge on a dedicated network segment to minimize exposure.
- **Restricting physical access** - control who can physically access the deployment hardware.

Configure a System Proxy

Enhance the security and reliability of your Cribl deployment by leveraging proxy servers.

- To configure a system proxy for outbound HTTP/S traffic: Set the HTTP_PROXY and HTTPS_PROXY environment variables before starting Cribl Edge, specifying the proxy's IP address or FQDN and optionally the port number. For details, see System Proxy Configuration.
- To configure a SOCKS proxy for secure communication between Leader and managed Nodes: Follow the steps in Configure a SOCKS proxy. This will allow you to bypass network restrictions and ensure uninterrupted data flow.

Create a Dedicated User

To enhance security, avoid running Cribl Edge with root privileges. Instead, create a dedicated user account with limited permissions.

For details, see Setting Capabilities for Cribl Stream or Running Edge as an Unprivileged User.

Change Default Admin Password

After your initial login, immediately create a strong, unique password for the administrator account. This will help prevent unauthorized access.

Note: Edge Node passwords are managed by the Leader Node.

Security Files

For details on the `cribl.secret` master encryption key and other security files, see How Secrets Are Protected.

You can use the **Settings** > **Security** > **Secrets** section to create and update authorization tokens, username/password combinations, and API-key/secret-key combinations for reuse across the application. For details, see Secrets.

Set Your Remote Git Repo to Private

Cribl uses Git for efficient configuration management. In Distributed deployments, a local Git repository tracks configuration changes. For added security and disaster recovery, you can also connect to a remote Git repository. Here are some key considerations.

- **Private repositories** - Always ensure that your remote Git repository is private, to prevent unauthorized access to your configuration files.
- **Disaster recovery** - Remote repositories provide a valuable backup for your Cribl configuration in case of system failures or data loss.

FIPS Mode (Cribl Stream only)

Do not start Cribl Stream without FIPS mode enabled, or else you will be unable to run it in FIPS mode later. You must enable FIPS mode as described in the FIPS Mode document, after installing **but before starting** Cribl Stream.

Secure the Leader Auth Token

Cribl Edge uses authentication tokens to control communication between the Leader and Worker Nodes, Edge Nodes, and Outpost Nodes.

You can track token usage and, when needed, rotate or revoke tokens.

For more information on creating and managing tokens, see Create and Manage Authentication Tokens.

Set up Role-Based Access Control for Members

Cribl offers detailed role-based access control (RBAC) to ensure appropriate permissions and security. For details on how to define and manage fine-grained access control across Cribl products and resources, see Members and Permissions.

Enhance Security with an Identity Provider (IDP)

We strongly recommend using an external Identity Provider (IDP) to implement single sign-on (SSO) for Cribl. This enhances your organization's security, by centralizing user authentication and authorization.

For details, see:

- SSO with Okta and OIDC (on-prem)

- SSO with Okta and SAML
- SSO with Microsoft Entra ID (On-Prem)

Secure Your Communication

Secure your Cribl communication channels by using the following options.

- **SSL/TLS** - Encrypt Cribl access and traffic with SSL or TLS.
- **Custom headers** - Enhance security with custom HTTP headers.
- **Encryption** - Create and manage your own keys to encrypt events in real time.
- **Secrets** - Centrally manage secrets that your instances use to authenticate on integrated services.
- **KMS** - Use internal or external key management service for advanced key management.

Choose a combination that best aligns with your organization's security policies.

Secure Access to the Leader and Edge Nodes

You can secure access to the Cribl Edge API and UI by configuring Secure Sockets Layer (SSL) or Transport Layer Security (TLS). Do this on the Leader, to secure inbound communications to the Edge Nodes. You can use your own certs and private keys, or you can generate a pair with OpenSSL. For details, see Configure TLS for API and UI Access.

For TLS details, see the following:

- TLS Version Support and Defaults
- TLS Settings and Traffic Types
- System-wide TLS Settings Including Ciphers

Import an Existing Certificate and Key

You can secure Leader-to-Edge Node communications by using an existing TLS/SSL certificate and key, in `\.pem\` format. For details, see Add a Certificate.

Create a Self-signed Certificate

You also have the option to create a self-signed certificate and key by following the steps outlined in Generate a Self-Signed Certificate.

Connect to the Leader Securely

Configure secure communication between your Leader and Edge Nodes using either the user interface, the `instance.yml` configuration file, or environment variables. For details, see Configure TLS.

Secure Access to the Worker/Edge Nodes UI

Cribl recommends that in Enterprise Distributed deployments, you prevent direct browser access to the UI for all Edge Nodes. For details, see Secure Browser Access to Edge Node.

Configure TLS Mutual Authentication (optional)

Implement client certificate exchange to enhance security by allowing only authorized clients with valid certificates to connect to the Leader. Configure this feature after setting up encrypted TLS communication. For details, see Secure Leader-Node Communication with mTLS (On-Prem).

Secure Communication Between Sources and Destinations

To authenticate Cribl Edge with external data senders and receivers, configure certificates at the Fleet level. For details, see Secure Sources and Destinations with TLS and mTLS.

Configure Custom HTTP Headers

Custom HTTP headers are metadata that can be sent along with HTTP requests and responses. They provide a way to convey extra data that is not part of the standard HTTP protocol. You can customize Cribl's security settings with custom HTTP headers. For details, see Custom HTTP Headers.

Create Encryption Keys

You can create and manage keys that Cribl Edge will use for real-time encryption of fields and patterns within events. For details, see:

- Accessing Keys.
- Add New Key.
- Get Key Bundle.
- Safeguarding Unencrypted Private Key Files for Rollback (Edge/Stream).
- Restoring Unencrypted Private Keys.

Configure a Key Management Service (KMS)

Cribl offers a built-in Key Management Service (KMS) that strengthens the security of your data. With Standard and Enterprise license tiers, you have the option to integrate an external KMS. A KMS securely manages the encryption keys used to protect sensitive information on Fleets and Edge Nodes within Cribl Edge.

For details, see Configure KMS.

Create Secrets

Use the Cribl secrets store to isolate and simplify the management of authentication tokens, usernames/passwords, and API keys.

- To understand the master encryption key, see How Secrets Are Protected.
- To access secrets, see Accessing Secrets.
- To add a new secret, see Add New Secret.
- For secret types, see Secret Type.

Secure Data at Rest

You are solely responsible for implementing encryption for data at rest on systems hosting Cribl products. To secure data at rest, consider:

- **Filesystem-level encryption**: Encrypting the entire file system where Cribl data resides.
- **Hardware-level encryption**: Using self-encrypting drives (SEDs) or other hardware-based encryption mechanisms.

Secure Data in Motion

For an extra layer of protection, consider encrypting your data while it travels between Cribl Edge and your data Sources and Destinations. For details, see Data Encryption.

Currently, Cribl Edge supports decryption only when Splunk is the end system. For details, see Data Decryption.

For a comprehensive solution, we recommend configuring TLS. TLS encrypts the entire data stream, including all event fields, regardless of Source or Destination type. This provides a more robust security posture for your data in motion. For details, see Secure Sources and Destinations with TLS and mTLS.

Disable the Exec Source

The Exec Source, while powerful, can pose security risks if not configured and used carefully. To mitigate these risks, you can disable the Exec source by setting the `CRIBL_NOEXEC` environment variable. This prevents the execution of arbitrary commands, reducing the attack surface. For details, see Disable the Exec Source.

Restrict Remote Data Capture

To prevent Live Capture from sending event samples from a Edge Node to the Leader, set `CRIBL_DISABLE_FEATURES=remote_capture` on that Edge Node. For details, see `CRIBL_DISABLE_FEATURES`.

Filter Sensitive Information in API Responses

Use the `sensitiveFields` configuration property to filter sensitive information in the responses to API requests to `/inputs` and `/outputs` endpoints. Add an array that lists the attributes you want to filter under `sensitiveFields` in the `api` section of your `cribl.yml` configuration file, as shown in this example:

Example sensitiveFields array in cribl.yml

```
api:
  host: 0.0.0.0
  port: 9000
  sensitiveFields:
    - awsApiKey
    - awsSecret
    - token
    - password
  retryCount: 120
  ...
```

Copy

In the responses for `/inputs` and `/outputs` endpoints, Cribl returns empty values (`''`) for the attributes you list in the `sensitiveFields` array. In this example, Cribl will return empty values for the attributes `awsApiKey`, `awsSecret`, `token`, and `password`.

In a distributed deployment, the process that serves each request applies masking from its own `cribl.yml`. Cribl does not propagate `sensitiveFields` from the Leader to Worker Groups, so a Worker Group's Sources and Destinations are masked only when you set `sensitiveFields` in that group's `cribl.yml` (`groups/<group-id>/local/cribl/cribl.yml`). Set the property in each Worker Group whose Source and Destination responses you want to filter.

Use caution: the `sensitiveFields` configuration property affects UI workflows and applications that rely on the responses to `/inputs` and `/outputs` endpoints. The responses will contain empty values (`''`) instead of plaintext values for the attributes that you list in the `sensitiveFields` array. When you change or update a Source or Destination, you must also re-enter the correct value for any attribute that is listed in the `sensitiveFields` array.

Refer to the API reference for more information about the `/inputs` and `/outputs` endpoints and the attributes that appear in their responses.

11.3. Secure Node Access

As a security measure, we recommend you prevent direct browser access to the UI for all Edge Nodes.

Disable Exposing the API Service for Edge Nodes

Cribl recommends that in enterprise Distributed deployments, you disable exposing the API service to the network on the configured API port for all Edge Nodes.

1. Select a Fleet.
2. Open **Fleet Settings** (top right).
3. Under **General Settings** > **API Server Settings**, select **Advanced**.
4. Toggle **Listen on port** off.
5. Select **Save**.

Secure Browser Access to Edge Node

Cribl recommends that in enterprise Distributed deployments, you prevent direct browser access to the UI for all Edge Nodes.

> On the Leader Node, start by enabling UI access to Edge Nodes (Stream, Edge). This way, admins will still be able to tunnel through from the Leader to the UI on any Edge Node. This is also a prerequisite for securing Leader-Node Communication with TLS.

1. Select a Fleet.
2. Open **Fleet Settings** (top right).
3. Under **General Settings** > **API Server Settings**, select **Advanced**.
4. Toggle **Local UI access** off.
5. Select **Save**.

11.4. Create And Manage Authentication Tokens

Authentication tokens are issued by the Leader Node to control and secure communication between the Leader, Outpost Nodes, Workers, and Edge Nodes.

Types of Authentication Tokens

The following authentication token types are available:

- **Provisioning** tokens are the fundamental way to deploy new Stream Workers, Edge Nodes, and Outposts, and connect them to the Leader Node.
  You can later manage, rotate, and revoke provisioning tokens and track their usage in the UI.
- **Environment** tokens are authentication tokens you use for programmatic deployments, such as deployment using Docker Compose or Helm charts.

Authentication Tokens in New Deployments

New on-prem Cribl Edge deployments include no built-in provisioning tokens. You need to create a token to connect any hybrid Stream Workers, Edge Nodes, or Outposts to the Leader.

Cribl.Cloud deployments handle tokens for Cribl-managed Worker Groups in Cribl Stream automatically. However, you still need to create tokens for authenticating Outpost Nodes, Edge Nodes, and Workers in customer-managed (hybrid) Worker Groups.

Authentication Tokens in Upgraded Deployments

Cribl Edge deployments created on versions older than 4.20 used a different authentication token mechanism. On upgrade to 4.20, those deployments will automatically receive one **legacy** type token set to the value of the existing auth token.

Cribl recommends rotating the legacy token to a new provisioning token at your earliest convenience.

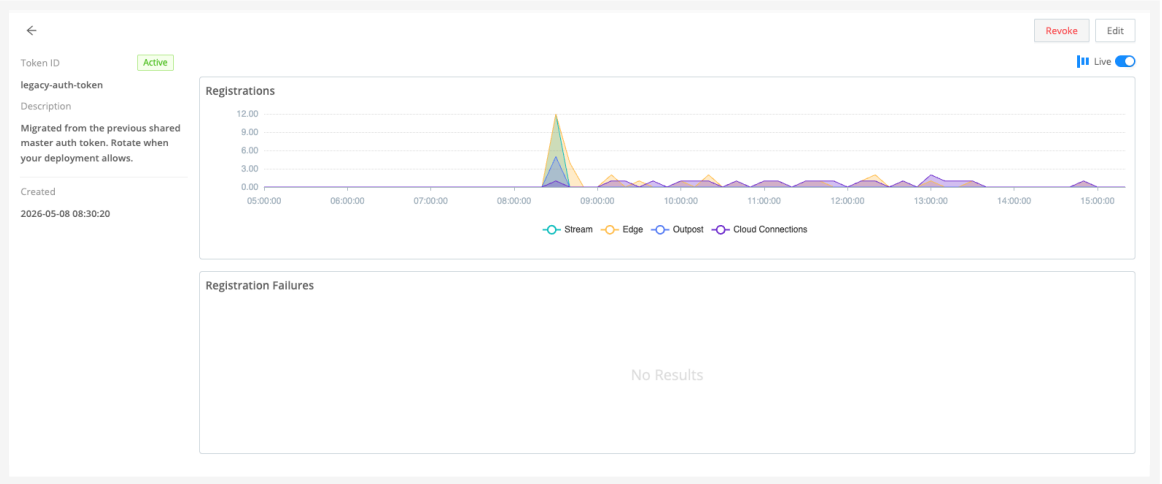
Create a New Provisioning Token

To create a new provisioning token:

1. In the sidebar, select **Settings**, then select **Global**.
2. Select **Security**, then **Provisioning Tokens**.
3. Select **Create Token**.
4. Enter a **Token ID**. Once the token is created, you can’t change this ID.
5. Optionally, enter a **Description** that will help identify the proper token to use.

6. Confirm with **Create Token**.
7. You will be shown the newly created token. Copy it and save it in a secure place. You can also select **Download** to download the token as a text file.
   The token will not be shown again.
8. Confirm with **Close**.

You can now use this token when creating a new Edge Node, for example, by inputting it in the **Add/Update Edge Node** modal.



Monitor Token Usage and Health

The list of tokens in **Settings** > **Global** > **Security** > **Provisioning Tokens** show tokens that are currently in use.

Each token has a status:

- **Active** - can be used for connecting Stream Workers, Edge Nodes, and Outposts.
- **Revoked** - has been revoked and can no longer be used by Nodes. Existing Nodes will remain connected until their next restart.

Select a token to see its details. This screen also shows you charts visualizing the number of Worker Nodes, Edge Nodes, Outposts, and Cloud Connections using this token, and the number of failed Node registrations.

An authentication token with its information

Rotate a Token

Rotating lets you switch Edge Nodes to use a different token.

To rotate a token for a selection of Edge Nodes:

1. On the top bar, select **Products**, then **Edge**, then **Edge Nodes**.
2. Select the Edge Nodes you want to rotate the token for.

3. Select **Rotate Token**.
4. In **Token ID**, select the token you want to rotate to.
5. Confirm with **Rotate and Restart**, or **Rotate** if you want to restart the Edge Nodes manually.

You must restart Edge Nodes after rotating for them to switch to connecting via the new token.

Revoke a Token

You can revoke a token to pull it back from all Edge Nodes that use it and ensure it won't be used to connect any new Edge Nodes.

You can't revoke the legacy token in a Cribl.Cloud deployment.

To revoke a token:

1. In the sidebar, select **Settings**, then select **Global**.
2. Select **Security**, then **Provisioning Tokens**.
3. Select the token you want to revoke.
4. Select **Revoke**. You will see a modal asking for confirmation. Type `REVOKE` to confirm.

You can't undo revoking a token.

5. Confirm with **Revoke Token**.
6. Restart the Edge Nodes you revoked the token for.

Token revocation will come into force only after you restart the Edge Nodes.

Environment Tokens

You can use environment tokens as a supplementary way of authenticating Nodes to the Leader without creating a provisioning token, for example, in scripts. Those tokens will not be visible in the UI and you cannot monitor, rotate, and revoke them like provisioning tokens.

An environment token takes the form of a string and is passed to the Leader Node in the `CRIBL_DIST_AUTH_TOKENS` environment variable.

Cribl recommends using strings that contains at least 14 characters and includes uppercase letters, lowercase letters, and numbers.

11.5. Configure TLS

Cribl Edge lets you use the Transport Layer Security (TLS) to secure communications in the following contexts.

Leader-Edge Node Communications

You can secure communication between the Leader Node, Outpost Nodes, and Edge Nodes with either one-directional, standard TLS or mutual TLS (mTLS). With standard TLS, you create a certificate on the Leader (and on Outpost Nodes) that the Edge Nodes must trust to confirm a secure connection.

Standard TLS is enabled by default on the Leader Node in Cribl.Cloud, but needs to be enabled and configured manually in on-prem deployments.

See Secure Leader-Node Communication with TLS for more information about standard TLS, and Secure Leader-Node Communication with mTLS for guidelines about mTLS (on-prem only).

Source/Destination Communications

You can secure communication between Edge Nodes and supported integrations via TLS or mTLS to authenticate data senders and receivers, protect data in transit, and prevent unauthorized access.

Create or import a certificate to a Fleet and enable TLS to ensure only TLS traffic is accepted by a Cribl Source or sent by a Cribl Destination.

See Secure Sources and Destinations with TLS and mTLS for more information.

Leader API and UI Access

You can also secure the Leader by enabling TLS for the UI and API inbound communications.

See Configure TLS for API and UI Access for more information.

11.5.1. Add TLS Certificates And Keys

You can add and manage TLS certificates and keys in Cribl Edge to be reused across multiple purposes, including:

- Securing Leader-Node Communication with TLS
- Securing Sources and Destinations with TLS and mTLS
- Configuring TLS for API and UI Access

Certificate Requirements

Cribl Edge expects certificates and keys to be formatted in privacy-enhanced mail (`.pem`) format.

You can use:

- Certificates from a public certificate authority (recommended for production; trusted by most clients by default).
- Certificates issued by your organization internal PKI (requires adding the root and intermediate CA certificates to client trust stores).
- Self-signed certificates (for lab/test environments only; requires manual trust configuration).

Generate a Self-Signed Certificate (Optional)

For non-production or lab environments, you can generate a self-signed certificate and private key using OpenSSL:

```
openssl req -nodes -new -x509 -newkey rsa:2048 \
  -keyout myKey.pem \
  -out myCert.pem \
  -days 420
```

Copy

This command generates:

- `myCert.pem`: a self-signed certificate (valid for 420 days).
- `myKey.pem`: an unencrypted 2048-bit RSA private key.

Add a Certificate

Once you have a certificate generated or prepared, you can add it on the on-prem Leader or Fleet.

On the Leader

Add a certificate on an on-prem Leader Node to secure communications from Outposts or Edge Nodes to the Leader.

> You do not need to add certificates to Cribl.Cloud Leaders. Leaders in Cribl.Cloud are secured with TLS certificates managed and configured by Cribl.

1. In the sidebar, navigate to **Settings** > **Global** > **Security** > **Certificates**.
2. Select **Add Certificate**.
3. Enter a descriptive **Name** (for example, `leader-ui-tls` or `worker-tls`).
4. In the **Certificate** field, do one of the following:
   - Drag and drop your `.pem` certificate file into the field.
   - Select the upload button to browse for the file.
   - Open the certificate file, copy its contents, and paste them into the field.

   Certificate should have the following form:

```
-----BEGIN CERTIFICATE-----
CERTIFICATE CONTENT
-----END CERTIFICATE-----
```

Copy

5. In the **Private key** field, upload or paste the corresponding private key in PEM format.
   An unencrypted private key should have the following form:

```
-----BEGIN RSA PRIVATE KEY-----
HIDDEN PRIVATE KEY
-----END RSA PRIVATE KEY-----
```

Copy

   An encrypted private key uses a different heading and footer:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----
HIDDEN ENCRYPTED PRIVATE KEY
-----END ENCRYPTED PRIVATE KEY-----
```

Copy

6. (Optional) If your private key is encrypted, enter the **Passphrase**.
7. (Optional) If you're using a certificate signed by an external certificate authority (for example, a downloaded Splunk Cloud certificate), you have mTLS enabled, and need to validate client certificates, upload or paste the CA certificate chain into the **CA certificate** field. For details, see Obtain the Certificate Chain (TLS/SSL).
8. (Optional) Add a **Description** to help identify the certificate's purpose.
9. Select **Save**.

On a Fleet

You can use certificates added at Fleet level to secure connection to external services through Sources.

To add certificates at the Fleet level:

1. In the sidebar, select **Fleets**, then select the Fleet you want to configure.
2. Select **Fleet Settings**.
3. Navigate to **Security** > **Certificates**.
4. Select **Add Certificate**.
5. Enter a descriptive **Name** (for example, `leader-ui-tls` or `worker-tls`).
6. In the **Certificate** field, do one of the following:
   - Drag and drop your `.pem` certificate file into the field.
   - Select the upload button to browse for the file.
   - Open the certificate file, copy its contents, and paste them into the field.

   Certificate should have the following form:

```
-----BEGIN CERTIFICATE-----
CERTIFICATE CONTENT
-----END CERTIFICATE-----
```

Copy

7. In the **Private key** field, upload or paste the corresponding private key in PEM format.
   Private key should have the following form:

```
-----BEGIN RSA PRIVATE KEY-----
HIDDEN PRIVATE KEY
-----END RSA PRIVATE KEY-----
```

Copy

An encrypted private key uses a different heading and footer:

```
-----BEGIN ENCRYPTED PRIVATE KEY-----
HIDDEN ENCRYPTED PRIVATE KEY
-----END ENCRYPTED PRIVATE KEY-----
```

Copy

8. (Optional) If your private key is encrypted, enter the **Passphrase**.
9. (Optional) If you're using a certificate signed by an external certificate authority (for example, a downloaded Splunk Cloud certificate), upload or paste the CA certificate chain into the **CA certificate** field. For details, see Obtain the Certificate Chain (TLS/SSL).
10. (Optional) Add a **Description** to help identify the certificate's purpose.
11. Select **Save**.
12. **Commit and Deploy** the Fleet's new configuration.

Manage Existing Certificates

To view and manage certificates you've already added:

1. Navigate to **Settings** > **Global** > **Security** > **Certificates** (Leader) or **Fleet Settings** > **Security** > **Certificates** (Fleet level).
2. Select a certificate name to view or edit its details.
3. To delete a certificate, click the delete icon next to the certificate entry.

Before deleting a certificate, verify it's not in use by any TLS configuration (Leader UI/API, Leader–Edge Node communications, Sources, or Destinations).

Using Certificates

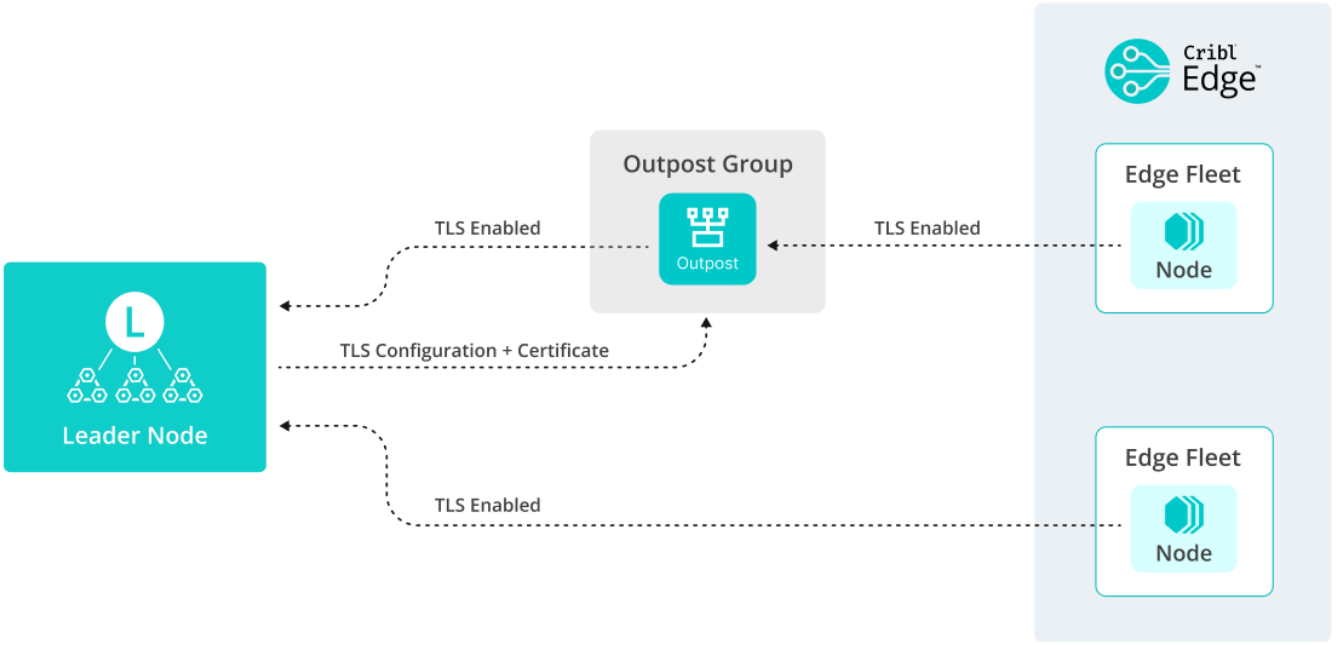
After adding a certificate, you can reference it by name in various TLS configurations:

Purpose	Where to Configure
Leader UI/API	**Settings** > **Global** > **General Settings** > **API Server Settings** > **TLS** > **Certificate**
Leader–Edge Node Communications	**Settings** > **Global** > **System** > **Distributed Settings** > **TLS Settings** > **Certificate**
Edge Node TLS	**Edge Node Settings** > **System** > **Distributed Settings** > **TLS Settings** > **Certificate**
Sources/Destinations	Individual Source or Destination TLS settings

Maintaining TLS Certificates

Certificate revocation can lead to unexpected service interruptions. To mitigate risks:

- Regularly review and renew certificates.
- Implement robust monitoring and alerting systems to detect potential issues.
- Ensure secure storage of certificates and private keys.



11.5.2. Secure Leader-Edge Node Communication With TLS

Secure the communication between Leader Node, Outposts, and Workers/Edge Nodes with TLS.

You can use TLS to secure communication between the Leader Node, Outpost Nodes, and Workers/Edge Nodes.

In Leader-Node communication, Leader serves as the TLS server, and Nodes, whether Outposts, Edge Nodes or Workers, act as the client. When securing communication between an Outpost and a Worker/Edge Node, Outpost is the server, while the Worker/Edge Node is the client.

The recommended order of steps when configuring such TLS settings is to configure the Leader Node, then optionally configure Outposts, and finally, enable TLS on all Workers and Edge Nodes.

Overview of TLS connection between Leader, Outpost, and Edge Nodes

The Leader distributes TLS configurations and certificates to Outposts, Workers, and Edge Nodes. Outposts use them to configure the Outpost listener, and Worker and Edge Nodes for their API interfaces. These certificates are also used for secure connections with Sources and Destinations.

Each Worker, Edge Node, or Outpost must have TLS settings configured locally for communications to the Leader.

Configure TLS on the Leader Node

In Cribl.Cloud, TLS is enabled and configured for you by default for Leader-Node communication. TLS is also enabled by default on Stream Workers in Cribl-managed Worker Groups.

In an on-prem deployment, you need to manually enable and configure TLS on the Leader Node.

1. On the Leader Node, add a certificate that will secure the TLS connection. See Add a Certificate for more information.
2. Enable TLS. Select **Settings** > **Global** > **System** > **Distributed Settings** > **TLS Settings** and toggle **Enable Server TLS** on.
3. In **Server Certificate**, select a certificate in the **Certificate** drop-down, or enter **Certificate path** and **Private key path** manually.
4. Confirm with **Save**.

If you have existing Stream Workers, Edge Nodes, or Outposts connected to the Leader, they will disconnect at this point, until you configure them to use TLS as well.

Configure Leader-Outpost TLS Communication

If you use an Outpost to relay control plane communications between the Leader Node and Edge Nodes, secure it by enabling TLS for the Outpost Group.

TLS must be enabled for an Outpost Node to connect to a Leader in Cribl.Cloud.

If the Leader Node has TLS enabled and configured, new Outpost Nodes you create using the bootstrap script will automatically use TLS to connect to it. If you create Outpost Nodes via direct download, or if you enable TLS on a Leader that already connects to Outposts, you must update the configuration for each Outpost to use TLS.

Enable Outpost TLS with Bootstrap Script

To enable TLS on an existing Outpost Node using the bootstrap script, run the Update version of the script. The script will automatically establish a TLS connection with the Leader.

Enable Outpost TLS with a CLI Command

To enable TLS connection on an existing Outpost Node with the `mode-outpost` command, pass the `-S 1` parameter to the command.

The CLI commands reset all the Outpost Node information, so you need to pass all the parameters to the command, not only `-S`.

Configure Outpost-Edge Node TLS Communication

To configure TLS for communication between an Outpost and Edge Nodes, enable TLS per Outpost Group:

1. In the sidebar, select **Outposts**, then select the Outpost Group you want to configure.
2. Select **Settings**.
3. Under **Distributed Settings** > **TLS Settings**, toggle **Enabled** on.
4. In **Server Certificate**, provide the **Certificate**, or **Private key path** and **Certificate path** as needed.
5. Select **Save**, then commit and deploy the changes.

If you have existing Stream Workers or Edge Nodes connected through the Outpost, they will disconnect at this point, until you configure them to use TLS as well.

Configure TLS on Edge Nodes

If the Leader or Outpost Node has TLS enabled and configured, new Edge Nodes you create using the bootstrap script will automatically use TLS to connect to it. If you create Edge Nodes with any other method, or if you enable TLS on a Leader/Outpost that already connects to Edge Nodes, you must update the configuration for each Edge Node to use TLS.

TLS must be enabled for a Edge Node to connect to a Leader in Cribl.Cloud.

If the Leader Node uses a certificate issued by a certificate authority (CA) that the Edge Node doesn't trust, provide the Edge Node with a CA certificate so it can validate the Leader's certificate. Do it by configuring the `CRIBL_DIST_LEADER_URL` environment variable with `tls.caPath` or providing the path directly to the `NODE_EXTRA_CA_CERTS` variable.

Enable Edge Node TLS with Bootstrap Script

To enable TLS on an existing Edge Node using the bootstrap script, run the Update version of the script. The script will automatically establish a TLS connection with the Leader.

Alternatively, you can enable TLS on the Edge Node:

- Via CLI commands.
- In the UI.
- In the `instance.yml` file.
- With an environment variable.

Enable Edge Node TLS with a CLI Command

To enable TLS connection with the `mode-managed-edge` command, pass the `-S 1` parameter to the command.

The CLI commands reset all the Edge Node information, so you need to pass all the parameters to the command, not only `-S`.

Enable Edge Node TLS in the UI

To enable TLS connection on a Edge Node via the UI, navigate to the Edge Node's **Node Settings** > **System** > **Distributed Settings** > **TLS Settings**, and toggle **Enable Server TLS** on.

You do not need to fill in any other settings in this page to connect the Edge Node to the Leader.

Enable Edge Node TLS in the `instance.yml` File

To enable TLS connection in the `instance.yml` file, set `distributed.master.tls.disabled` to `false`.

Enable Edge Node TLS with an Environment Variable

You can enable TLS connection by using the `CRIBL_DIST_LEADER_URL` environment variable, by replacing the `tls://` scheme instead of `tcp://`.

11.5.3. Secure Leader-Node Communication With MTLS (On-Prem)

Once you have configured TLS on the Leader Node, you can implement client certificate exchange to enable mutual authentication (mTLS). This allows Cribl Edge to permit only explicitly authorized clients, which hold valid certificates, to connect to the Leader.

For encrypting data in transit and simple server verification, standard TLS is sufficient. Opt for mTLS when security policies mandate additional client verification.

When a client certificate is presented to a Leader, two things happen:

1. The Leader validates the client certificate presented to Cribl Edge. The **Validate client certificates** setting is optional, but highly recommended. When enabled, the Leader checks the certificate against the trust store, to see if it has been signed by a valid certificate authority (CA).
   The Leader checks the list of certificates in **Trusted client CA path** first (if populated), then against the list of built-in system certificates.
2. The Leader checks whether the Common Name (CN) matches the regular expression in the configuration. Cribl Edge's default is to accept any value in the **Common name** field. You can customize this as needed.
   Within the Common Name, Cribl Edge validates against the value after the `CN=string`. If your Common Name is `CN=stream.worker`, you would enter `stream\.worker` in the **Common name** field - including the backslash, because the value entered is a regular expression.

Prerequisites for mTLS for Leader Communication

Enabling mTLS for Leader communication requires:

- A CA certificate chain that can validate the client certificates.
- Client certificates issued to each client that will connect to to the Leader.
- Client systems configured to present their certificates during connection.

You can't use mTLS for Leader-Node communication in Cribl.Cloud.

Certificate Requirements for mTLS

mTLS provides a significantly higher security posture by requiring both the server and the client to prove their identities. For this handshake to succeed, Cribl Edge relies on the underlying TLS stack to validate the integrity and purpose of each certificate.

Before enabling mTLS, verify that your certificate infrastructure meets the standards outlined below. If a certificate is expired, uses a legacy algorithm, or cannot be traced back to a trusted root, the TLS connection will be rejected immediately to prevent unauthorized access.

General Certificate Standards

Regardless of their role in the handshake, all certificates used by the Leader, Worker/Edge Nodes, and Sources/Destinations must adhere to these baseline criteria:

- **Validity Period**: Certificates must be current. TLS handshakes will fail if the system time is outside the NotBefore or NotAfter window.
- **Modern Cryptography**: Use certificates signed with modern algorithms (such as `RSA` or `ECDSA`). Avoid legacy or deprecated hash functions like `MD4`, `MD5`, or `SHA-1`, which are often blocked by TLS.
- **Chain of Trust**: The peer validating the certificate must be able to build a complete path from the end-entity certificate through any Intermediate CAs to a trusted root. In Cribl Edge, this trust is established via **Trusted client CA path** (on the Leader) or the host system trust store.

Server-Specific Requirements

Server certificates are presented by components that terminate TLS (such as the Leader on its management port). These certificates must prove they are authorized to act as a "server" to the connecting client:

- **Key usage**: The certificate Extended Key Usage (EKU) must include `serverAuth`.
- **Hostname Verification**: To prevent man-in-the-middle attacks, the Common Name (CN) or Subject Alternative Name (SAN) must exactly match the `hostname` or IP address that clients use to connect (for example, `leader.cribl.com`).

Client-Specific Requirements

Client certificates are presented by the component initiating the connection (such as a Worker/Edge Node connecting to a Leader). These are subject to stricter identity checks:

- **Client Authentication**: The certificate EKU must explicitly include `clientAuth`. Public CAs (such as Let's Encrypt) have increasingly disallowed this attribute in their standard issuance policies to comply with stricter industry root program requirements. For mTLS, you will likely need to use an internal PKI or a specialized certificate product that permits client-side usage.
- **Identity Constraints**: Client certificates must be leaf certificates (where **Basic Constraints** are set to `CA=false`). Root or Intermediate CA certificates should never be used as client identifiers.
- **CN Regex Matching**: Cribl Edge provides an additional layer of security by checking the certificate CN against a user-defined regular expression to ensure only specific named clients are permitted.

Limitations on mTLS Authentication

When configuring mTLS authentication on Edge Nodes, make sure you place your certificates into a separate directory outside of `$CRIBL_HOME`. If you place the certificates inside `$CRIBL_HOME`, they'll be removed when the next config bundle is deployed from the Leader.

Similarly, you can't bootstrap Edge Nodes with mutual authentication already populated. To bootstrap Edge Nodes, you supply only the shared authentication token. Certificates should be viewed as two-factor authentication; so placing the certificates in the config bundle defeats the purpose of two-factor authentication.

Configure mTLS Communication

To configure mTLS for Leader-Edge Node communication, first, enable mTLS on the Leader side.

1. Select **Settings** > **Global** > **System** > **Distributed Settings** > **TLS Settings**.
2. Toggle **Enable Server TLS** on and configure **Server Certificate** if you have not already.
3. Open **Mutual Authentication (mTLS)** and toggle **Authenticate client (mutual auth)** on.
4. In **Trusted client CA path**, enter the path to the CA that signs client certificates.
5. Optionally, set **Validate client certificates** and adjust **Common name**.
6. Select **Save**.

Next, configure the Edge Node certificates. You can do it via the UI, the `instance.yml` config file, or the `CRIBL_DIST_LEADER_URL` environment variable.

Configure Edge Node mTLS via the UI

To configure mTLS on a Edge Node via the UI:

1. Navigate to a Edge Node's **Node Settings** > **System** > **Distributed Settings** > **TLS Settings**.
2. Toggle **Enable Server TLS** on.
3. In **Server Certificate**, select a **Certificate**, or enter **Private key path** and **Certificate path**.
4. Open **Mutual Authentication (mTLS)**, enable **Authenticate client (mutual auth)**, and enter **Trusted client CA path** to validate the Leader's certificate.
5. Optionally, in **TLS Version**, set **Minimum TLS version** and **Maximum TLS version**.

Configure Edge Node mTLS Using YAML Config File

To set up mTLS authentication via the Edge Node's `instance.yml` config file, use the following configuration:

```
distributed:
  mode: managed-edge
  master:
    host: <hostname>
    port: 4200
    authToken: <token>
    tls:
      disabled: false
      rejectUnauthorized: true # false if ignoring untrusted certs
      requestCert: true
      privKeyPath: /path/to/certs/worker.key
      certPath: /path/to/certs/worker.pem
      caPath: /path/to/certs/root.pem
    resiliency: none
  group: default_fleet
```

Copy

Configure Edge Node mTLS Using Environment Variables

You can set up mTLS authentication by configuring the `CRIBL_DIST_LEADER_URL` environment variable, using the format shown in this example:

```
CRIBL_DIST_LEADER_URL="tls://<authToken>@leader.cribl:4200?tls.privKeyPath=/path/to/c
```

Copy

Once you've set this variable, restart the Edge Node. You should see the Edge Node successfully reconnect to the Leader.

If the Edge Node doesn't connect, check `cribl.log` on both the Edge Node and Leader for more context about the problem. You should see errors related to `dist leader communications`.

To build your own Certificate Authority (a self-signed CA), see our blog post on How to Secure Cribl Stream Worker-to-Leader Communications.

11.5.4. Secure Sources And Destinations With TLS And MTLS

Cribl offers two methods for securing communications between Edge Nodes and Sources or Destinations:

- **Transport Layer Security (TLS)** - Encrypts data during transmission and authenticates the server.
- **Mutual TLS (mTLS)** - Adds client authentication on top of standard TLS.

For encrypting data in transit and simple server verification, standard TLS is sufficient. Opt for mTLS when security policies mandate additional client verification.

Use Cribl-Provided Certificates

In Cribl.Cloud, you can use Cribl-provided certificates to secure the communication between Edge Nodes and selected Sources.

Cribl-provided certificates offer the following benefits:

- **Reliable, ready-to-use security**: When you enable TLS and enter the correct environment variables for Cribl-provided certificates in the Source configuration, data in transit is always encrypted.
- **Zero maintenance**: Cribl-provided certificates are publicly valid and automatically managed and rotated before they expire. No action is required from you. The certificate issuer can change, so do not pin a Cribl-provided certificate or its issuer.
- **Simplified deployment**: No need to generate or install custom certificates.

You only need to use your own private key or configure mTLS if specifically required by your security team or company policies. If you need custom certificates, see Secure Source and Destinations Comms with a Custom Certificate.

While TLS encryption ends at individual Nodes upon data arrival in Cribl.Cloud, data at rest is protected by other robust security measures within the platform.

Cribl-provided certificates are unique to each Workspace and Organization.

Cribl.Cloud supports Cribl-provided certificates for Sources including Cribl TCP, Cribl HTTP, Syslog, HTTP, and Splunk TCP. To view a complete list of the supported Sources, along with their corresponding ports and ingress addresses:

1. On the top bar, select **Products**, and then select **Workspace** under **Cribl**.
2. In the sidebar, select **Data Sources**.

Enable TLS on Sources Using Cribl-Provided Certificates

To enable TLS using Cribl-provided certificates for a supported Source, configure the following in **TLS Settings (Server Side)**:

1. Toggle **Enabled** on.
2. In **Server Certificate**, set:
    - **Private key path**: Enter `$CRIBL_CLOUD_KEY`. This environment variable represents the path to the default private key in Cribl.Cloud.
    - **Certificate path**: Enter `$CRIBL_CLOUD_CRT`. This environment variable represents the path to the default certificate in Cribl.Cloud.
3. In **TLS Version**, set:
    - **Minimum TLS version**: Select `TLSv1.2`.
    - **Maximum TLS version**: Select `TLSv1.3`.

When a Source is configured to listen on a port in the Cribl.Cloud ingress range (20000–20010), you **must** set **Private key path** to `$CRIBL_CLOUD_KEY` and **Certificate path** to `$CRIBL_CLOUD_CRT`. These environment variables resolve to the Cribl.Cloud-managed certificates that are valid for those ports. Using any other certificate paths will cause TLS initialization to fail on those ports.

The **Minimum TLS version** and **Maximum TLS version** settings on the Source must be compatible with the corresponding settings on its peer Destination. If the two version ranges do not overlap, the TLS handshake will fail and no data will flow. Set the same version range on both sides — for example, `TLSv1.2` minimum and `TLSv1.3` maximum. For details and configuration examples, see Match TLS Versions Between Source and Destination.

When you finish configuring the Source, select **Save**, then **Commit** and **Deploy**.

For an example on how to securely forward syslog data to your Cribl.Cloud instance, see Syslog TLS to Cribl.Cloud (Palo Alto Example). This topic demonstrates a vendor-specific configuration (Palo Alto) for secure data ingestion.

Secure Source and Destinations Comms with a Custom Certificate

In on-prem deployments, or in Cribl.Cloud where no Cribl-provided certificate exists, you need to provide TLS certificates for Sources and Destinations manually.

Cribl Edge stores and manages custom TLS certificates at the Fleet level. When you add a certificate to a Source or Destination, Cribl Edge creates it within the same Fleet where you configured the integration.

For information about how certificate references work in Packs, see Use Named TLS Certificates.

1. Add a certificate on the Fleet your integration is in. Refer to the instructions for adding a certificate on a Fleet for details.
2. Open the configuration settings for your Source or Destination.
3. Select **TLS Settings (Client Side)** or **TLS Settings (Server Side)**, depending on the integration.
4. Toggle **Use TLS** on (Destinations and client-side Sources) or **Enabled** on (server-side Sources).
5. In **Server Certificate** (server side) or **Mutual Authentication (mTLS)** (client side), select the certificate you created in the **Certificate** drop-down. This auto-populates the related path fields.
6. Select **Save**.

Enable mTLS Authentication for Source/Destination Communications

When standard TLS isn't sufficient and you need client authentication, you can enable mTLS.

Enabling mTLS for Source/Destination communication requires:

- A CA certificate chain that can validate the client certificates.
- Client certificates issued to each client that will connect to Cribl.Cloud.
- Client systems configured to present their certificates during connection.

You configure mTLS authentication separately for each Source.

This requires a CA certificate chain that can validate the client certificate used for authentication. For secure communication using mTLS authentication, you need to provide the root CA certificate of your client certificate. If you don't have the root CA certificate, you can also provide a CA certificate chain that includes all intermediate certificates leading back to a trusted root certificate.

1. Create a CA certificate. Refer to the instructions for adding a certificate on a Fleet for details.

   While the **Add Certificate** form requires you to provide a Private Key and Certificate, these fields are not necessary for client certificate validation. This is a design limitation that requires you to provide some properly formatted values to proceed. You can use a self-signed certificate for this purpose.

2. Navigate to the Source where you want to enable mTLS and open the configuration modal. In **TLS Settings (Server Side)**:
    1. Toggle **Enabled** on and configure **Server Certificate** as usual.
    2. Open **Mutual Authentication (mTLS)** and toggle **Authenticate client (mutual auth)** on.
    3. In **Trusted client CA path**, enter the path to your CA certificate.
    4. Select **Save**, then **Commit** & **Deploy**.

11.5.5. Configure TLS For API And UI Access

To safeguard inbound communications to your Leader UI and API (default port 9000), enable Transport Layer Security (TLS) on the Leader.

For Cribl.Cloud deployments, TLS is enabled by default and managed automatically. You only need to enable TLS for Leader UI and API in on-prem deployments.

Prerequisites

Before you enable TLS for the Leader UI/API, you need a TLS certificate and private key added to Cribl Edge. For details on generating or adding certificates, see Add TLS Certificates and Keys.

Enable TLS for the Leader UI/API

After you have a certificate added at **Settings** > **Global** > **Security** > **Certificates**, enable TLS for the Leader UI/API listener:

1. In the Leader UI, go to **Settings** > **Global** > **General Settings** > **API Server Settings** > **TLS**.
2. Toggle **Enabled** on.
3. Select a certificate in **Certificate**, or enter **Certificate path** and **Private key path** manually.
4. (Optional) Enter a **Passphrase** if the private key is encrypted.
5. Select **Save**.

After you save, the Leader UI/API will start listening on HTTPS. Access the UI/API using: `https://<hostname>:<port>/`, for example: `https://leader.example.com:9000/settings/system`.

After enabling TLS, you must prepend `https://` to all Cribl Edge URLs on the Leader Node.

Configure TLS via Config Files

Most deployments should configure TLS through the UI. Use this method only when you have a clear config-as-code workflow. Avoid ad-hoc manual edits of local config files on running systems; prefer the UI or a consistent automation pipeline that owns these files.

If you manage Cribl Edge via automation (for example, configuration management, containers, or Cribl as Code), you can configure the Leader UI/API listener in `cribl.yml`.

Example `cribl.yml` snippet:

```
api:
  host: 0.0.0.0
  port: 9000
  disabled: false
  ssl:
    disabled: false
    privKeyPath: /path/to/myKey.pem
    certPath: /path/to/myCert.pem
```

Copy

For details on generating and importing certificates and keys used in this example, see Add TLS Certificates and Keys.

11.5.6. TLS Defaults And System-Wide Settings

Cribl Edge prioritizes secure communication by default. This ensures the integrity and confidentiality of data transmitted between your Cribl Edge instance and various Sources and Destinations.

TLS Version Support and Defaults

The minimum supported TLS version in Cribl Edge is `TLS 1.2` by default. This default applies to all secure connections, including supported Sources and Destinations, Worker/Leader communications, and Cribl.Cloud.

Cribl.Cloud and on-prem deployments use the same TLS settings, with `TLS 1.2` being the default minimum version.

You can check whether a Source or Destination supports TLS by reviewing the information box at the beginning of its corresponding documentation page.

Deployment Scope for Defaults

The TLS version and cipher defaults described on this page apply to both Cribl.Cloud and on-prem Cribl Edge deployments. However, the **Encryption: Default disabled** values in the TLS Settings and Traffic Types table reflect the base defaults for on-prem deployments only.

For Cribl.Cloud Leader deployments, TLS is enabled and managed by the Cribl.Cloud platform by default for Leader API/UI access and Leader–Worker communications. You do not need to manually enable TLS on the Leader in Cribl.Cloud. For details, see Secure Leader-Node Communication with TLS.

Match TLS Versions Between Source and Destination

When TLS is enabled on a Source (server) and its peer Destination (client), their **Minimum TLS version** and **Maximum TLS version** settings must be compatible. TLS negotiation selects the highest version that both sides support. If no version falls within both the Source range and the Destination range, the TLS handshake fails and no data flows.

To prevent negotiation failures, configure the same minimum and maximum TLS versions on both the Source and the Destination. The following example shows a matching configuration for a Cribl HTTP Source (server side) and its peer Cribl HTTP Destination (client side):

Source TLS Settings (Server Side)

```
{
  "tls": {
    "disabled": false,
    "privKeyPath": "$CRIBL_CLOUD_KEY",
    "certPath": "$CRIBL_CLOUD_CRT",
    "minVersion": "TLSv1.2",
    "maxVersion": "TLSv1.3"
  }
}
```

Copy

Destination TLS Settings (Client Side)

```
{
  "tls": {
    "disabled": false,
    "minVersion": "TLSv1.2",
    "maxVersion": "TLSv1.3"
  }
}
```

Copy

Ensure TLS is consistently enabled or disabled on both the Source and its peer Destination. A connection between a TLS-enabled endpoint and a TLS-disabled endpoint will fail.

TLS Settings and Traffic Types

This table shows TLS client/server pairs, and encryption defaults per traffic type. The **Default disabled** values apply only to on-prem deployments.

Traffic Type	TLS Client	TLS Server	Encryption	Cert Auth	CN* Check
UI	Browser	Cribl Edge	Default disabled	Default disabled	Default disabled
API	Worker/Edge Node	Leader	Default disabled	Default disabled	Default disabled

Traffic Type	TLS Client	TLS Server	Encryption	Cert Auth	CN* Check
Worker-to-Leader	Worker/Edge Node	Leader	Default disabled	Default disabled	Default disabled
Data	Any data sender	Cribl Edge (Source)	Default disabled	Default disabled	Default disabled
Data	Cribl Edge (Destination)	Any data receiver	Default disabled	Default disabled	Default disabled
Authentication	——–	——–	——–	——–	——–
Local*	Browser	Cribl Edge	Default Disabled	N/A	N/A
LDAP*	Cribl Edge	LDAP Provider	Custom	N/A	Default Disabled
Splunk*	Cribl Edge	Splunk Search Head	Default Enabled	N/A	Default Disabled
OIDC†/Okta*	Browser and Cribl Edge	Okta	Default Enabled	N/A	Enabled (Browser)
OIDC†/Google*	Browser and Cribl Edge	Google	Default Enabled	N/A	Enabled (Browser)

** Common name*
† OpenID Connect

System-wide TLS Settings Including Ciphers

You can configure advanced, system-wide TLS settings - minimum and maximum TLS versions, default cipher lists, and ECDH curve names. Select **Settings** > **Global** > **System > General Settings > Default TLS Settings**.

In the **Default cipher list** field, you can specify one or more ciphers from the following list:

- `ECDHE-RSA-AES128-GCM-SHA256`
- `ECDHE-ECDSA-AES128-GCM-SHA256`
- `ECDHE-RSA-AES256-GCM-SHA384`
- `ECDHE-ECDSA-AES256-GCM-SHA384`
- `DHE-RSA-AES128-GCM-SHA256`
- `ECDHE-RSA-AES128-SHA256`
- `DHE-RSA-AES128-SHA256`

- ECDHE-RSA-AES256-SHA384
- DHE-RSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA256
- DHE-RSA-AES256-SHA256
- HIGH
- !aNULL
- !eNULL
- !EXPORT
- !DES
- !RC4
- !MD5
- !PSK
- !SRP
- !CAMELLIA

CA Certificates and Environment Variables

For any Cribl Edge Source or Destination that supports TLS, you can configure a **Trusted server CA path/Trusted client CA path** field that points to a Certificate Authority (CA) `.pem` file(s). However, you can also use environment variables to manage CAs globally. Here are some common scenarios:

- **Add a set of trusted root CAs to the list of trusted CAs that Cribl Edge trusts.** Set the `NODE_EXTRA_CA_CERTS` environment variable for each Edge Node. For example, if you are using systemd, add the following line in each Edge Node's systemd unit file (replace `/<path>/<to>/<the>/<directory>/<containing>/<certs>/ca.pem` with the path to your CA `.pem` file):

```
...
[Service]
Environment="NODE_EXTRA_CA_CERTS=/<path>/<to>/<the>/<directory>/<containing>/<ce
...
```

Copy

When configuring TLS authentication on Edge Nodes, make sure you place your certificates into a separate directory outside of $CRIBL_HOME. If you place the certificates inside $CRIBL_HOME,

they'll be removed when the next config bundle is deployed from the Leader.

For details about `NODE_EXTRA_CA_CERTS`, see the node.js documentation.

- **Configure Cribl Edge to accept all TLS certificates, regardless of their validity**. Set the `NODE_TLS_REJECT_UNAUTHORIZED` environment variable for each Edge Node. For example, if you are using systemd, add the following line in each Edge Node's systemd unit file:

```
...
[Service]
Environment="NODE_TLS_REJECT_UNAUTHORIZED=0"
...
```

Copy

`NODE_TLS_REJECT_UNAUTHORIZED=0` disables TLS certificate validation, which can decrease the security posture of your Cribl installation. For this reason, we recommend avoiding `NODE_TLS_REJECT_UNAUTHORIZED=0` in production environments. Instead, use the `NODE_EXTRA_CA_CERTS` environment variable to explicity trust the necessary certificates.

For details about `NODE_TLS_REJECT_UNAUTHORIZED`, see the node.js documentation.

As a result of a Known Issue, passphrases in TLS certificates configured for Sources or Destinations in a Cribl Edge Fleet will not be decrypted correctly when a Subfleet inherits the configuration.

Avoid using passphrases with TLS certificates if you intend to have Subfleets inherit Source or Destination configurations.

Global CA Certificates and Sources

While Cribl Edge supports using environment variables like `NODE_EXTRA_CA_CERTS` to add trusted root CAs globally, this approach is not applicable to all Sources. Some Sources, such as the Windows Events Fowarder (WEF), require a specific CA certificate configured at the Source level to function correctly.

Additionally, OS certificate stores accessed through Node.js boot flags (such as `--use-bundled-ca`, `--use-

11.6. Custom HTTP Headers

You can encode custom, security-related HTTP headers as needed. In a Distributed deployment, navigate to Fleet Settings, then **API Server Settings** > **Advanced** > **HTTP Headers**. (In a Single-instance deployment, the **API Server Settings** are within **Global Settings** > **General Settings**.) Define HTTP headers as key-value pairs, selecting **Add Header** as needed.

Implement a Custom Content Security Policy (CSP)

Content Security Policy (CSP) helps protect Cribl Edge from Cross-Site Scripting (XSS) and other web injection attacks by controlling which resources the browser is allowed to load. You can implement CSP using the custom HTTP Headers setting described above.

Basic Configuration

To configure a basic CSP for Cribl Edge, add the following header in your **HTTP Headers** settings:

Header Name: `Content-Security-Policy`

Header Value:

```
default-src 'self'; script-src 'self' 'unsafe-eval' 'sha256-ZaAN8+jAf3MdnSLRdmTuExUhA
```

Copy

Test your CSP policy thoroughly in a development environment before deploying to production and monitor the browser console for CSP violations after implementation.

SAML SSO Configuration

If you are using SAML Single Sign-On, you'll need a modified CSP policy to accommodate the dynamic JavaScript and form submissions required for SAML authentication:

Header Name: `Content-Security-Policy`

Header Value for SAML:

```
default-src 'self'; script-src 'self' 'unsafe-eval' 'unsafe-inline'; connect-src 'sel
```

Copy

Replace `YOUR_IDP_DOMAIN` with your actual Identity Provider's domain (for example, your Okta domain).

SAML configurations require additional permissions that reduce the restrictiveness of the CSP compared to the basic configuration.

11.7. Configure System Proxy

Configure the proxy server to handle HTTP/S requests.

You can direct all outbound HTTP/S requests to go through proxy servers. You do so by setting environment variables before starting Cribl Edge.

Learn how to configure environment variables.

See System Proxy Configuration on Windows for details of Windows-specific proxy configuration.

Configure the `HTTP_PROXY` and `HTTPS_PROXY` environment variables, either with your proxy's IP address, or with a DNS name that resolves to that IP address. Optionally, follow either convention with a colon and the port number to which you want to send queries. Ensure you explicitly include the protocol (`http://` or `https://`) in the variable values.

`HTTP_PROXY` examples:

```
HTTP_PROXY=http://10.15.20.25:1234
HTTP_PROXY=http://proxy.example.com:1234
```

Copy

`HTTPS_PROXY` examples:

```
HTTPS_PROXY=http://10.15.20.25:5678
HTTPS_PROXY=http://proxy.example.com:5678
```

Copy

In the above examples, note that when you set an `HTTPS_PROXY` environment variable, the referenced URL should generally be in `http` format.

To set up Leader/Worker communication, use the CRIBL_DIST_WORKER_PROXY environment variable.

Restarts and Case Conflicts

Initial configuration of, and changes to, these variables require restarting Cribl Edge on the affected Nodes, if the application is already running when you apply the changes.

> The environment variables' names can be either uppercase or lowercase. However, if you set duplicate versions of the same name, the lowercase version takes precedence. For example, if you've set both `HTTPS_PROXY` and `https_proxy`, the IP address specified in `https_proxy` will take effect.

HTTP and/or HTTPS?

Several Cribl Edge endpoints rely on the HTTPS protocol - the Cribl telemetry endpoint, which must be accessed with some license types, as well as the CDN used to propagate application updates and certain documentation features (API Reference and docs PDFs).

You might configure certain other Cribl Edge features (such as REST API Collectors) that require access to HTTP endpoints. For maximum flexibility, consider setting environment variables to handle both the HTTPS and HTTP protocols.

Authenticating on Proxies

You can use HTTP Basic authentication on HTTP or HTTPS proxies. Specify the user name and password in the proxy URL. For example:

```
HTTP_PROXY=http://username:password@proxy.example.com:1234
HTTPS_PROXY=http://username:password@proxy.example.com:5678
```

Copy

Proxies and Certificates

If a proxy presents its own certificate, Cribl Edge must trust the entire certificate chain.

To ensure the entire chain is available:

1. Gather all the required CA certificates in PEM format, including the root and intermediate certificates.
2. Create a single PEM file containing all the certificates, in the correct order, starting with intermediate certificates, ending with the root. You can do it with the follow command:

```
$ cat intermediate1.pem intermediate2.pem root_ca.pem > my_proxy_ca_chain.pem
```

Copy

3. Place the PEM file in a directory outside `$CRIBL_HOME`.

Bypassing Proxies with `NO_PROXY`

If you've set the above environment variables, you can negate them for specified (or all) hosts. Set the `NO_PROXY` environment variable to identify URLs that should bypass the proxy server, to instead be sent as direct requests. Use the following format:

```
NO_PROXY="<list of hosts/domains>"
```

Cribl recommends including the Leader Node's host name in the `NO_PROXY` list.

Client Configuration and Leader Reference

The way a client references the Leader Node depends on its configuration, which originates from the Distributed Settings for that particular Node. These settings reside in the `$CRIBL_HOME/local/_system/instance.yml` file.

When deploying a configuration update, the Leader Node informs all connected clients (Workers and Edge Nodes) within its Group or Fleet that a new configuration bundle is available. The Leader will reference itself using the same method (IP address or FQDN) that clients already use to connect to it in the distributed environment. This ensures a seamless download process for the clients, regardless of their initial connection method.

If a Worker is configured to use the Leader's IP for communication, the URL will also contain that specific IP. Consequently, the `NO_PROXY` variable on the client must match the IP address used in the client configuration and Leader URL for optimal operation.

Cribl v.4.6.0 introduces direct S3 downloads for configuration bundles, bypassing the Leader Node and scaling deployments with many Edge Nodes. However, if your Edge Nodes are firewalled or requires access controls, a proxy might be needed. In such scenarios, you need to exclude the S3 bucket address from the "NO_PROXY" list for successful downloads.

`NO_PROXY` Usage

Within the `NO_PROXY` list, separate the host/domain names with commas or spaces.

Optionally, you can follow each host/domain entry with a port. If not specified, the protocol's default port is assumed.

To match subdomains, you must either list them all in full (for example, `NO_PROXY="foo.example.com","bar.example.com"`), or apply a wildcard by prefixing the domain name with a period or `*.`: `NO_PROXY=".example.com"` or `NO_PROXY="*.example.com"`.

To match the whole domain including its subdomains, add it both with and without wildcard to the list: `NO_PROXY="example.com,.example.com"`.

To disable all proxies, use the `*` wildcard: `NO_PROXY="*"`. `NO_PROXY` with an empty list disables no proxies.

Cloud `NO_PROXY` Usage

You must include any cloud metadata endpoints (such as the AWS Instance Metadata Service) in the `NO_PROXY` list:

- AWS EC2 and Azure VM instances must include `169.254.169.254` in the list. If using IPv6 on AWS EC2, add `fd00:ec2::254` to the list.
- AWS ECS Fargate tasks must include `169.254.170.2`.
- GCP (Google Cloud Platform) VM instances must include `metadata.google.internal` and `169.254.169.254`.

Where Proxies Apply

Proxy configuration in Cribl Edge applies to components that initiate outbound HTTP or HTTPS connections from the Edge Node. This typically includes:

- HTTP/S Destinations that send data to remote services. For example, cloud logging platforms, object stores, and observability APIs.
- Notification targets that call external webhooks or API endpoints over HTTP/S.

Proxies are not used for data collection, such as system metrics, file monitoring, Syslog, or other Sources that do not make outbound HTTP/S requests.

Support for proxies varies by integration. For any specific Edge Destination or Notification target, see its individual documentation page to confirm whether it supports proxies.

Testing Proxies

To initially test your proxy configuration, consider setting up a simple, free proxy server like mitmproxy (https://mitmproxy.org), and then monitoring traffic through that server. Verify that you can trace proxied requests from your Cribl Edge instance, and can validate that outgoing requests (to Destinations) are working properly.

Proxying Multiple Edge Instances in One Browser

Cribl Edge stores authentication tokens based on each http header's URI scheme, host, and port information. Within a given browser, Cribl Edge enforces a same-origin policy to isolate instances.

This means that if you want to run multiple proxied Cribl Edge instances in one browser session, you must assign them different URI schemes, hosts, and/or ports. Otherwise, logging into an extra Cribl Edge instance will expire the prior instance's session and log it out.

For example, assume that you've set up this pair of Apache proxy forward rules:

- https://web/cribla forwards to `cribl_hosta:8001/cribla`.
- https://web/criblb forwards to `cribl_hostb:8001/criblb`.

These two proxied addresses cannot be run simultaneously in the same browser session. However, this pair - which lead with separate URI schemes - could:

- https://web/cribla forwards to `cribl_hosta:8001/cribla`.
- https://web2/criblb forwards to `cribl_hostb:8001/criblb`.

Where separate instances **must** share URI formats, a workaround is to open the second instance in an incognito/private browsing window, or in a completely different browser.

11.8. Configure SOCKS Proxy

This document outlines how to configure Cribl Edge to use a SOCKS proxy server for outbound communication.

By using a SOCKS proxy, you can enhance security, bypass network restrictions, and route specific traffic through a controlled intermediary server.

The SOCKS proxy is exclusively for Outposts and Edge Nodes to communicate with a Leader Node. The Leader Node doesn't use the proxy for its outbound communications.

Architectural Overview: SOCKS Proxy in Cribl Deployments

A SOCKS proxy acts as an intermediary for outbound network connections from a client application (in this case, your Outpost/Edge Node). It allows you to centralize and control the egress points for your Cribl infrastructure. The specific architectural flow depends on whether your Cribl deployment is entirely on-prem or on Cribl.Cloud.

Management vs. Data Plane Communications

If you are using a proxy for Cribl software cluster communications, it must be a SOCKS proxy (Layer 4), not an HTTP proxy. This is because cluster communications use raw TCP connectivity on port 4200, which HTTP proxies cannot handle.

Communication Types Overview

Cribl products require distinct proxy types for different communication streams. Management communications between Leaders and Edge Nodes use a proprietary protocol over persistent TCP connections (port 4200), necessitating a **SOCKS (Layer 4) proxy** for relaying.

Direct configuration bundle downloads always use standard HTTP/HTTPS protocols, regardless of whether the bundle is retrieved from the Leader Node or from S3. If you're using a proxy for these direct downloads, it needs to be an **HTTP proxy** (configured via `HTTP_PROXY`/`HTTPS_PROXY` environment variables) with access to the Leader Node's ports (443/4200) or S3 endpoints. This differs from the SOCKS proxy needed for management communications. For details, see Manage Config Bundles. When Edge Nodes connect through Outpost, the Outpost-to-Leader upstream connection can use SOCKS, so Leader-hosted bundle requests relayed through Outpost can traverse that SOCKS connection.

Given these different proxy requirements, you'll often find your deployment needs both SOCKS and HTTP proxies. It really depends on your network environment and whether you choose to use proxies for specific communication types.

The table below summarizes the communication type and proxy support for each.

Communication Type	Protocol Requirements	Proxy Support	Port	Purpose
Control Plane	TCP (Layer 4)	SOCKS only HTTP proxies NOT supported	`4200`	Leader ↔ Edge Node control, configuration, and status
Outpost-Relayed Management and Bundle Traffic	TCP tunnel from Outpost to Leader	SOCKS supported for the Outpost-to-Leader communication	`4200`	Outpost relays Edge Node management traffic and Leader-hosted bundle requests to the Leader
Direct Config Bundle Downloads	HTTP/HTTPS (Layer 7)	SOCKS proxies NOT supported HTTP proxies only (`HTTP_PROXY/HTTPS_PROXY`)	`443/4200`	Edge Node downloads configuration bundles directly from the Leader or S3
Data Plane	HTTP/HTTPS (Layer 7)	HTTP proxies (`HTTP_PROXY/HTTPS_PROXY`)	Various	Data ingestion, forwarding to destinations (S3, Splunk, etc.)

On-prem Deployment Architecture

In an on-prem deployment, all Cribl components - the Leader Node, Outpost, and the Edge Node - are deployed and managed within your organization's network. If you choose to use a SOCKS proxy, it will exclusively control the outbound communication from your Edge Nodes and Outposts to their Leader Node.

Cribl.Cloud/Hybrid Deployment Architecture

In a Cribl.Cloud deployment, the Leader Node is hosted and managed by Cribl within the Cribl.Cloud infrastructure. Your Outposts and Edge Nodes, however, are typically deployed within your own on-prem network or private cloud. A SOCKS proxy can be used to route the outbound communication from your customer-managed Worker Nodes and Outposts to the Cribl-managed Leader in the cloud.

Configure SOCKS Proxy

SOCKS proxy settings are applied directly to the specific Cribl Nodes (Leader, Outpost, Worker, or Edge) that need to use the proxy for their outbound communication.

There are three ways to define SOCKS proxy settings in Cribl Edge.

- **Environment Variables**: Ideal for most scenarios, especially when automating deployments or managing a large number of Edge Nodes.
- **`instance.yml`**: Suitable for file-based configuration management.
- **UI Configuration**: Suitable for smaller deployments or when manual configuration is preferred. However, be aware of the additional steps and potential complexities involved.

Configure via Environment Variables

This is the most straightforward and flexible method, ideal for automated deployments, containerized environments (Docker, Kubernetes), or managing a large number of Nodes.

For Outposts or Edge Nodes Connecting to a Leader

Use the `CRIBL_DIST_WORKER_PROXY` on each Outpost/Edge Node to configure its connection to the Leader Node.

```
CRIBL_DIST_WORKER_PROXY="socks5://<username>:<password>@<proxy_host>:<proxy_port>"
```

Copy

The default protocol is SOCKS5, which uses the format: `socks5://<username>:<password>@<host>:<port>`. Specify the SOCKS proxy host, port, and optional authentication credentials in the variable.

- `<username>:<password>`: Optional authentication credentials for your SOCKS proxy.
- `<proxy_host>`: The hostname or IP address of your SOCKS proxy server.
- `<proxy_port>`: The port on which your SOCKS proxy server listens.

You can alternatively specify SOCKS4 as the protocol with the format: `socks4://<proxyhost>:<port>.` To authenticate on a SOCKS4 proxy with username and password, use this format: `socks4://<username>:<password>@<proxyhost>:<port>`. The `<proxyhost>` can be a `hostname`, `IPv4`, or `IPv6`.

For Leader Node Connections (On-Prem Specific)

In on-prem deployments, if your Leader Node needs to route its own outbound connections (e.g., to external services like CDNs for software updates, licensing servers, or telemetry endpoints) through a web proxy, configure this using standard HTTP proxy settings. Note that Leader Nodes do not initiate connections to Outposts or Edge Nodes - those connections are always initiated by the Outpost/Edge Nodes to the Leader. SOCKS proxy configuration is not supported for Leader Node outbound connections to cloud services.

Where to set environment variables:

- **Systemd Service:** For Linux deployments, add `Environment="<VARIABLE_NAME\>=..."` under the `[Service]` section in your systemd override file (such as,

`/etc/systemd/system/cribl.service.d/override.conf`).

- **Docker/Kubernetes:** Set as environment variables in your Dockerfile, `docker run` command, or Kubernetes Deployment/StatefulSet manifests.
- **Directly on Host:** For manual installations, you can set it in a shell script that starts Cribl, or in a profile file (for example, `.bashrc`, `.profile`) for the user running Cribl.

After setting the environment variable, restart the Cribl service on the Node for the changes to take effect.

Config bundle downloads cannot be sent via a SOCKS proxy, but instead use an HTTP proxy that allows requests to the Leader or an S3 bucket.

Configure via `instance.yml`

To configure a SOCKS proxy in the `instance.yml` configuration file, set `distributed.master.proxy.disabled` to `false`.

Use the `host` and `port` keys under `distributed.master.proxy` to configure the proxy. The configuration will use SOCKS5 by default, unless you specify `type: 4` to use SOCKS4. If the SOCKS proxy requires authentication, add `userId` and `password`.

$CRIBL_HOME/local/_system/instance.yml

```
distributed:
  master:
    proxy:
      disabled: false
      host: <socks-proxy-host>
      port: <socks-proxy-port>
      type: 4
      userId: <proxy-user>
      password: <proxy-password>
```

Copy

Restart the Cribl service after changing `instance.yml`.

If both `CRIBL_DIST_WORKER_PROXY` and `distributed.master.proxy` are set, `CRIBL_DIST_WORKER_PROXY` takes precedence.

Configure via the UI

Configuring a SOCKS proxy for Cribl Edge using the UI is more complex than using environment variables due to the multi-step process involved. It requires enabling direct access to the Leader, setting up the proxy on the Edge Nodes, and then configuring the SOCKS proxy settings. Additionally, using the UI might not be suitable for all deployment scenarios, especially those with large numbers of Edge Nodes or complex network configurations.

Configuring a SOCKS proxy for Cribl Edge using the UI is suitable for individual Edge Nodes or smaller deployments where direct access to each Edge Node's UI is feasible.

To configure a SOCKS proxy for Cribl Edge, follow these steps.

1. **Enable direct access**: Allow Edge Nodes to access the Leader Node directly.
    - Cribl Edge: Set up Leaders and Edge Nodes.
    - Cribl Stream: Set up Leaders and Worker Nodes.
    - Remember to enable UI Access (and teleport) to Workers or Edge Nodes as applicable.
2. **Set up Edge Nodes and SOCKS proxy**: Configure the Edge Nodes and ensure the SOCKS proxy server is running and accessible.
3. **Configure proxy details**: You can access the Edge Node via teleporting. To configure without teleporting, log in to each Edge Node directly using a local user account.
4. Select **Edge Node Settings** from the Edge Node submenu. Navigate to **Distributed Settings** > **Leader Proxy Settings** and configure the following fields:
    - **Username**: Enter the username for the SOCKS Proxy authentication.
    - **Password**: Enter the password for the SOCKS Proxy authentication.
    - **Proxy host**: Enter the proxy server host. Can be a `hostname`, `IPv4`, or `IPv6`.
    - **Proxy port**: The port on which your SOCKS proxy server listens.
    - **Protocol version**: Version of the SOCKS protocol. Defaults to `5` for `socks5`.
5. **Save the settings**: The Edge Nodes will automatically reconnect to the Leader node using the configured SOCKS proxy.
6. **Disable direct access**: Verify the SOCKS proxy configuration is verified. To ensure all traffic between Edge Nodes and Leader is routed through the SOCKS proxy, disable the direct network connections between them. This includes removing any firewall rules or network configurations that allow direct communication.

Best Practices & Troubleshooting

For successful SOCKS proxy implementation, consider the following.

- **Firewall Rules**: Set up your firewall rules properly for a seamless deployment.
    - **Edge Node to SOCKS Proxy:** Allow outbound TCP from Cribl Edge Node to your SOCKS proxy on its configured `proxy_port`.
    - **SOCKS Proxy to Leader (TCP 4200)**: Your SOCKS proxy must have outbound access to the Leader Node on TCP port 4200. For on-Prem deployments, ensure your Leader Node accepts inbound connections from the SOCKS proxy on TCP 4200. For Cribl.Cloud deployments, allow outbound access from your SOCKS proxy to the Cribl.Cloud Leader's IPs for the Network Load Balancers (found in **Workspace** > **Access** > **Leader NLB IPs**). For details, see View Workspace Detail.
- **DNS Resolution**: The SOCKS proxy server must resolve the Leader Node's hostname (on-prem Leader or `your-workspace.cribl.cloud`).
- **Proxy Placement (On-Prem)**: Strategically place the SOCKS proxy to optimize network paths and minimize latency.
- **Egress Control (Cribl.Cloud)**: The SOCKS proxy provides a vital, controlled egress point for Cribl Nodes' communication with Cribl.Cloud, aligning with corporate security policies.
- **Authentication**: Securely manage and ensure correct credentials if your SOCKS proxy requires authentication.
- **Other Proxy Types**: SOCKS proxies (`CRIBL_DIST_WORKER_PROXY`) are for communication between the Leader and Edge Node. Other outbound traffic (for example, to external Sources/Destinations) may require standard HTTP/HTTPS proxies (`HTTP_PROXY`/`HTTPS_PROXY`). For details, see Configure System Proxy.

11.9. Centralize And Reuse Global Secrets

Use global secrets to define credentials once and reuse them across Cribl Stream and Edge by referencing them in Source, Destination, and Collector configurations. Teams that span products can use the same credentials instead of maintaining duplicate credentials that can drift out of sync. When you rotate credentials, you can update the values for global secrets in one place.

Cribl organizes global secrets in secret folders that are backed by secret stores. Worker Group and Edge Fleet access to global secrets is controlled at the folder level. Manage secret stores, secret folders, and global secrets in the UI under **Global Settings** > **Security** > **Secrets** or with the Cribl API.

Any legacy secrets that you use in existing resource configurations will continue to work as you migrate to global secrets.

Global secrets are not supported when GitOps is enabled in Cribl Stream, and you cannot enable GitOps on a Leader that already has global secrets configured. Cribl excludes global secret values from Git, so those values never reach a Git remote and cannot promote across environments. If GitOps is enabled, use legacy secrets instead.

A typical workflow for global secrets is:

1. Connect an external provider to add a secret store, or use the built-in `cribl` secret store.
2. Add a secret folder and make it accessible to Worker Groups or Edge Fleets. You can also clone an existing secret folder to create a new secret folder that uses the same secret store.
3. Add global secrets to the secret folder.
4. Reference global secrets in Cribl resources that support them.
5. Commit and deploy your configuration.
6. Rotate credentials as needed in the built-in `cribl` secret store or an externally backed secret store.

Deployment Scope

In Cribl.Cloud, global secrets are scoped to a single Workspace. Workspaces in the same Organization cannot access each other's global secrets.

In on-prem deployments, global secrets are scoped to one Leader. Unrelated Leader installations cannot access global secrets configured on a different Leader.

The Leader persists global secrets configuration and resolves secret values. In Cribl.Cloud, this means the Leader for the Workspace. In on-prem deployments, this means the Leader Node. Cribl adds global secrets to deployment bundles for Worker Groups and Edge Fleets through the bundle push path. Cribl adds a global

secret when its secret folder is accessible to the Group or Fleet, even if no resource configuration in the Group or Fleet references the secret.

Global secrets are available only in Distributed deployments. If you run Cribl Edge in single-instance mode, use legacy secrets instead.

Secret Stores

Secret stores are the backing stores for the secret folders that contain global secrets. You can use the built-in `cribl` secret store or connect an externally backed secret store.

The built-in `cribl` secret store cannot be deleted, and it persists encrypted global secret values on the Leader. To delete a secret store that is backed by an external provider, you must first delete all of its secret folders.

Cribl Edge uses `cribl.secret` as the primary encryption key to protect sensitive values in configuration files. It is created when the Leader starts and is stored by default at `$CRIBL_HOME/local/cribl/auth/cribl.secret`. Global secrets in the built-in `cribl` secret store are encrypted with this key.

When you configure an external KMS provider (HashiCorp Vault or AWS KMS) to manage `cribl.secret`, the key is removed from disk and managed by the KMS provider instead. This protection extends to global secrets in the built-in `cribl` secret store. The KMS provider configuration is separate from the global secret store. When using an external KMS, ensure that IAM permissions are correctly scoped (for example, `kms:Decrypt` for AWS KMS). Misconfigured permissions can prevent the Leader from starting.

Back up `cribl.secret` before major changes such as enabling an external KMS or rotating keys.

Secret Folders

Within secret stores, global secrets are organized into secret folders. Each secret folder can only belong to one secret store.

For secret folders backed by the built-in `cribl` secret store, Cribl persists encrypted secret values on the Leader in per-folder storage. For secret folders that are backed by external secret stores, Cribl stores metadata for folders and global secrets on the Leader and resolves secret values from the external provider at runtime.

Access Model

Global secrets are defined once on the Leader within the deployment scope. Cribl controls global secrets at the folder level, not per secret.

When you add a secret folder, the **Accessible to** setting determines which Worker Groups and Edge Fleets can use the folder's global secrets in resource configurations. Adding a Worker Group or Edge Fleet to the folder's

Accessible to list makes every global secret in that folder available to use throughout the Group or Fleet. If you make a secret folder accessible to an Edge Fleet or Subfleet, its Subfleets inherit the ability to use the global secrets in the folder.

Deployment bundles include every global secret in a folder that is accessible to the Worker Group or Edge Fleet. Take care to make folders accessible only to the Groups and Fleets that should be able to use the secrets that the folders contain.

After a secret folder is accessible to a Worker Group or Edge Fleet, supported resources in that Group or Fleet expose references to the global secrets in the folder. Within one Workspace (Cribl.Cloud) or Leader (on-prem), any Worker Group or Edge Fleet that can use the folder can reuse the same global secret definitions.

To remove a Worker Group or Edge Fleet from a secret folder's **Accessible to** list, first remove all references to the global secrets in the folder from resources in the Group or Fleet. This includes references used in Subfleets that will lose the ability to use those secrets if you remove the parent Fleet or Subfleet from the list.

Making a secret folder accessible to a Worker Group or Edge Fleet does not grant Member Permissions on the folder. Members with the **Admin** Permission on a higher-level object can view and manage the folder's secrets. For other Members and Teams, an Admin must share the folder and assign the **Shared Folder Secrets Viewer** or **Shared Folder Secrets Maintainer** Permission.

Leader Restart and Externally Backed Secret Folders

When the Leader restarts, it reinitializes each secret store that is backed by an external provider and loads global secrets from the external provider. The Leader keeps externally backed secret values in memory only (they are not persisted on disk).

If credential values changed in the external store since the last commit and deploy, the Leader might resolve the updated values after it restarts. This does not distribute the new credentials to Worker Groups or Edge Fleets. Commit and deploy still controls when updated global secrets reach nodes. To rotate credentials through the normal workflow, see Rotate Global Secrets in Externally Backed Secret Stores.

If the Leader cannot reach the external provider when it restarts, store initialization or secret resolution can fail because it has not fetched and cached global secret values. Cribl surfaces the failure through secret store health checks as system bulletin messages. Deploy is blocked for Worker Groups and Edge Fleets with access to secret folders that are backed by the unhealthy store until the Leader successfully resolves those secrets. You can still commit configuration changes.

11.9.1. Add, Use, And Deploy Global Secrets

Configure secret folders and global secrets so that you can reference them when you configure supported resources.

For the built-in `cribl` secret store, you can add secret folders and global secrets immediately. Cribl encrypts and stores secret values on the Leader. For externally backed secret stores, configure the secret store first. Then add secret folders and global secrets that reference secrets in the external provider.

> Global secrets are not supported when GitOps is enabled in Cribl Stream, and you cannot enable GitOps on a Leader that already has global secrets configured. Cribl excludes global secret values from Git, so those values never reach a Git remote and cannot promote across environments. If GitOps is enabled, use legacy secrets instead.

Add Secret Folders

The steps for adding a secret folder are the same whether the folder is backed by the built-in `cribl` secret store or an external provider secret store.

To add a secret folder:

1. In **Global Settings** > **Security** > **Secret Folders**, select **Add Secret Folder**.
2. In the **New Secret Folder** modal, enter the following information:
    - **Secret store**: The secret store to use for the folder.
    - **Folder Name**: Name for the folder. To help keep folders organized, name them after a team, environment, or data domain (for example, `finance-prod` or `observability-shared`).
    - **Description**: Optional brief description for the folder.
    - **Accessible to**: Select the Worker Groups and Edge Fleets that can access the global secrets in the folder.
        - **All Worker Groups**: Toggle on to make the folder accessible to all Worker Groups in the Workspace (Cribl.Cloud) or on the Leader (on-prem).
        - **Worker Groups**: Select the Worker Groups to make the folder accessible to.
        - **All Fleets**: Toggle on to make the folder accessible to all Edge Fleets and Subfleets in the Workspace (Cribl.Cloud) or on the Leader (on-prem).
        - **Fleets**: Select specific Edge Fleets to make the folder accessible to. The Edge Fleet's Subfleets inherit access to the secrets in the folder.
3. Select **Save**.

Clone Secret Folders

Clone a secret folder to create a new folder that uses the same secret store. The new secret folder inherits the source folder's secret store. You cannot change the secret store for the new secret folder in the cloning configuration.

1. In **Global Settings** > **Security** > **Secret Folders**, find the secret folder to clone.
2. In the **Actions** column for the source secret folder, select the ellipses (three dots), then select **Clone**.
3. In the **Clone Secret Folder** modal, enter the following information:
    - **Folder Name**: Name for the new folder.
    - **Description**: Optional brief description for the new folder.
    - **Accessible to**: Access settings for the new secret folder. The initial settings match the configuration for the source secret folder, but you can change them on the new folder to grant access to different Worker Groups and Edge Fleets.
        - **All Worker Groups**: Toggle on to make the folder accessible to all Worker Groups in the Workspace (Cribl.Cloud) or on the Leader (on-prem). Toggle off to display the **Worker Groups** field and select specific Worker Groups to grant access to.
        - **All Fleets**: Toggle on to make the folder accessible to all Edge Fleets and Subfleets in the Workspace (Cribl.Cloud) or on the Leader (on-prem). Toggle off to display the **Fleets** field and select specific Edge Fleets to grant access to. When you grant access to an Edge Fleet, its Subfleets inherit access to the secrets in the new folder.
    - Select **Clone secrets from this folder to the new one** to copy all global secrets from the source secret folder into the new folder. Leave the check box clear to create an empty secret folder that uses the same secret store as the source folder.
        - For secret folders backed by the built-in `cribl` secret store, Cribl copies the encrypted secret values into the new secret folder.
        - For secret folders backed by an external provider, Cribl copies the global secret metadata and external references into the new secret folder. The secret values remain in the external provider.
4. Select **Save**.

After you clone a secret folder, confirm the access settings for the new secret folder before you reference its global secrets in resources.

Share Secret Folders with Members and Teams

Members with the **Admin** Permission on a higher-level object can share secret folders with other Members and Teams to grant the **Shared Folder Secrets Viewer** or **Shared Folder Secrets Maintainer** Permissions on individual secret folders.

To share a secret folder with Members and Teams:

1. In **Global Settings** > **Security** > **Secret Folders**, find the secret folder that you want to share.
2. In the **Actions** column for the secret folder, select the ellipses (three dots) and then **Share**.
3. Select the Members and Teams to share the secret folder with. Assign each one the **Shared Folder Secrets Viewer** or **Shared Folder Secrets Maintainer** Permission on the secret folder.
4. Select **Save**.

Add Global Secrets

To add a global secret, you must have a secret folder to store it in. Worker Group and Edge Fleet access to global secrets is controlled at the folder level, so confirm that the folder settings are correct for the secret before you add it.

To add global secrets to a secret folder, Members must have the **Shared Folder Secrets Maintainer** Permission on the secret folder or the **Admin** Permission on a higher-level object.

Add Global Secrets in Secret Folders Backed by the Built-in `cribl` Secret Store

For secret folders backed by the built-in `cribl` secret store, you enter all global secret values directly. Cribl encrypts and stores the values locally.

To add a global secret in a secret folder that is backed by the built-in `cribl` secret store:

1. In **Global Settings** > **Security** > **Secret Folders**, select the secret folder where you want to add the global secret.
2. Select **Add Secret**.
3. In the **New Secret** modal, add the following information:
    - **Secret name**: Name for the global secret.
    - **Secret type**: Select the type of the global secret and add values in the type-specific fields. Use `latin1` encoding for global secret values.
        - `Text`: Enter the secret in the **Secret value** field.
        - `API key and secret key`: Enter key values in the **API key** and **Secret key** fields.
        - `Username and password`: Enter the username and password values in the **Username** and **Password** fields.

You cannot change a global secret's type after you create it. Instead, delete the global secret and create a new one with the desired type.

- **Description**: Optional description for the global secret. The description helps Git reviewers identify the secret in the marker file.
- **Tags**: Optional comma-separated list of labels for organizing and identifying the global secret.

4. Select **Save**.

Add Global Secrets in Externally Backed Secret Folders

For secret folders backed by external secret stores, provide the values for sensitive fields (text secrets, secret keys, and passwords) as references to secrets in the external provider. Enter non-sensitive fields like usernames and API keys directly as plaintext.

To add a global secret in a secret folder that is backed by an external secret store:

1. In **Global Settings** > **Security** > **Secret Folders**, select the secret folder where you want to add the global secret.
2. Select **Add Secret**.
3. In the **New Secret** modal, add the following information:
   - **Secret name**: Name for the global secret.
   - **Secret type**: Select the type of the global secret and add references in the type-specific fields.
     - `Text`: Enter the secret reference in the **External secret reference** field.
     - `API key and secret key`: Enter the API key in the **API key** field and the secret key reference in the **Secret key reference** field.
     - `Username and password`: Enter the username in the **Username** field and the password reference in the **Password reference** field.

You cannot change a global secret's type after you create it. Instead, delete the global secret and create a new one with the desired type.

   - **Description**: Optional description for the global secret. The description helps Git reviewers identify the secret in the marker file.
   - **Tags**: Optional comma-separated list of labels for organizing and identifying the global secret.
   - **Response field**: For JSON secret values, the top-level key to extract from the JSON in the external provider. Omit if the external provider returns the secret value as a plain string.
     - For example, for HashiCorp Vault, if the secret is the `apiKey` value in a JSON object stored at the path `secret/finance/prod` (where `secret` is the default KV v2 mount configured on the secret store), enter `finance/prod` in **External secret reference** and `apiKey` in **Response field**.

4. Select **Save**. Cribl fetches the referenced value from the external provider, records a baseline fingerprint (`contentSha`), and updates Git diffs for the global secret metadata and the marker file for affected Worker Groups and Edge Fleets.

Cribl extracts the specified key's value and supplies it to any resource that references the global secret.

Use Global Secrets

To use a global secret when configuring a supported resource:

1. In the configuration modal for the resource, select the **Secret** option for the field where you want to use the global secret. Supported fields depend on the resource. For example, some Sources and Destinations support using global secrets for **Authentication > Authentication method**.
2. Select the **Select global secret** option.
3. In **Folder**, select the secret folder.
4. In **Secret**, select the global secret.
    - If the selected secret folder does not contain the global secret that you want to use, select the **Create** button to the right of the **Secret** field. In the **Create new secret** modal, add the global secret and select **Save**. Cribl adds the secret to the selected folder and selects it for the resource.

To create a global secret, Members must have the **Shared Folder Secrets Maintainer** Permission on the secret folder or the **Admin** Permission on a higher-level object.

Saved resource configurations store only references to global secrets, not the secret values. Cribl does not embed a copy of the global secret in the resource object and does not show any sensitive global secret values in the UI or in API responses.

In JavaScript expression fields, which have no **Secret** option, reference a global secret with `C.Secret()` and pass the secret folder ID as the third argument, such as `C.Secret('api_key', 'keypair', 'finance-prod')`. Without the secret folder ID, the expression resolves to `undefined`.

For global secrets in externally backed secret stores, the Leader fetches values when it starts and serves cached values afterward so that routine operation does not depend on external provider availability.

Packs and Global Secrets

Sources, Destinations, and Collectors inside a Pack can reference global secrets the same way as resources outside a Pack. Saved configurations store only the reference (`secretFolderId/globalSecretId`), not the secret value.

Before you install a Pack from the Dispensary or import a Pack whose Sources, Destinations, or Collectors use global secrets, add the referenced secret folders and global secrets on the Leader and make the folders

accessible to the target Worker Groups and Edge Fleets. Cribl does not create secret folders or global secrets during Pack install.

Deploy Global Secrets

Resource configurations on the Leader store references to global secrets, not credential values. Worker Groups and Edge Fleets receive the resolved values only after you commit and deploy configuration for each affected Group or Fleet.

Global Secrets in Deployment Bundles and Git

When you commit configuration with Git, Cribl excludes secret values from Git-tracked artifacts. At deploy time, Cribl injects secret values into each deployment bundle. Before it builds the bundle, the Leader must resolve every global secret in a secret folder that is accessible to the Worker Group or Edge Fleet. Deploy is blocked if the Leader cannot resolve any of the global secrets, even when no resource configuration references an unresolvable secret.

If an externally backed secret store is unhealthy but the Leader already cached the referenced secrets in memory, deploy can proceed using the cached values. See Secret Store Health Check Failures.

Cribl writes global secrets into the deployment bundle's `secrets.yml` file when the Leader deploys, alongside other encrypted legacy secret rows for the Worker Group or Edge Fleet. Each global secret row is keyed by the composite string `secretFolderId/globalSecretId`. Each legacy secret row is keyed by the secret's `id` alone. All rows are encrypted with the same `cribl.secret` material, and nodes use the same mechanism to decrypt and resolve global secret rows as for legacy secret rows in the bundle's `secrets.yml` file.

Global secret rows in the deployment bundle's `secrets.yml` are not committed to Git. To review global secret changes in Git, use the marker file.

Delete Global Secrets, Secret Folders, and Secret Stores

Cribl enforces the following deletion dependencies for global secrets, secret folders, and secret stores:

- A global secret cannot be deleted while it is still referenced in a resource configuration.
- A secret folder cannot be deleted while it still contains global secrets.
- A secret store that is backed by an external provider cannot be deleted while it still contains one or more secret folders.
- The built-in `cribl` secret store cannot be deleted.

To delete a global secret using the UI:

1. Remove all references to the global secret from resource configurations.
2. In **Global Settings** > **Security** > **Secret Folders**, select the secret folder that contains the global secret.

3. Find the global secret that you want to delete. Select the check box next to the global secret and **Delete Selected Secrets**.

To delete a secret folder using the UI:

1. Delete all global secrets in the secret folder.
2. In **Global Settings** > **Security** > **Secret Folders**, find the secret folder that you want to delete.
3. Select the check box next to the secret folder and **Delete Selected Secret Folders**.

To delete a secret store that is backed by an external provider using the UI:

1. Delete all secret folders that are backed by the secret store.
2. In **Global Settings** > **Security** > **Secret Stores**, select the secret store that you want to delete.
3. Select the check box next to the store and **Delete Selected Secret Stores**.

You can also use the following endpoints in the Cribl API to delete global secrets, secret folders, and secret stores:

- `DELETE /system/secret-folders/{folderId}/secrets/{id}` to delete a global secret.
- `DELETE /system/secret-folders/{id}` to delete a secret folder.
- `DELETE /system/secret-stores/{id}` to delete a secret store that is backed by an external provider. The built-in `cribl` secret store cannot be deleted.

View Resources that Reference a Global Secret

Use the `GET /system/secret-folders/{folderId}/secrets/{id}/refs` endpoint in the Cribl API to get a list of the resources that reference a specific global secret. For each reference to the global secret, the response specifies the resource type and ID, Cribl product context, Worker Group or Edge Fleet ID, and the name of the field in the resource configuration that uses the reference.

Responses list only direct global secret field references: `secretFolderId/globalSecretId` stored in supported resource configuration fields. Responses do not include global secrets referenced through C.Secret() JavaScript expression fields.

11.9.2. Rotate Global Secrets

Rotate global secrets when credentials change in the built-in `cribl` secret store or in an external provider. Update the value at its backing store, then commit and deploy affected Worker Groups and Edge Fleets so that nodes load the updated credential.

Rotate Global Secrets in the Built-in `cribl` Secret Store

To rotate a global secret that is backed by the built-in `cribl` secret store, update the value directly in Cribl:

1. In **Global Settings** > **Security** > **Secret Folders**, select the secret folder and existing global secret. Manually update the rotated value. You can also update the global secret value using the Cribl API endpoint `PATCH /system/secret-folders/{folderId}/secrets/{id}`.
2. Review the Git diffs for each affected Worker Group and Edge Fleet, especially `global-secrets-marker.yml`, and confirm that fingerprints changed only for the global secrets that you intended to rotate.
3. Commit and deploy the changes.

After you deploy, the `secrets.yml` file in the deployment bundle includes global secrets from secret folders shared with each affected Worker Group or Edge Fleet. Cribl restarts affected processes on nodes so that they load the new credential. The new global secrets are not applied silently to processes that are already running.

For the built-in `cribl` secret store, global secret values remain in encrypted `values.json` on the Leader. You do not need to reload the secret folder.

Rotate Global Secrets in Externally Backed Secret Stores

For secret folders that are backed by external secret stores, rotating a global secret value in the external store alone does not update what Cribl serves until you reload the secret folder. A Leader restart loads current values from the external provider without explicit reload, but Worker Groups and Edge Fleets do not receive updated credentials until you commit and deploy.

When you reload a secret folder, Cribl:

1. Re-fetches global secrets in the secret folder from its backing store.
2. Invalidates the Leader's cached resolution for the folder.
3. Compares content fingerprints to detect rotated references.
4. Persists updated metadata.
5. Refreshes `global-secrets-marker.yml` for each affected Worker Group and Edge Fleet so that Git diffs show which secrets changed without exposing values for sensitive fields.

Cribl re-fetches only global secrets that are already defined in the secret folder. Reload does not validate new references to external global secrets. Cribl validates those references when you add or update global secrets.

To rotate a global secret in a secret folder with an externally backed secret store:

1. In the external store, update the credential using your normal security process.
2. In Cribl, in **Global Settings** > **Security** > **Secret Folders**, find the secret folder that contains the rotated global secret.
3. In the **Actions** column for the secret folder, select the ellipses (three dots). Select **Reload** for the secret folder to fetch the referenced values from the external provider for the rotated global secret.
    - If reload fails or the external provider returns access errors, fix the underlying issue and reload again.
    - You can also reload the secret folder using the Cribl API endpoint `POST /system/secret-folders/{id}/reload`.

    Reload API requests share a rate limit of 10 requests per minute across all secret folders. If you script bulk reloads, allow time between requests or handle `429` responses using the `Retry-After` header.
4. Review the Git diffs for each affected Worker Group or Edge Fleet, especially `global-secrets-marker.yml`, and confirm that fingerprints changed only for the secrets that you intended to rotate.
5. Commit and deploy the changes.

After you deploy, the `secrets.yml` file in the deployment bundle includes referenced secrets for each affected Worker Group or Edge Fleet. Cribl restarts affected processes on nodes so that they load the new credential. The new global secrets are not applied silently to processes that are already running.

11.9.3. Back Up, Audit, And Troubleshoot Global Secrets

On the Leader, Cribl persists global secrets configuration under `$CRIBL_HOME/local/cribl/`. The following table describes the files that hold the global secrets configuration.

File	Purpose
`secret-stores.yml`	Secret store declarations, including store type, connection URL, authentication settings, TLS configuration, and health check settings.
`secret-folders.yml`	Secret folder declarations, including the backing `secretStoreId`, description, and sharing configuration (`groupIds`, `fleetIds`).
`secret-folders/<folder-id>/global-secrets.yml`	Per-secret-folder secret metadata, including secret type, description, tags, and (for folders in externally backed secret stores) secret references with paths and response fields. Does not contain values for sensitive fields.
`secret-folders/<folder-id>/values.json`	Encrypted sensitive values for global secrets in secret folders backed by the built-in `cribl` secret store. Not present for secret folders backed by external secret stores. Not tracked in Git. Do not edit or delete manually.

Cribl updates these files when you save changes to secret stores, secret folders, or global secrets. Do not manually edit these files. Incorrect or missing files can prevent the Leader from correctly loading global secrets.

Git tracks the YAML metadata but excludes the `values.json` file for each secret folder. Without `values.json`, global secrets in the built-in `cribl` secret store cannot be recovered from Git alone.

Backup and Restore in Cribl.Cloud

In Cribl.Cloud, for the built-in `cribl` secret store, Cribl backs up global secret configuration and encrypted values. You do not need to back up Leader filesystem paths manually. To restore global secrets from a backup, contact Cribl Support.

For secret stores that are backed by an external provider, Cribl caches secret values in memory only and never persists them on disk. When the Leader restarts, it reinitializes each secret store client and re-fetches global secrets from the external provider. You do not need to restore the global secrets in Cribl because the source of truth is the external provider. If the external secret store is healthy, Cribl automatically re-resolves the global secrets.

Backup and Restore in On-Prem Deployments

Back up these files on the Leader Node:

- `$CRIBL_HOME/local/cribl/secret-stores.yml` (all secret stores, including externally backed secret store configurations)
- `$CRIBL_HOME/local/cribl/secret-folders.yml` (all secret folders)
- `$CRIBL_HOME/local/cribl/secret-folders/<folder-id>/global-secrets.yml` (one file per secret folder; all secret stores)
- `$CRIBL_HOME/local/cribl/secret-folders/<folder-id>/values.json` (built-in `cribl` secret store only; encrypted payloads; not in Git)
- `$CRIBL_HOME/local/cribl/auth/cribl.secret` (required to decrypt `values.json` and bundle `secrets.yml` rows)

The `secret-stores.yml`, `secret-folders.yml`, and folder-specific `global-secrets.yml` files are tracked in Git when you use Git to manage configuration. Without Git or filesystem backups of those YAML files, you must manually recreate secret store connections, folder definitions, sharing rules, and global secrets.

For the built-in `cribl` secret store, secret values are encrypted in `values.json` on the Leader. Back up and restore `values.json` and `cribl.secret` together. Without both, you cannot recover global secrets in the built-in `cribl` secret store. Secret folders that are backed by external secret stores do not use `values.json`. Instead, Cribl fetches values from the external provider at runtime and stores only connection metadata and external provider path references on the Leader. Plan disaster recovery for externally backed secret folders separately in your external provider's environment.

In Distributed deployments, also back up `secrets.yml` and `global-secrets-marker.yml` files for each Worker Group and Edge Fleet under `$CRIBL_HOME/groups/<group-id>/local/cribl/` when the Worker Group or Edge Fleet has access to secret folders. This applies for both the built-in `cribl` secret store and externally backed secret stores. At deploy time, Cribl resolves global secret values (including values from external providers) and encrypts them into `secrets.yml` using `cribl.secret`. The `global-secrets-marker.yml` file is tracked in Git. Restoring injected rows in `secrets.yml` requires matching `cribl.secret` material for the Group or Fleet under `$CRIBL_HOME/groups/<group-id>/local/cribl/auth/`.

Automatic backups that Cribl Edge creates during upgrade cover only the `bin` and `default` directories. They do not include global secrets files under `local/cribl`. If `cribl.secret` is lost or inaccessible, the Leader cannot decrypt `values.json` or deployed `secrets.yml` entries until you recover the key and redeploy affected Groups or Fleets.

Restore Backups in On-Prem Deployments

Restore unencrypted backups to `$CRIBL_HOME/local/cribl/auth/cribl.secret` and restart the Leader.

If AWS KMS manages `cribl.secret`, use the AWS CLI with `kms:Decrypt` permissions to recover the plaintext key from an encrypted backup. Place the recovered file at `$CRIBL_HOME/local/cribl/auth/cribl.secret` and restart the Leader.

```
aws kms decrypt \
  --ciphertext-blob fileb://cribl.secret.encrypted.decoded \
  --region <region> \
  --key-id <KMS key ARN> \
  --output text \
  --query Plaintext | base64 --decode > cribl.secret
```

Copy

Audit and Review Change History

Cribl provides two complementary views of global secrets activity:

- **Git-tracked metadata**: Cribl stores definitions for secret stores, secret folders, and global secrets in Leader files under `$CRIBL_HOME/local/cribl/`. Secret values are not stored in Git.
    - When you perform a global commit, those files participate in commits like the rest of Leader configuration. Diffs show changes to metadata and sharing rules, not plaintext secret values. Git commit history records who committed the changes. See Marker Files for Git Review for more information.
- **Leader `audit.log`**: Create, update, delete, reload, and related operations on secret stores, secret folders, and global secrets emit JSON lines to the Leader's `audit.log`.
    - Each line includes details about the operation like the time, action, resource type (`global-secrets`, `secret-folders`, or `secret-stores`), authenticated user or API key context, resource identifiers, outcome, and a reason in case of failure. **Cribl never writes global secret values to `audit.log`.**
    - Audit events are written only on the Leader, not per node. To read and export `audit.log`, see Internal Logs.

  The following example demonstrates an `audit.log` line for deleting a global secret:

```
{"time":"2026-06-14T08:43:01.945Z","action":"delete","type":"global-secrets","us
```

Copy

Marker Files for Git Review

To give each Worker Group and Edge Fleet a safe audit trail of global secret changes in Git, Cribl writes a marker file, `global-secrets-marker.yml`, under the Group or Fleet configuration path (for example, `$CRIBL_HOME/groups/<groupId>/local/cribl/global-secrets-marker.yml`). The file holds

fingerprints of credential fields, not the global secret values themselves, so that diffs show which fields changed without listing secret values in plain text. Deploy then follows the normal commit-and-deploy path with an updated configuration bundle.

Git cannot show a readable diff for global secret values because Cribl stores them only as encrypted data on the Leader or resolves them from an external secret store. Cribl uses fingerprints to record changes to credential material for the Worker Group or Edge Fleet while omitting secrets from the diff, and refreshes `global-secrets-marker.yml` when those fingerprints change. The `global-secrets-marker.yml` file might be absent until the first refresh, or contain only an empty map after entries are cleared.

Cribl refreshes fingerprints when:

- Sharing rules change for a secret folder (so different Worker Groups and Edge Fleets gain or lose access to secrets in that folder).
- A secret folder reloads from an externally backed secret store (so resolved values from the external provider might have changed even when Cribl metadata paths did not).
- Global secrets in a secret folder that is accessible to a Worker Group or Edge Fleet are added, updated, or removed (including field-level edits such as rotated passwords).

Marker File Structure

In `global-secrets-marker.yml`, each top-level key identifies one global secret using the same composite form as references. For example:

```
'secretFolderId/globalSecretId':
  description: 'My global secret'
  secrets:
    username: a1b2c3d4e5f67890
    password: 90f8e7d6c5b4a321
```

Copy

The values mapped to each key include:

- `secrets` (required): A map of field names to fingerprint strings. For every populated credential field on the global secret, Cribl stores the first 16 hexadecimal characters of the SHA-256 digest of the field's value to keep the diff short and readable. This applies for both sensitive fields (like `password`, `secretKey`, and `value`) and non-sensitive fields (like `username` and `apiKey`).
- `description` (optional): If the global secret has a description, Cribl includes it in plain text to provide non-sensitive context for the fingerprints.

Cribl writes keys in sorted order for stable diffs.

Git Commits and Marker Files

When you use the Git workflow to commit configuration for a Worker Group or Edge Fleet, the commit always includes `global-secrets-marker.yml`. You cannot deselect `global-secrets-marker.yml` in the commit file list. This ensures that global secret changes are visible to reviewers and deploy picks up a new configuration bundle when fingerprints change. Do not remove or omit `global-secrets-marker.yml` from commits made outside the UI, such as manual Git edits.

Marker File Limitations

Fingerprints reflect what Cribl last wrote into the Worker Group or Edge Fleet configuration for review and deploy. They do not prove which credential value a node is using at the moment. If behavior does not match the latest marker entries, reload the affected secret folder or commit and deploy the Worker Group or Edge Fleet again.

Marker file entries are digests and optional description text. They facilitate audits and make diffs more readable, but they are not a substitute for access control, external provider audit logs, or runtime monitoring.

Treat truncated digests as change indicators: a new fingerprint means that Cribl recorded an updated value for the field when it refreshed the marker file. Identical fingerprints for two different secrets are unlikely in normal use but are not a cryptographic guarantee of equality across unrelated secrets.

If an externally backed secret store is unavailable when the Leader restarts, Cribl might not resolve global secrets from that store during startup marker file sync. The marker file can omit entries for those secrets or remove existing entries, so `global-secrets-marker.yml` might show a diff even though the credentials did not change. After the secret store recovers and Cribl successfully resolves the secrets again, a subsequent marker refresh can show another diff when the entries return. See Secret Store Health Check Failures and Leader Restart and Externally Backed Secret Folders.

Troubleshooting

This troubleshooting section addresses issues with global secrets during deploy or Pack clone, as well as GitOps-related conflicts. For HTTP status codes for secret store, secret folder, and global secret API operations, see the Cribl API reference.

Secret Store Health Check Failures

Cribl checks connectivity to each secret store that is backed by an external provider every 30 seconds. After five consecutive failed health checks, Cribl sets the secret store's status to unhealthy, displays a system bulletin message, and blocks reload for the store's secret folders. A single transient failure can clear on its own.

Cribl blocks deploy when the Leader must fetch global secrets from the unhealthy secret store and the secrets are not already cached in memory, such as during Leader startup before it successfully resolves secrets from

the external provider. You can still commit configuration changes. If the Leader already cached the global secrets, deploy can proceed using the cached values even while the secret store is unhealthy.

The system bulletin message includes external provider-specific errors that explain the reason for the failed health check. Take the appropriate action based on the error message to resolve the issue in the external provider. The connection pages for each external provider include a list of the error messages for the provider.

After the issue is fixed, the next periodic health check will automatically detect recovery. When the next health check succeeds, Cribl clears the bulletin message and unblocks reload for affected secret folders. If deploy failed because the Leader could not resolve global secrets while the secret store was unhealthy, deploy will succeed again when the Leader can fetch secrets from the recovered store.

Deploy Failures

While the Leader assembles a deployment bundle for a Worker Group or Edge Fleet, it must resolve global secrets in secret folders that are accessible to the Group or Fleet. If the Leader cannot resolve global secrets, deploy will fail before the Leader produces a valid bundle with the error `Failed to deploy bundle: Could not fetch global secrets. Please try again!.`

To resolve the issue:

1. Verify that the Workspace Leader (Cribl.Cloud) or Leader Node (on-prem) is healthy and that **Global Settings** > **Security** > **Secret Stores** does not show a non-healthy status for the relevant store. If the Leader restarted recently, wait a few minutes and retry the deploy.
2. Verify that every global secret in folders that are accessible to the Worker Group or Edge Fleet resolves successfully. A misconfigured or unresolvable secret can block deploy even when no configuration references it.
3. Retry the commit and deploy.

Cloning Packs and Sharing Global Secrets

When you clone a Pack into a Worker Group or Edge Fleet, Cribl checks whether referenced global secrets are accessible to the target Group or Fleet. If the necessary secret folders are not accessible, clone returns an error like `Global secrets "<folder>/<secret>" are not shared with destination "<group>". Referenced global secrets will be inaccessible.` If several global secrets are inaccessible, Cribl lists each reference in the error message, separated by commas.

To resolve the issue:

1. Make the secret folder that contains the global secret accessible to the target Worker Group or Edge Fleet or change the Pack configuration to remove or replace the global secret references.
2. Retry the Pack clone operation.

GitOps-Related Conflicts

Global secrets are not supported when GitOps is enabled in Cribl Stream, and you cannot enable GitOps on a Leader that already has global secrets configured. Cribl excludes global secret values from Git, so those values never reach a Git remote and cannot promote across environments. If GitOps is enabled, use legacy secrets instead.

If you enable GitOps while secret folders exist, Cribl returns HTTP 409 with an error like:

```
Cannot enable GitOps while Global Secret folders exist: native secret values are stored outside Git and cannot be promoted across environments. Remove all Global Secret folders (or migrate those credentials) before enabling GitOps.
```

To resolve the issue, migrate any credentials saved as global secrets in the secret folders to legacy secrets. Delete the secret folders on the Leader and enable GitOps again.

If a GitOps Production sync fails because the incoming revision includes secret folder configuration, Cribl returns HTTP 409 with an error like:

```
Cannot sync: the incoming revision defines Global Secret folders, which are incompatible with GitOps because native secret values are not stored in Git. Remove the Global Secret folder configuration from the source environment before promoting this revision.
```

To resolve the issue, remove the secret folder configuration from the source environment, then promote the revision and retry the sync.

11.9.4. Connect External Secret Stores

An externally backed secret store connects Cribl to an external provider that already holds your credentials. Every secret folder in the secret store uses the external provider as its backing store. The global secrets that you add to the secret store hold references to secrets in the external provider rather than secret values. The external provider remains the system of record for the credentials.

Cribl persists the secret store configuration and the global secret references on the Leader, but not the secret values. The Leader resolves each reference against the external provider and distributes the resolved values to Worker Groups and Edge Fleets.

You can add externally backed secret stores for the following providers:

- Azure Key Vault
- HashiCorp Vault

Each secret store connects to one external provider, and you can add more than one secret store for the same provider. Configure the secret store first, then add secret folders and global secrets that reference the secrets from the external provider.

11.9.4.1. Connect Azure Key Vault Secret Stores

Configure a secret store that is backed by Azure Key Vault. Cribl authenticates to Microsoft Entra ID as a service principal to retrieve global secrets.

1. In **Global Settings** > **Security** > **Secret Stores**, select **Add Secret Store**.
2. In the **New Secret Store** modal, configure the store using the following fields:
    - **Secret store**: Select `Azure Key Vault`.
    - **Store name**: Unique identifier for the secret store.
    - **Description**: Brief description of the secret store (optional).
    - **Key Vault URI**: HTTPS URI of the Azure Key Vault to retrieve global secrets from. Cribl determines the Azure cloud from the URI. Cribl does not support managed Hardware Security Module (HSM) URIs. Supported URI suffixes are:
        - Azure Public Cloud: `.vault.azure.net` (for example, `https://my-vault.vault.azure.net`)
        - Azure Government: `.vault.usgovcloudapi.net`
    - **Authentication** > **Authentication method**: Method to use for authenticating to Microsoft Entra ID as a service principal. Enter credentials from the Microsoft Entra app registration that you created for the service principal.
        - **`Client secret`**: Authenticate with a client secret.
            - **Tenant ID**: Directory (tenant) ID of the Microsoft Entra tenant that owns the app registration.
            - **Client ID**: Application (client) ID of the app registration.
            - **Client secret**: Client secret generated for the app registration in the Azure portal.
        - **`Client certificate`**: Authenticate with a stored certificate.
            - **Tenant ID**: Directory (tenant) ID of the Microsoft Entra tenant that owns the app registration.
            - **Client ID**: Application (client) ID of the app registration.
            - **Certificate**: PEM certificate stored in Cribl that you registered as credentials for the app registration.

        Azure Key Vault secret stores support only PEM certificates. PKCS#12 (`.pfx`) certificates are not supported. Add the public certificate to the app registration, and import the PEM certificate and corresponding private key on the Leader.
3. Select **Test and Save**.

The **Test and Save** check and health checks confirm that the Leader can reach the vault and that Microsoft Entra ID accepts the credentials. They do not confirm that Cribl can retrieve secret values or resolve secrets at runtime.

To retrieve secret values and resolve secrets at runtime, you must assign the `Key Vault Secrets User` Azure role to the service principal on the Azure Key Vault resource. Secret-level assignment alone is insufficient.

Reference Azure Key Vault Secrets

When you add a global secret in a secret folder that is backed by an Azure Key Vault secret store, enter the name of the secret in Azure Key Vault in the **External secret reference**, **Secret key reference**, or **Password reference** field, depending on the secret type. The name must have between 1 and 127 characters and can contain only letters, digits, and hyphens. Do not enter a path: the name cannot contain `/`.

Leave **Response field** empty to use the entire Azure secret value. For a JSON secret, enter a key (for example `token`) to extract that field.

Cribl retrieves the current versions of secrets from Azure Key Vault and does not support referencing a specific version of a secret.

Adding or updating a secret reference fails if the Azure secret is disabled, past its expiration date, or not yet past its activation date. If a referenced secret becomes disabled, expires, or is not yet active, Cribl continues to serve the secret and writes this warning to the Leader logs: `Azure Key Vault secret is outside its validity window; serving anyway.`

Health Check Error Messages

After five consecutive failed health checks for an Azure Key Vault-backed secret store, Cribl displays a system bulletin message. Health checks run every 30 seconds, so a single transient failure can clear on its own. For details about health checks and reload, deploy, and recovery, see Secret Store Health Check Failures.

Health check errors that mention `List` or `Get` are referring to connectivity checks that Cribl runs, not the Azure role to assign. Assign the `Key Vault Secrets User` Azure role (`Get`) to the service principal on the Azure Key Vault resource (not on individual secrets).

Do not assign only the `Key Vault Reader` (`List`) Azure role. `Key Vault Reader` can pass **Test and Save** and health checks, but Cribl cannot retrieve secret values without `Key Vault Secrets User`.

If an error tells you to grant `Key Vault Reader` or `Get` on `cribl-gsm-connectivity-probe`, grant `Key Vault Secrets User` on the vault resource instead.

Failure	Error message

The connectivity probe timed out.	`Azure Key Vault List secrets probe for store "<store-id>" timed out after 5000ms`
	
	`Azure Key Vault Get secret probe for store "<store-id>" timed out after 5000ms`

Microsoft Entra authentication failed.	`Azure Key Vault authentication failed for store "<store-id>"` followed by a credential-specific hint, when available

Azure Key Vault returned HTTP 401.	`Azure Key Vault List secrets probe for store "<store-id>" returned HTTP 401. Verify the authentication configuration.`
	
	`Azure Key Vault Get secret probe for store "<store-id>" returned HTTP 401. Verify the authentication configuration.`

Azure Key Vault denied access while validating the store.	`Azure Key Vault denied List and Get for store "<store-id>". Grant Key Vault Reader or Key Vault Secrets User, or Get on "cribl-gsm-connectivity-probe".`

Azure Key Vault throttled the request.	`Azure Key Vault throttled the List secrets probe for store "<store-id>" (HTTP 429); usually transient.`
	
	`Azure Key Vault throttled the Get secret probe for store "<store-id>" (HTTP 429); usually transient.`

Azure Key Vault returned a server error.	`Azure Key Vault returned a server error during the List secrets probe for store "<store-id>" (HTTP <status-code>).`
	
	`Azure Key Vault returned a server error during the Get secret probe for store "<store-id>" (HTTP <status-code>).`

Azure Key Vault is unreachable.	`Azure Key Vault List secrets probe for store "<store-id>" could not be reached`
	
	`Azure Key Vault Get secret probe for store "<store-id>" could not be reached`
	
	Error message includes the HTTP status code if the failure is not `401`, `429`, or `5xx`.

If you revoke or rotate the Microsoft Entra credentials for a secret store that is already healthy, health checks can continue to succeed for up to one hour. Cribl reuses a Microsoft Entra token it already obtained and does not detect that the credentials are no longer valid until the token expires or the secret store reinitializes (for example, due to a Leader restart).

Azure Key Vault Firewalls and IP Allowlists

When the Leader resolves global secrets from Azure Key Vault, it connects to the Key Vault URI that you configured. Cribl.Cloud Leaders must be able to reach the vault's public endpoint. On-prem Leaders can use an Azure private endpoint if they can reach the vault on your network.

Cribl.Cloud

Cribl.Cloud Leaders are not on your Azure virtual network. They can reach Azure Key Vault only at the vault's public endpoint. A vault that you can reach only over an Azure private endpoint is not reachable from Cribl.Cloud.

Cribl.Cloud Workspaces use public egress by default, and the Leader's egress IP is ephemeral. When Cribl replaces the Leader during upgrades or maintenance, the egress IP changes. If you configure the Azure Key Vault firewall to allow selected networks, you must use a stable Leader egress IP and add it to the vault's IP allowlist.

To enable static egress for a Workspace, contact Cribl Support. With static egress enabled, Cribl provisions one stable egress IP per Availability Zone. Add every egress IP to your Azure Key Vault allowlist.

Static egress is irreversible. You cannot disable static egress after it is enabled for a Workspace or return to public egress.

On-Prem Deployments

In on-prem Cribl deployments, the Leader Node typically has a stable egress IP that you control. If the Leader reaches the vault over the public internet and you configure the Azure Key Vault firewall to allow selected networks, add that IP address (or the IP addresses for all Leaders that resolve Azure Key Vault secrets, such as in a Leader HA pair) to your Azure Key Vault allowlist.

11.9.4.2. Connect HashiCorp Vault Secret Stores

Configure a secret store that is backed by HashiCorp Vault to retrieve global secrets from the KV v2 secrets engine. The KV v1 secret engine is not supported.

1. In **Global Settings** > **Security** > **Secret Stores**, select **Add Secret Store**.
2. In the **New Secret Store** modal, configure the store using the following fields:
    - **Store name**: Unique identifier for the secret store.
    - **Description**: Brief description of the secret store (optional).
    - **Vault URL**: URL where your HashiCorp Vault instance is running (for example, `https://vault.example.com:8200`).
    - **Namespace**: Full path to the HashiCorp Vault Enterprise namespace where Cribl should retrieve global secrets. Enter the full path from the root namespace, not only the leaf segment (such as `admin/engineering/sre` for HashiCorp Cloud Platform (HCP) Vault or `root/engineering/sre` for self-hosted Vault). Omit if you do not use Vault namespaces.
        - HashiCorp Vault Enterprise namespaces are isolated and do not inherit authentication configurations from parent namespaces. If you store secrets in more than one Vault namespace, add a separate Vault-backed secret store in Cribl for each namespace.
        - In each namespace, your Vault administrator must configure an authentication method and policies that allow Cribl to authenticate and read the paths that you provide when you add a global secret.
        - When you add a global secret, Cribl validates each path against the namespace you provide. If HashiCorp Vault does not have a secret at the specified path (for example, because the secret is in a different namespace), Cribl will not add the global secret.
    - **Mount**: Mount point of the HashiCorp Vault KV v2 secrets engine to retrieve global secrets from. Default is `secret`. The KV v1 secrets engine is not supported.
    - **Authentication** > **Authentication provider**: Provider to use for authenticating to HashiCorp Vault.
        - **Token**: In the **Token** field, enter your HashiCorp Vault authentication token.
        - **`AWS IAM`**:
            - **Authentication method**: Select `Auto` or `Manual`.
                - `Auto`: Use credentials from the environment. Cribl authenticates to HashiCorp Vault from the Leader using the Leader's attached IAM role or AWS environment variables.
                - `Manual`: Use static credentials. Enter your **Access key** and **Secret key** credentials.

- **Vault AWS IAM Server ID**: Value for the `X-Vault-AWS-IAM-Server-ID` header. Must match the value configured for IAM authentication on your HashiCorp Vault server.
- **Vault role**: Name of the role configured in the HashiCorp Vault AWS auth method that grants Cribl access to secrets stored in Vault.
    - If you provided the path to a HashiCorp Vault Enterprise namespace in the **Namespace** field, this role must be configured in the same namespace. Namespaces do not inherit authentication configurations from parent namespaces.
- **Custom authentication path**: Auth method mount path in HashiCorp Vault, if different from the default `aws` (optional).
- **AssumeRole > Enable for Vault Auth**: Toggle on to assume a different IAM role via AWS Security Token Service (STS) before authenticating to HashiCorp Vault. Use when the Cribl instance's own IAM role does not have direct Vault access, such as for cross-account access.
- **AssumeRole > AssumeRole ARN**: ARN of the IAM role to assume. Required when **AssumeRole** is enabled.
- **AssumeRole > External ID**: Identifier required to authorize third-party access. Required when the role's trust policy enforces an external ID condition.
- **AssumeRole > Duration (seconds)**: Duration of the Assumed Role session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Default is 3600 (1 hour).

Your Vault administrator must allow the IAM principal that matches the **Authentication method** and **AssumeRole** settings. In Cribl.Cloud, when multiple Workspaces run in the same AWS account, each Workspace authenticates with a different IAM principal, so the Vault role must include every principal that needs access.

- **`AWS EC2`**:
    - **Vault role**: Name of the HashiCorp Vault role to authenticate against when using AWS EC2 authentication.
    - **Custom authentication path**: Auth method mount path in HashiCorp Vault, if different from the default `aws` (optional).
- **`AppRole`**:
    - **Role ID**: Identifier for the AppRole defined in HashiCorp Vault.
    - **Secret ID**: Secret credential associated with the AppRole defined in HashiCorp Vault.
    - **Custom authentication path**: Auth method mount path in HashiCorp Vault, if different from the default `approle` (optional).

- **TLS Settings (Client Side)**:

  If your HashiCorp Vault deployment uses a self-signed certificate or a certificate signed by a private certificate authority (CA), add the CA certificate to the trusted CA list on the Leader. For details, see CA Certificates and Environment Variables.

  - **Server name (SNI)**: Server Name Indication (SNI) value to send in the TLS handshake. Use when the HashiCorp Vault server certificate CN or SAN does not match the Vault URL hostname.
  - **Minimum TLS version**: Minimum TLS version that Cribl will accept when connecting to HashiCorp Vault.
  - **Maximum TLS version**: Maximum TLS version that Cribl will accept when connecting to HashiCorp Vault.

- **Health Check > Health check endpoint**: HashiCorp Vault API path to use for health checks to validate Vault connectivity. Default is `/v1/sys/health`.

3. Select **Test and Save**.

Health Check Error Messages

After five consecutive failed health checks for a HashiCorp Vault-backed secret store, Cribl displays a system bulletin message. Health checks run every 30 seconds, so a single transient failure can clear on its own. For details about health checks and reload, deploy, and recovery, see Secret Store Health Check Failures.

Failure	Error message
Connection was refused or Vault is unreachable	`Could not validate the provided Vault configuration: ECONNREFUSED`
Vault is sealed	`Vault is sealed and cannot serve requests`
Token is invalid or expired	`Vault rejected the configured credentials (token invalid or expired)`
Authentication credentials configured for the secret store do not have the correct permissions to read the Vault health check endpoint.	`Vault access denied (HTTP 403). Verify that Cribl's token or policy has not been revoked.`
Health endpoint returned a non-`200` response	HTTP status code and response body for diagnosis

Self-Hosted HashiCorp Vault and IP Allowlists

When the Leader resolves global secrets from a self-hosted HashiCorp Vault instance, it makes outbound connections to your Vault server to authenticate and resolve secrets. These connections come from the Leader's egress IP address. If your HashiCorp Vault server uses an IP allowlist to restrict inbound connections, your Vault administrator must add the Leader's egress IP address to the Vault allowlist.

Cribl.Cloud

Cribl.Cloud Workspaces use public egress by default, and the Leader's egress IP is ephemeral. When Cribl replaces the Leader during upgrades or maintenance, the egress IP changes, and the allowlist entry that uses the existing egress IP stops working. You must use a stable Leader egress IP for a reliable integration if your HashiCorp Vault server uses an IP allowlist.

Enable static egress for the Workspace region so the Leader uses a stable set of outbound IPs. Your Vault administrator must add every address listed in **Workspace** > **Connections** > **Static Egress IP** to the Vault allowlist. If you later disable static egress, those IPs change and the Vault allowlist must be updated.

On-Prem Deployments

In on-prem Cribl deployments, the Leader Node typically has a stable egress IP that you control. Add that IP address (or the IP addresses for all Leaders that resolve Vault secrets, such as in a Leader HA pair) to your HashiCorp Vault allowlist.

11.10. Create And Manage Legacy Secrets In Cribl Edge

Legacy secrets are different from centralized global secrets, which you define once and reuse across Cribl resources. Existing legacy secrets will continue to work as you migrate to global secrets.

This topic describes legacy secrets in Cribl Edge: authorization tokens, passwords, API keys, and other sensitive values you define on **Manage Secrets** pages, such as for individual Fleet in a distributed deployment.

Use the **Manage Secrets** page to create and update legacy secrets. Reference legacy secrets programmatically with the C.Secret Function.

To ensure they can be decoded correctly, all secrets in Cribl Edge must use `latin1` encoding.

How Secrets Are Protected

`cribl.secret` is the master encryption key used by Cribl Edge to protect sensitive values such as credentials, tokens, and other secrets stored in configuration files. It is the root of trust for securing encrypted values across the platform and is created when Cribl Edge first starts.

File Location

By default, `cribl.secret` is stored at:

```
$CRIBL_HOME/local/cribl/auth/cribl.secret
```

Copy

When you configure an external KMS provider, `cribl.secret` is removed from disk and managed by that provider instead. Supported providers include AWS KMS and HashiCorp Vault.

Back up `cribl.secret` securely before major changes such as enabling an external KMS or rotating keys.

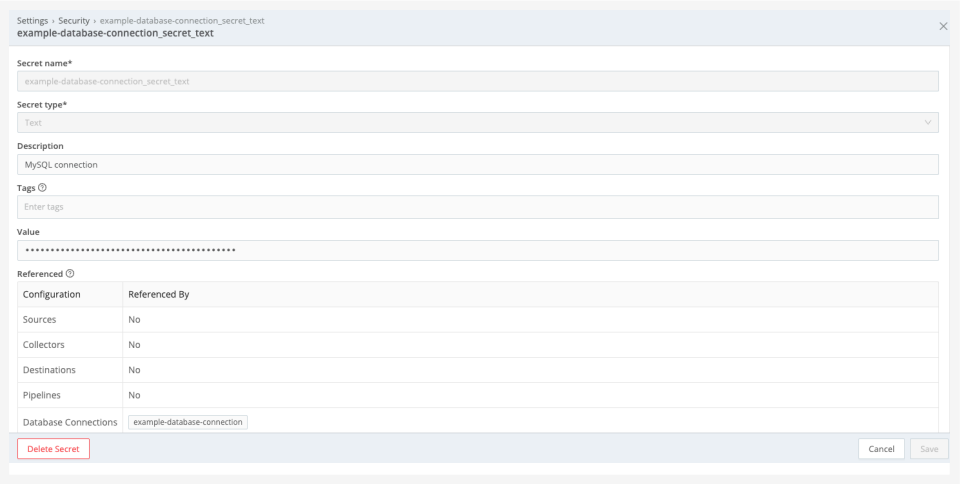
When using an external KMS, ensure that IAM permissions are correctly scoped (for example, `kms:Decrypt` for AWS KMS). Misconfigured permissions can prevent the Leader from starting. For details, see Configure KMS Providers.

Other Security Files

When you install Cribl Edge, a `keys.json` file is also created. This file contains cryptographic keys used for internal operations within Cribl Edge.

- **Single-instance deployment** - this file is located in `$CRIBL_HOME/local/cribl/auth/`.
- **Distributed deployment** - this file resides on the Leader Node, in `$CRIBL_HOME/groups/<group-name>/local/cribl/auth/`.

Access Secrets



- In a Single-instance deployment, select **Settings** > **Security** > **Secrets**.
- In a Distributed deployment with one Fleet, select **Configure** > **Settings** > **Security** > **Secrets**.
- In a Distributed deployment with multiple Fleets, secrets are managed on each Fleet. Select **Fleet** > `<Name>` > **Fleet Settings** > **Security** > **Secrets**.

On the **Manage Secrets** page, you can configure existing legacy secrets, and/or click **New Secret** to define new ones.

View Secret References

To view where a secret is used in your deployment:

1. Select a secret from the secrets list.
2. View the **Referenced** table at the end of the secret details. This table lists all Sources, Destinations, Pipelines, or Database Connections that currently reference that secret. If a secret is not referenced in one of those resources, the **Referenced By** column displays **No**.

View where secrets are referenced in your deployment

Add New Secret

The **New Secret** modal provides the following controls:

- **Secret name**: Enter an arbitrary, unique name for this secret.
- **Secret type**: Some options for this field expose additional controls, as described below.
- **Description**: Optionally, enter a description summarizing the purpose of the secret.
- **Tags**: Optionally, enter one or multiple tags related to this secret.

Secret Type

This drop-down offers the following types:

- **Text**: This default type exposes a **Value** field where you directly enter the secret.
- **API key and secret key**: Exposes **API key** and **Secret key** fields, used to retrieve the secret from a secure endpoint. This is the only secret type that Cribl Edge supports for its AWS-based Sources, Collectors, and Destinations, and its Google Cloud Storage Destination.
- **Username with password**: Exposes **Username** and **Password** fields, which you fill to retrieve the secret using Basic Authentication.

Encrypt Secrets Using the Command Line

You also have the option to create and encrypt sensitive values using the same mechanism Cribl Edge employs internally for all sensitive fields. This ensures consistency and leverages the built-in encryption capabilities within Cribl Edge.

This approach allows you to store all your secrets securely in a password store, keeping them out of your Git repository, and adheres to strict organizational security standards that prohibit storing secrets in version control.

Modifying credentials directly through the Cribl Edge UI won't be possible, even in development environments. This approach prioritizes security by keeping secrets out of the UI altogether.

For details, see encrypt in the CLI Reference doc.

Recover cribl.secret

If `cribl.secret` is lost or inaccessible, the Leader will fail to start because it cannot decrypt protected values. Recovery depends on whether you have an unencrypted backup or only an encrypted version.

Recover from an Unencrypted Backup

If you have an unencrypted backup, restore it to the following path and restart the Leader:

```
$CRIBL_HOME/local/cribl/auth/cribl.secret
```

Copy

Recover from an Encrypted Backup (AWS KMS)

If you only have an encrypted version under AWS KMS, use the AWS CLI with `kms:Decrypt` permissions to recover the plaintext key:

```
aws kms decrypt \
  --ciphertext-blob fileb://cribl.secret.encrypted.decoded \
  --region <region> \
  --key-id <KMS key ARN> \
  --output text \
  --query Plaintext | base64 --decode > cribl.secret
```

Copy

Place the recovered file at `$CRIBL_HOME/local/cribl/auth/cribl.secret` and restart the Leader.

Recover After KMS Failure

If your AWS KMS integration is misconfigured and the Leader won't start, switch back to the local KMS provider by editing:

```
$CRIBL_HOME/local/cribl/kms.yml
```

Copy

If you only have the encrypted version `cribl.secret.encrypted`, use the AWS CLI decrypt command above to recover the plaintext key, then restart the Leader.

Rotate cribl.secret

To rotate the master encryption key for the Leader, follow these steps. Note that all credentials encrypted with the current key will need to be re-entered.

Take a full backup of the `$CRIBL_HOME` directory before proceeding. Use `tar` to create an archive and store it in a secure location.

1. Copy the current auth token from the Leader and store it securely. Navigate to **Global Settings** > **System** > **Distributed Settings** > **Leader Settings** > **Auth Token**.
2. Stop the Cribl systemd service.
3. Delete the `$CRIBL_HOME/local/cribl/auth/cribl.secret` file.
4. Edit the `$CRIBL_HOME/local/cribl/auth/users.json` file and reset the password for at least the admin user. For details, see Manual Password Replacement.
5. Start the Leader and log in with the new credentials.
6. Restore the auth token you saved earlier. Navigate to **Global Settings** > **System** > **Distributed Settings** > **Leader Settings** > **Auth Token**. Once restored, Edge Nodes should reconnect to the Leader.
7. Reset passwords for other users through the UI, if applicable.
8. Reconfigure TLS and SSO settings if needed.
9. Replace each secret in Sources, Destinations, and Fleets. Secrets are stored in `$CRIBL_HOME/local/cribl/secrets.yml`. To find all references to secrets, search for strings starting with `#42:`:

   ```
   grep -Rn '#42:' $CRIBL_HOME/local/cribl/
   ```

   Copy
10. For each secret, generate a new encrypted value:

    ```
    cribl encrypt -v PLAINTEXT_SECRET
    ```

    Copy

    Update the secret and all references with the new encrypted value.

Migrate to Global Secrets

Migrate Fleet-level and inline legacy secrets to global secrets in phases. Legacy secrets continue to work during the transition, so you do not need to replace everything at once.

Plan the Migration

Before you migrate, decide how you want to organize global secrets. Secret folders both organize and control access to global secrets, so plan folders based on real needs such as environment, team, or application. Consider which Worker Groups and Edge Fleets need each global secret.

Plan to migrate in small batches. A good starting point is inline secrets that are stored directly in resource configurations.

You do not need to migrate every legacy secret at once. Legacy Fleet-level secrets continue to work during the transition. You can migrate the supported and highest-value legacy secrets first, and complete the migration when you're ready.

Migrate Legacy Secrets to Global Secrets

Migrating requires adding a global secret that corresponds to each legacy secret that you're using and replacing legacy secrets in resource configurations with references to the correct global secret. Follow this pattern to migrate:

1. Identify a legacy secret to migrate and the resource configurations where it is used.
2. Open the secret folder where you want to add the global secret or add a new secret folder.
3. Confirm that the secret folder is accessible to the Worker Groups and Edge Fleets that need access to the global secret.
4. Add the global secret in the secret folder using the same value or credential pair as the legacy secret.
5. Confirm that each migrated global secret appears in the catalog for the Worker Groups and Edge Fleets that need it. In the **Worker Group Settings** > **Security** > **Secrets** page for each Group or Fleet, the global secret should appear as a read-only entry with metadata that identifies the secret folder.
6. Update the resource configurations to replace the legacy secret with the corresponding global secret reference.
7. Repeat these steps for each legacy secret that you want to migrate in the same batch.
8. Review the Git diff for each affected Worker Group or Edge Fleet:
    - Confirm that resource configurations reference global secrets instead of legacy secrets.
    - Confirm that the `global-secrets-marker.yml` marker file for each Worker Group and Edge Fleet includes an entry for each migrated global secret.
9. Commit and deploy the updated configurations, and verify your migration.

Verify the Migration

Complete the following checks to verify that the migration succeeded for a Worker Group or Edge Fleet.

- **Test each resource that you changed.** For example, run a connection test or send sample events through the updated resource. Confirm that authentication succeeds and each resource works as you expect.
- **Confirm that global secrets appear in resource configuration drop-down menus.** Check a few resource configurations to confirm that the expected global secrets appear in the secret drop-down menus.

- **Confirm sharing settings for each secret folder.** For each global secret in a batch, open its secret folder in **Global Settings** > **Security** > **Secret Folders** and verify that the folder is accessible to the correct

11.11. Configure KMS Providers

Cribl Edge's Key Management Service (KMS) maintains the keys that protect sensitive information throughout your deployment. Cribl Edge offers two options for key management:

- **Internal KMS (Stream Internal)** - The default built-in key management system.
- **External KMS Providers** - Enterprise-grade options with HashiCorp Vault and AWS KMS integration (requires Enterprise license).

The table below summarizes the key differences between the Internal vs. External KMS.

Feature	Internal KMS (Stream Internal)	External KMS Providers (HashiCorp Vault and AWS KMS)
Master Key Storage	Stores `cribl.secret` directly on the filesystem.	Stores `cribl.secret` in a separate key management system.
Master Key Location	In a file called `cribl.secret`.	Completely removed from Cribl Stream's filesystem.
License Requirement	Available by default on all license tiers.	Requires an Enterprise license/plan.
Management	Managed entirely within Cribl Edge.	Managed by the external provider (Vault or AWS).
Configuration/Secrets	Maintained through Cribl's Settings interface.	Configured through Cribl's Settings interface.
Setup Complexity	Simpler to set up.	More complex to set up.
Security	Less separation between the application and its encryption keys.	Enhanced security through separation of encryption keys from the application.
Centralized Key Management	None.	Enables centralized key management across your organization.
Availability	Available by default. Unavailable if an external KMS is enabled for the same Leader Node/Fleet.	Unavailable if internal KMS is enabled for the same Leader Node/Fleet.
Supported Providers	N/A	HashiCorp Vault, AWS KMS.

How Encryption Works in Cribl Edge

The Role of `cribl.secret`

At the core of the Cribl Edge encryption system is a master encryption key called `cribl.secret`. This key is used to encrypt sensitive configuration elements such as:

- Authentication credentials in Sources and Destinations (stored in `inputs.yml` and `outputs.yml`)
- API keys and tokens
- Database connection strings (stored in `database-connections.yml`)
- TLS certificates and associated private keys (stored in the `auth/certs` directory
- Other sensitive attributes throughout Cribl Edge
- Secrets stored in `secrets.yml`

KMS Provider Interaction

When using the default Cribl Edge KMS provider:

- The `cribl.secret` value is stored directly on the filesystem in a file called `cribl.secret`.
- Cribl Edge uses this key to encrypt sensitive information in various configuration files.

When you configure an external KMS provider (HashiCorp Vault or AWS KMS):

- The `cribl.secret` file is removed from the filesystem.
- Cribl Edge sets and retrieves the `cribl.secret` value via the chosen external KMS provider.
- The external KMS provider only handles the master encryption key (`cribl.secret`) itself.
- All other sensitive information (Source/Destination credentials, TLS certificates, database connection strings, etc.) remains in the Cribl Edge configuration files, encrypted using the externally-managed key.
- Some sensitive configuration elements may remain in plaintext in the configuration files, depending on the specific attribute.

Manage KMS Across Distributed Environments

In Distributed deployments:

- Each environment (Leader Node, Fleet) can have its own KMS configuration.
- The internal KMS is unavailable for any environment where an external KMS is enabled.
- Other environments without external KMS configured will continue to use the internal KMS.
- Each environment requires its own distinct secret that cannot be shared between environments.

External KMS Providers and Fleets

Some guideines to keep in mind when using an external KMS provider in a Distributed deployment:

- To integrate an external KMS provider into an on-prem Distributed deployment, the Leader Node must have internet access.
- After initial license installation in Distributed mode, you may need to take the following steps to activate KMS features within Fleets:
    - Open **Settings** > **Global** > **Service Processes** > **Processes**.
    - In the list of processes, locate any process with a Role of `CONFIG_HELPER`.
    - Select the **Restart** button next to that process.
    - Upon restarting, the KMS will be available for use in the corresponding Fleet.

Deployment Scenarios

The KMS configuration varies depending on your deployment type:

- In an on-prem Single-instance deployment, you configure the KMS at **Settings** > **Global** > **Security** > **KMS** > **Configure**.
- In a Distributed deployment, you configure the Leader's KMS at the same global location, while additional KMS configs for each Fleet are available at the Fleet's **Group Settings** > **Security** > **KMS** > **Configure** page.

Available KMS Providers

The KMS **Configure** drop-down currently provides these options:

- Stream Internal: The only option available without an Enterprise license/plan. With this option, the secrets themselves are configured and maintained in Cribl Secrets section.
- HashiCorp Vault: Stores the `cribl.secret` key securely in HashiCorp Vault, completely removing it from Cribl's local filesystem.
- AWS KMS: Stores the `cribl.secret` key directly within AWS Key Management Service, completely removing it from Cribl's local filesystem.

External KMS Providers and Fleets

To integrate an external KMS provider into an on-prem Distributed deployment, Cribl Edge's Leader Node must have internet access.

When you initially install a license in Distributed mode, a known bug prevents immediate use of KMS features within Fleets. Here is the workaround:

1. Open **Settings** > **Global** > **Service Processes** > **Processes**.
2. In the list of processes, locate any process with a Role of `CONFIG_HELPER`.

3. Select that process' **Restart** button.

Upon restarting, KMS will be available for use in the corresponding Fleet.

Internal KMS

The **KMS provider** field defaults to `Stream Internal`. With this option, no further configuration here is required (or possible). See Secrets to configure individual secrets.

HashiCorp Vault

Cribl Edge's integration with HashiCorp Vault uses a Vault policy to define the capabilities granted to tokens used for KMS access. This policy ensures tokens have the necessary permissions to interact with Vault paths relevant to KMS functionality.

Vault Policy Permissions

This table outlines the required Vault policy permissions for different access scenarios.

Path	Capabilities	Description
`<path to vault secret>`	Create, Update, Read	Grants access to create, update, and read secrets at the specified path.
`auth/token/create`	Update	Grants permission to update authentication tokens (only required for Token authentication).
`sys/health`	Read	Allows reading system health information (only needed if enabling health checks).

`<path to vault secret>` represents the actual path to the secret within your Vault hierarchy.

Keep these capabilities in mind as you proceed with the configuration.

Setting the **KMS provider** drop-down to `HashiCorp Vault` exposes the following configuration options:

KMS Settings

Vault URL: Enter the Vault server's URL (for example, `http://localhost:8200`).

Namespace: If you are using HashiCorp Vault Enterprise namespaces, enter the desired namespace.

Authentication

Auth Provider: The method for authenticating requests to HashiCorp Vault server. Select one of `Token`, `AWS IAM`, or `AWS EC2`. Your selection determines the remaining **Authentication** options displayed.

Token-based Authentication

Token: Enter the authentication token. This token will be used only to generate child tokens for further authentication actions.

AWS IAM Authentication

In HashiCorp Vault, the term "method" can refer to `userpass`, `token`, or `aws`, among others, but the `aws` method supports two authentication types: `iam` and `ec2`. Meanwhile, in Cribl Edge, you'll see "method" used differently, for example in the **Authentication method** setting described below.

Use the **Authentication method** buttons to select one of the following:

- **Auto**: Uses the AWS instance's metadata service to automatically obtain short-lived credentials from the IAM role attached to an EC2 instance, local credentials, sidecar, or other source. The attached IAM role grants Cribl Edge Edge Nodes access to authorized AWS resources. Can also use the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. Works only when running on AWS.
- **Manual**: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials directly or by reference. This is useful for Edge Nodes not in an AWS VPC, for example, those running in a private cloud. It prompts you to provide an **Access key** and a **Secret key**.

Vault AWS IAM Server ID: Value to use for the `Vault-AWS-IAM-Server-ID` header value. This should match the value configured with IAM authentication on Vault.

Vault Role: Authentication role to use in Vault.

Custom Auth Path: If you enabled authentication in HashiCorp Vault with a custom path, enter that path again here.

For example:

- If you enabled authentication with the HashiCorp Vault command `vault auth enable -path /my-auth aws` instead of `vault auth enable aws` you would set a custom path of `my-auth`. Subsequently, when you perform actions using the `vault write` command, you'd specify an auth type with the `auth_type=ec2` or `auth_type=iam` options.

Assume Role

This section is displayed for all AWS IAM authentication methods.

When using **Assume Role** to access resources in a different Region than Cribl Edge, you can target the AWS Security Token Service (STS) endpoint specific to that Region by using the `CRIBL_AWS_STS_REGION` environment variable on your Edge Node. To specify a custom STS endpoint, set the `CRIBL_AWS_STS_ENDPOINT` environment variable. If both are set, `CRIBL_AWS_STS_ENDPOINT` takes precedence. Setting an invalid Region or endpoint results in a fallback to the global STS endpoint.

Enable for Vault Auth: Toggle on if you want to use your Assume Role credentials to access Vault authentication.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming the role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

AWS EC2 Authentication

Vault Role: Enter the authentication role to use in Vault.

Custom auth path: If you enabled authentication in HashiCorp Vault with a custom path, enter that path again here. For example:

- You could have used the HashiCorp Vault command `vault auth enable -path /my-auth aws` to enable authentication with a custom path of `my-auth`. Subsequently, when you perform actions using the `vault write` command, you'd specify an auth type with the `auth_type=ec2` or `auth_type=iam` options.

Secret Engine

Mount: Mount point of the Vault secrets engine to use. (Currently, only the KVv2 engine is supported.) Defaults to `secret`.

Secret Path: Enter the path on which the Cribl Edge secret should be stored. For example, `<somePath>/cribl-secret`.

In a Distributed deployment, the Leader, and each Fleet, require a distinct secret. This location cannot be shared between them.

Advanced

Enable Health Check: Whether to perform a health check before migrating secrets data. Defaults to toggled on.

Health check endpoint: Configurable endpoint to use for validating system health. Defaults to `/v1/sys/health`.

AWS KMS

Setting the **KMS provider** drop-down to `AWS KMS` exposes the following configuration options:

Authentication

Authentication method: Select an AWS authentication method.

- **Auto**: This default option uses the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`, or the attached IAM role. Works only when running on AWS.
- **Manual**: You must select this option when not running on AWS.

The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to `env.AWS_ACCESS_KEY_ID`, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to `env.AWS_SECRET_ACCESS_KEY`, or to the metadata endpoint for IAM credentials.

Assume Role

When using **Assume Role** to access resources in a different Region than Cribl Edge, you can target the AWS Security Token Service (STS) endpoint specific to that Region by using the `CRIBL_AWS_STS_REGION` environment variable on your Edge Node. To specify a custom STS endpoint, set the `CRIBL_AWS_STS_ENDPOINT` environment variable. If both are set, `CRIBL_AWS_STS_ENDPOINT` takes precedence. Setting an invalid Region or endpoint results in a fallback to the global STS endpoint.

Enable for KMS: Toggle on if you want to use Assume Role credentials to access the AWS KMS.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID in order to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Service Configuration

KMS Key ARN: Enter the Amazon Resource Name (ARN) of the AWS KMS Key to use for encryption. This entry is required.

When you configure your IAM account/role in AWS, grant access to the following permissions on the KMS key that will be used:

- `kms:Encrypt`
- `kms:Decrypt`

Then use that account for authentication.

11.12. Create And Manage Encryption Keys

You can create and manage keys that Cribl Edge will use for real-time encryption of fields and patterns within events. For details on applying the keys that you define here, see Encryption Keys.

After setting up a key, you can also reference it in Cribl Search, using the `encrypt` and `decrypt` functions in your queries.

Access Keys

- In a Single-instance deployment, select **Settings** > **Security** > **Encryption Keys**.
- In a Distributed deployment with one Fleet, select **Settings** > **Security** > **Encryption Keys**.
- In a Distributed deployment with multiple Fleets, keys are managed per Fleet. Select **Manage** > **Groups** > `<groupName>` **Group Settings** > **Security** > **Encryption Keys**.

On the resulting **Manage Encryption Keys** page, you can configure existing keys, and/or use the following options to add new keys.

Get Key Bundle

To import existing keys, click **Get Key Bundle**. You'll be prompted to supply a login and password to proceed.

Add New Key

To define a new key, click **New Key**. The resulting **New Key** modal provides the following controls:

Key ID: Cribl Edge will automatically generate this unique identifier.

Description: Optionally, enter a description summarizing the purpose of the key.

Encryption algorithm: Currently, Cribl Edge supports the `aes-256-cbc` (default) and `aes-256-gcm` algorithms.

KMS for this key: Currently, the only option supported here is `local` (the Key Management Service built into Cribl Edge).

Key class: Classes are arbitrary collections of keys that you can map to different levels of access control. For details, see Key Classes. This value defaults to `0`; you can assign more classes, as needed.

Expiration time: Optionally, assign the key an expiration date. Directly enter the date or select it from the date picker.

Use initialization vector: If enabled, Cribl Edge will seed encryption with a nonce to make the key more random and unique. Optional (and defaults to disabled) with the `aes-256-cbc` algorithm; automatically enabled (and cannot be disabled) with the `aes-256-gcm` algorithm.

Initialization vector size: Length of the initialization vector (IV), in bytes. This option is displayed only with the `aes-256-gcm` algorithm. Defaults to `12` bytes to optimize interoperability, but you can use the drop-down to set this anywhere between `12` to `16` bytes.

Modify Keys

To protect against accidental changes, a key's parameters - once saved - can be edited only through configuration files.

When you update keys by editing the `keys.json` file, you must add them back to the directories above (respectively, on a single instance or on a Distributed deployment's Leader Node).

Sync `auth/(cribl.secret|keys.json)`

Cribl Edge performs decryption only when the data is being sent to Splunk. For details, see Decryption of Data in Splunk

To successfully decrypt data, the `decrypt` command will need access to the same keys that were used to encrypt, **in the Cribl instance where encryption happened**.

- In a Single-instance deployment, the `cribl.secret` and `keys.json` files reside in: `$CRIBL_HOME/local/cribl/auth/`.
- In a Distributed deployment, the `cribl.secret` and `keys.json` files reside on the Leader Node in: `$CRIBL_HOME/groups/<group-name>/local/cribl/auth/`.
- When using the UI, you can download these files by selecting **Get Key Bundle**.

Sync/copy these files over to their counterparts on the Search Head/decrypting side, residing in: `$SPLUNK_HOME/etc/apps/cribl/local/cribl/auth/`.

11.13. Compliance

Cribl offers compliance options with the FIPS security standard:

- FIPS on Linux
- FIPS on Windows

For Cribl.Cloud compliance reports and third-party security assessments, see Request Access to TrustCloud.

11.13.1. FIPS Mode For Cribl Edge (Linux)

Federal Information Processing Standards FIPS represent a set of US government standards and guidelines for information security. You can deploy Cribl Edge in **FIPS mode**. This mainly restricts the cryptographic algorithms used within Cribl Edge and also enforces FIPS compliant password requirements.

Do not start Cribl Edge without FIPS mode enabled, or else you will be unable to run it in FIPS mode later. You must enable FIPS mode as described in this section, after installing **but before starting** Cribl Edge.

Requirements

This section describes the system and password requirements for FIPS mode.

FIPS Mode System Requirements

To run Cribl Edge in FIPS mode, your environment must satisfy the following requirements.

Operating Systems

Must support FIPS 140-2 or FIPS 140-3. Several Linux distributions meet this standard. See NIST's list of tested configurations here.

While RHEL 9 can be configured to run in FIPS mode at the operating system level, this **does not automatically enable FIPS mode within Cribl Edge.** You must still follow the procedures outlined in this document to explicitly enable Cribl Edge's FIPS mode. Cribl Edge relies on its own configuration to ensure FIPS compliance, independent of the OS-level FIPS setting.

OpenSSL

The operating system environment must have a FIPS validated version of OpenSSL installed.

- **For Cribl Edge versions 4.5.0 through 4.8.1**: The FIPS provider version must be 3.0.8 or 3.0.9, and the system-wide OpenSSL version must also be 3.0.8 or version 3.0.9, with its associated certificate.
- **For Cribl Edge starting with version 4.8.2**: The FIPS provider version requirement must be >= 3.0.5, and the system-wide OpenSSL version is no longer a factor. Cribl Edge now verifies the OpenSSL version bundled within the binary.

Enterprise Linux 9 is the only version of Enterprise Linux that includes OpenSSL version 3.0.9 out of the box. While it's possible to manually install compatible versions of OpenSSL on older Enterprise Linux versions, this

process is complex and generally not recommended. Therefore, the minimum recommended Enterprise Linux version for running Cribl Edge in FIPS mode is 9.

Even when running Cribl Edge on a FIPS-enabled RHEL 9 system, you must still explicitly enable Cribl Edge's FIPS mode as described in the Running Cribl Edge in FIPS Mode section below. The OS being in FIPS mode is not sufficient for Cribl Edge to operate in a FIPS-140 compliant manner.

FIPS Mode Restrictions on Cryptographic Algorithms

When running in FIPS mode, Cribl Edge uses only those cryptographic algorithms that satisfy the FIPS standards. This means that Cribl Edge operates exclusively with FIPS-compliant cryptographic algorithms, disallowing the use of non-compliant algorithms like MD5 (message-digest) or CRC-32 (Cyclic Redundancy Check 32) algorithms.

To ensure proper functionality in FIPS mode, the FIPS provider version must be at least `3.0.5`.

Therefore, in FIPS mode:

Cribl expressions **that rely on MD5 or CRC-32 will fail silently.** This includes expressions that use the `C.Mask.md5()` method and can in turn affect the behavior of parent Functions and their existing parent Pipelines.

The UI will hide certain options normally made available by the typeahead feature.

No Source, Destination, or Email Notification target that uses the Amazon AWS SDK v2 will perform checksums. This is because that SDK uses MD5 to verify checksums, and it applies to both incoming or outgoing payloads. Specifically:

- The Amazon Kinesis Data Streams Source will not perform checksums and the **Verify KPL checksums** setting will not be available.
- The Amazon SNS Notification target will not perform checksums.
- The following Destinations will not perform checksums:
    - Amazon CloudWatch Logs
    - Amazon Kinesis Data Streams
    - Amazon SQS
    - Google Cloud Storage
    - MinIO
    - Prometheus

Role-Based Access Control (RBAC) Controls

Cribl Edge's FIPS mode requires RBAC to be enabled for enhanced security. This ensures proper access management within FIPS-compliant environments. To enable RBAC, the Cribl Edge instance has to be running in Distributed mode. FIPS mode is available on certain license tiers. For details, see Pricing.

If FIPS mode is already enabled and RBAC is subsequently disabled, Cribl Edge will automatically disable FIPS mode and log a message stating:

```
"Disabling FIPS due to Role-based Access Control (RBAC) being disabled."
```

Check `<cribl_install_dir>/local/_system/instance.yml` to ensure Cribl is running in Distributed mode. The default installation directory is typically `/opt/cribl`. The `mode` setting in this file should be set to `distributed`. If it is set to `standalone`, you will need to switch to a Distributed deployment to use FIPS mode with RBAC enabled.

FIPS Mode Password Rules

When Cribl Edge is in FIPS mode, all passwords must:

- Contain eight or more characters.
- Use characters from three or more of the following categories:
  - Lowercase letters.
  - Uppercase letters located after the first character in the password.
  - Digits located before the last character in the password.
  - Non-alphanumeric ASCII characters such as `#`, `!`, or `?`.
  - Non-ASCII characters such as `ñ`, `€`, or emoji.

As of Cribl Edge version 4.5.0, these rules apply for all passwords, whether or not Cribl Edge is running in FIPS mode, with one exception:

- For Cribl Edge not running in FIPS mode, local users whose passwords existed before Cribl Edge 4.4.4 was released can continue to use their passwords, even if those passwords do not satisfy the rules.
- When these users change to new passwords, the new passwords must satisfy the rules.
- New users must create passwords that satisfy the rules.

If you get locked out of your account, you need to reset your password manually.

Running Cribl Edge in FIPS Mode

To begin using Cribl Edge with FIPS enabled, complete either the non-systemd or the systemd procedure below, **before you start Cribl Edge for the first time after installing**.

Enabling FIPS Mode on a Non-systemd Distribution

If the Linux distribution on which you run Cribl Edge **does not** use systemd:

1. Complete **either** of the two following steps:
   - Set the `CRIBL_FIPS` environment variable to `1` (true), **or**,
   - Edit `cribl.yml`, adding this top-level element:

     ```
     fips: true
     ```

     Copy

     Note that `fips: true` is the entire top-level element. For this element, the following "stanza" syntax would be incorrect - **do not** use it:

     ```
     # stanza syntax is incorrect for the fips element
     # even if other elements use it
     fips
       fips: true
     ```

     Copy

2. If you have installed a non-default OpenSSL binary (otherwise, skip this step):
   - Run the following command, and in the output, note the values of `MODULESDIR` and `OPENSSLDIR`.

     ```
     <binary_of_non-default_OpenSSL> version -a
     ```

     Copy

   - Set `OPENSSL_MODULES` to the value of `MODULESDIR`.
   - Set `CRIBL_OPENSSL_DIR` to the value of `OPENSSLDIR`.
3. Ensure RBAC is configured in Cribl Edge.
4. Start Cribl Edge.

Finally, verify that you are in FIPS mode as explained below.

Enabling FIPS Mode on a systemd Distribution

If the Linux distribution on which you run Cribl Edge **does** use systemd:

1. Run the following command, and in the output, note the values of `MODULESDIR` and `OPENSSLDIR`. (As shown, the command will run the default OpenSSL binary. If you have installed a different OpenSSL binary, you can modify the command to run that one instead.)

```
openssl version -a
```

Copy

2. Run the following command, replacing the placeholders with the relevant paths from your environment. (This assumes that you do not already have a `nodejs.cnf` file. If you **do** have one, complete the workaround below instead of this step.)

```
<path_to_Cribl_binary> generateFipsConf -d <path_to_OpenSSL_root_directory>
```

Copy

   If you encounter issues generating the FIPS configuration file, a discrepancy in the OpenSSL path might be the cause. For more detailed troubleshooting specific to RHEL 9, refer to the knowledge base article: Installing Cribl Edge in FIPS Mode on RHEL 9.

   An example of a successful command and its output:

```
useralice@123456791234:/# /opt/cribl/bin/cribl generateFipsConf -d /lib/usr/ssl
/opt/cribl/state/nodejs.cnf
```

Copy

   This command creates `nodejs.cnf` - the configuration file that NodeJS uses to run in FIPS mode as Cribl Edge starts.

3. Run the following command to open an empty temporary file in an editor:

```
systemctl edit cribl
```

Copy

4. Add the following content to the file, replacing the first placeholder with the value of `MODULESDIR` that you noted in Step 1, and the second with the path to your `nodejs.cnf` file:

```
[Service]
Environment="OPENSSL_MODULES=<value_of_MODULESDIR>"
Environment="OPENSSL_CONF=<path_to_nodejs.cnf_file>"
```

Copy

5. Save and exit the editor.
6. Run the following commands to reload the systemctl overrides and start Cribl:

```
systemctl daemon-reload
systemctl start cribl
```

Copy

7. Finally, verify that you are in FIPS mode as explained below.

When a `nodejs.cnf` File Already Exists

If you already have a `nodejs.cnf` file, replace Step 2 above with the following workaround:

1. Create a file with the following content, replacing `<placeholder>` with the value of `OPENSSLDIR`. Name the file something other than `nodejs.cnf`.

```
nodejs_conf = nodejs_init
openssl_conf = nodejs_init

.include /<placeholder>/fipsmodule.cnf

[nodejs_init]
providers = provider_sect

[provider_sect]
default = default_sect
# The fips section name should match the section name inside the
# included fipsmodule.cnf.
fips = fips_sect
[default_sect]
activate = 1
```

Copy

2. Resume the main procedure above, starting with Step 3.

Verify FIPS Mode

- On the Leader or Edge Node, search `cribl.log` for this message:

```
"level":"info","message":"running with FIPS enabled", "OpenSSLVersion":"3.0.13+q
```

Copy

- The presence of the above message confirms that Cribl Edge is in FIPS mode.

11.13.2. FIPS Mode For Cribl Edge (Windows)

This guide will walk you through the process of setting up and running Cribl Edge in FIPS (Federal Information Processing Standards) mode on Windows systems.

FIPS 140-2 or FIPS 140-3 compliance is required for software deployed in U.S. Federal Government and regulated industries. Cribl Edge supports operation in FIPS mode to meet these requirements.

Prerequisites

- Cribl Edge Windows installer (.msi).
- Administrative access to the Windows system.
- FIPS-validated OpenSSL provider (instructions below).

What You Need to Know About Pre-Configuration

Before configuring FIPS-enabled Edge Nodes, ensure your Leader environment is already configured and running in FIPS mode.

- When running in FIPS mode, Cribl Edge uses only FIPS-approved cryptographic algorithms, ensuring all data handling meets Federal security standards.
- When connecting to a FIPS-configured Leader, Cribl Edge must also be in FIPS mode for full compliance.

Set up Cribl Edge in FIPS Mode

To set up Cribl Edge in FIPS mode, you'll need to build your own OpenSSL FIPS provider. For details, see OpenSSL: Notes for Windows platforms.

Build Your Own FIPS Provider

This section guides you through the process of building your own OpenSSL FIPS provider.

Install Required Tools

1. Install Strawberry Perl, which includes the Netwide Assembler – (NASM).
2. Microsoft C++ toolchain (Visual Studio).
3. If you have `git` installed, you may need to rename/move its `perl.exe` to avoid conflicts.

Build the Provider

1. Find and open the Visual Studio (20XX) Native Tools Command Prompt for `x64` architecture. You can search for it, by typing `x64` in the **Start** menu. Right-click on it and select **Run as administrator**. (Do not use PowerShell or plain CMD).
2. Download the latest FIPS-validated version of OpenSSL:

   ```
   curl -LO https://www.openssl.org/source/openssl-3.0.9.tar.gz
   tar -xf openssl-3.0.9.tar.gz
   cd openssl-3.0.9
   ```

   Copy

   If you run into an error message: `ERROR: module machine type 'x86' conflicts with target machine type 'x64'`, it means you're not using the right version of the command prompt for what you're trying to do. Make sure you've selected the `x64 Native Tools Command Prompt`.
3. Run the following commands in the Visual Studio Developer Command Prompt (with `x64` architecture selected):

   ```
   perl configure VC-WIN64A enable-fips
   nmake
   ```

   Copy

   The build process might take considerable time to complete. Once the build is complete, you'll have a `providers` directory. The providers directory is created within the OpenSSL build directory (for example, `openssl-3.0.9/providers/`).
4. Once built, you'll need the following files from the build directory:
   - `providers\fipsmodule.cnf` - This specific file from your build is essential as it contains a unique hash that validates the DLL you built.
   - `providers\fips.dll`
   - `providers\legacy.dll`

Set up the Provider

This step creates a dedicated directory for Cribl's FIPS-related files and copies the necessary DLL and configuration files into it, preparing the application for FIPS-compliant operation.

In the same Native Tools Command Prompt, type the following:

```
mkdir "C:\Program Files\Cribl-FIPS"
copy providers\fips.dll "C:\Program Files\Cribl-FIPS"
copy providers\legacy.dll "C:\Program Files\Cribl-FIPS"
copy providers\fipsmodule.cnf "C:\Program Files\Cribl-FIPS"
```

Copy

Generate the `nodejs.cnf` Configuration File

This step creates a necessary configuration file that enables FIPS compliance for the `Node.js` environment used by Cribl. You have two options.

Option 1: Manual Configuration Creation

1. Open an Administrative Command Prompt
2. Run the following command to create and open the configuration file:

```
notepad "C:\Program Files\Cribl-FIPS\nodejs.cnf"
```

Copy

3. Copy and paste the following configuration content into the file:

```
nodejs_conf = nodejs_init
openssl_conf = nodejs_init
.include "C:\\Program Files\\Cribl-FIPS\\fipsmodule.cnf"

[nodejs_init]
providers = provider_sect
alg_section = algorithm_sect

[provider_sect]
default = default_sect
fips = fips_sect

[default_sect]
activate = 1

[algorithm_sect]
default_properties = fips=yes
```

Copy

4. Save the file and close Notepad.

This configuration redirects `Node.js` to use FIPS-compliant cryptographic modules and algorithms. The file includes references to the FIPS module configuration and sets default properties to enforce FIPS compliance across all cryptographic operations.

Option 2: Using the Cribl CLI (Post-Installation)

Alternatively, after installing Cribl Edge, you can generate the configuration file using the Cribl CLI:

```
cribl generateFipsConf -d <fully qualified path to fipsmodule.cnf>
```

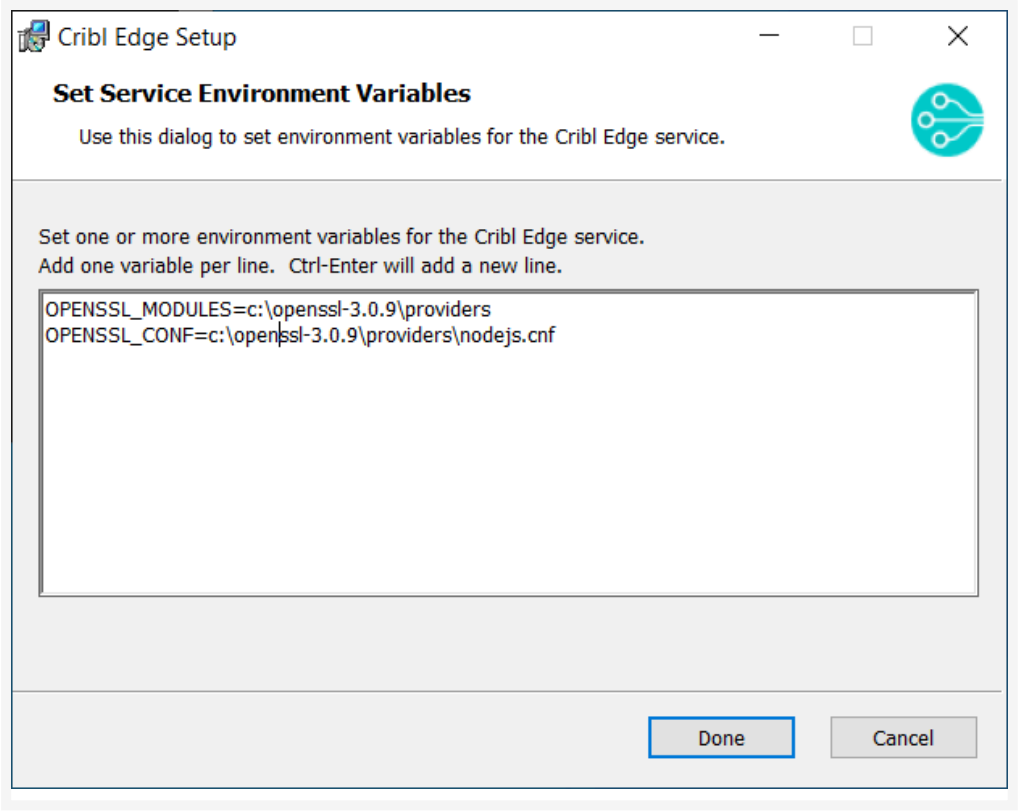
You can generate the `nodejs.cnf` configuration once on any machine and then distribute it to others, eliminating the need to repeat this step on each individual machine.

Install Edge with FIPS Configuration

To install Cribl Edge with FIPS mode enabled:

1. Use the `SETENVVARS` parameter with the MSI installer:

```
msiexec /i CriblEdge-<version>.msi SETENVVARS="OPENSSL_MODULES=C:\Program Files\Cribl
```



Copy

2. This opens the Windows Installer Wizard. Choose `Managed Mode` and complete the configuration to connect to the FIPS-enabled Leader.

When executing the MSI installer command, pay attention to these important parameter requirements:

- The pipe character (|) separates multiple environment variables.
- Make sure to enclose the entire `SETENVVARS` string in quotes.
- `OPENSSL_MODULES` points to the directory containing the provider files.
- `OPENSSL_CONF` points to the specific configuration file.

Alternatively, you can set the environment variables through the Installation Wizard:

Set Environment Variables

For details, see Install Cribl Edge on Windows.

Confirm Cribl Edge is in FIPS Mode

After installation, validate that Edge is running in FIPS mode by checking for FIPS initialization messages:

1. On the Leader or Edge Node, search `cribl.log` for this message:

```
"level":"info","message":"running with FIPS enabled", "OpenSSLVersion":"3.0.13+quic
```

Copy

2. In the UI, navigate to: **Node Settings** > **Diagnostics** > **System Info**.

The presence of the above message confirms that Cribl Edge is in FIPS mode.

Troubleshooting

If Edge fails to start after FIPS configuration:

- Verify that all required files exist in the specified locations.

11.13.3. SELinux (Enforcing Mode) Configuration

SELinux (Security-Enhanced Linux) is a mandatory access control system for Linux that provides a granular level of security by defining access controls for applications, processes, and files. It uses security policies, which are a set of rules that tell SELinux what can or can't be accessed, to enforce the access allowed by a policy.

SELinux has two modes, **enforcing** and **permissive**. When running in enforcing mode, it strictly enforces the SELinux policy and denies access based on policy rules. This can sometimes cause conflicts with applications that aren't explicitly allowed to perform certain actions.

Cribl Edge and SELinux

To effectively integrate Cribl Edge with SELinux, consider the different policy requirements for in-stream processing and network ports.

- Cribl Edge's in-stream processing often involves predefined processes and files, allowing for a relatively restrictive SELinux policy.
- Network ports might require a more permissive policy because users configure them within the UI.

Key Steps for SELinux Configuration

To ensure optimal integration of Cribl Edge with SELinux, begin by verifying the current SELinux status and the context of the Cribl Edge binary.

Check SELinux Status

Use the `getenforce` command to determine the current status of SELinux on your system.

The output will be one of the following:

- `Enforcing`
- `Permissive`
- `Disabled`

If the output is `Enforcing`, SELinux is enabled and enforcing policies.

Verify Cribl Edge's SELinux Context

Use the command `ls -Z /opt/cribl/bin/cribl` to list the contents of the directory `/opt/cribl/bin` while displaying their SELinux security contexts.

The output should show the SELinux context for the Cribl Edge binary.

Example output:

```
-rwxr-xr-x. cribl cribl cribl unconfined /opt/cribl/bin/cribl
```

Deploy Cribl Edge directly to `/opt` to avoid context issues. Do not deploy Cribl Edge to a user's home directory, or to root (`/`), and then move it to `/opt`.

Revert Labels on Files and Directories

If needed, you can also use `restorecon`, an SELinux policy utility from the `policycoreutils-python-utils` package, to revert labels on files and directories to their default SELinux security context:

```
restorecon -R -v /opt/cribl
```

Copy

Check for SELinux Denials

Use `auditd` to log SELinux denials. Look for messages related to Cribl Edge in the `/var/log/audit/audit.log` file.

Modify SELinux Policy

If you encounter SELinux denials, you might need to modify the SELinux policy. There are three options ranging from least secure to most secure.

Use `semanage` (Less Secure)

Using `semanage` is the simplest but least secure method. It grants permissive access to the `cribl_t type`, allowing all operations.

```
semanage permissive -a cribl_t
```

Copy

Use `audit2allow` (Slightly More Secure)

Using `audit2allow` creates SELinux policy rules to permit actions that were previously denied.

To identify and address SELinux denials related to Cribl Edge, follow these steps:

1. Find denied operations:

```
sudo grep cribl /var/log/audit/audit.log | audit2allow -M cribl
```

Copy

2. Install the generated policy:

```
sudo semodule -i cribl.pp
```

Copy

Create a Custom Policy (Most Secure)

Use tools like `secil` or `policycoreutils` to create a custom policy tailored to Cribl Edge's needs. This provides the highest level of security but requires more technical expertise.

Reload SELinux Policy

Once you've altered the SELinux policy using tools like `semanage`, `audit2allow`, or through custom policy creation, use this command to ensure that the new rules take effect immediately.

```
sudo semanage reload -a
```

Copy

Specific Cribl Edge Considerations

In addition to the general SELinux guidelines, pay close attention to these Cribl Edge-specific factors:

- **Cribl Edge configuration**: Review Cribl Edge configuration files for any settings that might conflict with SELinux restrictions.
- **Integration with other applications**: Ensure that Cribl Edge's interactions with other applications are compatible with their SELinux contexts and permissions.

Additional Considerations

In addition to the basic configuration, these factors are also important for optimal performance:

- **SELinux booleans**: Check the SELinux documentation for relevant booleans that might affect Cribl Edge's behavior.
- **SELinux context labeling**: Ensure files and directories used by Cribl Edge have the correct SELinux context. Use tools like `restorecon` to relabel files.

- **SELinux troubleshooting tools**: Use tools like `audiscan` and `audit2why` to analyze SELinux audit logs.

SELinux Troubleshooting

SELinux problems usually surface when you try to start the Cribl Edge service. Users immediately receive an error like the following:

```
Job for cribl.service failed because the control process exited with error code.
See "systemctl status cribl.service" and "journalctl -xe" for details.
```

Copy

One indication that the problem is in SELinux configuration, not in the Cribl Edge service itself, is when (1) nothing has been logged in `$CRIBL_HOME/log/cribl.log`, and (2), when you run `journalctl -xe` you see errors like the following:

Errors from journalctl -xe

```
cribl.service: Failed to execute command: Permission denied
cribl.service: Failed at step EXEC spawning /opt/cribl/bin/cribl: Permission denied

cribl.service: Control process exited, code=exited status=203
cribl.service: Failed to execute command: No such file or directory
cribl.service: Failed at step EXEC spawning /bin/rm -f /opt/cribl/pid/cribl.pid: Perm
```

Copy

You can confirm that SELinux configuration is the issue by verifying that the Cribl Edge service is able to start up on its own. To do this, run the `cribl start` command.

Here are three commands that you can think of as a basic SELinux troubleshooting toolkit:

- `getenforce` verifies that SELinux is enabled and enforcing policy.
- `sestatus -v` shows details of the SELinux policy that's in effect.
- `ls` with the `-Z` or `--context` option shows the SELinux tags on files and/or folders. In the output, the fifth column reports the SELinux context in the form `user:role:type:level`.

Example Problem

Suppose you run `ls -lZ /opt/cribl` to see the SElinux context for `/opt/cribl`.

If the output looks like the following, there is a problem: the presence of "home" among the `type` part of the Linux context. In this case, `user_home_t` is the offending type. When the type is `user_home_t` or `admin_home_t`, SELinux will not permit the service to read, write, or execute files.

Problematic SELinux context output

```
$ ls -laZ /opt/cribl
total 0
drwxr-xr-x. 6 cribl cribl unconfined_u:object_r:user_home_t:s0  62 Feb 16 08:31 .
drwxr-xr-x. 3 root  root  system_u:object_r:usr_t:s0            19 Feb 16 19:54 ..
drwxr-xr-x. 2 cribl cribl unconfined_u:object_r:user_home_t:s0 202 Feb 16 08:31 bin
drwxr-xr-x. 5 cribl cribl unconfined_u:object_r:user_home_t:s0  49 Feb 16 08:20 data
drwxr-xr-x. 6 cribl cribl unconfined_u:object_r:user_home_t:s0  59 Feb 16 08:31 defau
drwxr-xr-x. 3 cribl cribl unconfined_u:object_r:user_home_t:s0  22 Feb 16 08:31 third
```

Copy

Example Solution

To fix the labeling, download Cribl Edge again directly to `/opt`. **Do not** download Cribl Edge to a user's home directory, or to root (`/`), and then move it to `/opt` - that was what caused our example problem.

Downloading Cribl to /opt

```
curl -Lso - $(curl -s https://cdn.cribl.io/dl/latest) | sudo tar zxvf - -C /opt
```

Copy

A simpler option is to revert the labels using `restorecon`:

Reverting labels with restorecon

```
restorecon -R -v /opt/cribl
systemctl restart cribl
```

Copy

Once you correct the problem, the output will look like the following. Instead of `*home_t` listings in the `type` field, this SELinux context has `usr_t`, a type that will satisfy SELinux's criteria for allowing the service to read, write, and execute files.

Corrected SELinux context output

```
# ls -laZ /opt/cribl
total 0
drwxr-xr-x. 6 cribl cribl unconfined_u:object_r:usr_t:s0  62 Feb 16 08:31 .
drwxr-xr-x. 3 root  root  system_u:object_r:usr_t:s0      19 Feb 16 20:05 ..
drwxr-xr-x. 2 cribl cribl unconfined_u:object_r:usr_t:s0 202 Feb 16 08:31 bin
drwxr-xr-x. 5 cribl cribl unconfined_u:object_r:usr_t:s0  49 Feb 16 08:20 data
drwxr-xr-x. 6 cribl cribl unconfined_u:object_r:usr_t:s0  59 Feb 16 08:31 default
drwxr-xr-x. 3 cribl cribl unconfined_u:object_r:usr_t:s0  22 Feb 16 08:31 thirdparty
```

Copy

12. Integrations

Integrations enable seamless data flow between various systems. They encompass both Sources and Destinations, allowing you to get data from multiple origins and deliver processed data to various endpoints. Integrations are the entry and exit points in the event processing order.

- Sources are configurations that enable Cribl to receive data from various origins. They serve as the entry points in the event processing order, enabling the collection of raw data for subsequent processing.
- Destinations are configurations that define where Cribl sends processed data. They act as the exit points in the event processing order, sending enriched and transformed events to the appropriate systems for storage, analysis, or further processing.

Key Concepts for Optimal Data Flow

- Destination Backpressure Triggers: Understanding the conditions that can cause backpressure in Destinations is crucial for preventing data loss and ensuring smooth data flow, especially during peak load periods.
- Persistent Queues: To safeguard against data loss when integrations are slow or unavailable (backpressure events), persistent queues provide a temporary storage mechanism on disk.
- Load Balancing: Distributing data evenly across multiple Sources and Destinations is essential for maximizing performance and reliability.

12.1. Common Data Flows

The following topics describe common data flows in Cribl Edge.

Topic	Description
Collect Logs with File Monitor	Collect logs from a variety of files on your systems using the File Monitor
Collect Windows Event Logs and Metrics	Gain real-time visibility into system health, security, applications, and performance of your Windows environment by collecting Windows Event Logs and Windows metrics with Cribl Edge
Collect Kubernetes Logs, Events, and Metrics	Collect logs, events, and metrics from your Kubernetes deployment
Collect and Visualize Nvidia GPU Metrics	Collect Nvidia GPU metrics with the System Metrics Source on Cribl Edge and visualize them using Cribl Search Dashboards
Cribl Edge to Cribl Stream	Sending data from Cribl Edge to Cribl Stream
Send Data to Loki and Prometheus	Prepare your Cribl Edge data to send it to Grafana's Loki and Prometheus log and metrics tools

12.1.1. Collect Logs With File Monitor

Collect logs from a variety of files on your systems using the File Monitor.

To collect logs from files (including text files, compressed, archived, and some binary log files), you can use the File Monitor.

For a full description and reference of the Source's settings, see File Monitor Source.

For File Monitor guidance specific to CSV files, see Collect CSV Files with File Monitor.

The File Monitor Source collects those logs and converts them to events based on the extracted lines and records.

Cribl Edge comes with two preconfigured, but disabled File Monitor Sources: `in_file_auto` and `in_file_varlog`.

`in_file_auto` uses the **Auto** discovery mode, which automatically discovers files that running processes have open for writing. `in_file_varlog` is configured with the **Manual** discovery mode, which enables you to specify a single path from which Edge will collect log files. The predefined Source is aimed at the `/var/log/` path.

Use Preconfigured File Monitor Sources

To use one of the preconfigured File Monitor Sources:

1. On the top bar, select **Products**, and then select **Edge**. Under **Fleets**, select a Fleet.
2. Select **Collect**.
3. Select the **File Monitor** stack to view both preconfigured Sources.
4. Select and drag the plus icon next to one of the Sources to a Destination (for starters, you can choose DevNull).
5. In the **Connection Configuration** modal, select how you want the data to flow through to the Destination. Select `Passthru` to send all the data without processing, then select **Save**.
6. To start the Source, select **Commit**, enter a commit name, and select **Commit & Deploy**.

Now, ensure that data is being collected: hover over the File Monitor Source and select **Capture**. After a short time you should see sample data captured by the Source. Once you're satisfied, you can switch from DevNull to your desired target Destination.

Monitor Files in Specific Folders

To manually select a specific path to discover files in, configure a new File Monitor Source.

1. On the top bar, select **Products**, and then select **Edge**. Under **Fleets**, select a Fleet.
2. Select **More > Sources**. Select **File Manager**.
3. Next, select **Add Source**.
4. Enter a unique identifier for the Source in **Input ID**.
5. Make sure **Discovery Mode** is set to **Manual**.
6. In **Search path**, provide the path to the directory you want to discover. The path can't contain wildcards.
7. Optionally, set **Max depth** to define whether collection should be limited to a specified depth of subdirectories. To limit collection to the specified **Search path** only, set **Max depth** to `0`. A value of `1` will include only the next level of subdirectories, and higher values will dig deeper.

Further settings allow you to fine-tune the log collection.

You can control which files are monitored by filling in the **Filename allowlist**. For guidance on how to use allowlists without creating duplicates, see Using Allowlists Effectively.

To make sure that all desired files are read, you can fine-tune the length and composition of hashes that the File Monitor uses to track files. See File Tracking with Hashes for more information.

12.1.2. Collect CSV Files With File Monitor

Configure the File Monitor Source to successfully collect CSV files.

CSV files, due to their structure which includes file headers that contain crucial information for data parsing, require specific configuration to be successfully collected with the File Monitor Source.

For a full description and reference of the Source's settings, see File Monitor Source.

Create a New File Monitor Source

First, create a File Monitor Source dedicated to collecting CSV files.

1. On the top bar, select **Products**, and then select **Edge**. Under **Fleets**, select a Fleet.
2. Select **More** > **Sources**. Select **File Manager**.
3. Next, select **Add Source**.
4. Enter a unique identifier for the Source in **Input ID**.
5. Make sure **Discovery Mode** is set to **Manual**.
6. In **Search path**, provide the path to the directory you want to discover. The path can't contain wildcards.
7. In **Filename allowlist**, indicate CSV files so other file types don't get collected by mistake. For example, if the search path is `/tmp/csv/`, set **Filename allowlist** to `/tmp/csv/*.csv`.

This basic configuration lets you collect files from the selected path. Now, fine-tune the Source settings to ensure CSV files are collected correctly.

Configure File Monitor to Collect CSV Files

1. In File Monitor **General Settings**, disable **Collect from end**.
   This ensures that if collection of a specific file is interrupted, File Monitor will not lose track of the file header.
2. In **Processing Settings** > **Event Breakers**, select **Add Ruleset** and choose the `CSV Ruleset`.
3. Ensure that **Disable Event Breaker buffer timeout** is toggled on.
   This protects the File Monitor from losing track of the file header state due to timeout.
4. In **Advanced Settings**, set **Hash length** to be higher than the predicted length of the CSV file header (however, do not exceed `16384`).
   This ensures that File Monitor correctly tracks the state for each individual CSV file and doesn't confuse files with similar headers.

5. Additionally, or if setting **Hash length** is not enough, enable **Salt file hash** so that each file is given a unique hash based on the file name.

With this configuration, File Monitor will recognize individual CSV files, correctly recognize their headers, and track them even after collection is stopped and resumed.

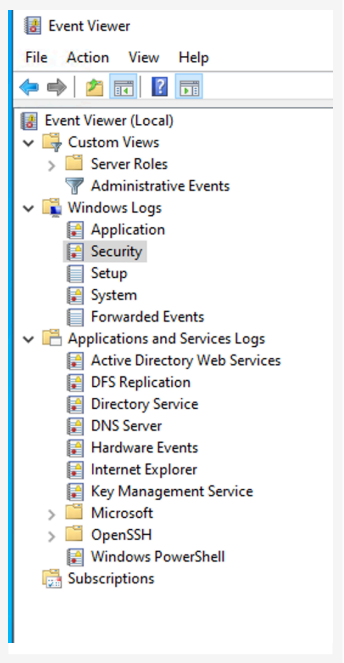
12.1.3. Collect Windows Event Logs And Metrics

Collecting Windows Event Logs and metrics in Cribl Edge allows you to gain real-time visibility into system health, security, applications, and performance of your Windows environment.

Collect Windows Event Logs

To collect Windows Event Logs, you need to create and configure a Windows Event Log Source and point it at correct logs on the server.

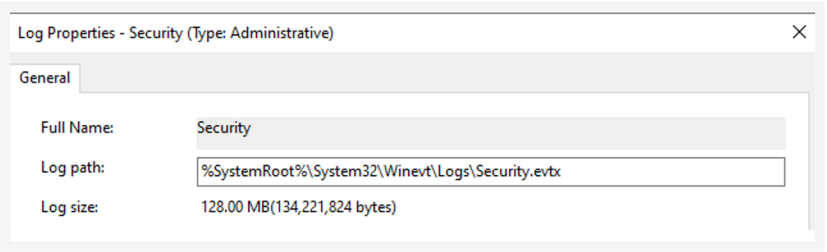
For a full description and reference of the Source's settings, see Windows Event Logs Source.



Locate Windows Event Logs on the Server

Event logs in Windows Servers are classified into the following broad categories:

- **System**: Events related to the system and its components. Failure to load the boot-start driver is an example of a system-level event.
- **Applications and Services**: Events related to software or an application hosted on a Windows computer get logged under the application event log. For example, if a user encounters a problem in loading the app, it will be logged.
- **Security**: Events related to the safety of the system. The event gets recorded via the Windows auditing process. Examples include failed authentication and valid logins.
- **Setup**: Events occur during the installation of the Windows operating system. On domain controllers, this log will also record events related to Active Directory.
- **Forwarded Events**: Contains event logs forwarded from other computers in the same network.

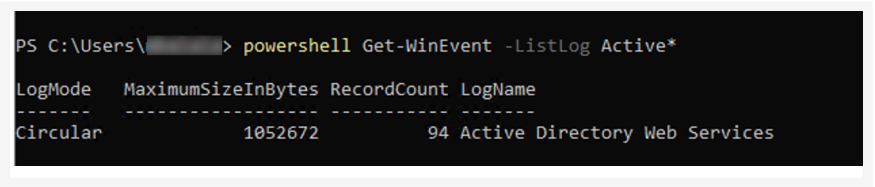


To find out what other event logs might be of interest:

1. Go to your Windows Server Event Viewer.

Event Viewer

2. To get the accurate name of a given event log, right-click it and select **Properties**.
3. From the **Properties** modal, copy the **Full Name** value to your clipboard. You'll use this value when configuring a Windows Event Log Source.

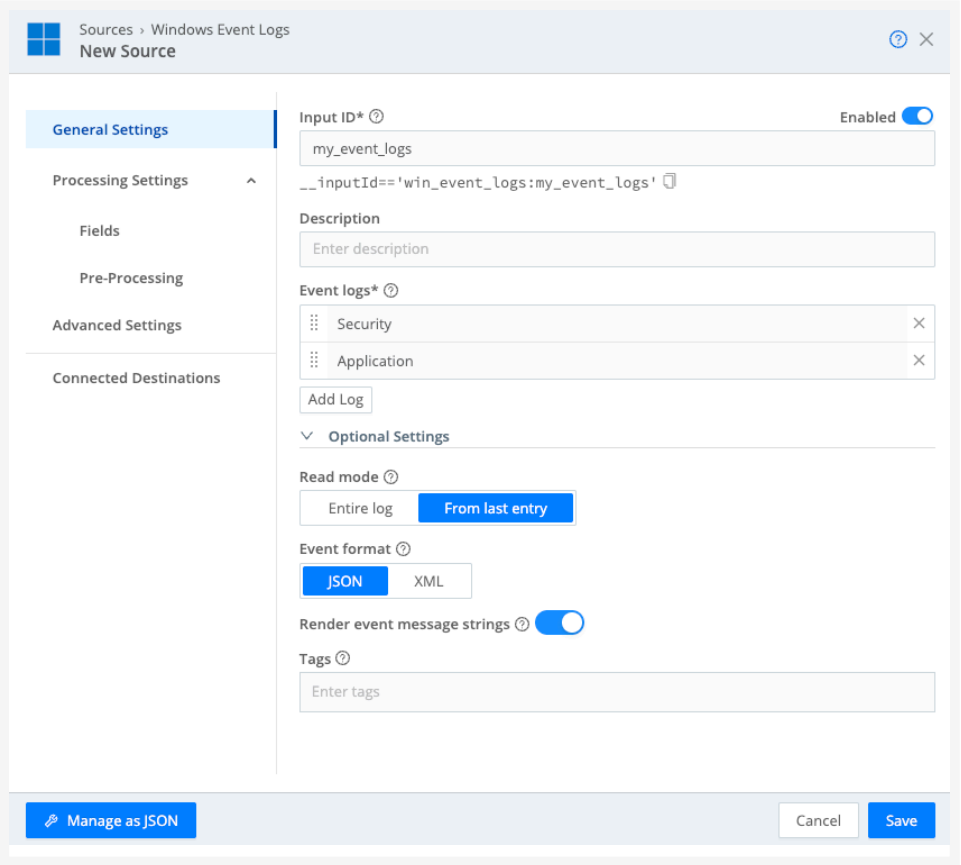


Log properties: Full name from the UI

Alternatively, you can execute the following PowerShell command to list a particular log's name. In this example, we are using a `*` wildcard.

```
powershell Get-WinEvent -ListLog Hardware*
```

Copy



Log Name from PowerShell

From the Powershell output, the **LogName** field is what you would specify in the Cribl UI. In the above screenshot, for example, you would enter `Active Directory Web Services` in the Cribl UI.

Configure the Windows Event Logs Source

Once you have the accurate names of the event logs you want to collect, you can configure and enable the Windows Event Logs Source in Cribl Edge.

1. On the top bar, select **Products**, and then select **Edge**. Under **Fleets**, select a Fleet.
2. Select **More** > **Sources** (Edge). Select **Windows Event Logs**
3. Next, select **Add Source**.
4. Enter a unique identifier for the Source in **Input ID**.
5. In **Event logs**, enter the log name you copied from the Event Viewer.
6. Optionally, configure other Source settings.

Configuring Windows Event Logs

7. Save the Source configuration.
8. To start the Source, select **Commit**, enter a commit name, and select **Commit & Deploy**.

After a few moment, you can check the **Live Data** tab and capture some data to make sure the logs are generated.

You can now send the event logs to your visualization tool of choice or any of Cribl Edge's supported Destinations.

Collect Windows Metrics

To collect Windows metrics rather than log events, configure Cribl Edge's Windows Metrics Source.

For a full description and reference of the Source's settings, see Windows Metrics Source.

A Windows Metrics Source is preconfigured for each of your Fleets with basic settings and enabled automatically. To have further control over the collection, modify its configuration. In particular, decide on the level of granularity for the metrics you want to collect.

To do this, in the **Windows Metrics** Source modal, select **Host Metrics**, then **Custom**. Here, we recommend setting the following granularity options for three of the configurable types:

- **CPU**: Select **Custom**, then enable **Per-CPU metrics**.
- **Network**: Select **Custom**, then enable **Per interface metrics**.
- **Disk**: Select **Custom**, then enable **Per volume metrics**.

12.1.4. Collect Kubernetes Logs, Events, And Metrics

Collect Kubernetes data with Cribl Edge to forward them for further observability and analytics.

Kubernetes environments generate large volumes of observability data, including logs, events, and metrics, making data collection complex. Cribl Edge offers the Kubernetes Logs, Kubernetes Events, and Kubernetes Metrics Source, as well as Prometheus Edge Scraper to simplify this task.

The Kubernetes Logs, Kubernetes Metrics, and Prometheus Edge Scraper Sources support disk spooling, which allows Cribl Search to query their output.

Collect Kubernetes Logs

The Kubernetes Logs Source connects to the Kubernetes API and loads the lists of Pods on the node on a configurable polling interval.

For a full description and reference of the Source's settings, see Kubernetes Logs Source.

Enable Preconfigured Kubernetes Logs Source

Cribl Edge has a preconfigured **in_kube_logs** Source that you can adapt to your needs. To enable log collection with the Source:

1. On the top bar, select **Products**, and then select **Edge**. Under **Fleets**, select a Fleet.
2. Select **Collect**.
3. Select the **in_kube_logs** Kubernetes Logs Source.
4. Select and drag the plus icon next to it to a Destination (while testing the procedure, you can choose DevNull).
5. In the **Connection Configuration** modal, select how you want the data to flow through to the Destination. Select `Passthru` to send all the data without processing, then select **Save**.
6. To start the Source, select **Commit**, enter a commit name, and select **Commit & Deploy**.

Now, ensure that data is being collected: hover over the Kubernetes Logs Source and select **Capture**. After a short time you should see sample data captured by the Source. Once you're satisfied, you can switch from DevNull to your desired target Destination.

Finetune Kubernetes Log Collection

Now that you have the basic Kubernetes log flow configured, you can customize the Source settings.

Configure Log Polling Interval

Set the polling interval based on the expected start and stop intervals of Pods in your environment. Higher volume log sources may require a faster polling interval to avoid rotating logs faster than you can collect them.

For example, if the container emits `1 MBps` and rotates logs at `10 MB`, the polling interval must be less than `10s`, to prevent hitting the `10 MB` rotation threshold twice in 10 seconds.

For more information about configuring the polling interval, see Polling Interval and Log Rotation.

Configure Log Filter Rules

The Source determines which Pods to report on based on the rules defined in **Filter Rules**. The default `!metadata.namespace.startsWith('kube-')` rule means the Source ignores Pods in the `kube-*` namespace.

You can use any Kubernetes Pod object fields in the filter, such as `metadata`, `spec`, and `status`.

Below the **Capture** button, select the Advanced Settings ⋯ button and then toggle **Show Internal Fields** on to explore the `__metadata` fields forwarded from the Cribl Edge Nodes. These metadata fields show information about the Pod, Node, and Cribl environment where they were collected.

See Kubernetes Pod Object definition for details.

Collect Kubernetes Events

Kubernetes events include state changes (such as Pod starts and jobs that fail to start) occurring on the Kubernetes cluster regarding workloads. To monitor such events, use the preconfigured Kubernetes Events Source called **in_kube_events**.

1. On the top bar, select **Products**, and then select **Edge**. Under **Fleets**, select a Fleet.
2. Select **Collect**.
3. Select the **in_kube_events** Kubernetes Events Source.
4. Select and drag the plus icon next to it to a Destination (while testing the procedure, you can choose DevNull).
5. In the **Connection Configuration** modal, select how you want the data to flow through to the Destination. Select `Passthru` to send all the data without processing, then select **Save**.
6. To start the Source, select **Commit**, enter a commit name, and select **Commit & Deploy**.

Now, ensure that data is being collected: hover over the Kubernetes Events Source and select **Capture**. After a short time you should see sample data captured by the Source. Once you're satisfied, you can switch from DevNull to your desired target Destination.

For a full description and reference of the Source's settings, see Kubernetes Events Source.

Configure Event Filter Rules

The Source determines which events to collect based on the rules defined in **Filter Rules**. No default rules are defined, which means all emitted events are collected.

As an example, you can filter out events based on their `type` with `object.type.equals('Warning')` or, based on the `reason`, with `object.reason.equals('Failed')`.

Collect Kubernetes Metrics

The Kubernetes Metrics Source lets you generate metrics periodically based on the status and configuration of a Kubernetes cluster and its Nodes, Pods, and containers.

See a full description and reference of the Source's settings in Kubernetes Logs Source, and more information about metrics collected in Kubernetes Metrics Details.

Collect Metrics with Prometheus Edge Scraper

You can also configure the Prometheus Edge Scraper to collect metrics from Pods and Nodes (as well as other Prometheus targets).

To collect Kubernetes metrics, Cribl Edge uses the `/metrics` and `/metrics/cadvisor` endpoints on the kubelet. This information gives you a good idea of what's going on on each Node and Pod.

Using the Prometheus Edge Scraper, you can discover and collect metrics in Kubernetes Clusters dynamically. There are two Kubernetes-specific modes of operation:

- **Kubernetes Node**: When configured to scrape Nodes, each Cribl Edge Node (Pod) will scrape from the configured port on every deployed Node in the DaemonSet. Use this to scrape endpoints on the Kubelet and other node-local interfaces.
- **Kubernetes Pods**: When configured for Pod scraping, a single Edge Node will be elected to scrape the metrics from the discovered endpoints.

For a full description of how to configure the Source and a reference of its settings, see Prometheus Edge Scraper.

12.1.5. Collect And Visualize Nvidia GPU Metrics

Collect Nvidia GPU metrics with Cribl Edge to monitor utilization, temperature, memory, power, and other related metrics on GPU-backed hosts.

GPU-backed workloads need visibility into hardware health and capacity. Cribl Edge can emit structured GPU metrics on a schedule, then route them to Cribl Stream, Cribl Lake, or other Destinations for analysis in Cribl Search or external dashboards.

For a full description and reference of the Source's settings, see System Metrics Source.

This guide presents how to collect GPU metrics on an Edge Node deployed on Linux. To collect GPU metrics from Windows Edge Nodes, use the Windows Metrics Source instead of the System Metrics Source.

Prerequisites

- A host with an Nvidia GPU and an Edge Node.
- Nvidia drivers installed, including the `nvidia-smi` utility (which is usually installed with the drivers).

Collect GPU Metrics With the System Metrics Source

The System Metrics Source includes a **GPU Metrics** Collector that emits metrics events. Configure **Basic** for basic, aggregated metrics, **All** for detailed, aggregated metrics, or **Custom** to toggle **Per GPU metrics** and **Detailed metrics**. See GPU Metrics for the exact options.

1. On the top bar, select **Products**, then **Edge**. Under **Fleets**, select a Fleet.
2. Select **More** > **Sources**, then **System Metrics**.
3. Select **Add Source** (or open the existing System Metrics Source, `in_system_metrics`).
4. Open **GPU Metrics** and choose **Basic** for basic, aggregate metrics, **All** for full detail, or **Custom** to toggle **Per GPU metrics** and **Detailed metrics**.
   See GPU Metrics for the exact options.
5. Select **Save**, then **Commit**, enter a commit message, and select **Commit & Deploy**.

To confirm the Source is working correctly, open the Source and select its **Live Data** tab to preview a sample of the metrics being collected.

For emitted metric names, types, and modes, see Linux System Metrics Details.

Send Metrics for Shaping, Storage, and Analysis

After GPU events flow from the System Metrics Source, you have a few ways of routing them further:

- You can pair a Cribl HTTP Destination in Cribl Edge with a Cribl HTTP Source in Cribl Stream to send the metrics to Cribl Stream and make use of its data enrichment and routing capabilities. Refer to Cribl Edge to Cribl Stream for more information.
- You can pass the metrics Cribl Lake for longer-term storage. To do it, follow Send Logs and Metrics to Cribl Lake.
- You can also send the data straight to Cribl Search using the Cribl Search Destination to analyze, shape, and visualize this data. See the following section for an example of how to do it and then visualize the metrics in a Search Dashboard.

Visualize GPU Metrics in Cribl Search

You can send GPU metric events from Cribl Edge to Cribl Search, then display them on a Dashboard.

For more details about sending data from Cribl Stream or Cribl Edge into Search Datasets, see Ingest Cribl Stream/Edge Data into Cribl Search.

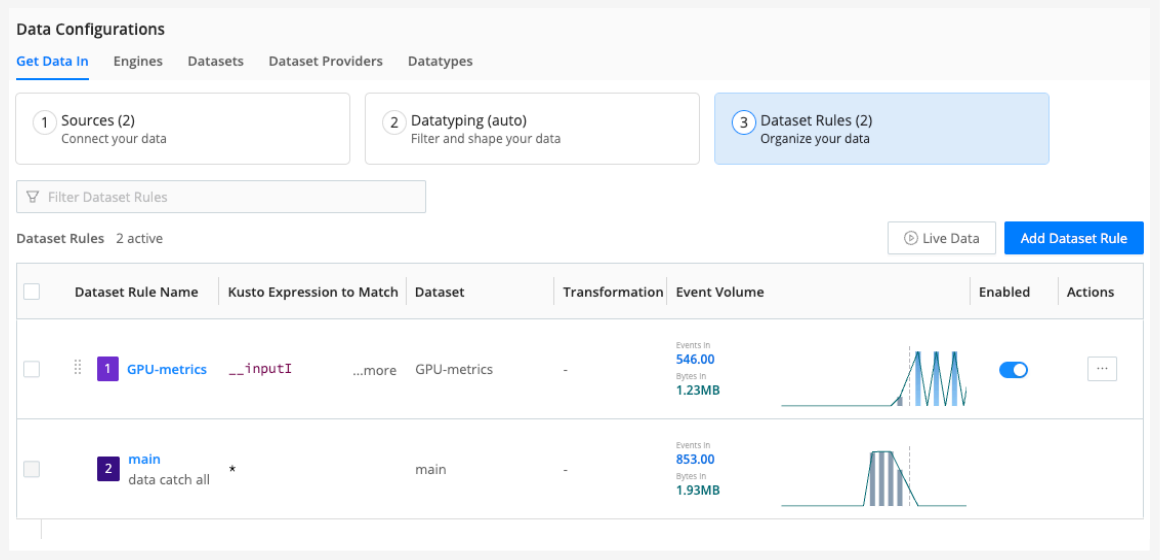
Send GPU Metrics to Cribl Search

First, you need to send the collected GPU metrics to Cribl Search by using the Cribl Search Destination.

1. In your Fleet, create a new Cribl Search Destination. Enter a unique name in **Output ID**. Accept the default **Cribl endpoint** value, which is auto-populated for you in Cribl.Cloud.
2. Optionally configure **Throttling**, **Backpressure behavior**, **Tags**.
3. Confirm with **Save**.
4. Select **Collect** and connect the System Metrics Source that collects the GPU metrics to the new Cribl Search Destination.
5. Commit and deploy your changes.

Create a Search Dataset in Cribl Search

1. Ensure Cribl Search has a lakehouse engine in **Ready** status .
2. On the top bar, select **Products** > **Search** > **Data** > **Datasets** > **Add Dataset**. See Create Search Datasets for specific options.
3. Under **New Dataset**, enter an **ID** for your Dataset (further examples use `GPU-metrics`), and select type **Search Dataset**.
4. Under **Search Dataset**, set **Retention period**, **Engine** to your existing Lakehouse Engine, and expected timestamp bounds as needed for your environment.
5. Select **Save**.



This procedure uses Auto-Datatyping to parse and structure the ingested data. If you want to learn more about this process, or parse your metrics using a custom Datatype rule, refer to Shape Data with Datatype Rules.

6. Now, move to **Data > Get Data In** and select **3. Dataset Rules**.
7. Select **Add Dataset Rule**.
8. Enter a **Name** for the rule, and in **Kusto expression to match**, enter an expression that will identify the data you want to capture in this Dataset.
   To catch the data being sent by the built-in Cribl HTTP Source in Search, use `__inputId = "cribl_http:in_cribl_http"`.
9. In **Send data to**, select `Dataset` and choose your new Dataset in the **Dataset** dropdown.

   You can shape the incoming metrics at the Dataset level by enabling **Modify Fields**. See Modify Fields in Dataset Rules for more information.

10. Save the new rule by selecting **Add**, and confirm with **Save** again.

At this point the metrics from your GPU in Cribl Edge should be flowing into the new Dataset. Wait a short while, and the charts next to Dataset Rules will show the change.

New Dataset Rule showing data flow into the GPU metrics Dataset

To verify data flow, you can select **Live Data** to preview the metrics being captured.

Create a Dashboard and Add Charts

Now that the GPU metrics are being stored in a Search Dataset, you can create a dashboard to visualize them. See Charts for chart types and options.

1. In Cribl Search, open **Dashboards** from the sidebar, then select **Add Dashboard**.
2. Enter a **Name** and optional **Description**, then select **Save**.
3. Select **Add** > **Visualization**.
4. To define a panel, choose **New Search**, enter a query, and select **Search**
5. Pick a chart type, then save the panel.
   See Create a Dashboard and Edit a Dashboard for details about visualizations.

Example queries (replace `GPU-metrics` with your Dataset **ID**):

- GPU count:

```
dataset="GPU-metrics" node_gpu_count*
| summarize gpu_per_host = max(node_gpu_count) by host
| summarize current_total_gpu_count = sum(gpu_per_host)
```

Copy

- Average GPU utilization for all nodes:

```
dataset="GPU-metrics"
| summarize latest_gpu_util=findlatest (node_gpu_utilization_gpu_percent_all) by host
| summarize avg_latest_gpu_util=avg(latest_gpu_util)
```

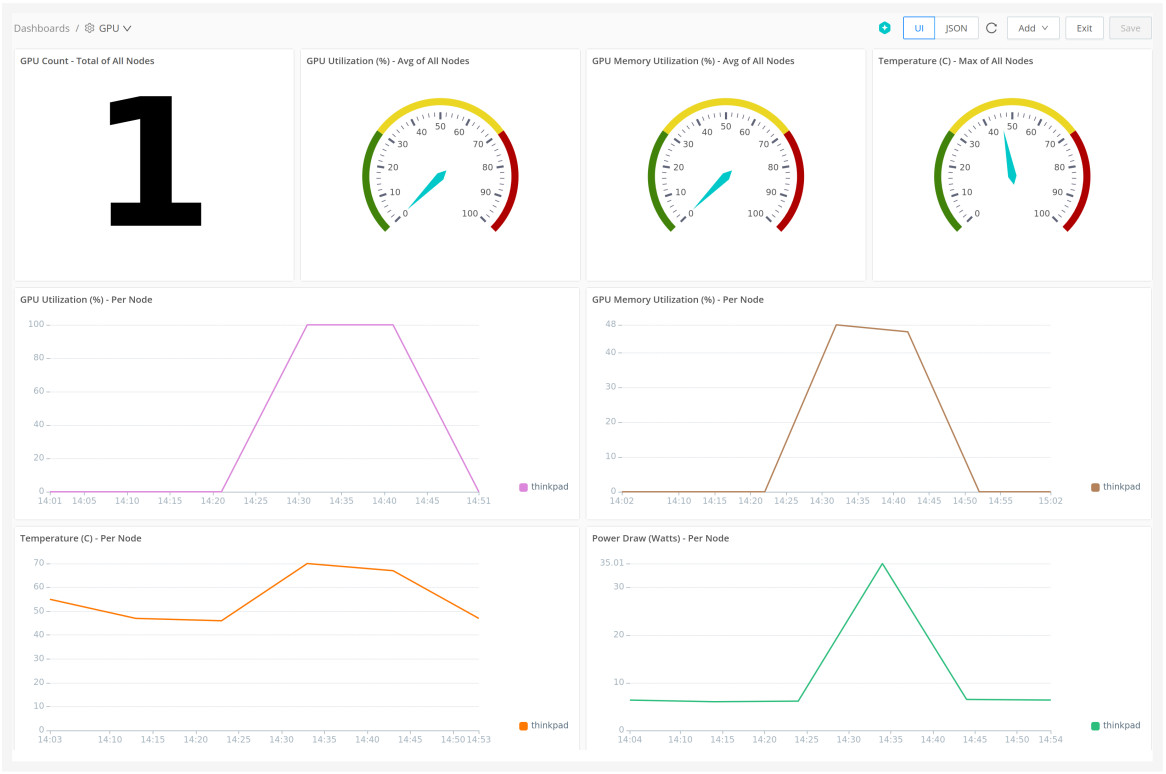
Copy

- Maximum temperature for all nodes:

```
dataset="GPU-metrics"
| summarize latest_temperature=findlatest(node_gpu_temperature_celsius_all) by host
| summarize avg_latest_temperature=max(latest_temperature)
```

Copy

- Percentage of GPU utilization per node:



```
dataset="GPU-metrics"
| timestats span=10m temp=max(node_gpu_utilization_gpu_percent_all) by host
```

Copy

- Power draw (in watts) per node:

```
dataset="GPU-metrics"
| timestats span=10m temp=max(node_gpu_power_draw_watts_all) by host
```

Copy

Search Dashboard with some basic GPU metrics

12.1.6. Send Data From Cribl Edge To Cribl Stream

You can send collected data from Cribl Edge Nodes to Cribl Stream Workers by using a Cribl HTTP Destination paired with a Cribl HTTP Source without incurring additional costs.

For more information about sending data between organizations and Workspaces without paying for data twice, see Transfer Data Between Workspaces or Environments.

To route data from a Cribl Edge Fleet to a Stream Worker Group, follow these steps:

- Configure a Source on Cribl Edge to collect data from Edge Nodes (for example, a System Metrics Source).
- Configure a Cribl HTTP Source in Cribl Stream to receive data from the Edge Node.
- Configure a Cribl HTTP Destination in Cribl Edge to send data to Cribl Stream.
- Configure QuickConnect to transfer the data from Cribl Edge to Cribl Stream.

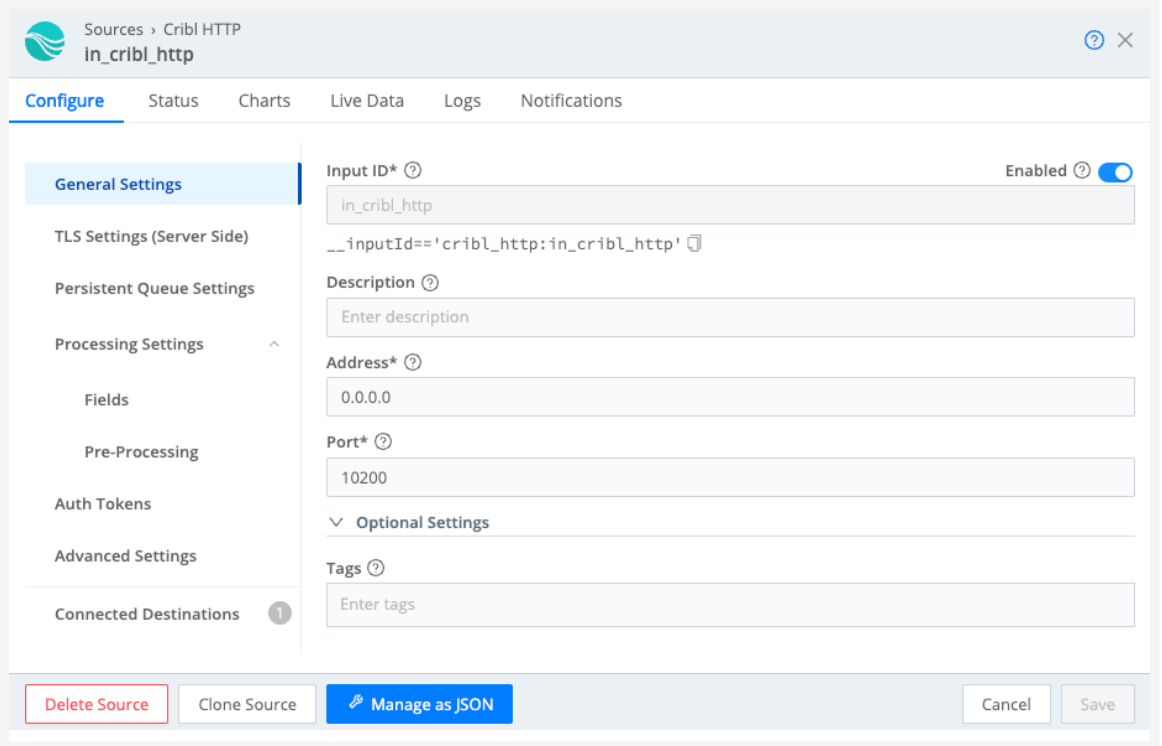
This scenario uses the example of a Cribl.Cloud deployment, where we recommend communication using a Cribl HTTP Source/Destination pair. In an on-prem deployment, you can also use a Cribl TCP Source/Destination pair over a trusted local network.

For different scenarios of sending data from Cribl Edge to Cribl Stream, including between different Workspace and Organizations, see Edge → Stream Communication Matrix.

Configure the System Metrics Source on Cribl Edge

Start by configuring a Source on your Edge Node that you will use to test the data flow. You can choose any Source, but examples here will use System Metrics.

Configure the Source, then preview your data on the modal's **Live Data** tab to make sure it flows correctly.



Configure the Cribl HTTP Source on Cribl Stream

In Cribl Stream, configure and enable a Cribl HTTP Source that will receive data from Cribl Edge.

1. In your Stream Worker Group, navigate to **Data** > **Sources** and select **Cribl HTTP**.
2. By default, you should see a predefined `in_cribl_http` Source. Select it.
3. Revise the Source settings. Leave the **Address** at its default value.
4. Take note of the **Port** value (by default, `10200`). You will need it later on.
5. Revise TLS settings. You must either enable or disable TLS on both the Cribl HTTP Source and the Cribl HTTP Destination it will be receiving data from, otherwise, no data will flow.

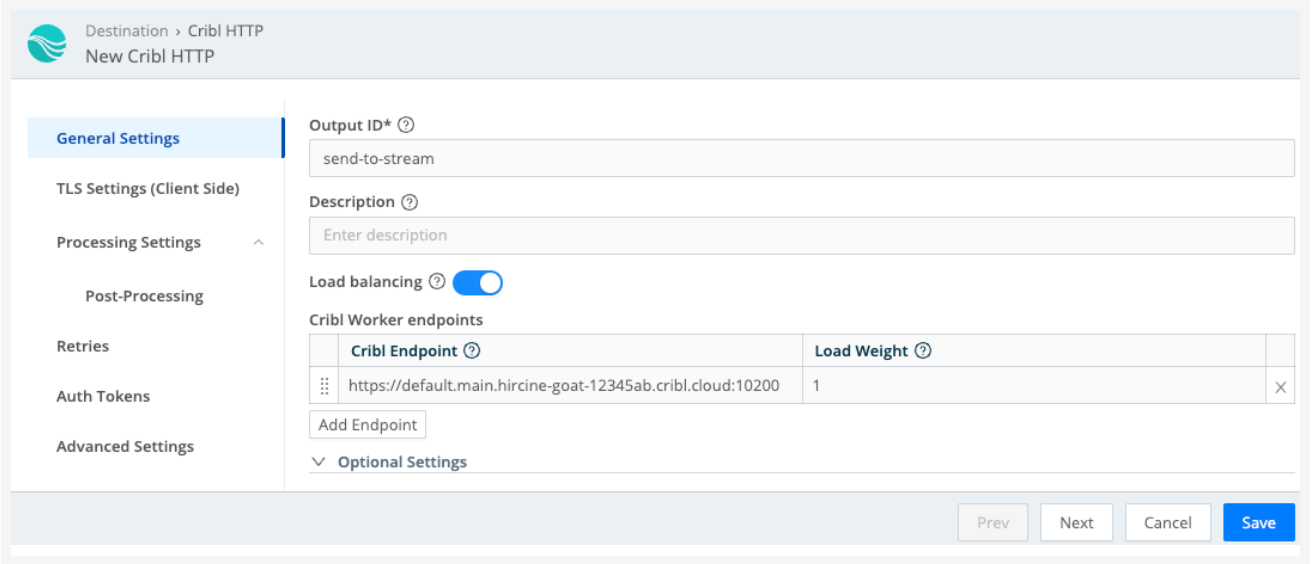
We recommend using TLS for all communications.

6. Make sure **Enabled** is toggled on and **Save**.
7. **Commit** and **Deploy** your changes.

Configuring a Cribl HTTP Source

Before moving on to the next step, open the Source configuration again and navigate to the **Status** tab to confirm that your Source is healthy.

Configure the Cribl HTTP Destination on Cribl Edge



Next, configure the Cribl HTTP Destination on the Edge side.

1. In your Cribl Edge Fleet, select **Collect**.
2. In the Destinations column, select **Add Destination**, hover over **Cribl HTTP** and select **Add New**.
3. Give the new Destination a unique **Output ID**.
4. In **Cribl endpoint**, configure the endpoint depending on where you configured the Cribl HTTP Source.
    - If the Source is on a Cribl-managed Cribl.Cloud Worker Group, access your Workspace's **Data Sources** page, and select the Worker Group from the **Group** drop-down. Locate the `in_cribl_http` Source in the **Sources Enabled by Default** table and copy its **Ingest Address**.

      If you are using a custom Cribl HTTP Source, not the built-in `in_cribl_http` one, replace the port in the ingest address with the port you configured for your Source.

- If the Source is configured on a customer-managed (hybrid) Worker Group (or if you are working in an on-prem deployment, not in Cribl.Cloud), use the **Address** and **Port** you entered on the Cribl HTTP Source.

5. Revise TLS settings and match them with what you selected for the Cribl HTTP Source. You must either enable or disable TLS on both the Destination and the Source, otherwise, no data will flow.
6. Select **Save**.
7. **Commit** and **Deploy** your changes.

Configuring a Cribl HTTP Destination

Once you've configured your Destination, test it to verify that your Edge Node can communicate with the Stream Worker Group.

1. Open the Destination configuration modal again and select the **Test** tab.
2. Select **Run Test**. If you see a success message, Cribl Edge and Cribl Stream are communicating correctly.

Send the Data

Finally, send actual data from Cribl Edge to Cribl Stream. You can do it by using QuickConnect.

1. In your Cribl Edge Fleet, select **Collect**.
2. In the Sources column, locate the Source that generates data (for example, the System Metrics Source), or select **Add Source** > **Select Existing**.
3. In the Destinations column, similarly locate or add the Cribl HTTP Destination you configured.
4. Drag the + icon from the Source tile to the Destination on the right.
5. Confirm using the **Passthru** option (you can also select a Pipeline or Pack to process the data).
6. **Commit** and **Deploy** your changes.

Confirm the Data Flow

To confirm that your data is flowing, navigate to Cribl Stream's Cribl HTTP Source and run a **Live Data** capture. You can also check the Monitoring page > **Data** submenu, to isolate the throughput on your Source.

At this point, with your data flowing, you can use Cribl Stream's capabilities to enrich, transform, and optimize the data and route it through Pipelines into selected Destinations.

12.1.7. Send Data To Loki And Prometheus

Prepare data for sending to Loki or Prometheus.

Loki and Prometheus, Grafana's systems for aggregating logs and for metrics-based monitoring, respectively, require specific setup to collect and store data coming from Cribl Edge.

Loki stores log contents unindexed, relying on labels and timestamps that are indexed to form event streams. The method is similar to how data would be stored in a bucket or index on other systems.

Similarly, Prometheus uses names, labels (dimensions), and numerical values.

For more straightforward setups where less customization is needed and you will ultimately use the data in Grafana Cloud, you can use the Grafana Cloud Destination.

Configure a Loki Pipeline

Loki stores logs based on labels. This is a great way to organize your stored data so that retrieval is easier when looking for specific log entries. By default, no labels are defined for the Loki Destination. Because Loki requires at least one label, Cribl will automatically add a default `label` source with the value `cribl_${__inputId}`.

See Loki Destination Processing settings for more information.

To ensure data is shaped correctly for Loki, you can configure a Pipeline with an Eval Function to add the labels to the `__labels` field.

To create a Pipeline called `loki-pipeline` in the Cribl Edge UI, follow these steps:

1. On the top bar, select **Products**, and then select **Edge**. Under **Fleets**, select a Fleet.
2. Select **More**, then **Pipelines**.
3. Select **Add Pipeline**.
4. In **ID**, enter `loki-pipeline` and provide an optional **Description**.
5. Confirm with **Save**.
6. Select **Add Function** and choose **Eval**.
7. In the **Evaluate Fields** section, add the configuration for your labels. For example, to prepare Kubernetes logs data, use:

Name	Value Expression
`__labels`	`{}`
`__labels.namespace`	`kube_namespace`
`__labels.pod`	`kube_pod`
`__labels.container`	`kube_container`

8. Select **Save**.

Next, in the Fleet's submenu, go to **Collect** to attach your Source (for example, a Kubernetes Logs Source) to Loki using the **loki-pipeline** Pipeline as connection.

Configure a Prometheus Pipeline

Cribl Edge offers a prebuilt `prometheus_metrics` Pipeline. You can modify it to change a few metadata fields and use it to connect to a Prometheus Destination.

1. On the top bar, select **Products**, and then select **Edge**. Under **Fleets**, select a Fleet.
2. Select **More**, then **Pipelines**, then **prometheus_metrics**.
3. Select the **Eval** Function and modify the fields in the **Evaluate Fields** section as needed. For example, to prepare Kubernetes metrics data, use:

Name	Value Expression
`job`	`job || 'cribl'`
`instance`	`__metadata.kube.node.metadata.name || host`

4. Select **Save**.

Next, in the Fleet's submenu, go to **Collect** to attach your Source (for example, a Kubernetes Metrics Source) to the Prometheus Destination, using the **prometheus_metrics** Pipeline as the connection.

12.2. Sources Overview

Each Cribl Edge **Source** is a configuration that enables Edge nodes to collect or receive observability data - logs, metrics, application data, and so on - in real time. Edge can receive continuous data input from Splunk, HTTP senders, Elastic Beats, Prometheus, TCP JSON, and many others. Sources can receive data from either IPv4 or IPv6 addresses.

Cribl Edge offers a configuration modal for each type of supported Source. However, you can add multiple instances of each Source type - with each configured to match the parameters of the corresponding sender. For example, you can have multiple File Monitors and multiple listeners for Syslog, Splunk, Elastic Beats, Prometheus, TCP JSON, and many others.

While Cribl Edge can receive inbound data via Syslog or TCP, we generally discourage using Edge to ingest large volumes of data from external sources, due to its single-process nature and its focus on running as an agent. Excessive network traffic can lead to performance bottlenecks or data loss.

This applies to any external data feed that is sent to the node hosting a Cribl Edge instance. If you require more performance, or need to scale your data collection, consider using Cribl Stream instead. Cribl Stream is designed for larger-scale data ingestion and processing, and our Sizing and Scaling guidance can help you determine the optimal configuration for your specific needs.

System and Internal Sources

Sources that generate data locally at the Edge Node, monitor resources, or move data among Edge Nodes and/or Stream Workers within your Cribl deployment.

- Cribl Internal
- Cribl HTTP
- Cribl TCP
- Datagen
- Exec
- File Monitor
- Journal Files
- Kubernetes Events
- Kubernetes Logs
- Kubernetes Metrics
- System Metrics
- System State

- Prometheus Edge Scraper
- Windows Event Logs
- Windows Metrics

Push Sources

Supported data Sources that **send** to Cribl Edge.

- Cloudflare (HTTP/S)
- Datadog Agent
- Elasticsearch API
- Grafana
- HTTP/S (Bulk API)
- Loki
- Metrics
- Raw HTTP/S
- OpenTelemetry (OTel)
- Prometheus Remote Write
- SNMP Trap
- Splunk HEC
- Splunk TCP
- Syslog
- TCP JSON
- TCP (Raw)
- UDP (Raw)
- Windows Event Forwarder

Comparison of Generic Push Sources

This table compares generic, protocol-level Push Sources. Refer to this table when you need to ingest raw data or custom formats over basic protocols like HTTP, TCP, or UDP.

Source	Key Differentiator	Best For...
HTTP/S (Bulk API)	**Protocol-aware:** Understands and responds using specific API semantics, including acknowledgments.	Receiving data from systems that require custom or generic HTTP/S event ingestion.

Source	Key Differentiator	Best For...
Raw HTTP/S	**Protocol-agnostic:** Accepts any HTTP/S payload without validating its structure.	Capturing any arbitrary or custom HTTP/S traffic where only the raw payload matters.
TCP JSON	**Content-aware:** Specifically designed to parse a stream of distinct JSON objects.	Ingesting a continuous stream of well-formed JSON objects over a reliable TCP connection.
TCP (Raw)	**Content-agnostic:** Treats the incoming data as an unstructured stream of bytes.	Ingesting binary data, custom application protocols, or any non-JSON data over TCP.
UDP (Raw)	**Stateless with best-effort delivery:** Offers lightweight, connectionless data ingestion.	High-volume, loss-tolerant data streams like syslog or SNMP traps.

Pull Sources

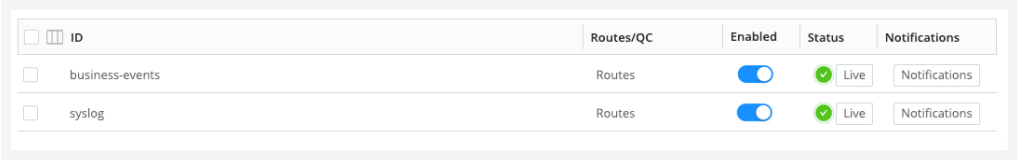
Cribl Edge does not contain any Sources categorized as **Pull**. The contents of the **Pull** tab will be blank.

Configuring and Managing Sources

For each Source *type*, you can create multiple definitions, depending on your requirements.

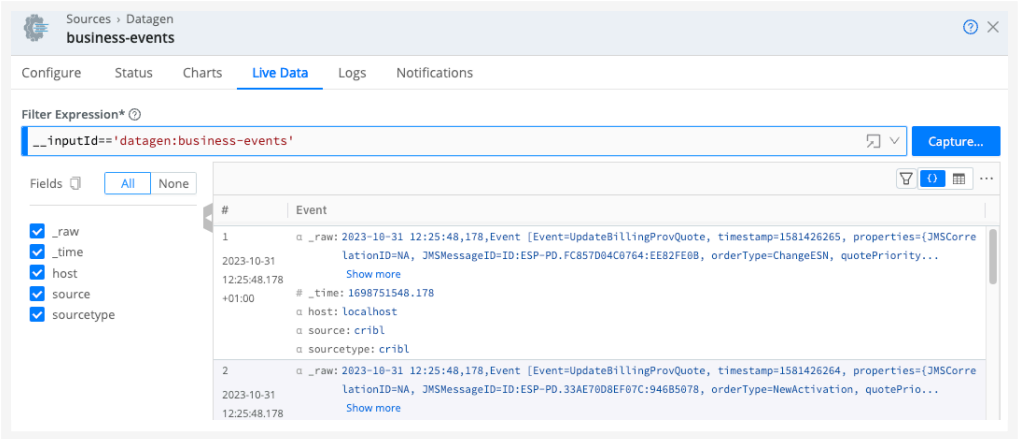
To configure Sources, from the top nav, select **Manage**, then select a **Fleet** to configure. Then, you have two options:

- To access the graphical QuickConnect UI, select **Collect**. Next, select either **Add New** or (if displayed), select **Existing**.
- To access the Routing UI, select **More** > **Sources**. On the resulting **Data Sources** page's tiles or left menu, select the desired type, then select **Add New**.



Capturing Source Data

To capture data from a single enabled Source, you can bypass the Preview pane, and instead capture directly from a **Manage Sources** page. Select the **Live** button beside the Source you want to capture.



In order to capture live data, you must have Edge Nodes registered to the Fleet for which you're viewing events. You can view registered Edge Nodes from the **Status** tab in the Source.

An Edge Node can refuse Live Capture when `CRIBL_DISABLE_FEATURES` includes `remote_capture`. The response is `HTTP 403` with the message `This node is configured to prevent remote data capture`. See Capture Refused by Node Policy.

Source > Live button

You can also start an immediate capture from within an enabled Source's configuration modal, by selecting the **Live Data** tab.

Source modal > Live Data tab

Monitoring Source Status

You can get a quick overview of Source health status by referring to their status icons.

Additionally, each Source's configuration modal offers two tabs for monitoring: Status and Charts.

Source Status Icons

Source status icons are available on the **Data** > **Destinations** page and for each individual Source in the list for a specific Source type.

The icons have the following meanings:

Icon	Meaning
	Healthy. Operating correctly.
	Warning. Experiencing issues. The Source is not functioning fully. Specific conditions will depend on the Source type.

Icon	Meaning
	Critical. Experiencing critical issues. Drill down to the Source's Status tab to find out the details.
	Disabled. The Source is configured, but not enabled.
	No health metrics available. This may mean that a Source is enabled, but has not been deployed yet.
	Inactive. When using GitOps, a Source appears `Inactive` if its **Environment** field (configured under **Advanced Settings**) does not match the currently active environment determined by the deployed Git branch. This ensures integrations only activate in their designated environments, preventing unintended data flow or misconfiguration.

Status Tab

The **Status** tab provides details about the Edge Nodes in the Fleet and their status. An icon next to each Edge Node uses color to clearly signal its health:

- : All systems go! Your Edge Node is operating normally.
- : Attention needed. There's a potential issue with this Edge Node.
- : Stop! This Edge Node has encountered a critical error.

The way you view Edge Node statuses depends on the size of your Fleet:

- **Fewer than 1000 Edge Nodes**: All Edge Nodes are conveniently displayed on the Status tab, along with their statuses. Use the **Status** checkboxes at the top to filter the list by health (healthy, warning, error). Select any Edge Node row to view specific details to help diagnose issues. The specific set of information provided depends on the Source type. Keep in mind that this data only reflects process `0` for each Edge Node.
- **More than 1000 Edge Nodes**: With a larger Fleet, you can select a specific Edge Node from the drop-down menu (showing up to 100 Nodes). You can search by `hostname` or `GUID` to find a specific Node. You can also use the **Status** checkboxes to filter which Edge Nodes appear in the drop-down list.

The content of the **Status** tab is loaded live when you open it and only displayed when all the data is ready. With a lot of busy Edge Nodes in a group, or nodes located far from the Leader, there may be a delay before you see any information.

The statistics presented are reset when the Edge Node restarts.

Charts Tab

The **Charts** tab presents a visual representation of Source activity using internal metrics. Unlike the status tab, this data is read almost instantly and does not reset when restarting an Edge Node.

The following data is available:

- Total events in
- Average throughput (events per second)
- Total bytes in
- Average throughput (bytes per second)

Configuring Time Ranges

At the top of the modal, a time range picker controls which time window the charts display:

- The picker offers the same presets as the main Monitoring time selector (for example, `5 min`, `15 min`, `1 hour`, `6 hours`, `1 day`).
- When you open the Source I/O metrics modal from **Monitoring**, the charts inherit the current Monitoring time range.
- When you open the modal from other areas of the UI (for example from **Data** > **Sources** or directly from a Source configuration modal), the Charts tab defaults to `10 minutes`.
- Changing the time range in the modal only affects that modal and is not persistent. It does not change the global time range on the originating page (for example, the **Monitoring** overview or the page-level time picker).

Use this picker to zoom in on short spikes or expand to longer windows when you're troubleshooting Source performance or throughput issues.

Preconfigured Sources

To accelerate your setup, Cribl Edge ships with several common Sources configured but not switched on. Open, clone (if desired), modify, and enable any of these preconfigured Sources to get started quickly.

On a Cribl.Cloud deployment, **do not delete** any preconfigured Sources. If you don't plan to use them, keep them disabled.

These default Sources are managed by Cribl Edge and are re-created from the default configuration when you create or clone Fleets, upgrade, or apply certain configuration bundles. As a result, they cannot be permanently deleted. Removing them in the UI only affects the current configuration copy, and they will reappear the next time defaults are re-applied.

- **System Metrics** - Basic Level
- **System State** > **in_system_state**
- **File Monitor** > **in_file_auto** - Auto Discovery Mode
- **File Monitor** > **in_file_varlog** - Manual Discovery Mode
- **Kubernetes Events** > **in_kube_events**
- **Kubernetes Logs** > **in_kube_logs**
- **Kubernetes Metrics** > **in_kube_metrics**
- **Cribl Internal** > **CriblLogs** - Internal
- **Cribl Internal** > **CriblMetrics** - Internal
- **Windows Metrics** > **in_windows_metrics**
- **Windows Event Logs** > **in_win_event_logs**
- **Journal Files** > **in_journal_local**

Single Source Support

The following Source types are limited to preconfigured Sources:

- Cribl Internal
- Kubernetes Events
- Kubernetes Logs
- Kubernetes Metrics

12.2.1. System

You can use the following Sources to receive data from internal senders.

Source	Description
Apple Unified Logs	Collects logs from Apple devices
Exec	Execute a command periodically, and collect its stdout output
File Monitor	Collect log files and generate events from the file content
Journal Files	Collects data from systemd's journald service
Kubernetes Events	Generate events for a Kubernetes cluster
Kubernetes Logs	Collects logs from containers on a Kubernetes node
Kubernetes Metrics	Generate events for Kubernetes clusters, nodes, Pods, and containers
System Metrics	Collect metrics from a host, and populate dashboards
System State	Collects the system's current state on a configurable schedule, relaying corresponding events to downstream systems.

12.2.1.1. Exec Source

The Exec Source enables you to periodically execute a command and collect its `stdout` output. This is typically used in cases when Cribl Edge cannot accomplish collection with native Collectors or other Sources.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **Yes**

This Source allows you to run **almost anything** on the host system. Make sure you understand the security and other impacts of commands you plan to execute, before proceeding. To disable it on your Edge Nodes, see Disable the Exec Source below.

Especially for monitoring or polling, you'll need to receive the command or script's output periodically. For this reason, the Exec Source lets you specify when the command or script should run, by time interval or by cron-style schedule.

Here are a few examples of what you can run from an Exec Source:

- Database queries.
- Custom commands to poll databases or apps.
- `ping` to check latency.
- `ps -ax` to get a list of running processes.
- `SNMP GET` requests to query an SNMP agent about network entities.
- `netstat -natp` to get lists of sockets and TCP ports, and what they're doing.
- `mtr -c 1 --report --json 8.8.8.8` to run a traceroute on a location (here, `8.8.8.8`), and packaging up a report in JSON format.

Configure an Exec Source

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:

- **Enabled**: Defaults to toggled on.
- **Input ID**: Enter a unique name to identify this Exec Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
- **Command**: Command to execute; supports Bourne shell syntax.
- **Schedule type**: Use the buttons to select either `Interval` or `Cron`. For details, see Schedule Type below.

3. Next, you can configure the following **Optional Settings**:
   - **Script**: Optional multiline script to send to the defined command. The content of this field will be piped into the `stdin` of the command. The `stdin` stream is closed after adding the script. See Run Custom Scripts for more information.
   - **Retry limit**: Maximum number of retry attempts in the event that the command fails.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Schedule Type

Customize the behavior in the corresponding field below the button.

- **Interval**: Specify how often, in seconds, the command should run. Defaults to `60`.
- **Schedule**: Enter a cron expression. (You enter the cron expression in UTC time, but the resulting **Estimated Schedule** displays in local time.)

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

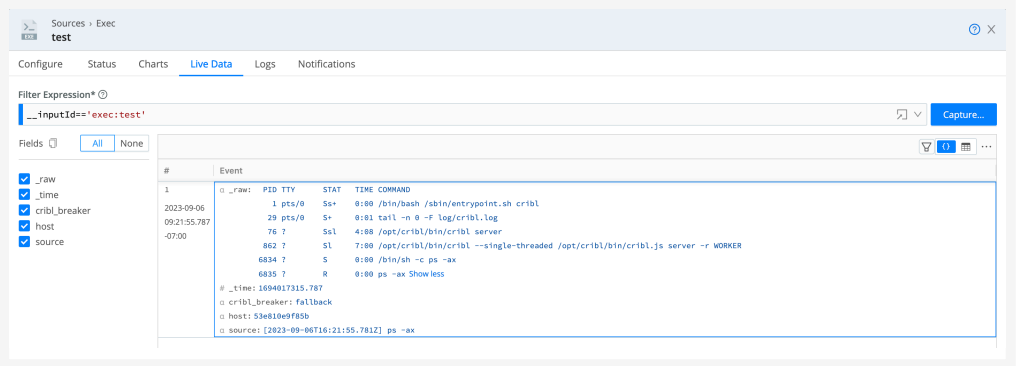
Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.



Internal Fields

Cribl Edge uses internal fields to assist in forwarding data to a Destination.

You can find the following event fields on the **Live Data** tab of the selected Exec Source, including the hostname and source of the event:

- `_raw`
- `_time`

- `cribl_breaker`
- `host`
- `source`

Event fields

Troubleshooting

If a command isn't running as expected, the **Logs** tab can help you identify issues by displaying the command executed, its elapsed time, and its exit code.

Event fields

Run Custom Scripts

You can use the Exec Source to run custom multiline scripts, for example in Powershell or Python. To do so, enter the command in the **Command** field and the script contents in the **Script** field.

For example, to run a Powershell script, enter:

Command: `powershell -NoLogo -NoProfile -`

Script:

```
$USER_NAME = whoami
$DATE = Get-Date
"Hi $USER_NAME, today is $DATE"
```

If you want to run a multiline script via `cmd`, create a batch file and run it via the **Command** field. This is because `cmd` doesn't allow suppressing interactive prompts while running a multiline script.

To run a Python script, enter:

Command: `python3 -`

Script:

```
#!/usr/bin/env python3
import getpass
from datetime import datetime
user_name = getpass.getuser()
date_now = datetime.now()
print(f"Hi {user_name}, today is {date_now}")
```

Execute Windows PowerShell Commands

On a Windows Edge Node, the Exec Source command is executed from a Windows command prompt, not from a PowerShell prompt. However, you can still run PowerShell commands in it with some modification.

The execution of PowerShell is resource-intensive and should be used with caution. On limited resource systems (e.g., domain controllers) it is best to run Exec with PowerShell carefully as the Source uses the host's CPU.

To run a PowerShell command in the Exec Source, you need to prepend the **Command** field with `powershell`, for example:

PowerShell Prompt Command	Cribl Exec Source configuration
`Get-Process`	`powershell Get-Process`

PowerShell Prompt Command	Cribl Exec Source configuration
`# cd c:\mydir` `# .\myps-script.ps1`	`powershell c:\mydir\myps-script.ps1`

You can handle a PowerShell command with parameters by placing the command and the parameters in double quotes (`""`), for example:

PowerShell Prompt Command	Cribl Exec Source configuration
`Get-CimInstance win32_process | select ProcessId, Name, commandline, HandleCount, WorkingSetSize, VirtualSize`	`powershell [-command] "Get-CimInstance win32_process | select ProcessId, Name, commandline, HandleCount, WorkingSetSize, VirtualSize"`

(Include the `-command` parameter if your PowerShell version requires it.)

Disable the Exec Source on a Node

To disable the Exec Source on a specific Edge Node, set the `CRIBL_NOEXEC` environment variable. This will override any configuration pushed from the Leader Node, ensuring the Exec Source remains disabled on that particular node.

The `CRIBL_NOEXEC` environment variable must be set outside of the Cribl product to disable the Exec Source. This variable cannot be modified within the product's interface.

How to Disable the Exec Source on Different Platforms

To disable the Exec Source, follow the platform-specific instructions below. Once you've set the `CRIBL_NOEXEC` environment variable, the Exec Source will be disabled. To re-enable it, remove or unset the variable.

Disable on Linux Platform

To disable the Exec Source on a Linux system running as a Systemd service, edit the appropriate service definition file:

- Cribl Edge: `/etc/systemd/system/(cribl|cribl-edge).service`
- Cribl Stream: `/etc/systemd/system/cribl.service`

To ensure the `CRIBL_NOEXEC` environment variable is set when the Cribl Edge service starts, add `CRIBL_NOEXEC=1` to the service's configuration. If the service is currently running, a restart is required for the change to take effect.

Disable on Docker

To disable the Exec Source on Docker, modify the `docker run` command (or equivalent) to include the `-e CRIBL_NOEXEC=1` flag.

Disable on Kubernetes/Helm

To disable the Exec Source on Kubernetes, add the `--set env.CRIBL_NOEXEC=1` flag to your `Helm install` command or modify the `values.yml` file to include this setting.

Disable on Windows (For Cribl Edge)

To add the `CRIBL_NOEXEC` environment variable to Cribl Edge on Windows, use the command prompt to execute the following command:

```
setx CRIBL_NOEXEC "1" /M
```

This command sets the environment variable for the current user account. The Cribl Edge service runs under `LocalSystem` user account by default.

12.2.1.2. File Monitor Source

The File Monitor Source generates events from text files, compressed, archived, and (some) binary log files, based on lines and records extracted from the content.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **Yes**

As of v.4.2.x, this Source can process the following file formats:

- **Compressed/archived**: `zip`, `gzip`, `zstd`, and `tar`. Cribl Edge only supports DEFLATE compression for `zip` files.
- **UTF-8**: `text`.
- **Non-identifiable binary**: Includes all file formats that aren't in the Cribl Edge-supported compressed, archived, and text categories.

Binary files are broken into base64-encoded chunks and streamed bypassing Event Breakers. Text files are processed normally through Event Breakers. (Before v.4.2.x, the File Monitor Source could handle only text files.) Also as of v.4.2.x, the File Monitor Source no longer excludes `*.gz` files by default.

The File Monitor Source periodically logs information such as the number of files discovered and handled. See Internal Logs for more information about accessing Cribl logs.

File Monitoring and One-Time Ingestion

Cribl Edge offers two options for ingesting file data (one-time ingest is not available in Cribl Stream):

- **File Monitor Source**: This is ideal for ongoing log file monitoring. By default it will prioritize processing the latest data in newly discovered files upon startup ("Collect from end"). Subsequently, it automatically monitors and ingests new content as it's added.

To automatically discover and ingest new log files, Cribl Edge requires privileged access for file scanning and reading. For alternative approaches, see Running Edge as an Unprivileged User.

- **One-time File Ingest**: This feature complements the File Monitor by allowing a one-time ingest of any file. It's useful for quickly processing specific files or initial data loads. If **Explore** is enabled, as it might be restricted in some environments for security reasons.

Discovering and Filtering Files to Monitor

To produce its initial list of files to monitor, the File Monitor Source runs a discovery procedure at a configurable **Polling interval**. The Source then applies a **Filename allowlist** to filter the initial list down into its

final form. Then, for each file on the list, the Source compares current state with previously-stored state. This comparison determines whether the File Monitor Source will actually watch a given file for a given polling interval, or just ignore the file.

In the simplest case, the Source discovers a file for which it has no stored state. This means that the file has just been created, and needs to be monitored. See the Examples for other possibilities, along with a description of the **Status** tab, which displays state information for all files being monitored.

How does the File Monitor Source discover files in the first place? You have the choice of two **Discovery Modes**: **Auto** or **Manual**.

Discovery involves scanning files to obtain their modification times, and can be time-consuming for extensive file systems. If you already know the specific files to monitor, you can optimize discovery speed by setting the **Discovery mode** to **Manual.** This bypasses the automatic file scanning process, reducing performance overhead and focusing resources on the files of interest. Limiting the scope of the File Monitor by using **Manual** mode's **Search path** and **Max depth** settings can significantly improve discovery speed.

- In **Auto** mode, the Source automatically discovers files that running processes have open for writing. Auto mode collects logs from the discovered active files that match the allowlist.
  Auto mode is useful to detect which files are being written to. For example, if you enter an allowlist of `*log`, Auto mode will find all the active logs within that directory, no matter what's writing to it, and it will exclude any rotated logs.
  Avoid using The File Monitor Source in **Auto** mode together with any other file monitors. It can cause unintended, duplicate collection. Use **Auto** mode carefully!

Cribl Edge currently supports Auto mode only when running on Linux, not on Windows or macOS. Windows and macOS deployments require using the Manual option. For a Windows-specific configuration, see Collect Logs with File Monitor.

- In **Manual** mode, the Source discovers files based on the specified directory and depth.
  Manual mode is often used to collect logs in a folder where the process that creates them rotates them when they get large. For example, if you specify a path of `/var/log` and an allowlist of `*/messages*`, Manual mode will capture the current `/var/log/messages`, as well as older logs from `/var/log/messages*`.
  Manual is the default discovery mode for new File Monitor Sources.

If you are using a tool like `rsync` to transfer files in chunks, the File Monitor Source might start collecting files before the transfer is complete. To prevent this, configure your tool to transfer files serially. (For example, use: `rsync --append`.)

Configure a File Monitor Source

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name to identify this File Monitor Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Discovery Mode**: Select either **Auto** or **Manual**. See Discovering and Filtering Files to Monitor for details on how each mode works.
        - **Auto**: Tells the Source to automatically discover files that running processes have open for writing.
        - **Manual**: Tells the Source to discover files within a single directory that you specify as the **Search path**, down to the **Max depth**.
            - **Search path**: Enter an absolute path (no wildcards). Defaults to the `/var/log` directory.
            - **Max depth**: Controls how many levels deep the Source will search within the **Search path**. If you leave the **Max depth** field empty, the Source will search subdirectories, and their subdirectories, and so on, without limit. If you specify `0`, the Source will discover only the top-level files within the **Search path**. For `1`, the Source will discover files one level down.
            - **Suppress errors when search path does not exist**: Toggle on to hide `Path does not exist` errors when a directory doesn't exist. When enabled, missing directories will not affect the File Monitor Source health status. This is useful when you know the search path contains nonexistent directories for some hosts, and you don't want to see the error messages in the File Monitor status and logs.
            - **Delete files**: Whether to delete the source file after it has been idle for the specified **Idle timeout** period. This toggle is under Advanced Settings.
3. Next, you can configure the following **Optional Settings**:
    - **Polling interval**: Interval of time in seconds to run the discovery procedure. Defaults to `10` seconds.

- **Filename allowlist**: Controls which files the Source discovers and monitors. Defaults to `*/log/*` and `*log`. You can use wildcards (`*`) to match any sequence of characters (including separators) and the exclamation mark (`!`) for negation. These patterns are matched against the full path of the file. For example:
  - Wildcard (`*`): `*DhcpSrvLog-*.log` collects file `/var/log/DhcpSrvLog-05-22-2025.log`.
  - Negation `!`: `!*cribl*access.log` prevents the Source from discovering Cribl Edge's own log files.

If you're using **Manual** discovery mode, always think through how your **Search path** and **Filename allowlist** settings interact. If you're not careful, you can inadvertently create overlapping monitor groups that deliver duplicates of some files. See Using Allowlists Effectively for details.

- **Apply filename allowlist internal to archive files**: Toggle on if you want the filename allowlist to apply to files inside archives such as `tar` or `zip`.
- **Minimum age duration**: Optionally, specify a minimum age of files to monitor. This Source will only start ingesting a file once its modification time exceeds the configured duration. Enter a duration in a format like 30s, 15m, 1h. Defaults to an empty field, which applies no age filters.
- **Maximum age duration**: Optionally, specify a maximum age of files to monitor. This Source will filter events with timestamps newer than the configured duration. (Where files don't have a parsable timestamp, it will set their events' timestamp to `Now`.) Enter a duration in a format like `30s`, `4h`, `3d`, or `1w`. Defaults to an empty field, which applies no age filters.
- **Check file modification times**: Toggle on if you want this Source to skip files with modification times older than the configured **Maximum age duration**. When you set an **Maximum age duration** threshold, the Source will open every file and read through all its contents to seek a timestamp. For best performance, also toggle **Check file modification times** on skip older files.
- **Collect from end**: When toggled on (default) this Source prioritizes processing the latest data by reading from the end of existing files on initial scan of the target directory. This allows focusing on new content in existing log files. However, this behavior only applies during the first encounter with a file, and disabling this setting after discovery is complete will have no effect. For newly discovered files after the initial scan and all subsequent discoveries, Cribl Edge will read from the head of each file. Disable this setting when using stateful Event Breakers, such as the CSV Event Breaker.
- **Enable binary files**: Toggle on if you want this Source to report the file as binary and stream it in Base64-encoded chunks. By default, the Source ignores binary (non-text) files such as JPEG images, MP3 audio files, or some binary data files.
- **Force text format**: Toggle on if you want this Source to display ingested data as text in the event (when the data isn't in a compressed or archived file). This option is helpful if you have files that contain binary mixed with text where the data should be streamed as all text (for example, AuditD logs can contain this type of data).

    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Disable Event Breaker buffer timeout: Default is toggled on (timeout disabled). When toggled off, the following additional setting becomes available:

- **Event Breaker buffer timeout (ms)**: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec.), maximum `43200000` (12 hours).

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For

Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

Advanced Settings

Idle timeout: Time, in seconds, before an idle file is closed. Defaults to `300` sec. (5 minutes).

Hash length: How many file header bytes to use in a hash for identifying a file uniquely. Defaults to `256` bytes. Do not set the hash length to more than `16384`, because it can cause issues when reingesting files. For details, see Configuring Hash Lengths.

Delete files: Default is toggled off. When toggled on: Cribl Edge will delete the source file after it has been idle for the specified **Idle timeout** period. This setting is only available in `Manual` mode. In the confirmation modal, select **Enable** to proceed. Files that fail to delete will be reported as errors on the **Status** tab for up to one hour.

Files might not be deleted if:

- The Cribl Service doesn't have proper permissions to access and delete the files.
- They are currently in use by other applications on Windows.
- They are being moved or renamed while Cribl Edge is collecting them.
- Their filenames are not on the allowlist.

To make sure files are deleted properly:

- Verify and grant necessary permissions to the Cribl Service. For details, see Configure Cribl Stream for Non-Root User and Running Edge as an Unprivileged User.
- Consider access patterns and how files are being used.
- Adjust system settings if necessary (such as, file sharing, antivirus exclusions).

Salt file hash: Default is toggled off. Toggle on to salt the hash with the source file name. Use this option for files with the same header (for example, CSV files) to ensure that each has a different hash and can be ingested correctly. A file will get a new hash and be re-ingested if you move or rename it. Additionally, toggling this setting on after the Source has started operating will cause all files to be re-ingested as well.

Enable load balancing: To handle high volumes of file data, enable load balancing. This improves the events per second (EPS) ingest rate, and is helpful when you need to ingest more file data EPS than a single Worker Process can handle.

When you enable this toggle, you should also increase the number of Worker Processes in Fleet Settings. The number of Worker Processes for load balancing depends on your file ingest volume.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Discovery Optimizations

The **Discovery Optimizations** section includes settings for optimizing the file discovery process.

These settings apply only in specific situations and can have an adverse effect when used incorrectly. Consult with Cribl Support to determine whether these settings are appropriate for your needs.

Optimize for leaf directories: Default is toggled off. Toggle on to reduce load on the filesystem for search paths with files in leaf directories. This will cause file discovery to skip rescanning unchanged directories (determined based on modification time), using an exponential backoff strategy. This might delay detection of new data.

Enable discovery Throttling: Default is toggled off. When toggled on, file discovery limits CPU usage to the **Discovery throttle CPU target (%)**. This setting is available only in **Manual** discovery mode. When toggled on, the following control appears:

- **Discovery throttle CPU target (%)**: Target CPU utilization during file discovery. Defaults to `25`. Minimum `1`, maximum `99`. Lower values reduce CPU usage but increase discovery time.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

This Source defaults to QuickConnect.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are not part of an event, but they are accessible, and Functions can use them to make processing decisions.

For the File Monitor Source, you can use internal fields to enrich events with container and host metadata. The following internal fields are available:

- `__baseFilename`
- `__source` / `source`
- `__raw`
- `__inputId`

- `container_id`
- `container_path`
- `__container`
- `host_path`
- `__unresolved_source` (This internal field represents the unresolved path for the symbolic link configured in the File Monitor Source.)

Monitoring Renamed Files' State

The File Monitor Source uses a simple scheme to find "backlog" files corresponding to a matching file: Tell it to tail `foo.log`, and it will look for `foo.log.[0-9]` and scrape those, too.

This Source keeps hashes that correspond to the start point within the file, and to the last-read point. This way, if Cribl Edge is stopped, files are rotated, and Cribl Edge is restarted, the File Monitor Source can find the resume point in those backlog files.

Similarly, if you rename the file **within the same backlog scheme** (for example, `foo.log` to `foo.log.0`), the File Monitor Source can resume at the right place. However, if you renamed `foo.log` to `bar.log` (a deviation from the expected naming scheme), this Source could not find its resume point.

Optimize File Monitor Collection

To optimize File Monitor to collect exactly the events you need, you can finetune the following Source settings.

Optimize File Discovery

To use the File Monitor Source effectively, it's important to understand the interplay among the **Search path**, **Max depth**, and **Filename allowlist** settings. The following settings only appear when the **Discovery mode** is set to `Manual`:

- **Search path** specifies the root directory from which the File Monitor will start searching for files.
- **Max depth** defines how deep the File Monitor will recurse into subdirectories. A value of `0` limits the search to the specified search path only, excluding subdirectories.
- **Filename allowlist** is a list of file patterns to include in the monitoring. The allowlist field accepts only file patterns, not directory paths.

The File Monitor Source first identifies potential files based on the **Search path** and **Max depth** settings. Then, it applies the **Filename allowlist** patterns to filter the list of files. Only files matching both the **Search path** and **Filename allowlist** criteria will be monitored.

Some guidelines to keep in mind:

- Specify the full path in the **Filename allowlist** for precise control over which files are monitored. For example: `/var/log/messages`. To optimize performance, avoid using excessive wildcards in the Cribl Search path, as this can significantly increase the number of files scanned.
- Use `max depth=0` for specific directories. If you want to monitor files only within a specific directory, set **Max depth** to `0` and specify the directory in the search path.
- Take advantage of the Explore UI. The Fleet's **Explore** > **Files** tab can help you visualize the file structure and test different allowlist patterns before deployment.

Optimize Time Settings

The **Maximum age duration** and **Check file modification times** settings apply to both **Manual** and **Auto** discovery modes in the File Monitor.

Some guidelines to consider when adjusting these settings are:

- **Setting Check file modification times alone is not effective**: If you only enable **Check file modification times** without specifying an **Age duration limit,** the File Monitor will still process all files that match the filter criteria. To effectively filter files based on age, you must specify both settings.
- **Setting age duration alone reads all files:** Without enabling **Check file modification times**, the File Monitor will read all files that match the specified **Filename allowlist**. No age criteria will be applied to the entire file. However, the **Maximum age duration** will still be used to filter events within the files that have a timestamp older than the specified duration.
- **Setting both ensures efficient filtering:** To achieve optimal filtering, set both **Maximum age duration** and **Check file modification times**. This configuration allows the File Monitor to skip files that are older than the specified duration, based on their modification time. And within the remaining files, it will skip events that are older than the specified duration.

File Tracking with Hashes

The File Monitor Source doesn't track state using filenames. Instead, it uses hashes of the head and tail of the file to identify it later so it can resume where it left off.

To make sure hashes are generated correctly to ingest the files you want, follow these better practices.

Configure Hash Lengths

For files with identical first lines, configure the hash length to be longer than the first line to ensure that the header includes something unique. It is common for a batch of `CSV` files or `IIS` logs to have identical first lines listing columns that appear in subsequent lines. However, do not exceed a hash length `16384`. Using a higher value can cause files to be reingested multiple times.

If you don't adjust the hash length, all files with headers larger than 256 bytes will appear to File Monitor as one file. As long as the hash length is greater than the header length, and the subsequent lines include something

unique, the File Monitor Source will identify them as different files.

Salt the Hashes

If you want to ingest files with identical first lines (such as CSV files), and configuring hash length does not yield satisfying results, you can ensure different hashes for the files by toggling the **Salt file hash** setting. See Salt file hash for more details.

See Collect CSV Files with File Monitor for more guidance on configuring the File Monitor to collect CSV files.

Avoid Race Conditions

The hashing logic isn't instantaneous, so it's possible for files with the same header and the same hash to be both collected. For example, quickly copying the same example file to separate `eg1.log` and `eg2.log` files in the Source's path will usually result in both files being collected even though they share the same hash. However, copying it to `eg3.log` shortly (not immediately) after will result in that third file being ignored because its hash matches an existing entry in the state-store.

Don't Ingest Multiple Copies of the Same File

Creating copies of the same file in the Source's path will not result in the file being ingested multiple times. The head-hashing logic used by the Source to determine what it's seen before and how far it's collected already prevents you from successfully testing multiple copies of the same.

Don't Point Multiple File Monitor Sources at the Same File

Multiple File Monitor Sources set to collect the same file will result in duplicate events. Sources run independently and don't coordinate with each other.

Using Allowlists Effectively

Done properly, file monitoring collects exactly the files you need to see, without duplication. You want to avoid inadvertently creating overlapping monitor groups that deliver duplicates, because this can "run the meter" twice for affected files, potentially causing issues with data ingestion volume limits.

The key is knowing how to craft allowlists.

Crafting Allowlists: Principles

To get the results you want from file monitoring, always apply the following principles.

Write allowlists to explicitly include the full path of files you want to collect.

The search path itself is **not** excluded from the match. For example, if you want to collect the file `/var/log/messages` when you've set your search path to `/var/log`, your filename allowlist needs to be either `/var/log/messages`, `/var/*/messages`, or `*/log/messages`.

Exclusions (`!`) also need to address the full file path. For example, if you want to collect everything from `/var/log/*` **except for** `/var/log/apache/*`, your allowlist must include one of the following:

- `!/var/log/apache/*`
- `!*/apache/*`
- `!*/log/apache/*`

Wildcards (`*`) match **any** part of the file path, including path separators. This behavior differs from a typical shell glob, where `*` matches only within a single directory level.

- `*log` matches `/var/foo/bar/myfile.log`.
- `*.log` matches anything ending in `.log`.
- `/var/log/*` matches anything in `/var/log`, subject to the **Max Depth** setting.

Put explicit matches (and exclusions) at the beginning of the allowlist, ahead of wildcard matches.

For example, an allowlist of `/var/log/*` followed by `!/var/log/apache/*` will fail to exclude the file `/var/log/apache/foo` because that file matches the first allowlist entry.

In allowlists, order matters!

Be as specific as possible, whenever possible, to prevent accidental matches.

Each of the following examples shows how to avoid matching unwanted files within the directories that you're monitoring.

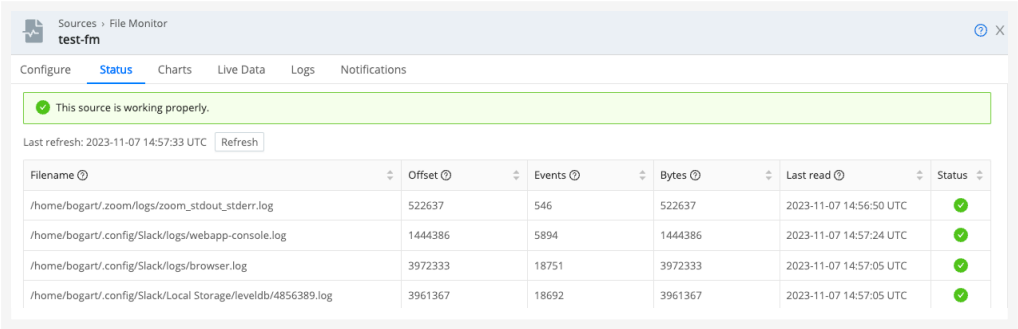
To collect `/var/log/boot.log` (and older versions of `boot.log.*`) as well as `/var/log/messages`:

Search path	Filename allowlist
`/var/log`	`/var/log/boot.log`, `/var/log/messages`

To collect everything in `/var/log` while excluding `/var/log/apache/*`:

Search path	Filename allowlist
`/var/log`	`!/var/log/apache/*`, `/var/log/*`

Examples of Allowlists



Below are typical scenarios where good allowlist technique will save you from duplication headaches.

Example: Excluding the System's Own Logs

Suppose you added a File Monitor Source on a Linux machine, set your **Discovery Mode** to **Manual**, and specified your home directory as the **Search path** (for example, `/home/bogart/`).

You do not want to monitor Cribl Edge's own log files, or any log files generated by Chrome, the web browser you're using. To exclude them, you add `!*cribl*access.log` and `!*chrome*` to your **Allowlist**. You **do** want to monitor any other log files that the Source can discover, so you also add `*log`.

After awhile, the Status tab looks like this:

The Status tab

Example: Fixing Overlapping Monitor Groups

Here's an example of the kind of overlapping monitor groups you should avoid:

Search path	Max depth	Filename allowlist
`/var`	(none)	`*/log/*`
`/var/log/apache`	`0`	`*`

The above configuration would collect all the files in `/var/log/apache/` twice. A better solution would be the following:

Search path	Max depth	Filename allowlist
`/var/log`	(none)	`!*/apache/*`
`/var/log/apache`	`0`	`*`

Troubleshooting

Common mistakes to avoid when exploring the File Monitor Source include the following.

Don’t Manually Edit Ingested Files

Do not test the File Monitor Source by editing and saving files using a text editor (such as vi or Notepad). Under the hood, these editors operate on a temporary file that they move into place when saved. As a result, the Source sees files get replaced and moved rather than appended to. This confuses the Source’s logic that assumes logs are appended to the existing file.

Instead, to test the Fole Monitor Source, run the command below to append logs to files: `echo "{ \"time\":\"$(date -Is -u)\", \"message\":\"...\" }" >> eg.log`

You end up with lines like this in the logs:

```
{ "time":"2023-09-19T20:08:42+00:00", "message":"..." }
```

Test File Ingestion with Event Breakers

To make sure that incoming files are split into individual events as expected, test sample file content with Event Breakers. When you configure the Event Breaker Ruleset, configure the timestamp correctly and verify that it

12.2.1.3. Journal Files Source

The Journal Files Source collects data from systemd's centralized logging, which is called the journald service. This service is a centralized location for all messages logged by different components in a systemd-enabled Linux system. This includes messages from kernel, boot, syslog, or other services. This Source is currently configured to collect data from the `user` journal, as `system` is privileged. This Source is disabled by default.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **No**

Discovering and Filtering Journal Files to Monitor

To determine all the names of all journals to read, the Journal Files Source runs a discovery procedure at a configurable **Polling interval**. The Source then applies an **Allowed list** to filter the initial list down into its final form. Then, for each journal on the list, the Source compares current state with previously stored state. This comparison determines whether the Journal Files Source will actually stream a given journal for a given polling interval. The Source then runs the files through the **Filter Rules** which allows you to set additional criteria.

Cribl Edge ships with a single, disabled instance of the Journal Files Source with a default configuration. The search path is configured to point to `$CRIBL_EDGE_FS_ROOT/var/log/journal/$MACHINE_ID` and defaults to streaming the primary `system.journal` it finds there. `$MACHINE_ID` is an environment variable that you can insert into the Source's search path. If you use the environment variable but don't assign a value, the Source will look up the local host `machine id` from `/etc/machine-id` and use that value.

Currently, this Source does not support all of the compression options that the journald service supports. The parser this Source uses to read the files can handle `LZ4` and `ZSTD` compression. When the parser encounters compressed fields it can't unpack, an error message emits in the logs. Below is an example of the error message:

```
Error reading journald event, dropping offset=31678152 evt="Mar 02 21:29:54
goats-xps15 multipassd: undefined"
```

Configure a Journal Files Source

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.

- To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.

2. In the **New Source** modal, configure the following under **General Settings**:
   - **Enabled**: Toggle on to enable the Source.
   - **Input ID**: Enter a unique name to identify this Source configuration. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
   - **Description**: Optionally, enter a description.
   - **Search path**: Specify the directory to search journals on. Accepts environment variables. The default value for this field varies depending on the product:
     - In Cribl Edge, it defaults to `$CRIBL_EDGE_FS_ROOT/var/log/journal/$MACHINE_ID`.
     - In Cribl Stream, it defaults to `/var/log/journal/$MACHINE_ID`.
   - **Suppress errors when search path does not exist**: Toggle on to hide `Path does not exist` errors when a directory doesn't exist. When enabled, missing directories will not affect the Journal Files Source health status. This is useful when you know the search path contains nonexistent directories for some hosts, and you don't want to see the error messages in the Source status and logs.
   - **Journal allowlist**: The full path of each discovered journal is matched against this wildcard list. Defaults to `system`.
3. Next, you can configure the following **Optional Settings**:
   - **Polling interval**: How often, in seconds, to collect metrics. If not specified, defaults to `10` seconds.
   - **Filter Rules**: Optionally, specify which journal objects to allow. Events are generated if all the rules' expressions evaluate to true, or if no rules are specified.
   - **Filter expression**: JavaScript expression to filter Journal objects. Returns `true` to include it. For details, see Filter Expressions below.
   - **Description**: Optional description of the rule.
   - **Current boot only**: Default is toggled on. When enabled, skips events that are not part of the current boot session.
   - **Age duration limit**: Optionally, specify a maximum age of journal objects to stream. This Source will filter events with timestamps newer than the configured duration. Enter a duration in a format like `30s`, `4h`, `3d`, or `1w`. Defaults to an empty field, which applies no age filters.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Filter Expressions

The default **Filter expression** is `severity <= 4` with a **Description** of `Allow events having 'emergency', 'alert', 'critical', 'error', or 'warning' priority.`

`The screenshot below shows other examples you can use:`

Filter expressions

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

Advanced Settings {advanced-tab}

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

In Cribl Edge, this Source defaults to QuickConnect. While, in Cribl Stream, it defaults to Send to Routes.

12.2.1.4. Kubernetes Events Source

The Kubernetes Events Source relies on the Kubernetes API watch capabilities to collect cluster-level events. These events are generated automatically in response to state changes or errors with nodes, pods, and containers. The Kubernetes API server acts as a notification server for the events we are watching in a given Kubernetes cluster. This Source acts in a listener/subscriber capacity to collect events for all namespaces from the cluster API. For a sample of the events captured, see Live Data.

To collect cluster-level events, the Kubernetes Events Source needs watch access to the Kubernetes API. For details, see RBAC for Kubernetes Events Source.

Type: **System and Internal** | TLS Support: **N/A** | Event Breaker Support: **No**

You can't configure custom Kubernetes Events Sources.

Discover and Filter Kubernetes Events

The Kubernetes Events Source connects to the Kubernetes API to set up a watch, and to request a starting point from the latest event at 5-minute polling intervals. The Source then runs the lists through the **Filter Rules** to determine what to report on.

This Source emits events in a way that might include some redundancies in the properties extracted. For details on the output, plus guidelines on what fields to drop, see Event Structure Details.

If no rules are configured, or if all of the rules evaluate to `true`, this Source generates events for the object. Conversely, if any of the rules evaluates to `false`, this Source skips the object, and does not generate any events for it.

Cluster/Daemonset Best Practices

For the Kubernetes Events Source to work as designed, Cribl recommends deploying Cribl Edge as a Daemonset. For details, see Deploying via Kubernetes.

This Source can generate redundant events when it is running inside the cluster, and can't determine which DaemonSet it's in or which Node it's on. This happens when you run Cribl Edge inside the cluster, but in a way that it can't detect the local Pod/node. In these cases, Edge will emit an error when it initializes this Source.

Configure Cribl Edge to Collect Kubernetes Events

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:

- To configure via QuickConnect, navigate to **Collect**. Select **Add Source** and select the Source you want from the list, then choose **Select Existing**.
- To configure via the Routes, select **More** > **Sources**. Select the Source you want.

2. Select the default `in_kube_events` to open the configuration modal.
3. Configure the following under **General Settings**:
   - **Input ID**: This is prefilled with the default value `in_kube_events`, which cannot be changed via the UI, due to the single-Source restrictions above.
   - **Description**: Optionally, enter a description.
4. Next, you can configure the following **Optional Settings**:
   - **Filter Rules**: Optionally, specify the Kubernetes objects which this Source should parse to generate events. If you specify no restrictive rules here, the Source will emit all events.
   - **Filter expression**: JavaScript expression to filter Event objects. For details, see Filter Expression below.
   - **Description**: Optional description of the rule.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, configure any Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Filter Expression

Filters are based on the Event Objects, and evaluated from top to bottom. The first expression evaluating to `false` excludes the Pod from collection.

Filter expressions examples include:

- Ignores events in the `kube-*` namespaces - `!object.metadata.namespace.startWith('kube-')`
- Ignore all events from DaemonSet - `object.regarding.kind != 'DaemonSet'`
- Collects events matching a specific object name - `object.regarding.name == 'object name'`

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

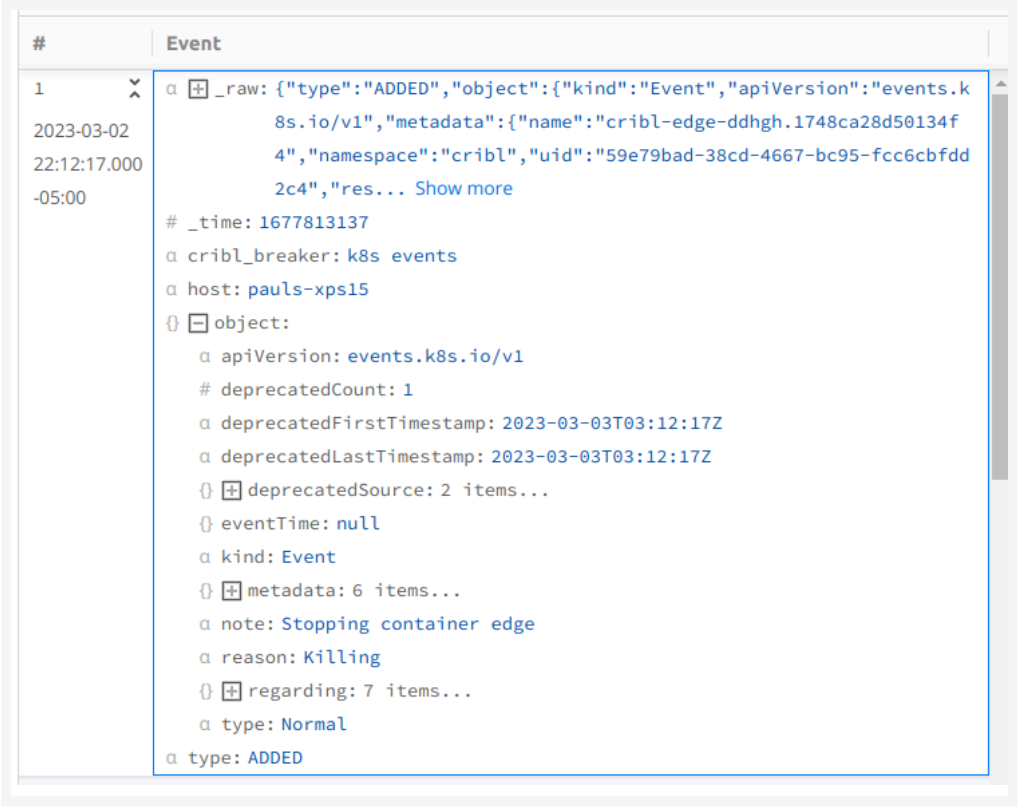
This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

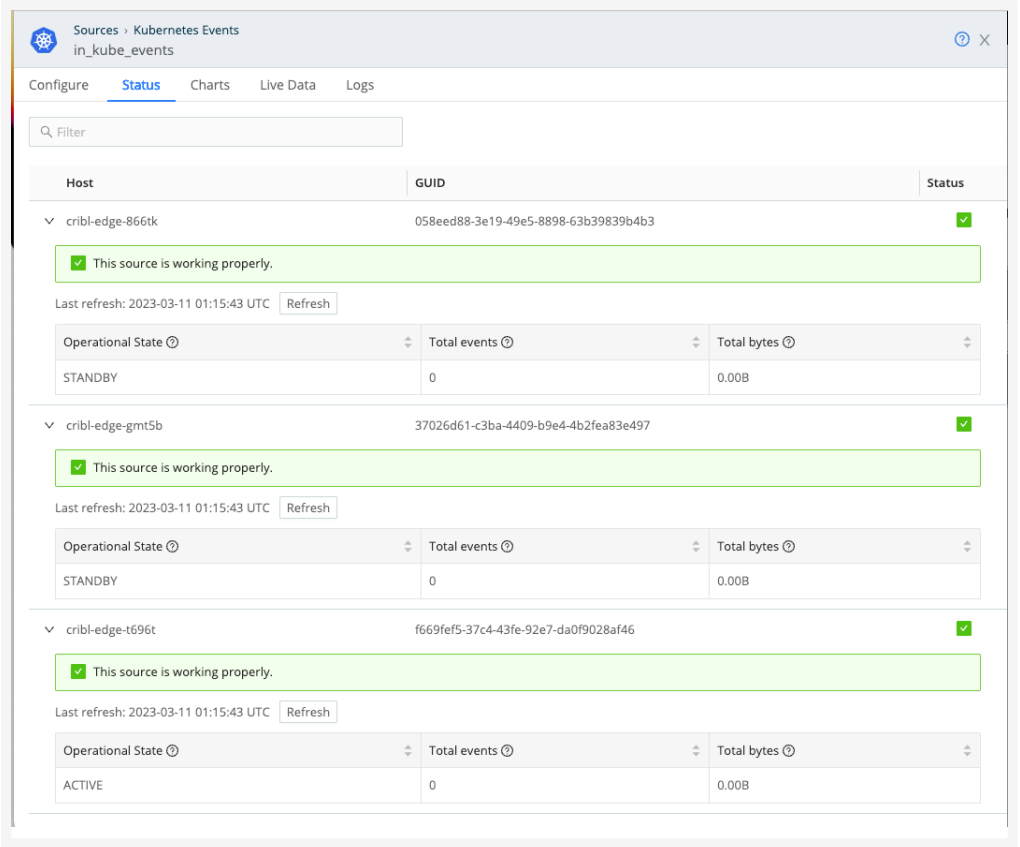


Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Event Structure Details

This Source emits a `_raw` property as a JSON-encoded object, as other Sources do. However, there are additional `object` and `type` properties from that extraction. The logic behind this is that `timestamp` and other fields had to be extracted to keep track of starting points.



If you are sending the events over a metered connection, then you will get three copies of the same data: `_raw`, `__raw`, and the extracted `object` fields. Consider dropping the redundant fields before sending them to your Destination(s).

Sample Event

Source Operational State

To check the Source's operational state, go to **Status** and expand the host details. The **Operational State** Column shows either an **Active** state or **Standby**. **Active** indicates the Source is running or won the election. **Standby** means it's waiting to be re-elected and not currently running.

12.2.1.5. Kubernetes Logs Source

The Kubernetes Logs Source collects logs from containers on a Kubernetes node. Optionally, you can filter and enrich incoming logs. You must authorize this Source to access the Pods in all namespaces. For details, see RBAC for Kubernetes Logs Source.

Type: **System and Internal** | TLS Support: **N/A** | Event Breaker Support: **Yes** | Uses Key-Value Store

You can't configure custom Kubernetes Logs Sources.

Discover and Filter Kubernetes Pods to Monitor

The Kubernetes Logs Source connects to the Kubernetes Cluster API for metadata and to the kubelet API on the local node to discover Pods. The connection happens on a configurable **Polling interval**. The Source then runs the Pods through the **Filter Rules** to determine which ones to report on.

If no rules are configured, or if all of the rules evaluate to `true`, the Source generates logs for the Pod's containers. Conversely, if any of the rules evaluate to `false`, the Source skips the Pod's containers, and does not generate any logs for it.

The Kubernetes Logs Source can also collect logs from long-running sidecar containers (available from Kubernetes v1.33), but not init or other short-running containers.

To visualize and analyze these Kubernetes logs in more detail, consider using the Kubernetes Explorer UI in Cribl Edge. You can preview logs by navigating to the **Logs** view, filtering logs, and defining event breakers.

Cluster/Daemonset Best Practices

For the Kubernetes Logs Source to work as designed, Cribl recommends deploying Cribl Edge as a Daemonset. For details, see Deploying via Kubernetes.

This Source will refuse to run when it connects to the cluster API instead of to the `kubelet` on the local node. This happens when you run Cribl Edge outside of the cluster; or when you deploy it inside the cluster, but in a way that it can't detect the local Pod/node. In these cases, Edge will emit an error when it initializes this Source.

Configure Cribl Edge to Collect Kubernetes Logs

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Collect**. Select **Add Source** and select the Source you want from the list, then choose **Select Existing**.

- To configure via the Routes, select **More** > **Sources**. Select the Source you want.

2. Select the default `in_kube_logs` to open the configuration modal.
3. Configure the following under **General Settings**:
   - **Input ID**: This is prefilled with the default value `in_kube_logs`, which cannot be changed via the UI, due to the single-Source restrictions above.
   - **Description**: Optionally, enter a description.
4. Next, you can configure the following **Optional Settings**:
   - **Polling interval**: How often, in seconds, to collect metrics. If not specified, defaults to `15` seconds. For considerations, see Polling Interval and Log Rotation below.
   - **Filter Rules**: Optionally, specify the Kubernetes Pods that this Source should parse to generate logs. If you specify no restrictive rules here, the Source will emit all events.
   - **Filter expression**: JavaScript expression to filter Kubernetes Pod objects. For details, see Filter Expression below.
   - **Enable timestamps**: When toggled on, Cribl Edge prefixes a timestamp to each line of the container's raw console output. When you enable timestamps, you must select the `kubernetes_logs` pre-processing Pipeline. This Pipeline removes conflicting timestamps prepended by the Source. This combination is designed for working with containers whose console output lacks proper timestamps (either because the timestamps are missing altogether or because they specify time only but not date).
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, configure any Processing, Disk Spooling, and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

The Kubernetes Logs Source only collects logs from running containers, which means it can miss logs from short-lived containers or those that exit before they start running.

Polling Interval and Log Rotation

The Kubernetes Logs Source polls the kubelet on the local node. This operation is lightweight and has minimal performance impact. However, the polling interval is crucial for capturing all log data, especially when dealing with high log volumes and frequent log rotations.

During each poll, the Source not only discovers new Pods, but also checks existing log streams for stalls, which can occur due to container runtime log rotations. If a log rotation happens more than once between polls, one or more rotated log files will be missed, resulting in log loss.

To prevent log loss, set the **Polling interval** value to shorter than the log rotation time. For example, given a `10` second rotation interval, a polling interval closer to `5` seconds, would be more appropriate. This is because if two rotations occur within a single polling window, log data can be lost.

While Kubernetes 1.29 mitigates log rotation issues, polling intervals still matter. Long intervals can cause missed logs, especially from short-lived containers that start and stop between polls. Consider adjusting the **containerLogMaxSize** setting to prevent excessive log rotations by Kubernetes itself. This can help reduce the frequency of rotations and lessen the chance of missing logs due to polling intervals.

Filter Expression

You can use filter expressions to match specific patterns in log messages, labels, or namespaces. The filter expressions are applied to all Edge Nodes, so carefully configure these expressions to match your specific requirements.

Filters are based on the Kubernetes Pod Object definition, and evaluated from top to bottom. The first expression evaluating to `false` excludes the Pod from collection. The default filter is `!metadata.namespace.startsWith('kube-')`, which ignores Pods in the kube-* namespace.

Other **Filter expressions** examples include:

- Collect logs from Pods on a specific Node - `spec.nodeName == 'node1'`
- Ignore all DaemonSets - `metadata.ownerReferences[0].kind != 'DaemonSet'`
- Ignore Pods with specific Container names - `spec.containers[0].name != 'edge'`
- **Description**: Optional description of the rule.

Pods are either included or excluded entirely based on the Filter Rules.

Processing Settings

Event Breakers

This section defines event breaking rulesets that will be applied, in order, on the `/raw` endpoint.

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec.), maximum `43200000` (12 hours).

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Select a **Pipeline** (or Pack) from the drop-down to process this Source's data. Required to configure this Source via **Data Routes**; optional to configure via **Collect/QuickConnect**.

Disk Spooling

Enable disk spooling to search for spooled Kubernetes logs directly from Edge Nodes, without needing to forward specific logs to a Destination for storage first.

Data buckets are partitioned into subdirectories for Pods and containers, but it will be faster to search for your data by Pods.

Enable disk spooling: Determine whether or not to save Kubernetes logs to disk. When set to **Yes**, the configuration fields below become available.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`). Kubernetes logs are high-volume, so consider the time span you enter here (as a long time span could cause the disk to fill up quickly).

Data size limit: This is the maximum amount of disk space that spooled data is allowed to consume. Once data reaches this amount, Edge will delete data starting with the oldest buckets.

Data age limit: The duration of time for which Cribl Edge will retain data. Edge will delete data that exceeds the max age entered in this field. Example values are `2h`, `4d`. The default value is 24 hours (`24h`).

Compression: The codec that Edge uses to compress the data. The default is `gzip`.

Cribl Edge will write events to the default location:

`$CRIBL_SPOOL_DIR/in/kube_logs/{inputId}/{timeBucket}/{namespace}/{pod}/{container}`

By default, By default, `$CRIBL_SPOOL_DIR` points to `$CRIBL_HOME/state/spool`.

To change the base spool path, use the `CRIBL_SPOOL_DIR` environment variable.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Enable load balancing: To handle high volumes of Kubernetes logs, enable load balancing. This improves the events per second (EPS) ingest rate, and is helpful when you need to ingest more Kubernetes logs EPS than a single Worker Process can handle.

When you enable this toggle, you should also increase the number of Worker Processes in Fleet Settings. The number of Worker Processes for load balancing depends on your Kubernetes log ingest volume. To ingest 40k EPS, try starting with two or four Worker Processes, then increase if needed.

Line buffer limit: Maximum number of bytes the Source will buffer while reassembling a single log line. If a line exceeds this limit, Cribl Edge flushes the buffered data as is, either as a complete line or a partial line. Defaults to `1048576` bytes (`1 MB`).

Increase this value when containers emit large logs where any individual line might exceed 1MB.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

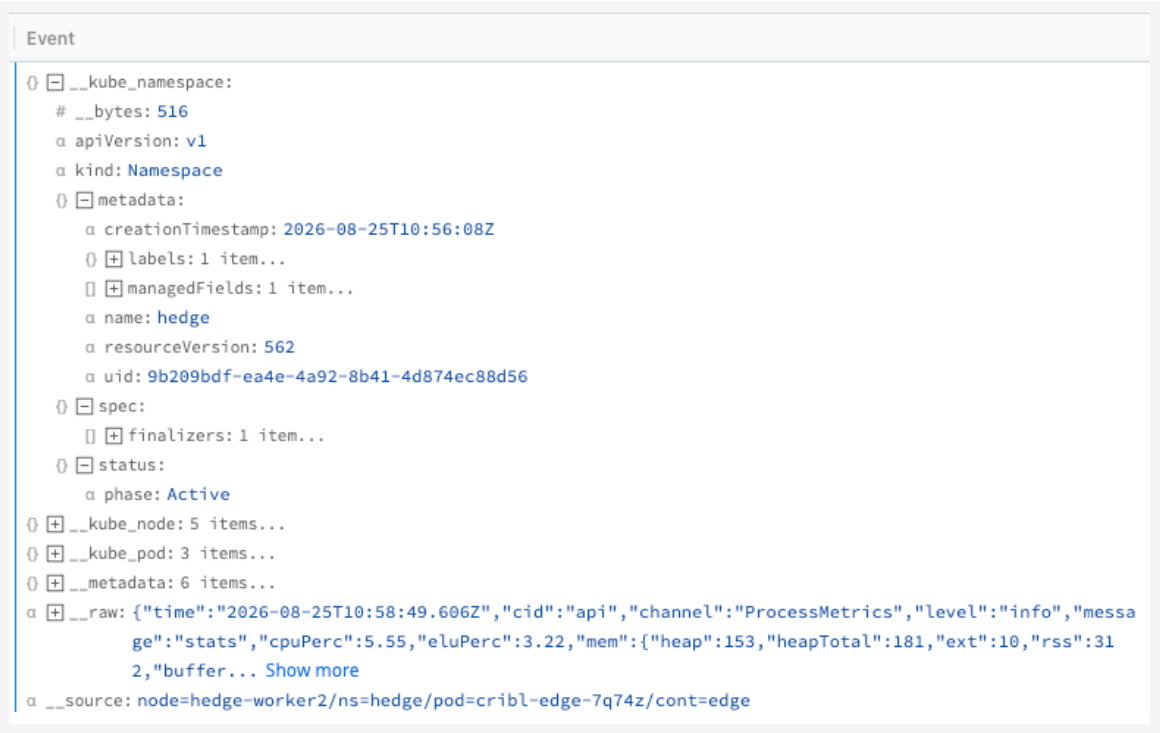
Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

These are the full objects from the Kubernetes API, showing the namespace, node, and Pod where the log originated:

- `__channel`
- `__extractedTime`
- `__final`
- `__isBroken`

- `__kube_namespace`
- `__kube_node`
- `__kube_pod`
- `__raw`
- `__source`
- `_raw`
- `_time`

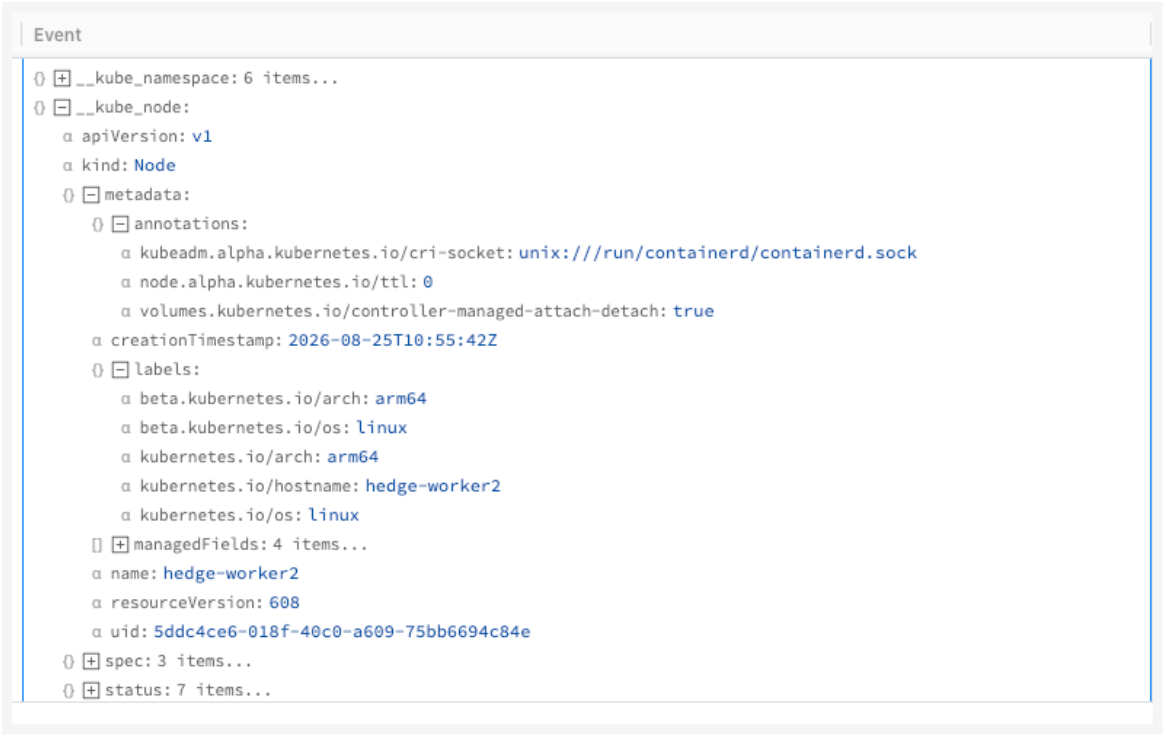
For details, see Objects in Kubernetes.



Key-Value Store

The Kubernetes Logs Source uses key-value store for container information. Container IDs are used as.

Sample Log Event



The following screenshots show the `__kube` objects corresponding to a sample log event.

Pod Metadata

Pod Metadata

12.2.1.6. Kubernetes Metrics Source

The Kubernetes Metrics Source generates events periodically based on the status and configuration of a Kubernetes cluster and its nodes, pods, and containers. For metrics details, see Kubernetes Metrics Details.

For a sample of the events this Source emits, see Live Data.

You must authorize this Source to read metric information from many resources in your cluster. For details, see RBAC for Kubernetes Metrics Source.

Type: **System and Internal** | TLS Support: **N/A** | Event Breaker Support: **No**

You can't configure custom Kubernetes Metrics Sources.

Discover and Filter Kubernetes Objects to Monitor

The Kubernetes Metrics Source connects to the Kubernetes API and loads the lists of K8s nodes, Pods, and containers in the cluster, on a configurable **Polling interval**. The Source then runs the lists through the **Filter Rules** to determine what to report on.

If no rules are configured, or if all of the rules evaluate to `true`, the Source generates metrics for the object. Conversely, if any of the rules evaluates to `false`, the Source skips the object, and does not generate any metrics for it.

Cluster/Daemonset Best Practices

For the Kubernetes Metrics Source to work as designed, Cribl recommends deploying Cribl Edge as a Daemonset. For details, see Deploying via Kubernetes.

This Source can generate redundant events when running inside the cluster and it isn't able to determine which DaemonSet it's in or which Node it's on. This happens when you run Cribl Edge inside the cluster, but in a way that it can't detect the local Pod/node. In these cases, Edge will emit an error when it initializes this Source.

Configure Cribl Edge to Collect Kubernetes Metrics

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Collect**. Select **Add Source** and select the Source you want from the list, then choose **Select Existing**.
    - To configure via the Routes, select **More** > **Sources**. Select the Source you want.

2. Select the default `in_kube_metrics` to open the configuration modal.
3. Configure the following under **General Settings**:
    - **Input ID**: This is prefilled with the default value `in_kube_metrics`, which cannot be changed via the UI, due to the single-Source restrictions above.
    - **Description**: Optionally, enter a description.
4. Next, you can configure the following **Optional Settings**:
    - **Polling interval**: How often, in seconds, to collect metrics. If not specified, defaults to `15s`.
    - **Collect kubelet metrics**: Toggle on to scrape kubelet metrics from `https://<nodeIP>:10250/metrics`. Requires Cribl Edge to run as a DaemonSet with direct network access to the node.
    - **Collect cAdvisor metrics**: Toggle on to scrape cAdvisor container metrics from `https://<nodeIP>:10250/metrics/cadvisor`. Requires Cribl Edge to run as a DaemonSet with direct network access to the node.
    - **Filter Rules**: Optionally, specify the Kubernetes objects which this Source should parse to generate events. If you specify no restrictive rules here, the Source will emit all events.
    - **Filter expression**: JavaScript expression to filter Kubernetes objects. For details, see Filter Expression below.
    - **Description**: Optional description of the rule.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, configure any Processing, Disk Spooling, and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Filter Expression

Filters are based on the Kubernetes Pod Object definition, and evaluated from top to bottom. The first expression evaluating to `false` excludes the Pod from collection. The default filter is `!metadata.namespace.startsWith('kube-')`, which ignores Pods in the kube-* namespace.

Other **Filter expressions** examples include:

- Collect metrics from Pods on a specific Node - `spec.nodeName == 'node1'`
- Ignore all DaemonSets - `metadata.ownerReferences[0].kind != 'DaemonSet'`
- Ignore Pods with specific Container names - `spec.containers[0].name != 'edge'`

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Select a **Pipeline** (or Pack) from the drop-down to process this Source's data. Required to configure this Source via **Data Routes**; optional to configure via **Collect/QuickConnect**.

Disk Spooling

Enable disk persistence: Whether to save metrics to disk. Toggle on to expose this section's remaining fields.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`).

Max data size: Maximum disk space the persistent metrics can consume. Once reached, Cribl Edge will delete older data. Example values: `420 MB`, `4 GB`. Default value: `100 MB`.

Max data age: How long to retain data. Once reached, Cribl Edge will delete older data. Example values: `2h`, `4d`. Default value: `24h` (24 hours).

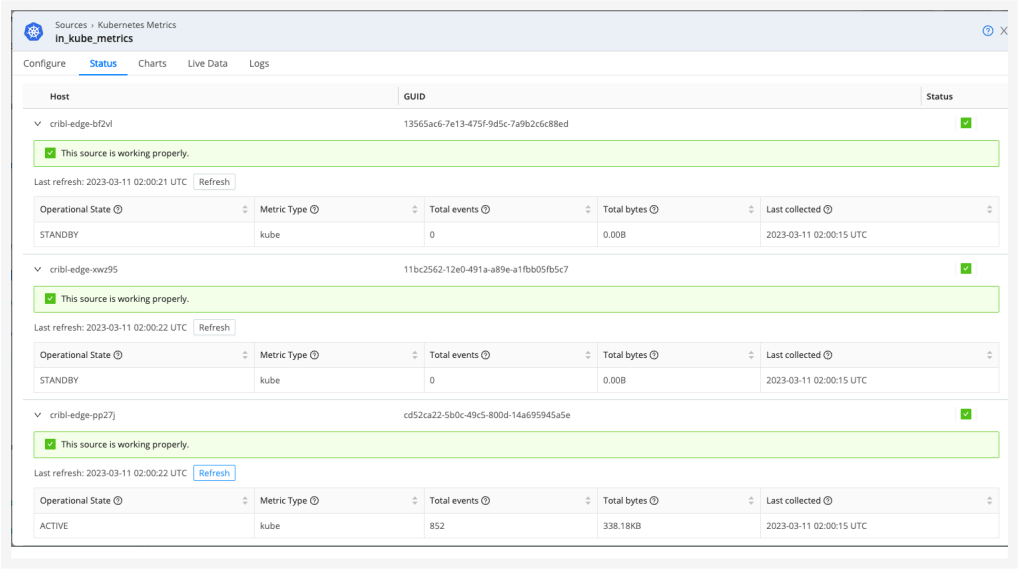
Compression: Optionally compress the data before sending. Defaults to `gzip` compression. Select `none` to send uncompressed data.

Path location: Path to write metrics to. Default value is `$CRIBL_HOME/state/kube_metrics`.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

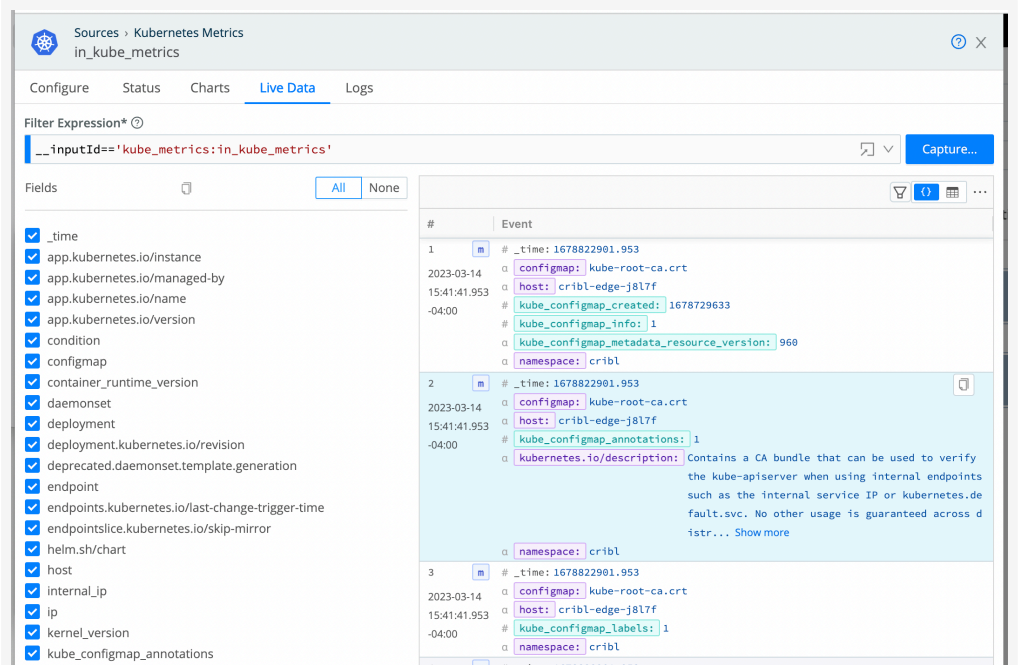


Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Source Operational State

To avoid collecting the same metrics from multiple nodes, the Kubernetes Metrics Source uses an election method to collect metrics from only one node. The election happens every 5 minutes on all of the nodes, and the oldest node in the cluster wins.



To check which node is being polled, go to **Status** and expand the host details. The **Operational State** Column shows either an **Active** state or **Standby**. **Active** indicates the host is running or won the election. **Standby** means it's waiting to be re-elected and not currently running.

Operational State

Source Live Data

To see a sample of the Source's data, select the **Live Data** tab.

12.2.1.7. System Metrics Source

Cribl Edge instances can collect metrics from their hosts (on Linux and, in Cribl Edge, on macOS), and can populate some standard metrics dashboards right out of the box. To see all of the metrics this Source supports, check out Linux System Metrics Details and MacOS System Metrics Details.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **No**

Cribl Edge Nodes support the System Metrics Source only when running on Linux on macOS. To collect metrics from Windows hosts, use the Windows Metrics Source.

Prerequisites

In order to collect Nvidia GPU metrics using the System Metrics Source, install Nvidia drivers, together with the included `nvidia-smi` utility.

Configure Cribl Edge to Collect System Metrics

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `in_system_metrics`, which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
3. Next, you can configure the following **Optional Settings**:
    - **Polling interval**: How often to collect metrics, in seconds. Defaults to `10`.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can configure metrics for Host, Process, Container, or adjust Processing, Advanced settings and Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Host Metrics

Use the buttons to select a level of detail.

- **Basic** enables minimal metrics, averaged or aggregated.
- **All** enables full, detailed metrics, specified for individual CPUs, interfaces, and so on.
- **Custom** displays sub-menus and buttons from which you can choose a level of detail (**Basic**, **All**, **Custom**, or **Disabled**) for each type of event.
- **Disabled** means that no metrics will be generated.

The meaning of **All** and **Disabled** are self-evident. **Basic** and **Custom** have different meanings depending on event type, as follows:

System

Basic level captures load averages, uptime, and CPU count.

Custom toggles **Process** metrics on or off; these are metrics for the numbers of processes in various states.

CPU

Basic level captures active, user, system, idle, iowait percentages over all CPUs.

Custom toggles the following on or off: **Per CPU metrics**, **Detailed metrics** (meaning, for all CPU states), and **CPU time metrics** (meaning raw, monotonic CPU time counters).

Memory

Basic level captures captures total, used, available, `swap_free`, and `swap_total`.

Custom toggles **Detailed metrics** on or off. Detailed means for all memory states.

Network

Basic level captures bytes, packets, errors, connections over all interfaces.

Custom exposes the following:

- The **Interface filter**, which specifies which network interfaces to include or exclude (all are included if the filter is empty).
- **Per-interface metrics**, which toggle on or off.

- **Detailed metrics**, which toggle on or off. If on, the **Protocol metrics** toggle appears, allowing you to choose whether to generate metrics for ICMP, ICMPMsg, IP, TCP, UDP, and UDPLite.

Disk

Basic level captures disk used in percent, bytes read and written, and read and write operations, over all mounted disks.

Custom exposes the following:

- The **Device filter**, which specifies which block devices to include or exclude (all are included if the filter is empty). Wildcards and ! (not) operators are supported.
- The **Mountpoint filter**, which specifies which filesystem mountpoints to include or exclude (all are included if the filter is empty). Wildcards and ! (not) operators are supported.
- The **Filesystem type filter**, which specifies which filesystem types to include or exclude (all are included if the filter is empty). Wildcards and ! (not) operators are supported.
- **Per-device metrics**, which toggle on or off.
- **Detailed metrics**, which toggle on or off. If on, the **Enable inode metrics** toggle appears, allowing you to choose whether to generate metrics for filesystem inodes.

Process Metrics

With Process Metrics enabled, Cribl Edge captures process-specific metrics from Linux and macOS servers and reports them as events. This allows you to monitor specific processes on Cribl.Cloud instances. You can generate events for any process object.

To collect a process metrics event, create a Process Set and add a filter expression. Processes that match the filter are returned as individual events. See Collecting Metrics. Process Sets are separate from aggregate and host-wide metrics.

Process-specific metrics are **not** affected by the **Host Metrics** detail setting.

Adding a Process Set

To add a Process Set:

1. Open the System Metrics Source and access the **Configure** tab.
2. Select the **Process Metrics** menu, then **Add Process Set**.
3. Configure the details:
    - **Set Name**: The name for this process set.
    - **Filter Expression**: The JavaScript expression that will filter the processes.

- **Include Child Processes**: When toggled on, the processes that match the filter include metrics for child processes.

Filtering Processes

You can filter processes using the field names and values from each process object.

Tip

To see all processes currently running on an Edge Node, select **Explore** in the submenu and open the Processes Tab.

Example filters

This filter looks for Java processes in the sleep state (an interruptible wait) that are using more than 100% of the CPU or more than 25% of memory:

```
cmdline.args[0] == 'java' && status == 'S' && (cpu > 100 || memory_percent > 25)
```

This filter looks for running NGINX web servers that have more than 12 open file descriptors:

```
service == 'nginx' && fds > 12
```

Here are some more Linux processes you could find metrics for:

- `cmdline.args[0].endsWith('/java') && cmdline.args[1] == 'nifi'`
- `exe.path == '/usr/bin/sshd'`
- `uid == 2`
- `cgroup.0 == /user.slice/user-1000.slice/`
- `stat.status == R`
- `stat.starttime > 943517`
- `cpu > 30`
- `memory_percent > 30`
- `stat.num_threads > 10`

The **Filter expression** field expects a specific syntax in order to apply the filter to the processes. These expressions evaluate to either `true` or `false`. See Build Custom Logic to Route and Process Your Data: Filter Expressions for more information.

Collecting Metrics

Once you have at least one Process Set created and saved, Cribl Edge will begin collecting process metrics at the interval defined in the **Polling interval** field (**General Settings** menu).

To view the status of the Collector and total events collected, click the **Status** tab in the System Metrics Source.

To view a live capture of individual metrics gathered from processes that match the Process Set, click the **Live Data** tab. The Process Set that owns each metric is represented by the `__process_set` internal field.

Supported Processes

To view the complete table of supported process metrics, their descriptions, types, and dimensions, see Process-Specific Metrics for Linux and macOS.

Using Advanced Mode

To test your filter expression against a sample input, click the **Advanced mode** button within the **Filter expression** field. The **Filter expression** modal will open. See Test and Validate Expressions in Advanced Mode for more information.

Container Metrics

Use the buttons to select a level of detail.

- **Basic** generates the server event and per running container events.
- **All** adds per-device and detailed metrics.
- **Custom** provides controls for customizing which containers to generate metrics from.
- **Disabled** means that no metrics will be generated.

The **Custom** buttons displays additional controls, as follows:

- **Container filters**: Enter a filter expression to govern which containers to generate metrics from. Leave empty (the default) to generate metrics from all containers.
- **All containers**: Toggle on to include stopped and paused containers.
- **Per-device metrics**: Toggle on to generate separate metrics for each device.
- **Detailed metrics**: Toggle on to generate full container metrics.

The **Basic**, **All**, and **Custom** buttons provide the following **Advanced Settings**, which are different from those in the main **Advanced Settings** tab:

- **Docker socket**: Enter the full path(s) for Docker's UNIX domain socket. Defaults to `/var/run/docker.sock` and `/run/docker.sock`.
- **Docker timeout**: Timeout, in seconds, for the Docker API. Defaults to `5`.

GPU Metrics

GPU Metrics track the usage of Nvidia GPUs.

Use the buttons to select a level of detail.

- **Basic** enables capturing basic metrics, such as temperature, GPU utilization, and memory utilization.
- **All** enables full, detailed metrics.
- **Custom** enables the following toggles:
    - **Per GPU metrics** collects metrics per individual GPU.
    - **Detailed metrics** collects metrics for all known GPU metrics.
- **Disabled** means that no metrics will be generated.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

If desired, choose a **Pipeline** from the drop-down if you want to process data from this Source before sending it through the Routes.

Disk Spooling

Enable disk spooling: Whether to save metrics to disk. When toggled on, exposes this section's remaining fields.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`).

Data size limit: Maximum disk space the persistent metrics can consume. Once reached, Cribl Edge will delete older data. Example values: `420 MB`, `4 GB`. Default value: `100 MB`.

Data age limit: How long to retain data. Once reached, Cribl Edge will delete older data. Example values: `2h`, `4d`. Default value: `24h` (24 hours).

Data compression format: Optionally compress the data before sending. Defaults to `gzip` compression. Select `none` to send uncompressed data.

Path location: Path to write metrics to. Default value is `$CRIBL_HOME/state/system_metrics`.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Populating Dashboards with System Metrics

Cribl has configured a Prometheus dashboard to display Cribl Edge System Metrics, and shared the dashboard in the Grafana library, which is public. This is a relatively simple dashboard suitable for showing aggregate metrics. Try this dashboard if you prefer **Basic** mode for most of your metrics.

Another useful dashboard is the one that's commonly used with Prometheus and their Node Exporter agent, found here. This dashboard can handle the highly detailed metrics. To use this dashboard, attach the `prometheus_metrics` pre-processing pipeline, and choose **All** mode.

For details on how populate your Grafana Cloud dashboards with system metrics, see System Metrics to

12.2.1.8. System State Source

The System State Source collects snapshots of the host system's current state, on a configurable schedule, and sends them out as events to downstream systems for operational and security analytics.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **No**

Cribl Edge on macOS offers support for only a subset of System State collectors (see Cribl Edge on MacOS).

Configure Cribl Edge to Collect System State Events

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `in_system_state`, which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
3. Next, you can configure the following **Optional Settings**:
    - **Polling interval**: How often to collect metrics, in seconds. Defaults to `300`. Each run of the state collector generates events with identical `_time` values.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Collector, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Collector Settings

Cribl Edge contains the following System State collectors:

- Host Info
- Disks and File Systems
- DNS
- Firewall
- Hosts File
- Interfaces
- Listening Ports
- Logged-In Users
- Routes
- Services
- Users and Groups

Host Info

With the **Enabled** toggle on (the default), Cribl Edge will create events based on entries collected from the hosts file.

A partial list of Host Info events includes:

- `host`
- `hostOs` (when Cribl Edge is running in a container)
- `timestamp`
- `cribl.version`
- `cribl.mode`
- `cribl.group`
- `cribl.config_version`
- `os.arch`
- `os.cpu_count`

See the **Explore** > **System State** > **Host Info** UI for a full list of events.

The System State Source provides live system information, with most tabs updating periodically based on the **Polling Interval** configured in the Source. However, the data in the **Host Info** tab is collected

once when the Source is started and does not update dynamically.

Disks and File Systems

With the **Enabled** toggle on (the default), Cribl Edge will collect entries on physical disks, partitions, and mounted filesystems. These entries can help you monitor drive status, including available space, percent utilization, inode availability, wait times, and number of blocks free.

On Cribl Edge, this option is available for Windows and Linux. You must create a different Fleet for each OS. For details see, Mapping Edge Nodes to Fleets.

For each physical disk, Cribl Edge will collect:

- name
- size (in blocks)
- blockSize (in bytes)
- model
- serial
- firmware
- partitions (count)
- interface type

For each partition on a physical disk, Cribl Edge will collect:

- disk (name)
- disk ID (number)
- type (primary or logical)
- label
- offset
- size (in blocks)
- blockSize (in bytes)
- filesystem (mount point)

For each mounted filesystem, Cribl Edge will collect:

- mount point (path)
- disk (name)
- partition (ID)

- filesystem type
- size (in blocks)
- blockSize (in bytes)
- blocksFree
- inodes
- inodesFree
- flags

Mount point refers to the directory where a filesystem is currently mounted. This information reflects the active filesystems, not entries in the `/etc/fstab` file.

DNS

With the **Enabled** toggle on (the default), Cribl Edge will create events for DNS resolvers and search entries. The event field mapping depends on the operating system.

When Cribl Edge is deployed in a container, the **DNS** Collector does not collect any events.

Linux

Cribl Edge emits events with the following fields:

Event Field	Description
`nameServer`	Name server entries from the file.
`search`	Search entries from the file.
`source`	The source of the data used to populate the event.

Windows (Cribl Edge Only)

Cribl Edge on Windows emits events with the following fields:

Event Field	Description
`ifAlias`	Interface alias name (if present).
`ifIndex`	Interface index (if present).
`addressFamily`	IPv4 or IPv6.
`nameServer`	Array of name servers.

Event Field	Description
`search`	Array of search suffixes .
`source`	The source of the data used to populate the event.
`dnsClient`	Reports `MSFT_DnsClient` when the native WMI method is used (default). Reports `Get-DnsClient` when the **Use Windows Tools** toggle is enabled in **Advanced Settings**.

Hosts File

With the **Enabled** toggle on (the default), Cribl Edge will collect entries from the `hosts` file and emit them as events.

Examples of entries in the `hosts` file are:

- `ip`: IP address of the host.
- `hostnames`: list of hostnames per IP address.

Firewall

With the **Enabled** toggle on (the default), Cribl Edge will collect events from host's defined firewall rules.

Chain Policy/References Rule(s) Event Fields

Cribl Edge emits events with the following fields:

- `chain`: Name.
- `policy`: Policy name.
- `pkts`: Total bytes packets processed by the chain.
- `bytes`: Total bytes processed by the chain.
- `references`: Number of chains referencing the current chain.

Chain Rule(s) Event Fields

Cribl Edge emits events with the following fields:

- `chain`: Name.
- `num`: Rule sequence number.
- `pkts`: Number of matched messages processed.
- `bytes`: Cumulative packet size processed (bytes).
- `target`: If the message matches the rule, the specified target is executed.

- `prot`: The specified protocol can be one of `tcp`, `udp`, `udplite`, `icmp`, `icmpv6`, `esp`, `ah`, `sctp`, `mh`, or the special keyword `all`.
- `opt`: Rarely used, this column is used to display IP options.
- `in`: Inbound network interface.
- `out`: Outbound network interface.
- `src`: The source IP address or subnet of the traffic, the latter being anywhere.
- `dest`: The destination IP address or subnet of the traffic, or anywhere.
- `match`: `ctstate`, `state`, `ADDRTYPE` info added to a state field.
- `comment`: Comment defined on the rule.
- `prot_family`: `IPv4` or `IPv6`.

Windows (Cribl Edge Only)

On Cribl Edge Windows, this collector emits events with the following fields:

- `ruleName`: Rule Name.
- `displayName`: Display Name.
- `direction`: Specifies which direction of traffic to match with this rule. The acceptable values for this parameter are `Inbound` or `Outbound`.
- `enabled`: `True` or `False`.
- `action`: Specifies the action to take on traffic that matches this rule. The acceptable values for this parameter are `Allow` or `Block`.
- `group`: Specifies the rule group (if applicable).
- `icmpType`: Specifies the `ICMP` type used.
- `policyStoreSource`: Contains a path to the policy store where the rule originated.
- `profile`: Profile conditions associated with a rule.
- `protocol`: protocols associated with firewall and `IPsec` rules.
- `localPort`: Rules for local-only port mapping.
- `remotePort`: Rules for remote port mapping.

Interfaces

With the **Enabled** toggle on (the default), Cribl Edge will create events for each of the host's network interfaces.

Cribl Edge will create separate events for each entry. All events will have identical timestamp values.

Linux IPV4/IPV6

On Linux, Cribl Edge creates `interface` events with the following fields:

- `ifIndex`: Interface index identification numbers.
- `ifName`: The name of the network interface.
- `flags`: Flags.
- `mtu`: Maximum transmission unit (MTU) in bytes for packets sent on this interface.
- `operstate`: Operational State.
- `linkType`: Physical link type.
- `macAddress`: Media Access Control address.
- `broadcast` Broadcast address.
- `addrInfo`: Array of `{family, ipAddress, mask, prefix}`.

Windows (Cribl Edge Only): IPV4/IPV6

On Windows, Cribl Edge creates `interface` events with the following fields:

- `ifIndex`: Interface index identification numbers.
- `interface`: The name of the network interface.
- `mtu`: Maximum transmission unit (MTU) in bytes for packets sent on this interface.
- `flags`: Flags.
- `macAddress`: Media Access Control address.
- `addrInfo`: Array of `{family, ipAddress, mask, prefix}`.

Listening Ports

With the **Enabled** toggle on (the default), Cribl Edge will create events from the list of listening ports and their associated process identifier (pid).

Cribl Edge will create separate events for each entry. All events will have identical timestamp values.

Sample entries include:

- `Protocol Family`: `ipv4` or `ipv6`.
- `Protocol`: `TCP`, `UDP`, or `UNIX`.
- `Socket`: `${addr}:${port}`, or `${path}` for UNIX sockets.
- `Process id`: The process identifier.
- `Program`: The program listening on the port.

- `listeningPorts`: In Cribl Edge (Windows), reports `MSFT_NetTCPConnection` and `MSFT_NetUDPEndpoint` when the native WMI method is used (default). Reports `Get-NetTCPConnection` and `Get-NetUDPEndpoint` when the **Use Windows Tools** toggle is enabled in **Advanced Settings**.

Logged-In Users

With the **Enabled** toggle on (the default), Cribl Edge will collect entries from currently logged-in users.

Linux

Cribl Edge emits events with the following fields:

- `uid`: User ID.
- `Last Login date`: Last login date.
- `terminal`: Type of the terminal device.
- `hostname`: Display the hostname of the system, if the user is connected from a remote computer.
- `userName`: Logon name of the user.

Windows (Cribl Edge Only)

Cribl Edge Windows emits events with the following fields:

- `userName`: Login name of the user.
- `sessionName`: `rdp` (Remote desktop/terminal services login session) or `console` (Direct login session).
- `id`: Session ID.
- `state`: `active` (Active session) or `disc` (Disconnected/inactive session).
- `logonTime`: Date and time the user logged on.
- `source`: Set to `Query User`.

Routes

With the **Enabled** toggle on (the default), Cribl Edge will collect entries from host's network routes and emit them as events.

Sample entries include:

- `address_family`: `ipv4` or `ipv6`.
- `destination`: The destination network or host.
- `prefix`: Emits only from Linux IPv6.
- `flags`: Flags.

- `gateway`: The gateway address.
- `interface`: Interface to which packets for this route will be sent.
- `ifIndex`: Interface ID. Emits only from Windows.
- `mask`: The netmask for the destination net. Emits only from Linux IPv4.
- `metric`: The distance to the target.
- `sequence`: Sequence number in the table.
- `source`: The source of the data used to populate the event.
- `routes`: In Cribl Edge on Windows, reports as `MSFT_NetRoute` when the native WMI method is used (default). Reports `Get-NetRoute` when the **Use Windows Tools** toggle is enabled in **Advanced Settings**.

Services

With the **Enabled** toggle on (the default), Cribl Edge will create events for each configured service (for example `systemd` and `initd`) along with their enabled and running status.

Sample entries include:

- `Name`: Name of the service.
- `Unit Activation Status`: The high-level unit activation state, i.e. generalization of `SUB` for `systemctl`. For `sysV` system value can be `enabled` or `disabled`.
- `Unit Load Status`: Reflects whether the unit definition was properly loaded. (Only `systemctl`).
- `Sub Unit Activation Status`: The low-level unit activation state, values depend on unit type.
- `Description`: Description of the service.
- `windowsService`: In Cribl Edge on Windows, reports as `Win32_Service` when the native WMI method is used (default). Reports `Get-Service` when the **Use Windows Tools** toggle is enabled in **Advanced Settings**.

When Cribl Edge is deployed in a container, the **Services** Collector does not collect any events.

Users and Groups

With the **Enabled** toggle on (the default), Cribl Edge will create events for users and groups.

Linux

The Linux collector reports exclusively on local users and groups defined within `/etc/passwd` and `/etc/group`. It does not include users or groups from external directory services like LDAP.

On Linux, Cribl Edge creates `user` events with the following fields:

- `username`

- `fullname`
- `loginShell`
- `userHome`
- `userid`
- `primaryGroup` (name of primary group, not group ID)
- `groups` (list of group names)

Cribl Edge also creates `group` events with the following fields:

- `name`
- `groupId`
- `users`

Windows (Cribl Edge Only)

Cribl Edge on Windows reports exclusively on local users and groups. On Windows hosts that are members of a domain (but are not domain controllers), Cribl Edge will only list local accounts. On Windows domain controllers, the collector will not list any users or groups as the local account list is replaced by the domain accounts.

On Windows, Cribl Edge creates `user` events with the following fields:

- `userName`
- `fullname`
- `description`
- `groups`

Cribl Edge also creates `group` events with the following fields:

- `name`
- `description`
- `users`

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Select a **Pipeline** (or Pack) from the drop-down to process this Source's data. Required to configure this Source via **Data Routes**; optional to configure via **Collect**/**QuickConnect**.

Disk Spooling

Enable disk spooling: Whether to save metrics to disk. When toggled on, exposes this section's remaining fields.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`).

Max data size: Maximum disk space the persistent metrics can consume. Once reached, Cribl Edge will delete older data. Example values: `420 MB`, `4 GB`. Default value: `100 MB`.

Max data age: How long to retain data. Once reached, Cribl Edge will delete older data. Example values: `2h`, `4d`. Default value: `24h` (24 hours).

Compression: Currently locked to `none`. Cribl plans to add (optional) disk-spooling compression in a future release.

Path location: Path to write metrics to. Default value is `$CRIBL_HOME/state/system_state`.

Advanced Settings

Use Windows Tools: Toggled off by default.

> **Deprecation Notice**
>
> This legacy setting will be removed in a future release. We highly recommend keeping this option disabled and using the newer native capabilities, which are faster and more reliable.

This setting affects Windows Edge Nodes only, it has no effect on Linux Edge Nodes or in Cribl Stream.

- If toggled off, the System State Source interacts directly with the Windows Management Instrumentation (WMI) API, resulting in faster data collection.
- If toggled on, the System State Source will collect events using Powershell cmdlets.

Use legacy collection for LastLog: Toggled off by default.

Toggle on if you encounter issues with collecting LastLog information to revert to the legacy collection method.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct

12.2.2. Internal

You can use the following Sources to receive data from internal senders.

Source	Description
Cribl HTTP	Receive data from peer Nodes managed by the same Leader when raw TCP traffic is not an option
Cribl TCP	Send data between Worker Nodes/Edge Nodes connected to the same Leader
Cribl Internal	Capture Edge's internal logs and metrics and send them through Routes and Pipelines
Datagen	Generate data from datagen files

12.2.2.1. Cribl HTTP Source

The Cribl HTTP Source receives data from a Cribl HTTP Destination. Relaying data between a Cribl HTTP Destination and Cribl HTTP Source pair prevents double-billing: You won't incur any additional charges or credit usage after initial ingest to the first Fleet (depending on your Leader setup - see Transfer Data Between Workspaces or Environments for more details).

It's common to send data from Cribl Edge to a Cribl Stream Worker Group using this kind of pairing.

Type: **Internal** | TLS Support: **YES** | Event Breaker Support: **No**

For guidance on when to choose this Source versus the Cribl TCP Source, see Interoperation Protocols.

For supported Stream and Edge combinations, auth tokens, and transports, see Cribl-to-Cribl compatibility matrix.

Within Cribl Stream, the Cribl HTTP Source is available only in Distributed deployments. In single-instance mode, or for testing, you can use the Raw HTTP/S Source instead. However, this substitution will not facilitate sending all internal fields, as described below.

Looking for the Cribl HTTP Source in **Cribl Search**? See Ingest Cribl Stream/Edge Data into Cribl Search.

How It Works

You can use the Cribl HTTP Source to transfer data between Edge Nodes and Workers. If the Cribl HTTP Source receives data from its Cribl HTTP Destination counterpart on another Worker, you're billed for ingress only once - when Cribl first receives the data.

Using a Cribl HTTP Destination/Source pair, you're not charged for subsequent data sent to:

- Workers that share a Leader.
- Workers that don't share a Leader, but are configured in Cribl.Cloud Workspaces within the same Organization.
- Workers that do not share a Leader, but that do have the exact same on-prem license installed.

This use case is common in hybrid Cribl.Cloud deployments, where a customer-managed (hybrid) Worker Node sends data to a Worker in Cribl.Cloud for additional processing and routing to Destinations. However, the Cribl HTTP Destination/Source pair can similarly reduce your metered data ingress in other scenarios, such as on-prem Edge to on-prem Stream.

As one usage example, assume that you want to send data from one Node deployed on-prem, to another that is deployed in Cribl.Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl.Cloud.
- Create an on-prem Cribl HTTP Destination.
- Create a Cribl HTTP Source, on the target Stream Worker Group or Edge Fleet in Cribl.Cloud.
- For an on-prem Node configure a File System Collector to send data to the Cribl HTTP Destination, and from there to the Cribl HTTP Source in Cribl.Cloud.
- On Cribl-managed Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl HTTP Destination and the Cribl HTTP Source it's sending data to, or enabled on both. Otherwise, no data will flow. On Cribl.Cloud instances, the Cribl HTTP Source ships with TLS enabled by default. In addition, the **Minimum TLS version** and **Maximum TLS version** on the Source and Destination must be compatible. Mismatched version ranges will also prevent data from flowing. For details, see Match TLS Versions Between Source and Destination.

Configure the Cribl HTTP Source

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name to identify this Cribl HTTP Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the address to bind on. Defaults to `0.0.0.0` (all addresses).
    - **Port**: Enter the port number to listen on, for example, `10200`.

The **Address** and **Port** values make up the endpoint that the Cribl HTTP Destination paired with this Source will use. See Cribl HTTP Destination for details.

3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use for filtering and grouping in the Cribl Edge UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.

4. Optionally, configure any TLS settings, Persistent Queue, Processing, Advanced settings and Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certificates if desired. When this Source listens on a port in the 20000–20010 range, set **Private key path** to `$CRIBL_CLOUD_KEY` and **Certificate path** to `$CRIBL_CLOUD_CRT`. See Enable TLS on Sources Using Cribl-Provided Certificates for full instructions.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject

Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

Enable Persistent Queue: Defaults to toggled off. When toggled on:

Mode: Choose a mode from the drop-down:

- With `Smart` mode, PQ will write events to the filesystem only when it detects backpressure from the processing engine.
- With `Always On` mode, PQ will always write events directly to the queue before forwarding them to the processing engine.

Buffer size limit: Maximum number of events to hold in-memory before dumping them to disk.

Commit frequency: Number of events to send before committing that Stream has read them.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `1 MB`.

Queue size limit: The maximum amount of disk space the queue is allowed to consume. Once this limit is reached, Cribl Edge stops queueing and applies the configured **Queue-full behavior**. Enter a numeral with units of KB, MB, and so on.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. Options are **Block** (default) and **Drop new data**. See What Happens to Data when the Queue is Full for more information.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Edge will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`; `Gzip` is also available.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Auth Token

This section is only available for Cribl.Cloud environments. It is intended for use when migrating data from an on-prem environment to a Cribl.Cloud environment.

If you previously had an on-prem deployment of Cribl and you are moving forward with a Cloud-first or Cloud only solution, you can use connected environments to onboard your data from on-prem Edge Nodes to their counterpart Cribl.Cloud Edge Nodes. See Migrate Data from On-Prem to Cribl.Cloud for implementation details.

Advanced Settings

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing

`__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

The Cribl HTTP Source (and the Cribl TCP Source) treat internal fields differently than other Sources do. That's because of the difference in the way that incoming data originates.

Other Sources ingest data that's not coming from Cribl Edge or Stream, meaning that no Cribl internal fields can be present in that data when it arrives at the Source, and the Source is free to add internal fields without clobbering (overwriting) anything that existed already.

By contrast, the Cribl HTTP Source and the Cribl TCP Source ingest data that's coming from a Cribl HTTP or Cribl TCP Destination. That data **can** contain internal fields when it arrives at the Source. This means that if the Source adds internal fields, those could potentially clobber what existed before.

To avoid this problem, the Cribl HTTP Source and the Cribl TCP Source add a unique `__forwardedAttrs` (i.e., "forwarded attributes") field. The nested structure of the `__forwardedAttrs` field contains any of the following fields that are present in the arriving data:

Internal Fields
`__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
`__inputId`
`__outputId`
`fleet/ group`
`__srcIpPort` - See details below.

Other Fields
`cribl_breaker`
`cribl_pipe`

These fields are **copied** into `__forwardedAttrs`, not moved there. As the data (apart from `__forwardedAttrs`) moves through the Source and any Pipelines, the values of these fields can be overwritten. But the copies of these fields in `__forwardedAttrs` remain unchanged, so you can retrieve them as necessary.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the HTTP client sending data to this Source.

When any proxies (including load balancers) lie between the HTTP client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Troubleshooting

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Dropping request because token invalid",“authToken”: “Bas…Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

12.2.2.2. Cribl TCP Source

The Cribl TCP Source receives data from a Cribl TCP Destination. Relaying data between a Cribl TCP Destination and Cribl TCP Source pair prevents double-billing: You won't incur any additional charges or credit usage after initial ingest to the first Fleet (depending on your Leader setup - see Transfer Data Between Workspaces or Environments for more details).

It's common to send data from Cribl Edge to a Cribl Stream Worker Group using this kind of pairing.

Type: **Internal** | TLS Support: **YES** | Event Breaker Support: **No**

For guidance on when to choose this Source versus the Cribl HTTP Source, see the Full Suite Reference Architecture.

For supported Stream and Edge combinations, auth tokens, and transports, see Cribl-to-Cribl compatibility matrix.

Within Cribl Stream, the Cribl TCP Source is available only in Distributed deployments. In single-instance mode, or for testing, you can use the TCP JSON Source instead. However, this substitution will not facilitate sending all internal fields, as described below.

How It Works

You can use the Cribl TCP Source to transfer data between Edge Nodes and Workers. If the Cribl TCP Source receives data from its Cribl TCP Destination counterpart on another Worker, you're billed for ingress only once - when Cribl first receives the data.

Using a Cribl HTTP Destination/Source pair, you're not charged for subsequent data sent to:

- Workers that share a Leader.
- Workers that don't share a Leader, but are configured in Cribl.Cloud Workspaces within the same Organization.
- Workers that do not share a Leader, but that do have the exact same on-prem license installed.

This use case is common in hybrid Cribl.Cloud deployments, where a customer-managed (hybrid) Worker Node sends data to a Worker in Cribl.Cloud for additional processing and routing to Destinations. However, the Cribl TCP Destination/Source pair can similarly reduce your metered data ingress in other scenarios, such as on-prem Cribl Edge to on-prem Cribl Stream.

As one usage example, assume that you want to send data from one Node deployed on-prem, to another that is deployed in Cribl.Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl.Cloud.
- Create an on-prem Cribl TCP Destination.
- Create a Cribl TCP Source, on the target Cribl Stream Worker Group or Cribl Edge Fleet in Cribl.Cloud.
- For an on-prem Node, configure a File System Collector to send data to the Cribl TCP Destination, and from there to the Cribl TCP Source in Cribl.Cloud.
- On Cribl-managed Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl TCP Destination and the Cribl TCP Source it's sending data to, or enabled on both. Otherwise, no data will flow. On Cribl.Cloud instances, the Cribl TCP Source ships with TLS enabled by default.

Configuration Requirements

The key points about configuring this architecture are:

- When you configure the Cribl TCP Destination, its **Address** and **Port** values must point to the **Address** and **Port** you've configured on the Cribl TCP Source.
- Cribl 3.5.4 was a breakpoint in Cribl TCP Leader/Worker communications. Nodes running the Cribl TCP Source on Cribl 3.5.4 and newer can send data only to Nodes running v.3.5.4 and newer. Nodes running the Cribl TCP Source on Cribl 3.5.3 and older can send data only to Nodes running v.3.5.3 and older.

Configure the Cribl TCP Source

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name to identify this Cribl TCP Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for TCP JSON data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter the port number to listen on, for example, `10300`.
3. Next, you can configure the following **Optional Settings**:

- **Tags**: Optionally, add tags that you can use for filtering and grouping in the Cribl Edge UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.

4. Optionally, configure any TLS settings, Persistent Queue, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common

Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

Enable persistent queue: Defaults to toggled off. When toggled on:

Mode: Choose a mode from the drop-down:

- With `Smart` mode, PQ will write events to the filesystem only when it detects backpressure from the processing engine.
- With `Always On` mode, PQ will always write events directly to the queue before forwarding them to the processing engine.

Buffer size limit: Maximum number of events to hold in memory before dumping them to disk. Defaults to `1000`.

Commit frequency: Number of events to send before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space the queue is allowed to consume. Once this limit is reached, Cribl Edge stops queueing and applies the configured **Queue-full behavior**. Enter a numeral with units of KB, MB, and so on.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. Options are **Block** (default) and **Drop new data**. See What Happens to Data when the Queue is Full for more information.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Edge will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`; `Gzip` is also available.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Auth Token

This section is only available for Cribl.Cloud environments. It is intended for use when migrating data from an on-prem environment to a Cribl.Cloud environment.

If you previously had an on-prem deployment of Cribl and you are moving forward with a Cloud-first or Cloud only solution, you can use connected environments to onboard your data from on-prem Edge Nodes to their counterpart Cribl.Cloud Edge Nodes. See Migrate Data from On-Prem to Cribl.Cloud for implementation details.

Advanced Settings

Enable proxy protocol: Toggle on if the connection is proxied by a device that supports proxy protocol v1 or v2.

Enable load balancing (Cribl Stream only): Toggle on to distribute the data from incoming TCP connections across multiple Worker Processes. This improves performance compared to the default of having all data from an incoming connection processed on a single Worker Process.

- This spins up an extra Worker Process (named `wLB` in **Settings** > **Processes**) on the Worker Node, which handles splitting data from incoming TCP connections across all other Worker Processes.

- When enabled, the option to include common fields in the JSON header is not supported. This means fields specified under `fields` in the JSON header are not automatically added to all events.

Load balancing is available in Cribl Stream single-instance and Distributed deployments when a TCP port is configured.

Active connection limit: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set to `0` for unlimited connections.

Socket idle timeout (seconds): The duration that Cribl Edge will wait for activity on an idle TCP socket before closing the connection. Disabled when set to `0`, the default.

Forced socket termination timeout (seconds): The extra time the server waits before forcibly closing a socket that has been idle (**TCP socket idle timeout**) or exceeded its maximum lifespan (**TCP socket max lifespan**) but has not yet properly closed. This prevents resource leaks caused by unresponsive clients or network issues. Configure based on network latency and client behavior. Default: `30` seconds. Set to `0` to disable.

Socket max lifespan (seconds): The duration that a socket is allowed to remain open, regardless of activity. This setting prevents resource exhaustion (such as TCP pinning) by limiting the lifespan of connections. Configure based on expected connection durations and resource availability. Disabled when set to `0`, the default.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the configuration will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

The Cribl TCP Source (and the Cribl HTTP Source) treat internal fields differently than other Sources do. That's because of the difference in the way that incoming data originates.

Other Sources ingest data that's not coming from Cribl Edge or Cribl Stream, meaning that no Cribl internal fields can be present in that data when it arrives at the Source, and the Source is free to add internal fields

without clobbering (overwriting) anything that existed already.

By contrast, the Cribl TCP Source and the Cribl HTTP Source ingest data that's coming from a Cribl TCP or Cribl HTTP Destination. That data **can** contain internal fields when it arrives at the Source. This means that if the Source adds internal fields, those could potentially clobber what existed before.

To avoid this problem, the Cribl TCP Source and the Cribl HTTP Source add a unique `__forwardedAttrs` (that is, "forwarded attributes") field. The nested structure of the `__forwardedAttrs` field contains any of the following fields that are present in the arriving data:

Internal Fields
`__srcIpPort`
`__inputId`
`__outputId`
`fleet` / `group`

Other Fields
`cribl_breaker`
`cribl_pipe`

These fields are **copied** into `__forwardedAttrs`, not moved there. As the data (apart from `__forwardedAttrs`) moves through the Source and any Pipelines, the values of these fields can be overwritten. But the copies of these fields in `__forwardedAttrs` remain unchanged, so you can retrieve them as necessary.

Periodic Logging

Cribl Edge logs metrics about incoming requests and ingested events once per minute.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker Process.

This kind of periodic logging helps you determine whether a Source is in fact still healthy even when no data is coming in.

12.2.2.3. Cribl Internal Source

The Cribl Internal Source enables you to capture and send Cribl Edge's own internal logs and metrics through Routes and Pipelines.

Type: **Internal** | TLS Support: **N/A** | Event Breaker Support: **No**

You can't configure custom Cribl Internal Sources.

Scope and Purpose

In Distributed mode, this Source's CriblLogs option can process internal logs only from Worker Processes. (Logs on the Leader remain on the Leader, because the Leader Node is not part of any processing path.)

In both Distributed and Single-instance mode, this Source's CriblLogs option omits API Process logs, meaning that it omits telemetry/license-validation traffic. You can, however, use a Script Collector to check for API Server (or Worker Group) events.

This Source's CriblMetrics option offers Cribl's most up-to-date and precise view of event throughput and transformation, aggregated every 2 seconds at the Worker Process level. The CriblLogs option is less granular - tracking logs that are written once per minute - so CriblLogs might fail to reflect Worker Process crashes or restarts.

Configure Cribl Internal Logs/Metrics as a Data Source

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, then choose **Select Existing**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want.
2. Next, select either the default `CriblLogs` or `CriblMetrics` to open the configuration modal.
3. Configure the **General Settings** for your selected Source.
    - For Cribl Logs, configure the following:
        - **Enabled**: This duplicates the parent page's **Enabled** toggle. Toggle on to enable Cribl logs as a Source.
        - **Input ID**: This is prefilled with the default value `CriblLogs`, which cannot be changed.
        - **Description**: Optionally, enter a description.

- For Cribl Metrics, configure the following:
  - **Enabled**: This duplicates the parent page's **Enabled** toggle. Toggle on to enable Cribl metrics as a Source.
  - **Input ID**: This is prefilled with the default value `CriblMetrics`, which cannot be changed.
  - **Description**: Optionally, enter a description.

4. Next, you can configure the following **Optional Settings** for your selected Source:
   - For Cribl Logs, configure the following:
     - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
   - For Cribl Metrics, configure the following:
     - **Metric name prefix**: Enter an optional prefix that will be applied to metrics provided by Cribl Edge. The prefix defaults to `cribl.logstream.`
     - **Full fidelity**: Toggle off to reduce CPU load by excluding metrics for any fields listed in **General Settings** > **Limits** > **Metrics** > **Disable field metrics**. See Control Metrics Volume for details. When **Full fidelity** is on, Cribl Edge generated metrics include:
       - `cribl.logstream.host.(in_bytes,in_events,out_bytes,out_events)`
       - `cribl.logstream.index.(in_bytes,in_events,out_bytes,out_events)`
       - `cribl.logstream.project.(in_bytes, in_events, out_bytes, out_events)`
       - `cribl.logstream.source.(in_bytes,in_events,out_bytes,out_events)`
       - `cribl.logstream.sourcetype.(in_bytes,in_events,out_bytes,out_events)`
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, configure any Processing and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

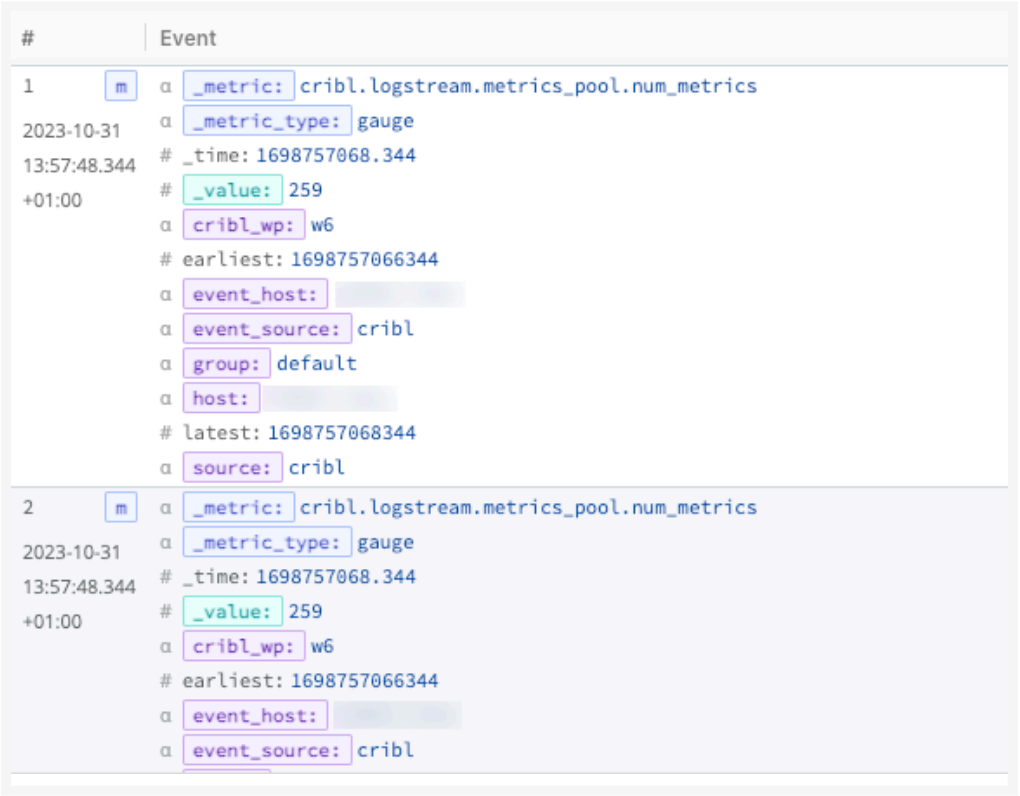
Reporting Metrics Less Frequently

By default, Cribl Edge generates internal metrics every 2 seconds. To consume metrics at longer intervals, you can use or adapt the `cribl_metrics_rollup` Pipeline that ships with Cribl Edge.

Attach this Pipeline to your **Cribl Internal** Source as a pre-processing Pipeline. The Pipeline's **Rollup Metrics** Function has a default **Time Window** of 30 seconds, which you can adjust to a different granularity as needed. This provides a second lever to reduce granularity, in addition to the Full fidelity toggle described above.

Omitting `sourcetype`

You can easily drop the `sourcetype` attribute from metrics events, leaving only `event_sourcetype`. This will prevent duplicate `sourcetype` events from being routed to Destinations.



To do this: In the same `cribl_metrics_rollup` pre-processing Pipeline (or a clone) that you attach to your Source, enable the final Eval Function, which applies this **Filter** expression to remove the `sourcetype` field: `_metric && _metric.startsWith('cribl.logstream.sourcetype.')`

Duplicated Fields/Dimensions

The CriblMetrics Source operates on metrics that Edge Nodes report to their Leader Nodes. Typically included are `source` and `host` fields.

Sending metrics from this Source to Splunk is one common use case. Because Splunk might overwrite these two fields, the Source copies their values into new dimensions with added `event_` prefixes: `event_source` and `event_host`. This way, if Splunk does overwrite `source` and/or `host`, their original values remain intact in the new dimensions with `event_` prefixes.

Here's an example of how the added dimensions look in the **Live Capture** window:

Doubled fields

If you are not sending to a downstream service that overwrites `source` or `host` fields, you can use an appropriate Function to drop the added dimensions. You also have the option to suppress these fields entirely by specifying them in **Settings** > **Global** > **System** > **General Settings** > **Limits** > **Metrics** > **Disable field metrics**.

Internal Fields

The following fields will be added to all events/metrics:

- `source`: set to `cribl`.
- `host`: set to the hostname of the Cribl instance.

Use these fields to guide these events/metrics through Cribl Routes.

All Cribl internal fields are subject to change and modification. Cribl provides them to assist with analytics and diagnostics, but does not guarantee that they will remain available.

12.2.2.4. Datagen Source

Cribl Edge supports generating data from datagen files, as detailed in Using Datagens. When a datagen is enabled, each Worker Process uses the specified data generator file to generate events. These events proceed through Routes and Pipelines, or through a QuickConnect configuration, to configured Destinations. Whichever Worker Process generated an event from the file will also send the same event.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **No**

Configure Cribl Edge to Generate Sample Data

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Datagens**: List of datagens. For details, see Datagen Fields below.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use for filtering and grouping in the Cribl Edge UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.
4. Optionally, configure any Processing and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Datagen Fields

To configure the list of datagens, include the following:

- **Data generator file**: Name of the datagen file.
- **Events per second per Worker Node**: Maximum number of events to generate per second, per Worker Node/Edge Node. Defaults to `10`.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`

12.2.3. Prometheus

You can use the following Sources to receive data from Prometheus services.

Source	Description
Prometheus Scraper	Receive batched data from Prometheus targets
Prometheus Remote Write	Receive metric data from Prometheus via the remote write protocol
Grafana	Receive metric and log data from Grafana Agent via Prometheus remote write
Loki	Receive log data from Grafana Loki

12.2.3.1. Prometheus Edge Scraper Source

Cribl Edge supports receiving batched data from Prometheus targets.

Type: **Internal** | TLS Support: **No** | Event Breaker Support: **No**

This Source currently does not support Prometheus metadata.

This is an Internal (Pull) Source. To ingest Prometheus streaming data, see Prometheus Remote Write.

Configuring Cribl Edge to Scrape Prometheus Data

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Collect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **More** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Discovery type**: Use this drop-down to select a discovery mechanism for targets. See Discovery Type below for the options and the resulting controls displayed. Some **Discovery type** options replace this section's **Targets** field with additional controls - while also adding an **AWS IAM** left tab to the modal.
    - **Poll interval**: Specify how often (in seconds) to scrape targets for metrics. Defaults to `15` seconds. This value must be an integer that divides evenly into `60`.
3. Next, you can configure the following **Optional Settings**:
    - **Extra dimensions**: Specify the dimensions to include in events. Defaults to `host` and `source`.
    - **Use field per metric**: Enable to use each metric name as the event field key instead of the default format. Metrics will use format similar to other Sources such as System Metrics, that is: `_metric : _value`.
    - **Tags**: Optionally, add tags that you can use for filtering and grouping in the Cribl Edge UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.

4. Optionally, configure any Authentication, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Discovery Type

Use this drop-down to select a discovery mechanism for targets. To manually enter a targets list, use Static (the default). To enable dynamic discovery of endpoints to scrape, select one of the other options. Each selection exposes different controls and/or tabs, listed below.

Static Discovery

The `Static` option adds a **General Settings** > **Targets** field, in which you enter a list of specific Prometheus targets from which to pull metrics. Click **Add Target** to expose a table with the following options:

- **Protocol**: Select `http` (the default) or `https` as the protocol to use when collecting metrics.
- **Host**: Specify the host name to pull metrics from.
- **Port**: Specify the port number to append to the metrics URL for discovered targets. Defaults to `9090`.
- **Path**: Specify a path to use when collecting metrics from discovered targets. Defaults to `/metrics`.

DNS Discovery

The `DNS` option adds the following extra fields to its **General Settings** tab:

- **Record type**: Select the DNS record type to resolve. Defaults to `SRV` (Service). Other options are `A` or `AAAA`.
- **DNS names**: Enter a list of DNS names to resolve.
- **Protocol**: Select `http` (the default) or `https` as the protocol to use when collecting metrics.
- **Path**: Specify a path to use when collecting metrics from discovered targets. Defaults to `/metrics`.

AWS EC2 Discovery

The `AWS EC2` option adds AWS IAM to the modal, and adds extra fields to the **General Settings** tab:

- **Protocol**: Select `http` (the default) or `https` as the protocol to use when collecting metrics.
- **Port**: Specify the port number to append to the metrics URL corresponding to discovered targets. Defaults to `9090`.
- **Path**: Specify a path to use when collecting metrics from discovered targets. Defaults to `/metrics`.
- **Region**: Select the AWS Region in which to discover EC2 instances with metrics endpoints to scrape.
- **Use public IP**: Toggle on (default) to use the public IP address for discovered targets. Toggle off to use a private IP address.

- **Search filter**: Click **Add filter** to apply filters when searching for EC2 instances. Each filter row provides two columns:
    - **Filter name**: Select standard attributes from the drop-down, or type in custom attributes.
    - **Filter values**: Enter values to match within this row's attribute, Press `Enter` between values. (If you specify no values, the search will return only `running` EC2 instances.)

Selecting `AWS EC2` also adds controls to the **Advanced Settings** tab, as described below.

Kubernetes Node

The `Kubernetes Node` option supports collecting metrics from an endpoint on the local node where Cribl Edge is running. Selecting this option adds the following extra fields to the **General Settings** tab:

- **Protocol**: Select `http` (the default) or `https` as the protocol to use when collecting metrics.
- **Port**: Specify the port number to append to the metrics URL corresponding to discovered targets. Defaults to `9090`.
- **Path**: Specify a path to use when collecting metrics from discovered targets. Defaults to `/metrics`.

Selecting `Kubernetes Node` also adds a control to the **Authentication** tab, as described below.

You must first authorize the Source to discover a Kubernetes Node. For details, see RBAC for Prometheus Edge Scraper.

Kubernetes Pods

The `Kubernetes Pods` option supports building a list of endpoints to collect from Pods on the same node where Cribl Edge is running. This option adds the following extra fields to the **General Settings** tab - use a custom expression to set the configuration properties on each field.

- **Protocol**: Set the protocol to use when collecting metrics. Defaults to: `metadata.annotations['prometheus.io/scheme'] || 'http'`
- **Port**: Specify the port number to append to the metrics URL corresponding to discovered targets. Defaults to: `metadata.annotations['prometheus.io/port'] || '9090'`
- **Path**: Specify a path to use when collecting metrics from discovered targets. Defaults to: `metadata.annotations['prometheus.io/path'] || '/metrics'`
- **Filter rules**: Optionally, add rules to determine which Pods to discover for metrics. If no rules are provided, Cribl Edge will search all Pods. Otherwise, it will search Pods where rules' expressions evaluate to `true`. Each rule consists of an expression and an optional description.
    - **Filter expression**: JavaScript expression applied to Pods' objects. Return `true` to include it. Filters are based on the Kubernetes Pod Object definition, and are evaluated from top to bottom. The first expression evaluating to `false` excludes a Pod from collection. The default filter is

`metadata.annotations['prometheus.io/scrape']`, which scrapes the Pod if the annotation is true.

- **Description**: Optional description of the rule.

Selecting `Kubernetes Pods` also adds a control to the **Authentication** tab, as described below.

You must first authorize the Source to discover Kubernetes Pods. For details, see RBAC for Prometheus Edge Scraper.

Kubernetes Service Monitor

The `Kubernetes Service Monitor (v4.18+)` option discovers and scrapes Prometheus endpoints by reading `ServiceMonitor` custom resources defined by the Prometheus Operator. For each `ServiceMonitor` found in the configured namespace, Cribl Edge resolves the matching Kubernetes Services and scrapes the endpoints those Services expose, injecting `ServiceMonitor` and Service metadata into each event.

This discovery type requires Cribl Edge version 4.18 or later. Avoid using this option in a Fleet containing Edge Nodes running older versions. See Limited Feature Functionality After Leader Upgrade for more information.

Selecting `Kubernetes Service Monitor (v4.18+)` adds the following fields to Source configuration:

- **ServiceMonitor Namespace** (**General Settings** tab): Namespace in which to search for `ServiceMonitor` resources. Leave empty to search all namespaces.
- **Authentication method** (**Authentication** tab): See Authentication Settings for Kubernetes.

You must first authorize the Source to read `ServiceMonitor` resources and their associated Services. For details, see RBAC for Prometheus Edge Scraper.

Authentication (Prometheus)

Use the **Authentication method** drop-down to select one of these authentication options for Prometheus:

- **Manual**: In the resulting **Username** and **Password** fields, enter Basic authentication credentials corresponding to your Prometheus targets.
- **Secret**: This option exposes a **Secret** drop-down, in which you can select a stored secret that references your credentials described above. The secret can reside in Cribl Edge's internal secrets manager or (if enabled) in an external KMS. Click **Create** if you need to configure a new secret.

Authentication Settings for Kubernetes

This additional setting appears only when **General Settings** > **Discovery Type** is set to `Kubernetes Node`, `Kubernetes Pods`, or `Kubernetes Service Monitor (v4.18+)`.

- **Kubernetes**: Select this option to use Kubernetes authentication. There are no details to configure, because Cribl Edge will authenticate using the Environment Variables or Service Account tokens mounted in the Edge Pod(s). For details, see Deploying via Kubernetes.

AWS IAM

With the AWS EC2 target discovery type, you can configure AssumeRole behavior on AWS.

Assume Role

- **Enable for EC2**: Toggle on if you want to use `AssumeRole` credentials to access EC2.
- **AssumeRole ARN**: Enter the Amazon Resource Name (ARN) of the role to assume.
- **External ID**: Enter the External ID to use when assuming the role.

AWS Authentication Options

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
2. **IAM Identity Center (SSO)**: Loaded from AWS IAM Identity Center configuration.
3. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
4. **IAM Roles for Amazon EC2/ECS**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance or ECS container.
5. **JSON File on Disk**: Loaded from a JSON file on disk.
6. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

Azure-based Cribl.Cloud Worker Groups do not have AWS credentials, so **Auto** finds none and authentication fails. On an Azure-based Worker Group, select another authentication method and supply your own AWS credentials.

SSO Providers

> When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Edge Nodes not in an AWS VPC, for example, those running a private cloud. This option displays:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. This option displays:

- **Secret key pair**: Use the drop-down to select a secret key pair that you've configured in Cribl Edge's internal secrets manager or (if enabled) an external KMS. Click **Create** if you need to configure a key pair.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Disk Spooling

Enable disk spooling: Whether to save metrics to disk. When toggled on, it exposes this section's remaining fields.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`).

Max data size: Maximum disk space the persistent metrics can consume. Once reached, Cribl Edge will delete older data. Example values: `420 MB`, `4 GB`. Default value: `1 GB`.

Max data age: How long to retain data. Once reached, Cribl Edge will delete older data. Example values: `2h`, `4d`. Default value: `24h` (24 hours).

Compression: Defaults to `gzip`.

Cribl Edge will write metrics to the default location: `CRIBL_HOME/state/spool/in/edge_prometheus/${inputId}`. Use the environment variable `CRIBL_SPOOL_DIR`, to change the default path.

Advanced Settings

HTTP Connection Timeout: The amount of time (in milliseconds) to wait for the HTTP connection to establish before it times out. `1-60000` is the allowable range. Enter `0` to disable the timeout.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Advanced Settings for AWS

These additional settings appear only when **General Settings** > **Discovery Type** is set to `AWS EC2`.

Endpoint: Specify an EC2-compatible service endpoint. If empty, this defaults to AWS' Region-specific endpoint.

Signature version: The signature version to use for signing EC2 requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. Toggling on (default) can improve performance.

Reject unauthorized certificates: Whether to reject certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to toggled on, the restrictive option.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__source`
- `__isBroken`
- `__inputId`
- `__final`
- `__criblMetrics`
- `__channel`
- `__cloneCount`
- `__kube_pod` when Discovery Mode is set to **Kubernetes Node**.
- `__kube_node` and `__kube_pod` when Discovery Mode is set to **Kubernetes Pods**.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

Dropping request because token invalid",“authToken”: “Bas...Njc=”

12.2.3.2. Prometheus Remote Write Source

Cribl Edge supports receiving metric data from Prometheus instances that are configured to send data via the remote write protocol.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source assumes that incoming data is snappy-compressed.

Looking for the Prometheus Remote Write Source in **Cribl Search**? See Ingest Prometheus Metrics into Cribl Search.

Configure Cribl Edge to Receive Metrics from Prometheus Remote Write Sources

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
    - **Remote Write API endpoint**: Enter the absolute path on which to listen for Prometheus requests. Defaults to `/write`, which will (in this example) expand as: `http://<your-upstream-URL>:<your-port>/write`.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header, or select **Generate** if you need a new token.
- **Auth token (text secret)**: Provide an HTTP token referenced by a secret. Select a stored text secret in the resulting drop-down, or select **Create** to configure a new secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials. Click **Generate** if you need a new password.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.

TLS Settings (Server Side)

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you

disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.

- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.
>
> All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

> **Deprecation Notice**
>
> To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:
>
> - Monitor your persistent queue usage so that you can allocate enough disk space.
> - Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
> - Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

> **Deprecation Notice**
>
> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always On`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

> When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

> Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__criblMetrics`
- `__final`
- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__inputId`
- `__srcIpPort` - See details below.
- `_time`
- `_value`

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Prometheus Remote Write client sending data to this Source.

When any proxies (including load balancers) lie between the Prometheus Remote Write client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Detecting Metrics' Types

Because Prometheus remote write requests don't specify metrics' types, Cribl Edge applies the following rules to determine the type as we ingest them:

- If the metric's name ends with `_total`, `_sum`, `_count`, or `_bucket`, the type is set to `counter`.
- Otherwise, the metric's type is set to `gauge`.

This is consistent with the type detection practiced by other services implementing the remote write protocol. See, for example, New Relic's and Elastic's documentation.

Note that Cribl Edge supports the `timer` type in addition to `counter` and `gauge`.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Common Issue

Dropping request because token invalid",“authToken”: “Bas…Njc=”

12.2.3.3. Grafana Source

Cribl Edge supports receiving metric and log data from Grafana Agent instances via the Prometheus remote write specification. The Grafana Agent uses Prometheus for metrics collection and Grafana Loki for log collection.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source assumes that incoming data is snappy-compressed.

Configure Cribl Edge to Receive Metrics and Logs from Grafana Agent Sources

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
3. Next, you can configure the following **Optional Settings**. However, at least one endpoint is required.
    - **Remote Write API endpoint**: Absolute path on which to listen for Grafana Agent's remote write requests. Defaults to `/api/prom/push`, which will (in this example) expand as: `http://<your-upstream-URL>:<your-port>/api/prom/push`.
    - **Logs API endpoint**: Absolute path on which to listen for Loki logs requests. Defaults to `/loki/api/v1/push`, which will (in this example) expand as: `http://<your-upstream-URL>:<your-port>/loki/api/v1/push`.

- **Enable structured metadata**: Toggle on to parse and extract structured metadata from incoming Loki log payloads. Structured metadata lets you attach arbitrary key-value pairs (beyond labels) to each log entry, supporting high-cardinality fields without polluting the label set. Extracted metadata is stored in the event field `__structuredMetadata` to be forwarded through your Pipeline.
- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

The **Authentication** tab provides separate **Loki** and **Prometheus** sections, enabling you to configure these inputs separately. The two sections provide identical options.

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Enter the bearer token that must be included in the authorization header.
- **Auth token (text secret)**: Provide an HTTP token referenced by a secret. Select a stored text secret in the resulting drop-down, or select **Create** to configure a new secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.

TLS Settings (Server Side)

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue

size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

> In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.
>
> You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__inputId`
- `__labels` - For log events only - will contain all the labels found in each event's corresponding Loki stream.
- `__structuredMetadata` - Added only when **Enable structured metadata** is toggled on.
- `__srcIpPort` - See details below.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Grafana client sending data to this Source.

When any proxies (including load balancers) lie between the Grafana client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Detecting Metrics' Types

Because Prometheus remote write requests don't specify metrics' types, Cribl Edge applies the following rules to determine the type as we ingest them:

- If the metric's name ends with `_total`, `_sum`, `_count`, or `_bucket`, the type is set to `counter`.

- Otherwise, the metric's type is set to `gauge`.

This is consistent with the type detection practiced by other services implementing the remote write protocol. See, for example, New Relic's and Elastic's documentation.

Note that Cribl Edge supports the `timer` type in addition to `counter` and `gauge`.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Common Issue

12.2.3.4. Loki Source

Cribl Edge supports receiving log data from Grafana Loki via an adaptation of the Protobuf (Protocol Buffers) specification.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source assumes that incoming data is snappy-compressed.

Configure Cribl Edge to Receive Loki Logs Data

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
    - **Logs API endpoint**: Absolute path on which to listen for Loki logs requests. Defaults to `/loki/api/v1/push`, which will (in this example) expand as: `http://<your-upstream-URL>:<your-port>/loki/api/v1/push`.
    - **Enable structured metadata**: Toggle on to parse and extract structured metadata from incoming Loki log payloads. Structured metadata lets you attach arbitrary key-value pairs (beyond labels) to each log entry, supporting high-cardinality fields without polluting the label set. Extracted metadata is stored in the event field `__structuredMetadata` to be forwarded through your Pipeline.
3. Next, you can configure the following **Optional Settings**: - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication type** drop-down to specify how Loki's Promtail agent will authenticate against Cribl Edge:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header.
- **Auth token (text secret)**: Provide an HTTP token referenced by a secret. Select a stored text secret in the resulting drop-down, or select **Create** to configure a new secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.

TLS Settings (Server Side)

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you

disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.

- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

> **Deprecation Notice**
>
> To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:
>
> - Monitor your persistent queue usage so that you can allocate enough disk space.
> - Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
> - Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

> **Deprecation Notice**
>
> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always On`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__final`
- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__inputId`
- `__labels` - Will contain all the labels found in each event's corresponding Loki stream.
- `__structuredMetadata` - Added only when **Enable structured metadata** is toggled on.
- `__srcIpPort` - See details below.
- `_time`

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Loki client sending data to this Source.

When any proxies (including load balancers) lie between the Loki client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Common Issue

Dropping request because token invalid",“authToken”: “Bas…Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

12.2.4. Splunk

You can use the following Sources to receive data from Splunk services.

Source	Description
Splunk HEC	Receive data over HTTP/S using the Splunk HEC
Splunk TCP	Receive Splunk data from Universal or Heavy Forwarders

12.2.4.1. Splunk HEC Source

Cribl Edge supports receiving data over HTTP/S using the Splunk HEC (HTTP Event Collector).

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

For examples of optimizing incoming Splunk events for downstream services, see our Splunk Stream to Cribl Stream, Splunk to Elasticsearch, and Splunk to Exabeam guides.

Also examine several Splunk Forwarder/UF Packs on the Cribl Packs Dispensary. These provide processing Pipelines to optimize Splunk Windows events and Universal Forwarder internal events. You can directly import these and adapt them to your needs.

The Splunk HEC Source is part of Cribl Edge's default configuration. If you delete it, Cribl Edge will re-create it when defaults are applied again (for example, when you create a new Fleet or deploy a configuration bundle). To prevent it from receiving data, disable it instead of deleting it.

Looking for the Splunk HEC Source in **Cribl Search**? See Ingest Splunk HEC Events into Cribl Search.

Configure Cribl Edge to Receive Data over Splunk HEC

Cribl Edge ships with a Splunk HEC Source preconfigured to listen on Port 8088. You can clone or directly modify this Source to further configure it, and then enable it.

In Cribl Edge, configure Splunk HEC:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:

- **Input ID**: Enter a unique name to identify this Splunk HEC Source definition. The default Source is prefilled with the value `in_splunk_hec`, which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
- **Description**: Optionally, enter a description.
- **Address**: Enter the hostname/IP on which to listen for HTTP(S) data. Such as: `localhost` or `0.0.0.0`. Supports IPv4 and IPv6 addresses.
- **Port**: Enter the port number.
- **Splunk HEC endpoint**: Absolute path on which to listen for the Splunk HTTP Event Collector API requests. Defaults to `/services/collector`.
  - This single endpoint supports JSON events via `/event`, raw events via `/raw`, and Splunk S2S events via `/s2s`. See the Splunk REST API endpoints documentation and the following examples. The Source will automatically detect where to forward the request.

3. Next, you can configure the following **Optional Settings**:
   - **Allowed Indexes**: List the values allowed in the HEC event index field. Allows wildcards. Leave blank to skip validation.
   - **Enable Splunk HEC acknowledgements**: Whether to enable Splunk HEC acknowledgments. Default is toggled off. See Working with HEC Acks below to learn about context and limitations.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing, Auth tokens and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Working with HEC Acks

Cribl Edge sends a `200` or similar HTTP response code when it receives an event.

Some senders also send **ack requests**, which differ from events. This type of request asks Cribl Edge to acknowledge delivery of an array of event IDs. (A sender might **require** HEC acks to be enabled. Cribl does not maintain a comprehensive list of senders that require acks - please refer to your sender's documentation.)

How Cribl Edge responds depends on **Optional Settings** > **Enable Splunk HEC acknowledgements**:

- When **Enable Splunk HEC acknowledgements** is toggled on, Cribl Edge will respond to an ack request with an acknowledgement affirming that Cribl Edge received each of the events whose IDs were listed in the array.
- When **Enable Splunk HEC acknowledgements** is toggled off, Cribl Edge will respond to an ack request with a `400` error and text saying that `ACK` is disabled.

It makes sense to turn on Splunk HEC acknowledgements for senders that keep TCP connections open while waiting for an ack, because this behavior can exhaust available file descriptors.

There is a caveat to how HEC acks work in Cribl Edge: The ack response simply cites whatever event IDs appeared in the ack request, regardless of whether or not those events were ever received or processed by Cribl Edge. In that sense, what Cribl Edge sends is a "fake ack:" unlike acknowledgements in some other systems, the ack in itself is meaningless. It mainly serves to spare a sender from keeping TCP connections open needlessly.

To determine whether Cribl Edge successfully ingested an event, pay no attention to acks. Instead, verify that the sender received a `200` or similar HTTP response from the Splunk HEC source.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.

- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.
>
> All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Event Breakers

Splunk HEC Source Event Breakers only function with the `/raw` endpoint. The `/event` and `/s2s` endpoints operate on the assumption that the data they receive is already properly formatted into individual events and therefore do not utilize event breakers.

- `/raw`: Event Breakers split incoming raw, unstructured data into distinct events before processing them through Pipelines.
- `/event`: Event Breakers are not applied since data is already segmented in JSON format.
- `/s2s`: Event Breakers are not applied since data is already structured in the Splunk-to-Splunk format.

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to determine field's value (can be a constant).

Fields specified on the **Fields** tab will normally override fields of the same name in events. But you can specify that fields in events should override these fields' values.

In particular, where incoming events have no `index` field, this Source adds one with the literal value `default`. You can override this value by using **Add Field** to specify an `index` field, and then setting its **Value** to an expression of the following form: `index == 'default' ? 'myIndex' : index`

Fields here are evaluated and applied **after** any fields specified in the Auth Tokens section.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

Auth Tokens

Provides the authentication token required to access this Source's data. Ensure the token is valid and has the necessary permissions for data retrieval.

Not providing a token allows **unauthorized access**.

If you exclusively use secret tokens for your Splunk HEC Source, be aware that Cribl Edge versions older than 4.8.2 will not recognize them. This can lead to unintended consequences, such as unsecured data ingestion. To ensure compatibility and security, configure both regular HEC tokens and secret tokens, especially in environments with mixed versions.

Authentication method: Choose between manually entering a **Token** or selecting a stored **Secret**. If you opt for manual entry, type the token directly or **Generate** a new one. For added security, use the secrets store to select a stored **Token (text secret)** or **Create** a new one.

Enable token: Controls the status of the specified authentication token. When toggled on, the specified auth token is active and can be used for client access. If toggled off, the token is disabled, causing it to be skipped and ignored during initialization. This means that any client attempting to use a disabled token will not be granted access.

Disabling a token can be helpful when you need to temporarily stop receiving data from a particular service or application. Disabling a token prevents the service or application from sending data to your endpoint without having to completely delete the token.

See also Periodic Logging for information on how auth tokens affect product logging.

Description: Optional (but recommended), the description for this token. Although this field is optional, the token description becomes the display name for the token. You can select this display name to expand or collapse the token details.

Allowed indexes: Optionally, specify which indexes are permissible for events ingested using this token. Supports multiple index values and wildcards.

Fields: Fields to add to events referencing this token. Each field is a **Name/Value** pair.

Fields specified on the **Auth Tokens** tab will normally override fields of the same name in events. But you can specify that fields in events should override these fields' values.

In particular, where incoming events have no `index` field, this Source adds one with the literal value `default`. You can override this value by using **Add Field** to specify an `index` field, and then setting its **Value** to an expression of the following form: `index == 'default' ? 'myIndex' : index`

Fields here are evaluated and applied **before** any fields specified in the Fields section.

Advanced Settings

Use Universal Forwarder time zone (S2S only): Toggle on (default) to have Event Breakers determine the time zone for events based on Universal Forwarder-provided metadata when the time zone can't be inferred from the raw event.

Drop control fields: Toggle on (default) to drop Splunk control fields such as `crcSalt` and `savedPort`. Toggle off if you want to retain these fields and store the data in the `__ctrlFields` internal field.

Extract metrics (S2S only): Toggle on if you're using Splunk's S2S protocol. When enabled, Cribl will identify and handle Splunk metric events, ensuring that metric events generated by Splunk are processed and forwarded as metrics.

Emit per-token request metrics: Toggle on to emit per-token `<prefix>.http.perToken` and summary `<prefix>.http.summary` request metrics. This enables Periodic Logging.

CORS allowed origins: If you need to enable cross-origin resource sharing with Splunk senders, use this field to specify the HTTP origins to which Cribl Edge should send `Access-Control-Allow-*` headers. You can enter multiple domains and use wildcards. This and its companion **CORS allowed headers** option should seldom be needed - see Working with CORS Headers below. Both options are available in Cribl Edge 4.1.2 and newer.

CORS allowed headers: List HTTP headers that Cribl Edge will send in a CORS preflight response to your configured (above) **CORS allowed origins** as `Access-Control-Allow-Headers`. Enter `*` to allow all headers.

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.

- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__hecToken`
- `__inputId`
- `__ctrlFields`
- `__s2sVersion` - value can be either `v3` or `v4`. This field is present only when the Source is receiving S2S-encoded payloads.

- `__srcIpPort` - See details below.
- `__TZ`

> **Universal Forwarder Time Zone**
>
> The `__TZ` field uses the universal forwarder time zone to mitigate cases where incoming events have timestamp strings but no time zone information. Event Breakers use the `__TZ` field to derive time zone information, enabling them to set the `_time` field correctly. See Using the UF Time Zone for additional information.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Splunk HEC client sending data to this Source.

When any proxies (including load balancers) lie between the Splunk HEC client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Working with CORS Headers

The **CORS allowed origins** and **CORS allowed headers** settings are needed **only** when you want JavaScript code running in a web browser to send events to the Splunk HEC Source. In this (uncommon) scenario, the code in question sends a preflight request that includes CORS (Cross-Origin Resource Sharing) headers, and the Splunk HEC Source includes CORS headers in its response.

If the settings (and thus the CORS headers in the response) are correct, the browser will allow the code in question to complete requests to the Splunk HEC Source - that is, allow the code to read the Source's responses. (These settings are optional because for some web applications it's sufficient to send requests **without** reading responses.)

The CORS header dance begins when the web browser sends a request with a header stating its origin. What happens next depends on how you've configured the CORS header settings, as explained in the tables below. (For these examples, we'll assume an origin of `https://mycoolwebapp:3001`.)

CORS allowed origins value	What Splunk HEC Source does	Does Browser then allow code to read response?
`*`	Send `Access-Control-Allow-Origin: *` header.	Yes
Multiple wildcard values	If origin value matches any wildcard, send `Access-Control-Allow-Origin: https://mycoolwebapp:3001` header.	Yes
Nothing (not configured)	Send neither an `Access-Control-Allow-Origin` nor an `Access-Control-Allow-Headers` header.	No

The web browser's request might also include an `Access-Control-Request-Headers` header that lists one or more headers that it wants to use in a subsequent `POST` request (that is, the "actual" as opposed to preflight request). The Splunk HEC Source can then respond with an `Access-Control-Allow-Headers` header **if and only if** it's also sending the `Access-Control-Allow-Origin` header.

CORS allowed headers value	What Splunk HEC Source does	Does Browser then allow code to read response?
`*`	Send `Access-Control-Allow-Headers` header with the same list the client sent.	Yes
Multiple wildcard values	If any headers from the client's list match wildcards, send `Access-Control-Allow-Headers` header listing the matching headers.	Yes
Nothing (not configured)	Do not send an `Access-Control-Allow-Headers` header.	Probably not

Format and Endpoint Examples

Splunk HEC to Cribl Edge

- Configure Cribl Edge to listen on port `8088` with an auth token of `myToken42`.
- Send a payload to your Cribl Edge receiver.

Note: Token specification can be either `Splunk <token>` or `<token>`.

Splunk HEC - JSON Event Examples | Splunk HEC - Raw Event Example | Splunk HEC - Health Event Example

```
curl -k "http://<myCriblHost>:8088/services/collector/event" \
-H "Authorization: myToken42" \
-d '{"event":"this is a sample event ", "host":"myHost", "source":"mySource", "fie

curl -k "http://<myCriblHost>:8088/services/collector" \
-H "Authorization: myToken42" \
-d '{"event":"this is a sample event ", "host":"myHost", "source":"mySource", "fie

# Multiple Events
curl -k "http://<myCriblHost>:8088/services/collector" \
-H "Authorization: myToken42" \
-d '{"event":"this is a sample event ", "host":"myHost", "source":"mySource", "fie

# Metrics Events
curl -k "http://<myCriblHost>:8088/services/collector/event" \
-H "Authorization: myToken42" \
-d '{"event":"metric", "host":"myHost", "fields":{"_value":3850,"metric_name":"ker

curl -k "http://<myCriblHost>:8088/services/collector/event" \
-H "Authorization: myToken42" \
-d '{"host":"myHost", "fields":{"_value":3850,"metric_name":"kernel.entropy_avail"

# Send the auth token as a query parameter, with no additional configuration
curl -k "http://<myCriblHost>:8088/services/collector/event?token=mToken42" \
-d '{"event":"this is a sample event ", "host":"myHost", "source":"mySource", "fie
```

Copy

Splunk HEC to Cribl.Cloud

- Navigate to Cribl.Cloud's Splunk HEC Source > **Auth Tokens** tab.
- Copy your token out of the **Token** field.
- From the command line, use `https`, your Cribl.Cloud portal's Ingress Address and port, and the token's value.

Splunk HEC > Cribl Cloud endpoint

```
curl -k "https://default.main.<organizationId>.cribl.cloud:8088/services/collector" \
-H "Authorization: <token>" \
-d '{"event": "Goats are better than ponies."}{"event": "Goats are better climbers."}
```

Copy

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to `<groupName>.<workspaceName>` when sending to other Fleets and/or Workspaces.

Periodic Logging

Cribl Edge emits metrics about incoming requests when **Advanced Settings** > **Emit per-token request metrics** is enabled. These metrics can be routed to a Destination by enabling the Cribl Metrics Source. There are two categories of metrics: per-token metrics provide details for each configured token, while summary metrics aggregate data across all tokens. If no tokens are configured, only summary metrics will be emitted.

Per-token metric names will be prefixed by `<basePrefix>.http.perToken.`, where `<basePrefix>` is the configured base prefix for the Cribl Metrics Source. The available metric names are listed below, excluding the prefix. As these are counter-type metrics, they will not be emitted if the value is zero.

- `bytesReceived`
- `numRequests`
- `numEvents`
- `numErrors` *Note: this is cumulative of specific error types below as well as a catch-all for other types*
- `numParserErrors`
- `numToDisabledToken`

The summary metric names will be prefixed by `<basePrefix>.http.summary.` where `<basePrefix>` is the configured base prefix for the Cribl Metrics Source. The available metric names are listed below, excluding the prefix. As these are counter-type metrics, they will not be emitted if the value is zero.

- `bytesReceived`
- `numRequests`
- `numEvents`
- `numErrors` *Note: this is cumulative of specific error types below as well as a catch-all for other types*
- `numParserErrors`
- `numToDisabledToken`
- `numAuthFailures`

- `numToWrongUrl`
- `numAckReqs`
- `numReqsAcked`

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Common Issues

"Malformed HEC event"

The event is missing both `event` and `fields` fields.

"Invalid token"

Auth token(s) are defined, but the token specified in the HEC request doesn't match any defined tokens, therefore it's invalid.

"Invalid index"

The Splunk HEC Source's **Allowed Indexes** field is configured with specific indexes, but the client's HTTP request didn't specify any of them.

"{"text":"Server is busy","code":9,"invalid-event-number":0}"

"Server is busy" is the equivalent of a 503 HTTP response code. The most likely cause is the **Active request limit** setting in the HEC input's Advanced Settings is insufficient to service the number of simultaneous HEC requests. Increase the value and monitor your clients to see if the 503 response is eliminated.

This is not logged in Cribl Stream, but would be found in the response payload sent to your HEC client.

"Could not find parser for URL path" and "Dropping request because parser not found"

12.2.4.2. Splunk TCP Source

Cribl Edge supports receiving Splunk data from Universal or Heavy Forwarders.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

For examples of optimizing incoming Splunk events for downstream services, see our Splunk Stream to Cribl Stream, Splunk to Elasticsearch, and Splunk to Exabeam guides.

Also examine several Splunk Forwarder/UF Packs on the Cribl Packs Dispensary. These provide processing Pipelines to optimize Splunk Windows events and Universal Forwarder internal events. You can directly import these and adapt them to your needs.

Looking for the Splunk TCP Source in **Cribl Search**? See Ingest Splunk Forwarder Data into Cribl Search.

Configure Cribl Edge to Receive Splunk TCP Data

Cribl Edge ships with a Splunk TCP Source preconfigured to listen on Port 9997. You can clone or directly modify this Source to further configure it, and then enable it.

In Cribl Edge, configure Splunk TCP:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `in_splunk_tcp`, which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for Splunk data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter port number.

3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing, Auth tokens and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex.

Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.
>
> All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination

becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Event Breakers

Event Breakers are applied only to raw, unparsed data. Data originating from Splunk Heavy Forwarders or Universal Forwarders with sourcetypes configured for event breaking or indexed extractions bypasses Event Breakers, as it is already segmented into discrete events.

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can

work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

Auth Tokens

Add Token: Select to add authorization tokens. Each token's section provides the fields listed below. If no tokens are specified, unauthorized access **will be permitted**.

Authentication method: Choose **Manual** to enter a token in this Source's configuration, or **Secret** to reference a stored secret. Defaults to **Manual**.

Token: Shared secrets to be provided by any Splunk forwarder (`Authorization: <token>`). Displayed when **Authentication method** is **Manual**. Select **Generate** to create a new token.

Token secret (text secret): Displayed when **Authentication method** is **Secret**. Choose **Select local secret** or **Select global secret**, then select a stored text secret or select **Create** to store a new, reusable secret. See Create and Manage Legacy Secrets and Add and Use Global Secrets.

Edge Nodes running Cribl Edge version 4.19.2 and older do not support stored secrets for auth tokens on this Source. Before you downgrade those nodes, switch auth tokens back to **Manual** entry. Leaving stored-secret tokens in place prevents this Source from authenticating or starting on the older version.

Description: Optional description for this token.

Advanced Settings

Enable proxy protocol: Toggle on if the connection is proxied by a device that supports Proxy Protocol v1 or v2.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (such as, all IPs).

Active connection limit: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set `0` for unlimited connections.

Socket idle timeout (seconds): The duration that Cribl Edge will wait for activity on an idle TCP socket before closing the connection. Disabled when set to `0`, the default.

Forced socket termination timeout (seconds): The extra time the server waits before forcibly closing a socket that has been idle (**TCP socket idle timeout**) or exceeded its maximum lifespan (**TCP socket max lifespan**) but has not yet properly closed. This prevents resource leaks caused by unresponsive clients or network issues. Configure based on network latency and client behavior. Default: `30` seconds. Set to `0` to disable.

Socket max lifespan (seconds): The duration that a socket is allowed to remain open, regardless of activity. This setting prevents resource exhaustion (such as TCP pinning) by limiting the lifespan of connections. Configure based on expected connection durations and resource availability. Disabled when set to `0`, the default.

Max S2S version: The highest version of the Splunk-to-Splunk protocol to expose during handshake. Defaults to `v4`; `v3` is also available.

Use Universal Forwarder time zone: Displayed (and enabled by default) only when **Max S2S version** is set to `v4`. Provides Event Breakers with a `__TZ` field, which derives events' time zone from UF-provided metadata. See Using the UF Time Zone and Configuring a Splunk Forwarder, below.

Drop control fields: Toggle on (default) to drop Splunk control fields such as `crcSalt` and `savedPort`. Toggle off if you want to retain these fields and store the data in the `__ctrlFields` internal field.

Extract metrics: Toggle on if you're using Splunk's S2S protocol. When enabled, Cribl will identify and handle Splunk metric events, ensuring that metric events generated by Splunk are processed and forwarded as metrics.

Compression: This setting controls how Cribl Edge reacts to incoming compressed Splunk-to-Splunk `v4` data. Select the **Compression** type from the drop-down list:

- `Automatic`: Cribl Edge will automatically decompress incoming `S2S v4` data.
- `Disabled`: Cribl Edge will reject compressed `S2S v4` connections, closing them immediately. This is the default setting for all Sources, both pre-existing (in versions 4.11 and older) and newly created.

This setting is not available when **Max S2S version** is set to `v3`.

Splunk Forwarder Connection Issues with Compression Disabled

> If upstream Splunk Forwarders are configured to send compressed `S2S v4` traffic (for example, `compressed = true` in `outputs.conf`), setting **Compression** to **Disabled** will cause Cribl Edge to reject the connection. Set **Compression** to **Automatic** to accept and decompress compressed `S2S v4` connections.

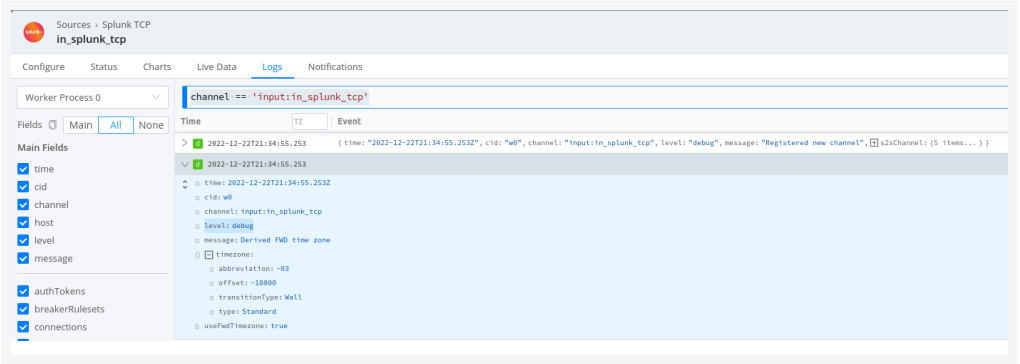
Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Using the UF Time Zone



Under Advanced Settings, the **Use Universal Forwarder time zone** toggle mitigates cases where incoming events have timestamp strings but no time zone information. For example:

```
12-15-2022 14:57:22.080 WARN TcpOutputFd [1607 TcpOutEloop] - Connect to 172.17.0.1:9
```

Copy

This gap can be problematic, especially if the originating Universal Forwarder is in a different time zone from the processing Edge Node.

The `__TZ` field is the solution. Event Breakers use the `__TZ` field to derive time zone information, enabling them to set the `_time` field correctly. Derived time zone information will appear in Cribl Edge's own logs as shown below:

Time zone information in logs

Setting the Log Level for Connection Messages

When a Splunk forwarder connects to Cribl Edge, Cribl Edge logs the following message at the `debug` level: `Connection with forwarder has been established successfully.`

To see this message, set the `:forwarders` level to `debug`.

Each message contains details specific to the forwarder, such as the protocol, Splunk version, or remote host, to name a few.

In some situations, logging each incoming connection can produce many messages, which can make it hard to find other messages.

You can adjust the level of these connection messages. To do so, follow these steps:

1. Select **Settings** > **Global Settings** > **Logging** > **Levels**.
2. Search for the channel that logs the connection messages. It will have a name in the form `input:<source-id>:forwarders`. For example: `input:in_splunk_tcp:forwarders`.
3. Set the channel to the log level you prefer, such as `debug` or `silly`.
4. Click **Save** to save your setting.
5. Commit and deploy the change.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__ctrlFields`
- `__s2sVersion` - value can be either `v3` or `v4`
- `__source`
- `__srcIpPort`
- `__TZ` - see above

Configuring a Splunk Forwarder

To configure a Splunk forwarder (UF, HF) use the following sample outputs.conf stanzas:

outputs.conf (on-prem) outputs.conf (Cribl Cloud)

```
[tcpout]
disabled = false
defaultGroup = cribl, <optional_clone_target_group>, ...
enableOldS2SProtocol = true

[tcpout:cribl]
server = [<cribl_ip>|<cribl_host>]:<port>, [<cribl_ip>|<cribl_host>]:<port>, ...
compressed = false
sendCookedData = true   # Required. Setting to false is not supported.
# As of Splunk 6.5, using forceTimebasedAutoLB is no longer recommended. Ensure th
# forceTimebasedAutoLB = false
```

Copy

---

sendCookedData Must Be True

The Splunk forwarder must have `sendCookedData = true` (the default) in `outputs.conf`. Setting `sendCookedData = false` is not supported, because the Splunk TCP (S2S) Source accepts only cooked data. When a forwarder sends uncooked (raw) data, the Source rejects the connection with an invalid header signature error, because raw mode omits the cooked-mode header the Source requires.

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to `<groupName>.main` when sending to other Fleets.

If your use case requires compression, use useClientSSLCompression vs compressed on forwarder to compress the data stream.

Preventing Data Loss with v3

If you set **Max S2S version** to `v3` and are using Splunk 9.1.0 or later, Cribl recommends that you use the `enableOldS2SProtocol = true` setting shown above to avoid data loss. If you are working with `v3` and a Splunk version earlier than 9.1.0, you should use `negotiateProtocolLevel = 0`. Depending on your environment, enabling `negotiateProtocolLevel` with a non-`0` value could cause Cribl Edge to not accept data from the forwarder.

If you set **Max S2S version** to `v4`, these settings are not necessary. The Splunk receiver will detect which version is in use and automatically use the correct handler.

See Internal Fields for information on the `__s2sVersion` field.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Splunk Forwarder Performance Issues

If you encounter performance issues with a Splunk Forwarder, Cribl recommends increasing the number of parallel ingestion Pipelines or increasing forwarder throughput. You can experiment with either or both of these settings.

To increase the number of parallel ingestion Pipelines, adjust the setting for `parallelIngestionPipelines` in `server.conf`. Experiment with values ranging from `2-4`.

To adjust forwarder throughput, increase the `maxKBps` value in `limits.conf`. The default value is `256`. A value of `0` removes all throttling from the forwarder.

"Connection rejected" with a `reason` of "Too many connections"

The maximum number of active Splunk TCP connections has been exceeded per Worker Process. The default is 1000.

Recommendation

12.2.5. Windows

You can use the following Sources to receive data from Windows services.

Source	Description
Windows Event Forwarder	Receive events from Windows platforms
Windows Event Logs	Read events from the Windows Events API
Windows Metrics	Collect metrics from a Windows host, and populate dashboards

12.2.5.1. Windows Event Forwarder Source

Cribl Edge supports receiving Windows events from the Windows Event Forwarding (WEF) mechanism built into modern versions of Microsoft Windows (including Windows 10, Windows Server 2012, and more-recent releases).

The integration between WEF and Cribl works by generating events on Windows systems, which are collected by Windows Event Collectors (WECs). These events are then forwarded to Cribl using WEF, secured by mutual TLS, Kerberos, or Negotiate (SPNEGO) authentication. Cribl receives the events through the Windows Event Forwarder Source, processes them according to configured pipelines, and sends the processed events to designated Destinations.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No** | Uses Key-Value Store

Looking for the Windows Event Forwarder Source in **Cribl Search**? See Ingest Windows Events into Cribl Search.

Prerequisites

- WEF is set up and enabled.
- WEF client(s) are pointed to WECs.
- You've configured client certificate authentication, or the Kerberos prerequisites that the Kerberos and Negotiate (SPNEGO) methods share.

On Cribl Edge, this Source supports Kerberos and Negotiate (SPNEGO) authentication only on Edge Nodes running on x86_64 Linux.

Configure Cribl Edge to Receive Windows Events

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the Source modal, configure the following under **General Settings**:
    - **Input ID**: A unique name that identifies this Windows Event Forwarder Source.

- **Description**: Optionally, enter a description.
- **Address**: The hostname/IP on which to listen for Windows events data. Example: `localhost` or `0.0.0.0`.
- **Port**: The port number. The default, `5986`, is the port used by Windows Event Collector for HTTPS-based subscriptions.
- **Authentication method**: The method for accepting incoming client connections: `Client certificate`, `Kerberos`, or `Negotiate (SPNEGO)`. See Choose an Authentication Method.

Kerberos and Negotiate (SPNEGO) appear in the **Authentication method** drop-down in Cribl.Cloud, but they are not supported for Cribl-managed Workers. They are enabled for customer-managed Fleets, whether on-prem or hybrid.

- For **Client certificate**:
  - **Certificate**: Choose the certificate you created.
  - **Private key path**: Server path containing the private key (in PEM format) to use. For Cribl.Cloud, the default path is `/opt/criblcerts/criblcloud.key` for a Cribl-managed Fleet in Cribl.Cloud. Path can reference `$ENV_VARS`.
  - **Passphrase**: Passphrase to use to decrypt private key.
  - **Certificate path**: Server path containing certificates (in PEM format) to use. For Cribl.Cloud, the default path is `/opt/criblcerts/criblcloud.crt` for a Cribl-managed Fleet in Cribl.Cloud. Path can reference `$ENV_VARS`.
  - **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`. If multiple certificates are present in a `.pem`, the first certificate in the chain should be the issuing CA certificate. If the first certificate is not the issuing CA, use the **CA fingerprint override** setting to specify the expected SHA1 fingerprint. This should match the order of traversing the chain from the host to the root CA cert.

The CA certificate that generated the Cribl Edge server certificate must match the root CA that signed all client certificates that will be forwarding Windows events to this Source. If the issuing CA is an intermediate CA, this CA must also match on the server and all client certs.

  - **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`.
    - Matches on the substring after `CN=`.
    - As needed, escape regular expression (regex) tokens to match literal characters. For example, to match the subject `CN=worker.cribl.local`, you would enter:

`worker\.cribl\.local`.

- If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

- Optionally, select the **Minimum TLS version** and **Maximum TLS version** to accept from connections.
- **Verify certificate via OCSP**: If toggled on, Cribl Edge will use an OCSP (Online Certificate Status Protocol) service to check that client certificates presented in incoming requests have not been revoked. Exposes the **Strict validation** toggle.
- **Strict validation**: If enabled, Cribl Edge will fail checks on **any** OCSP error. Otherwise, Cribl Edge will fail checks only when a certificate is revoked, and will ignore other errors (such as `OCSP server is unavailable` errors).

- For **Kerberos** or **Negotiate (SPNEGO)**: Provide the SPN and keytab file location that you set in Keytab file. Both methods use the same credentials and the same settings:
  - **Service principal name**: The Service Principal Name (SPN) in this format: `HTTP/<fully qualified domain name>@REALM`. This identifies the service in the Kerberos realm. The service principal name is case-sensitive, and must be exactly in the form used to export the keytab.
  - **Keytab location**: The path to the keytab file containing the service principal credentials. Cribl Edge uses `/etc/krb5.keytab` by default. This file contains the keys used for Kerberos authentication.
- Optionally, add **Tags** that you can use to filter and group Destinations in Cribl Edge's **Manage Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

3. **Subscriptions** define which logs to collect and how to filter them. You need to add at least one subscription. For comprehensive details on subscription settings and the query builder, refer to the subscriptions section.
4. Optionally, configure any Persistent Queue Settings, Processing Settings, and Advanced Settings outlined in the below sections.
5. Click **Save**, then **Commit & Deploy**.

Choose an Authentication Method

Client certificate secures the connection with mutual TLS. Windows clients connect over `https`, and the Subscription Manager GPO must include the `IssuerCA` thumbprint. See Client Certificate Authentication for Windows Event Forwarder.

Kerberos and **Negotiate (SPNEGO)** both authenticate against your Windows domain using the same service principal name and keytab. Both encrypt the WS-Management payload at the message level rather than at the transport level. For either method, Windows clients connect over `http` instead of `https`, the Subscription Manager GPO omits `IssuerCA`, and Cribl Edge disables this Source's TLS settings. See Kerberos Authentication for Windows Event Forwarder for the domain, keytab, and Group Policy setup that both methods require.

The two methods differ only in the HTTP authentication scheme they use:

- **Kerberos** challenges clients with `WWW-Authenticate: Kerberos` and labels encrypted payloads `application/HTTP-Kerberos-session-encrypted`. This is the raw Kerberos scheme that Windows uses by default.
- **Negotiate (SPNEGO)** challenges clients with `WWW-Authenticate: Negotiate` and labels encrypted payloads `application/HTTP-SPNEGO-session-encrypted`. Kerberos remains the underlying mechanism, and SPNEGO is the wrapper that negotiates it.

Select **Negotiate (SPNEGO)** when Windows clients present the Negotiate scheme instead of raw Kerberos. If you leave **Authentication method** set to **Kerberos**, those clients reject the challenge and no events arrive.

Both **Kerberos** and **Negotiate (SPNEGO)** accept either scheme on incoming requests, and Cribl Edge labels each encrypted response to match what the client sent. The setting you choose determines the scheme that Cribl Edge uses in its `401` challenge, which is what a policy-constrained client checks.

Subscriptions

Subscriptions control which events are collected from Windows endpoints and sent to the Cribl Edge Windows Event Forwarder Source. They filter the types of events to monitor, like security logs or application logs.

Due to the way subscription bookmarks are stored, Leader CPU usage is directly impacted by the number of subscriptions created for the Source and the number of clients receiving each subscription. To optimize performance, prefer to minimize the number of subscriptions by combining them where possible.

You can tailor your event collection to focus on the data that matters most to your Organization's security and monitoring needs. This helps reduce noise, save storage space, and ensure critical events are captured and analyzed.

Select **Add Subscription** and fill out the following fields to define at least one new, required subscription.

Subscription name: A friendly name for the subscription, which is only used to help you identify it.

Version: A read-only field that automatically updates whenever you save changes to the subscription. This version number reflects the specific configuration of the subscription and helps ensure that clients correctly

interpret and process the subscription data.

Format: You can choose `Raw` to receive only XML data about the subscribed events, or `RenderedText` to additionally include amplifying information generated by the client about the event's contents.

Heartbeat: The maximum allowable time, in seconds, before the client will check in with Cribl Edge even if it has no new events to send.

Batch timeout: The maximum time, in seconds, that the client should batch new events before sending them to Cribl Edge.

Windows Event Collector defines two delivery modes of "Event Delivery Optimization":

- The "Minimize Bandwidth" mode corresponds to a **Heartbeat** and **Batch timeout** of 6 hours (21,600 seconds).
- The "Minimize Latency" mode corresponds to a **Heartbeat** of 1 hour (3,600 seconds) and a **Batch timeout** of 30 seconds.

Locale: The language code to use for the events sent by the client, in RFC-3066 format (for example, `en-US`). The language code uses ISO 639, and the country code uses ISO 3166. Defaults to `en-US` when left blank.

Read existing events: Controls whether the client should send historical events when it first connects. The behavior of **Read existing events** is influenced by the **Use bookmarks** setting. See the table below for a complete overview.

Use bookmarks: Keeps track of which events it has received.

Setting	Behavior
Read existing events toggled off	Only new events generated after it receives the subscription are sent.
Read existing events toggled on and **Use bookmarks** toggled off	All historical events are sent on the initial subscription and each time a client *forcibly* renews its subscription (for example, after group policy update), all events matching the query will be sent. Restarting Cribl Edge or restarting the client will not cause all events to be re-sent.
Read existing events toggled on and **Use bookmarks** toggled on	Historical events are sent on the initial subscription, but only new events (later than the saved bookmark) are sent on subsequent (even forced) subscription renewals.

Important Considerations

- **Subscription changes**: If you change and save a subscription, the saved bookmarks are no longer valid (they are tied to a specific subscription version), and all events matching the updated subscription will be sent.

- **Leader and Edge Node interactions**: Edge Nodes continue to accept new events even when the Leader is down. They sync with the Leader when it's back up. However, bookmarks stored in memory can be lost if a Edge Node restarts while the Leader is down.
- **Client balancing and bookmarks**: If a client balances to a different Edge Node while the Leader is down, it might receive a stale bookmark. Bookmarks are only sent to the client when it requests a subscription, not when it delivers events. This typically happens on the `Refresh=XX` interval from the GPO.
    - If the Leader is down when a client requests a subscription, it will receive the last known bookmark from the Edge Node, which could be outdated.
    - If a Edge Node restarts while the Leader is down, the client might not receive any bookmark at all, potentially leading to duplicate events.

Compression: Sets whether Windows clients compress the events sent to Cribl Edge, using the Streaming Lossless Data Compression (SLDC) algorithm. Defaults to toggled on.

Queries: See the explanation in Configuring Queries below.

Query builder mode: See the explanation in Configuring Queries below.

Targets: Set the DNS names of the clients that should receive this subscription. This field supports wildcard matching.

Fields: Use this setting to add fields exclusively to the events that WEF delivers **for the subscription you are defining**, using Eval-like functionality. To add fields to all incoming events regardless of subscription, use **Processing Settings** > **Fields** instead:

Optionally, you can create the field such that its **Value** is the value of a subscription metadata element. (See the available subscription metadata elements listed below.)

To do this, specify a **Value** of `__subscription.<metadata_element>`. The Source will then find the metadata element you specified in the special object `__subscription` and set the value to that.

For example, if you wanted all events for the subscription to be tagged with its **Locale**, you could set the **Name** to `Locale` (or any arbitrary name) and **Value** to `__subscription.locale`.

- **Field Name**: Unique name for the field you're adding.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Subscription Metadata Elements

Metadata Element	Type	Corresponding UI Setting
`version`	string	**Version**

Metadata Element	Type	Corresponding UI Setting
`subscriptionName`	string	**Name**
`contentFormat`	`Raw` or `RenderedText`	**Format**
`readExistingEvents`	boolean	**Read existing events**
`heartbeatInterval`	number	**Heartbeat**
`batchTimeout`	number	**Batch timeout**
`sendBookmarks`	boolean	**Use bookmarks**
`compress`	boolean	**Compression**
`queries`	array	see About the Query builder mode below

Change Subscriptions

If you change a subscription that is in use, Windows Event Forwarder will discover the new subscription ID. Once the `Refresh=XX` interval has elapsed, if any events were sent to the now-invalid previous subscription ID, Windows will resend them to the new one (assuming that these events remain valid under the updated subscription parameters). The Receiver Refuses to Accept Delivery of Events warnings you'll see in this scenario are normal.

About Query Builder Mode

This setting produces the `queries` array in one of two different forms, depending on whether you select its **Simple** button or its **Raw XML** button.

Simple produces an array whose elements each contain `path`, a string that corresponds to **Queries** > **Path**, and `queryExpression`, a string that corresponds to **Queries** > **Query expression**.

Raw XML produces an array whose elements each contain only the `xmlQuery` metadata element. This is the XML query you specified, in the form of a string, that corresponds to the **XML query** setting.

To access any element in the array, use array indexing. For example:

- `__subscription.queries[0].path` will access the path to the first query in an array created by **Query builder mode** > **Simple**.
- `__subscription.queries[0].xmlQuery` will access the first query in an array created by **Query builder mode** > **Raw XML**.

Configure Queries

Queries determine which events to send from the clients. **At least one query is required.** The format is derived from the XPath implementation used by Windows Event Collector.

While a single XPath query in a WEF subscription is limited to approximately 22 EventIDs, you can monitor more by creating a structured XML query with multiple `<Query>` elements within a single subscription. This is the recommended approach for performance and resource efficiency.

You have two **Query builder mode** options: **Simple** or **Raw XML**.

- **Raw XML** allows you to enter your XPath query into the **XML query** field.
- **Simple** allows you to manually build queries. Click **Add Query** to define each new query. A query has the following properties:
  - **Path**: Set this to the `Path` attribute of a `Select` XPath element. See the example below.
  - **Query expression**: Set this to the value inside a `Select` XPath element. See the example below.

With either a **Simple** or **Raw XML** query, you can use the **Targets** field to specify the DNS names of the endpoints that should forward these events. Supports wildcards (for example, `*.mydomain.com`). The default global wildcard (`*`) enables all endpoints.

If you have both **Simple** and **Raw XML** queries defined within a given Subscription, the **Query builder mode** button that you select when saving this Source's configuration determines which query/queries Cribl Edge will send. To send both **Simple** and **Raw XML** queries, use the **Add Subscription** button to define multiple subscriptions.

Example

When creating a subscription in a Windows Event Collector, you can view the generated XML/XPath query. Consider a subscription that returns all events from the Security log that are of severities Critical, Error, or Warning, and that occurred within the last 24 hours. This subscription would generate XML like this:

```
<QueryList>
  <Query Id="0" Path="Security">
    <Select Path="Security">*[System[(Level=1  or Level=2 or Level=3) and TimeCreated
  </Query>
</QueryList>
```

Copy

To use this subscription in a Cribl Edge Windows Event Forwarder Source, you would either use the **Raw XML** option and paste the above XML, or use **Simple** mode and set the following query properties:

- **Path**: `Security`
- **Query expression**: `*[System[(Level=1 or Level=2 or Level=3) and TimeCreated[timediff(@SystemTime) <= 86400000]]]`

You do not need to use the `<Query>` element's `Id` or `Path` attributes anywhere in the Cribl Edge subscription config.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

Use this setting to add fields to **all events coming into the Source**, using Eval-like functionality. (To add fields on a per-subscription basis, use **Subscriptions** > **Fields** instead.)

Field Name: Unique name for the field you're adding.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Allow MachineID mismatch (client certificate only): Toggle on if you do not want to verify that the events sent by a client match the client's certificate Common Name (Subject CN). If toggled off, events where the `MachineID` (by default the client's machine name, like `CLIENT1.domainName.com`) do not match the CN will be rejected.

This setting applies only to client certificate authentication. If you use Kerberos or Negotiate (SPNEGO) authentication, this option will not appear and will be treated as if it is toggled off.

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

> When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source: `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Log CA fingerprint mismatch warning (client certificate only): Toggle on to log a warning message when the client certificate's issuing Certificate Authority (CA) fingerprint doesn't match the expected CA fingerprint configured in the Windows Event Forwarding Source. This mismatch prevents proper authentication and event forwarding. The log message is `Mismatched fingerprint` and includes both the expected `acceptedFingerprint` and actual `issuerFingerprint` fingerprints. Toggled off by default.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

> Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:
>
> - Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
> - Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

> Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever. For Kerberos or Negotiate (SPNEGO) authentication, see how to adjust timeouts.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge how long to wait for additional data before closing the socket connection. Defaults to `90` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the timeout, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

For Kerberos or Negotiate (SPNEGO) authentication, see how to adjust timeouts.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

CA fingerprint override (client certificate only): Use this setting only if the first certificate in the configured CA chain does not match the SHA1 fingerprint that the WEF client expects, such as an intermediate certificate. If that is the case, enter the expected SHA1 fingerprint. The thumbprint specified here must match the `IssuerCA` parameter in the Subscription Manager template.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Timeout Considerations for Kerberos and Negotiate Authentication

If you use Kerberos or Negotiate (SPNEGO) authentication, there are some trade-offs you should consider when you select settings in **Subscriptions** > **Batch timeout** and **Advanced Settings** > **Keep-alive timeout (seconds)**.

Windows expects socket connections to be long-lived for these methods so it can avoid the overhead of performing the two-step Kerberos authentication on each new batch delivery.

Set **Subscriptions** > **Batch timeout**, **Subscriptions** > **Heartbeat**, or both to be less than or equal to **Keep-alive timeout** (or the lowest **Batch timeout** if several subscriptions are used), especially when a load balancer is in front of the Edge Nodes.

Set **Socket timeout** higher than **Batch timeout** (or the lowest **Batch timeout** if several subscriptions are used). This ensures that connections aren't prematurely closed before batches are sent. If the **Socket timeout** has elapsed between event deliveries or heartbeats, Cribl Edge will still handle it gracefully, but incur an additional overhead of two network round trips.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Event Handling

The Windows Event Forwarder Source uses internal fields and a key-value store to manage and process events efficiently. Internal fields are metadata added to events for internal processing and should be treated as read-only to avoid unintended consequences. Key fields include:

- `__final`
- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__inputId`
- `__srcIpPort` - See details below.
- `__subscriptionName`
- `__subscriptionVersion`
- `_raw`
- `_time`

The key-value store uses the `machineId` as keys to store bookmark information when bookmarks are enabled. This ensures that events are processed correctly and efficiently by maintaining the state of event processing.

Together, the key-value store and internal fields work to ensure accurate and efficient event handling. The key-value store maintains the state of event processing, while internal fields provide necessary metadata for internal operations, enabling Cribl Stream to process and route events effectively.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the WEF client sending data to this Source.

In the WEF Source configuration, there's an option to handle the `X-Forwarded-For` header, which is commonly used by load balancers to pass the original client's IP address. When any proxies (including load balancers) lie between the WEF client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Troubleshoot

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Common Issues

High CPU Usage on Leader Node API Process

Problem: Experiencing high CPU usage on your Leader Node's API Process is often a symptom of having too many subscriptions (thousands). This can lead to performance issues and instability.

Solutions: First attempt to reduce or consolidate your subscriptions. This can often alleviate the problem without the need for additional configurations. However, since the process of consolidating subscriptions can vary significantly between environments, there is no one-size-fits-all approach.

If you are unable to reduce the number of subscriptions sufficiently, consider enabling Write-Ahead Log (WAL) mode for the key-value store (KV Store). We recommend working with Cribl Support to incorporate the new **KV Store** settings effectively. You can find these settings under **Settings** > **Global Settings** > **General Settings** > **Limits** or in the limits.yml file.

Security Event Log Forwarding Fails

Error: `Error "0x138C" Windows Event Forward plugin can't read any event from the query since the query returns no active channel.`

Solution: Enable the Network Service to read the security logs by configuring access for the Event Log Service.

When configuring a Group Policy Object (GPO) to add NETWORK SERVICE permissions, carefully review existing permissions to prevent unintended removal. Preserve all necessary permissions to avoid application issues.

Cannot Find the Certificate

Error: `The forwarder is having a problem communicating with subscription manager at address... The WS-Management service cannot find the certificate that was requested.`

For example:

```
The forwarder is having a problem communicating with subscription manager at address

Error code is 2150858882 and Error Message is <f:WSManFault xmlns:f=http://schemas.mi
```

Copy

Resolution:

- The `NETWORK SERVICE` user does not have permissions to use the private key of the certificate for authentication.
- Add the `NETWORK SERVICE` user to the list of users allowed to use the private key.

Receiver Refuses to Accept Delivery of Events

Warning: `The receiver refuses to accept delivery of events and requests that the subscription be canceled.`

If you make a change to a subscription that is in use, **and** if the Windows client tries to send events before the `Refresh=XX` interval has elapsed, the result is that these events are sent to the old subscription, which is now invalid because its query is outdated or because other subscription parameters have changed.

The warning message tells the WEF client to stop sending events to the now-invalid old subscription.

Resolution:

Windows Event Forwarder handles this scenario gracefully, and you do not need to take any action to resolve it:

- Once the `Refresh=XX` interval has elapsed, the WEF client will ask for and receive the updated subscription, and from then on should be able to successfully deliver events against that new subscription.
- Any events that were refused under the old/invalid subscription ID will be resent under the new one, assuming that they remain valid according to the new subscription parameters.

Subscription Cannot be Created

Error: `The subscription <subscription> can not be created. The error code is 5004.`

The error appears in the `Microsoft-Windows-Eventlog-ForwardingPlugin/Operational` log.

Resolution:

1. Apply the `O:BAG:SYD:...` permissions to make the log file readable.
2. Reboot the machine.

Verify that Client and Destination are Joined to a Domain

Error: `If Kerberos mechanism is used, verify that the client computer and the destination computer are joined to a domain.`

When you are using auto-enroll, the `Eventlog-ForwardingPlugin Operational` logs might display an error of this form.

Resolution:

In your auto-enroll template's **Client-Server Authentication Properties**, make sure the **Subject Name format** is set to **Common name**.

Resources

For processing Pipelines that you can import and adapt to your needs, examine these resources on the Cribl Packs Dispensary:

- Microsoft Windows Events - Shape events into JSON or Key=Value format, and dramatically reduce event sizes.
- Cribl Edge Windows for Common Schema - Transform Windows events into a Common Schema.
- Exabeam Pack for Windows - Forward specific Windows Event IDs to Exabeam.
- QRadar Pack for Windows Events - Optimize Windows events for delivery to QRadar.

Further Reading

12.2.5.1.1. Client Certificate Authentication For Windows Event Forwarder

This document covers the client certificate authentication setup steps you need to take before configuring a Windows Event Forwarder Source.

1. Set Up WEF

Follow this Microsoft guide for setting up Windows Event Forwarding (WEF) in a traditional Windows environment. Generally, you can follow the guide's "non-domain" section to correctly configure the endpoints/senders.

2. Configure Certificates

After setting up WEF, you need to configure certificates to ensure secure communication. Server certificate configuration varies depending on your deployment type. However, you'll always need to configure a client certificate.

On-prem deployments: Add the server certificate and CA chain to the Fleet, see Add TLS Certificates and Keys for details. Add the client certificate to Windows either manually or with certificate auto-enrollment through Group Policy to automatically configure unique device certificates. For specific configuration options, consult with your Windows administrators.

Cribl.Cloud deployment: Upload the CA chain for your client certificate, see Add TLS Certificates and Keys for details. The actual certificate/key pair in the chain doesn't matter for this purpose. It's solely to satisfy the technical requirement of uploading a chain. Use Cribl's provided certificate and key:

- `/opt/criblcerts/criblcloud.crt`
- `/opt/criblcerts/criblcloud.key`

3. Set Client Certificate Permissions

Set the appropriate permissions for the `NETWORK SERVICE` user to use the private key of the certificate for authentication.

Open the Certificate Manager tool (`certlm.msc`).

- Right-click your client certificate and select **All Tasks** > **Manage Private Keys...**.
- Add the `NETWORK SERVICE` user.

4. Configure the Subscription Manager and Log Forwarding Group Policies

1. On a domain controller, open the Group Policy Management Console (GPMC).
2. Create a new Group Policy Object (GPO) or edit an existing one that is linked to the organizational unit (OU) containing the computers you want to configure.
3. Navigate to **Computer Configuration** > **Policies** > **Administrative Templates** > **Windows Components**. Select **Event Forwarding** to open the Local Group Policy Editor.
4. Select **Configure target Subscription Manager** and use one of the following templates depending on your deployment type, substituting the appropriate values for the placeholders.
   On-Prem:

   ```
   Server=https://<cribl-worker-or-lb>:<wef-source-port>/wsman/SubscriptionManager/
   ```

   Copy

   Cribl.Cloud:

   ```
   https://<groupName>.main.<org-name>.cribl.cloud:<wef-source-port>/wsman/Subscrip
   ```

   Copy

   - The path portion `/wsman/SubscriptionManager/WEC` within the **Subscription Target URL** set using Group Policy Objects (GPOs) is the same as required for a WEC subscription and is strictly case-sensitive. If the capitalization is incorrect, WEF will encounter errors and fail to forward events to Cribl Edge.
   - The `IssuerCA` thumbprint is the SHA1 thumbprint of the issuing certificate, which could be an intermediate certificate. This must match the thumbprint of the first certificate in the certificate chain configured in the WEF Source's CA certificate path or the specified **CA fingerprint override**.
5. When complete, save the policy and apply it to affected endpoints. Link the GPO to the appropriate OU if it is not already linked.
6. To enable the Network Service to read the security logs, you'll need to configure access for the Event Log Service.

When configuring a Group Policy Object (GPO) to add NETWORK SERVICE permissions, carefully review existing permissions to prevent unintended removal. Preserve all necessary permissions to avoid application issues.

1. Open the Local Group Policy Editor tool (`gpedit.msc`).
2. Navigate to **Computer Configuration** > **Policies** > **Administrative Templates** > **Windows Components** > **Event Log Service**. Double-click **Security**, then in the **Settings** pane, select **Configure log access**.

Configuring log access

3. In the resulting modal, under **Options** > **Log Access**, enter the following Log Access configuration:

```
O:BAG:SYD:(A;;0xf0007;;;SY)(A;;0x7;;;BA)(A;;0x1;;;BO)(A;;0x1;;;SO)(A;;0x1;;;S-1-
```

Copy

4. Then, reboot your Windows machine to apply this setting. (Source: Microsoft's Security event log forwarding fails... topic.)

7. Check that events are flowing into Cribl Edge now according to the configured subscriptions. On client machines, run `gpupdate /force` to apply the new policy immediately. If events are not flowing, verify all of the following:
   - The clients can reach the Cribl Edge instance through the network to port `5986` (or other configured port) via TLS/HTTP. If clients are connecting to Cribl Stream via a proxy, you may need to toggle **Show originating IP** on (in the Advanced section of the Source configuration). Ensure that the correct outbound firewall port is opened on the client.
   - The certificate chain is correct
   - The endpoints have a valid CRL encompassing the CA cert
   - The CA cert is a trusted root on the clients
   - The server and client certs are issued by the same CA. The `CAPI2` Windows event log might reveal any errors here.
   - Check Cribl Edge for any errors, as well as the `EventForwarding-Plugin` and `Windows Remote Management` event logs on the clients.

Now you can provide client certificate authentication to a Windows Event Forwarder Source.

12.2.5.1.2. Kerberos Authentication For Windows Event Forwarder

This document covers the Kerberos authentication setup steps you need to take before configuring a Windows Event Forwarder Source.

These steps apply to both the **Kerberos** and **Negotiate (SPNEGO)** authentication methods, which use the same domain configuration, service principal name, and keytab. For the difference between the two methods, see Choose an Authentication Method.

Kerberos and Negotiate (SPNEGO) authentication are only supported on x86_64 Linux systems.

Initial Assumptions

To ensure a smooth configuration process, review the following prerequisites:

- The clients that will be sending events are in a Windows domain. In this example, the domain is `contoso.com`, the NETBIOS name is `CONTOSO`, and the domain controller is `DC01.contoso.com`.
- Kerberos KDC is already configured and working on the domain, and WEC with Kerberos authentication already works on the domain.
- You have an x86_64 Edge Node to which you have shell access. This guide assumes a recent Ubuntu distribution.
- The fully qualified domain name (FQDN) of this example Edge Node is `worker1.contoso.com`.
- You are using a Kerberos credential cache of the `DIR` or `FILE` type.

1. Initial Setup for the Edge Node

To set up the Edge Node:

1. Ensure that the Edge Node can resolve the domain controller's FQDN. You can test it with: `ping DC01.contoso.com`.
2. Ensure that the Edge Node's `hostname` is set to the FQDN. If it's not, you can set it with `hostnamectl set-hostname worker1.contoso.com`.
3. Ensure the Edge Node has its clock synchronized with the domain controller.
4. Install the `krb5-user` package and configure Kerberos to correctly identify your domain. Here's an example configuration (`/etc/krb5.conf`).

```
[libdefaults]
default_realm = CONTOSO.COM

[realms]
  CONTOSO.COM = {
    kdc = DC01.contoso.com
    admin_server = DC01.contoso.com
  }

[domain_realm]
  .contoso.com = CONTOSO.COM
  contoso.com = CONTOSO.COM
```

Copy

2. Setup for the Domain Controller

Configure the domain controller to support Kerberos authentication for your Edge Node. This involves setting up DNS records and creating a domain user with the necessary permissions and encryption settings. Proper configuration ensures that the Edge Node can securely authenticate and communicate within your network.

To set up the domain controller:

1. Set up forward and reverse DNS for the Edge Node's FQDN (that is, both A and PTR records).
2. Both `nslookup worker1.contoso.com` and `nslookup <worker's IP>` should work.
3. Create a domain user for the Edge Node. This guide assumes the user is called `svc-stream-worker1`.
4. Set the user's password to never expire.
5. Under the user's **Properties** > **Account** tab, set both `This account supports Kerberos AES 128 bit encryption` and `This account supports Kerberos AES 256 bit encryption`.
6. Create a keytab file for the Edge Node. This file will contain the necessary credentials for the Edge Node to authenticate with the domain controller. See the Keytab Export section below for instructions on how to generate the keytab file.

Keytab Export

This section guides you through exporting a keytab file, which is essential for Kerberos authentication. The keytab file contains the necessary credentials for the Edge Node to authenticate with the domain controller. You will generate this file using the `ktpass` command and then transfer it to the Edge Node. This step is crucial for enabling secure, authenticated communication between your Edge Node and the domain controller.

To export the keytab:

1. Export a keytab file for this user, which will also create the appropriate service principal name (SPN). The keytab will be exported to the root of the user profile running the command.
2. Open an elevated PowerShell prompt on the domain controller.
3. Run the following ktpass command to generate the keytab file: `ktpass /princ http/worker1.contoso.com@CONTOSO.COM /pass <password> /mapuser CONTOSO\svc-stream-worker1 /crypto AES256-SHA1 /ptype KRB5_NT_PRINCIPAL /out worker1.contoso.com.keytab`
    - `ktpass`: This is the command-line utility used to create keytab files for Kerberos authentication.
    - `/princ http/worker1.contoso.com@CONTOSO.COM`: Specifies the principal name. In this case, it is `http/worker1.contoso.com@CONTOSO.COM`. The principal name is a unique identifier for the service.
    - `/pass <password>`: Specifies the password for the user account. Replace `<password>` with the actual password for the `svc-stream-worker1` user.
    - `/mapuser CONTOSO\svc-stream-worker1`: Maps the principal name to the specified domain user account. Here, `CONTOSO\svc-stream-worker1` is the domain user created for the Edge Node.
    - `/crypto AES256-SHA1`: Specifies the encryption type to be used. `AES256-SHA1` is a strong encryption algorithm.
    - `/ptype KRB5_NT_PRINCIPAL`: Specifies the principal type. `KRB5_NT_PRINCIPAL` indicates that the principal is a Kerberos principal.
    - `/out worker1.contoso.com.keytab`: Specifies the output file name for the keytab. The keytab file will be saved as `worker1.contoso.com.keytab`.

    > **Windows SPN compatibility**
    >
    > The SPN prefix you use in the `ktpass /princ` parameter must match what your Windows clients use when connecting. The example here uses `http/worker1.contoso.com@CONTOSO.COM`, which works in most environments, but some newer Windows versions (such as Windows Server 2025) require `host/worker1.contoso.com@CONTOSO.COM` instead.
    >
    > To maximize compatibility across Windows versions, register both `http/worker1.contoso.com` and `host/worker1.contoso.com` SPNs on the account running the Edge Node. If Kerberos authentication fails with the `http/` example, regenerate the keytab using `/princ host/worker1.contoso.com@CONTOSO.COM` so it matches the SPN your clients require.
4. Note the SPN created here (in this example, `http/worker1.contoso.com@CONTOSO.COM`) as you will need it later. This SPN is case-sensitive.

5. Copy the keytab file to the Cribl Edge Edge Node. Carefully note the file's location on the Edge Node, because you will need it later. The keytab command and output will resemble this example:

```
PS C:\Users\Administrator> ktpass /princ http/wefkerb.weftest.local@WEFTEST.LOCAL /pa
Targeting domain controller: SUP-DC01.weftest.local
Using legacy password setting method

Successfully mapped http/wefkerb.weftest.local@WEFTEST.LOCAL to cribl.
Key created.

Output keytab to wefkerb.weftest.local.keytab:
Keytab version: 0x502
keysize 110 http/wefkerb.weftest.local@WEFTEST.LOCAL ptype 1 (KRB5_NT_PRINCIPAL) vno
```

Copy

If you rotate passwords on this user service account, you'll need to export a new keytab file and merge or replace the keytab on each Edge Node. Microsoft describes a general method for this task. The Microsoft method is for a different service, but it explains the general principles. You could also use a tool like `msktutil`.

3. Setup for the Windows Event Forwarding Target

To set up the Windows event forwarding target, you'll need to create group policy objects (GPOs) for the subscription target, the WinRM service, and the NETWORK SERVICE.

Create a GPO for the Subscription Target

Create a Group Policy Object (GPO) to configure the subscription target for Windows Event Forwarding (WEF). This GPO will define the target server and the refresh interval for event subscriptions.

1. Access the UI **Computer Configuration** > **Administrative Templates** > **Windows Components** > **Event Forwarding** > **Configure target Subscription Manager**.
2. Set to `Enabled`.
3. Go to **Subscription Managers** > **Show**.
4. Add `Server=http://worker1.contoso.com:5985/wsman/SubscriptionManager/WEC,Refresh=60` to the list.

Create a GPO for the WinRM Service

Create a Group Policy Object (GPO) to ensure that the Windows Remote Management (WinRM) service is automatically started on client machines. This is a crucial step for enabling remote management and communication between the clients and the Edge Node. By setting the WinRM service to start automatically, you ensure that the necessary remote management capabilities are always available.

1. Access the UI **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **System Services** > **Windows Remote Management (WS-Management)**.
2. Set **Startup type** to `Automatic`.

Create a GPO for the NETWORK SERVICE

Create a Group Policy Object (GPO) to grant the NETWORK SERVICE account the necessary permissions to read event logs. This is particularly important if you plan to subscribe to the Security event log. Properly configuring these permissions ensures that the `NETWORK SERVICE` account can access and forward the required event logs to the Edge Node.

1. Access the UI **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **Restricted Groups**.
2. In the right pane, right-click and select **Add Group**.
3. Enter `Event Log Readers` as the group name.
4. Under `Members of this group`, click **Add**.
5. Enter `NETWORK SERVICE` as the member name.

For the change to take effect, you'll have to restart computers after you apply this GPO.

Now you can provide Kerberos or Negotiate (SPNEGO) authentication to a Windows Event Forwarder Source.

12.2.5.2. Windows Event Logs Source

Cribl Edge supports collecting local Windows Event Logs.

For guidance on workflow, see our better practices doc: Collect Windows Event Logs and Metrics.

Type: **Pull** | TLS Support: **N/A** | Event Breaker Support: **No** | Uses Key-Value Store

Cribl Edge Workers support Windows Event Logs only when running on Windows, not on Linux.

You can collect standard event logs with the Windows Event Logs Source - Application, Security, and System - and any other event logs on the machine.

Configuring Cribl Edge to Collect Windows Event Logs

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Event logs**: Enter one or more event logs to collect. Click **Add log** to specify more event logs (for example, `Application` or `System`). To identify the name of the log to collect, you can use the Windows Server Event Viewer. For more information, see Locate Windows Event Logs on the Server.
3. Next, you can configure the following **Optional Settings**:
    - **Suppress missing event log errors**: Toggle on to hide errors when a configured event log does not exist on the host. When enabled, missing event logs will not affect the Windows Event Logs Source health status. This is useful when you have Fleets where some Edge Nodes may not have all the configured event logs. This setting applies only when **Use Windows Tools** is disabled.
    - **Read mode**: Select **From last entry** (the default) to read only new events. Select **Entire Log** to read all of the historical events and new events.

- **Event format**: Select JSON or XML as the event format. JSON is the default. You can change this setting at any time.
- Events include the `__winEvent` property in both XML and JSON format. This property is one of the default **Excluded fields** in the Cribl TCP Destination. For details, see `__winEvent` Property.
- **Render event message strings**: Toggle on to display rendered message strings in the XML and JSON event output.
  - This toggle only appears when you toggle **Use Windows Tools** off.
  - Defaults to toggled on when JSON is the selected event format and off when XML is the event format.
  - Events will not contain a `Message` property when toggled off.
- **Include empty JSON fields**: Toggle on to keep fields with empty values (`-`) in JSON events. When toggled off, the Source omits those fields from the JSON output. Toggling this setting on can increase event size.
- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Use Windows Tools: Toggled off by default.

Deprecation Notice

This legacy setting will be removed in a future release. We highly recommend keeping this option disabled and using the newer native capabilities, which are faster and more reliable.

- If toggled off:
  - The Windows Event Logs Source interacts directly with the Windows Event Log API, resulting in faster event log processing.
  - **Render event message strings** is available and allows you to include the `Message` property in JSON and XML events.
  - The event collector will drain the entire Windows event log (upon startup for the first time and when configured to read fully), or drain fully from the last place it read (upon subsequent reads and when Windows writes new events to the log). It will read as much as possible rather than in batches.
- If toggled on:
  - The Windows Event Logs Source will collect events using external tools like Powershell cmdlets or `wevtutil.exe`.
  - **Render event message strings** is not an option.
  - JSON events will contain rendered message strings, XML will not.

Polling interval: Specify how often, in seconds, to check for new event logs. Defaults to `10` seconds, and must be at least `1` second. Polling will read each log, up to the **Batch Size**, in their specified order. This Source will not make a polling request if it's still reading events from the previous request.

Batch size: Set the maximum number of events to read per polling request. By default, each request reads up to `500` events. Set as high as you need to; however, if you configure the Source to pull from multiple event logs, be aware that setting **Batch Size** higher can keep one log waiting longer while the Source collects a batch from another log.

Batch size and Polling interval only apply when **Use Windows Tools** is toggled on.

Max event bytes: The maximum number of bytes that can be in an event before Cribl Edge sends it to the Pipelines. Defaults to `51200`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Send to Routes: Enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

QuickConnect: Send this Source's data to one or more Destinations via independent, direct connections.

This Source defaults to QuickConnect.

`__winEvent` Property

The `__winEvent` property contains a JSON representation of the native XML data obtained from the Windows Event API. The Windows Event Logs Source attempts to convert the JSON representation to the JSON schema that Windows Tools uses - however, there are some cases where the automatic conversion process doesn't perfectly match the JSON schema. The `__winEvent` property provides the raw JSON representation, allowing you to extract any necessary data if the conversion process isn't perfect.

Configure Event Log Behavior When Full

In Windows Event Viewer, you can configure how Windows handles Event Logs when the event log reaches maximum size.

To configure Windows Event Logs in **Event Viewer**, right-click on an event log and select **Properties**.

There are three available modes:

- **Overwrite events as needed**: When the log is full, Microsoft overwrites oldest events as new events enter.
- **Archive the log when full, do not overwrite events**: When the log is full, Microsoft rotates the file and starts a new file.
- **Do not overwrite events (Clear logs manually)**: When the log is full, Microsoft drops events until you clear the log manually.

In Cribl Edge, we designed the Windows Event Logs Source primarily for use with Event Logs in **Overwrite** mode, where it can collect events continuously. The WEL source may drop events in Event Logs when rotation occurs or when the log clears.

Collect From the Forwarded Events Logs

You can collect XML and JSON events from the Windows Forwarded Events log, as long as **Use Windows Tools** is toggled off in Advanced Settings.

Collect ETL-Formatted Logs

Microsoft Debug, Analytic, and Tracing logs use the ETL format. These logs are intended for short-term recording of detailed logging for troubleshooting and are not suitable for use with continuous collection. They cannot be read when set to Overwrite mode and they don't support seeking to skip past previously collected events.

The WEL Source in Edge supports reading events from ETL logs, but using them for continuous event collection may result in dropped events and higher resource usage.

Key-Value Store

The Windows Event Logs Source uses key-value store for cursors for each Windows Event Log. Log names are used as keys.

Resources

For processing Pipelines that you can import and adapt to your needs, examine these resources on the Cribl Packs Dispensary:

- Cribl Edge for Windows - Transform Windows logs collected by Cribl Edge to forward to various downstream services.
- Microsoft Windows Events - Shape events into JSON or Key=Value format, and dramatically reduce event sizes.
- Exabeam Pack for Windows - Forward specific Windows Event IDs to Exabeam.
- QRadar Pack for Windows Events - Optimize Windows events for delivery to QRadar.

Troubleshooting

If you are running this Source to collect events on a Windows Node without admin access, change the permission on the registry entry for the `EventLog` key: `HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\Services\EventLog` to `Read`.

If you encounter CPU or memory issue when running this Source, refer to Windows Troubleshooting.

Can't Collect ETL/Analytic/Debug Logs

When collecting ETL/analytic/debug log channels (such as `Microsoft-Windows-DNSServer/Analytical`), you can encounter a "The requested operation cannot be performed over an enabled direct channel" error.

The error is caused by the fact that this type of logs can't be read with the overwrite option enabled.

To resolve this:

1. Locate the log in Windows Event Viewer.
2. Right-click the log and select **Properties**.
3. Clear **Enable logging**.
   At this point Cribl Edge will be able to read the existing log entries, but will not receive any new entries added to the log.
4. To ensure Cribl Edge collects new entries as well, under **When maximum event log size is reached**, select **Do not overwrite events (Clear logs manually)**. (See Configure Event Log Behavior When Full for more details about those options.)
   Then, select **Enable logging** again.
5. Confirm your changes with **Apply**, then select **OK**.

You are now ready to ingest the log again with the Windows Event Logs Source.

12.2.5.3. Windows Metrics Source

Cribl Edge collects metrics from Windows hosts on which it runs, and can populate some standard metrics dashboards right out of the box. This Source produces events compatible with the Prometheus Windows Exporter to send out system, CPU, memory, network, and disk metrics. For metrics details, see Windows System Metrics Details.

Type: **System and Internal** | TLS Support: **N/A** | Event Breaker Support: **No**

Edge Nodes support Windows Metrics only when running on Windows. (To collect metrics from Linux hosts, use the System Metrics Source.)

Configure Cribl Edge/Windows to Collect System Metrics

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Collect** . Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via Routes, select **More** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `in_windows_metrics`, which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
3. Next, you can configure the following **Optional Settings**:
    - **Polling interval**: How often, in seconds, to collect metrics. Defaults to `10` seconds.
    - **Tags**: Optionally, add tags that you can use for filtering and grouping in the Cribl Edge UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.
4. Optionally, you can adjust the Host Metrics, Process Metrics, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Host Metrics

Use the buttons to select a level of detail:

- **Basic** enables minimal metrics, averaged or aggregated. This is the minimum configuration needed to support the Cribl Edge landing page.
- **All** enables full, detailed metrics for individual CPUs, interfaces, etc.
- **Custom** displays submenus and buttons from which you can choose a level of detail (**Basic**, **All**, **Custom**, or **Disabled**) for each specific type of event.
- **Disabled** generates no metrics.

The meanings of **All** and **Disabled** are self-evident. **Basic** and **Custom** have different meanings depending on event type - see the following subsections.

System

Basic level captures load averages, uptime, and CPU count.

Custom level toggles **Detailed** metrics on or off. These are Windows-specific metrics including OS information, system uptime, CPU architecture, etc.

CPU

Basic level captures active, user, system, idle, and iowait percentages over all CPUs.

Custom level toggles the following on or off: **Per CPU metrics**, **Detailed metrics** (i.e., metrics for all CPU states), and **CPU time metrics** (i.e., raw, monotonic CPU time counters).

Memory

Basic level captures captures total, used, available, `swap_free`, and `swap_total`.

Custom level toggles **Detailed metrics** on or off. (These are metrics for all memory states.)

Network

Basic level captures bytes, packets, errors, and connections over all interfaces.

Custom level exposes the following:

- The **Interface filter**, which specifies which network interfaces to include or exclude. (An empty filter will include all metrics.)
- **Per-interface metrics**, which toggle on or off.
- **Detailed metrics**, which toggle on or off. If on, the **Protocol metrics** toggle appears, allowing you to choose whether to generate metrics for ICMP, ICMPMsg, IP, TCP, UDP, and UDPLite.

Disk

Basic level captures disk usage (%), bytes read and written, and read and write operations, over all mounted disks.

Custom level exposes the following:

- The **Volume filter**, specifying which Windows volumes to include or exclude. Supports wildcards and ! (not) operators. An empty filter will include all volumes.
- **Per-volume metrics**, which toggle on or off.
- **Detailed metrics**, which toggle on or off.

Process Metrics

With Process Metrics enabled, Cribl Edge captures process-specific metrics from Windows servers and reports them as events. This allows you to monitor specific processes on Cribl.Cloud instances. You can generate events for any process object.

To collect a process metrics event, create a Process Set and add a filter expression. Processes that match the filter are returned as individual events. See Collecting Metrics. Process Sets are separate from aggregate and host-wide metrics.

Process-specific metrics are **not** affected by the **Host Metrics** detail setting.

You can control the collection method for Process Metrics using a configuration option in the **Fleet Settings** > **Limits** > **Other** section. This setting allows you to choose between using PowerShell cmdlets or the more efficient native module. Be aware that when using PowerShell cmdlets, environment variables displayed in the **Explore** > **Processes** tab for Windows processes might be inaccurate. For details, see Other Limits.

Adding a Process Set

To add a Process Set:

1. Open the Windows Metrics Source and access the **Configure** tab.
2. Select the **Process Metrics** menu, then **Add Process Set**.
3. Configure the details:
    - **Set Name**: The name for this process set.
    - **Filter Expression**: The JavaScript expression that will filter the processes.
    - **Include Child Processes**: When toggled on, the processes that match the filter include metrics for child processes.

Filtering Processes

You can filter processes using the field names and values from each process object.

Tip

To see all processes currently running on an Edge Node, select **Explore** in the submenu and open the **Processes Tab**.

Example Filters

Here's an example filter and the results it could return.

This filter will retrieve processes with the name `explorer`:

```
processName === 'explorer'
```

Note that the strict equality (`===`) operator in the above expression forces case sensitivity in the filter.

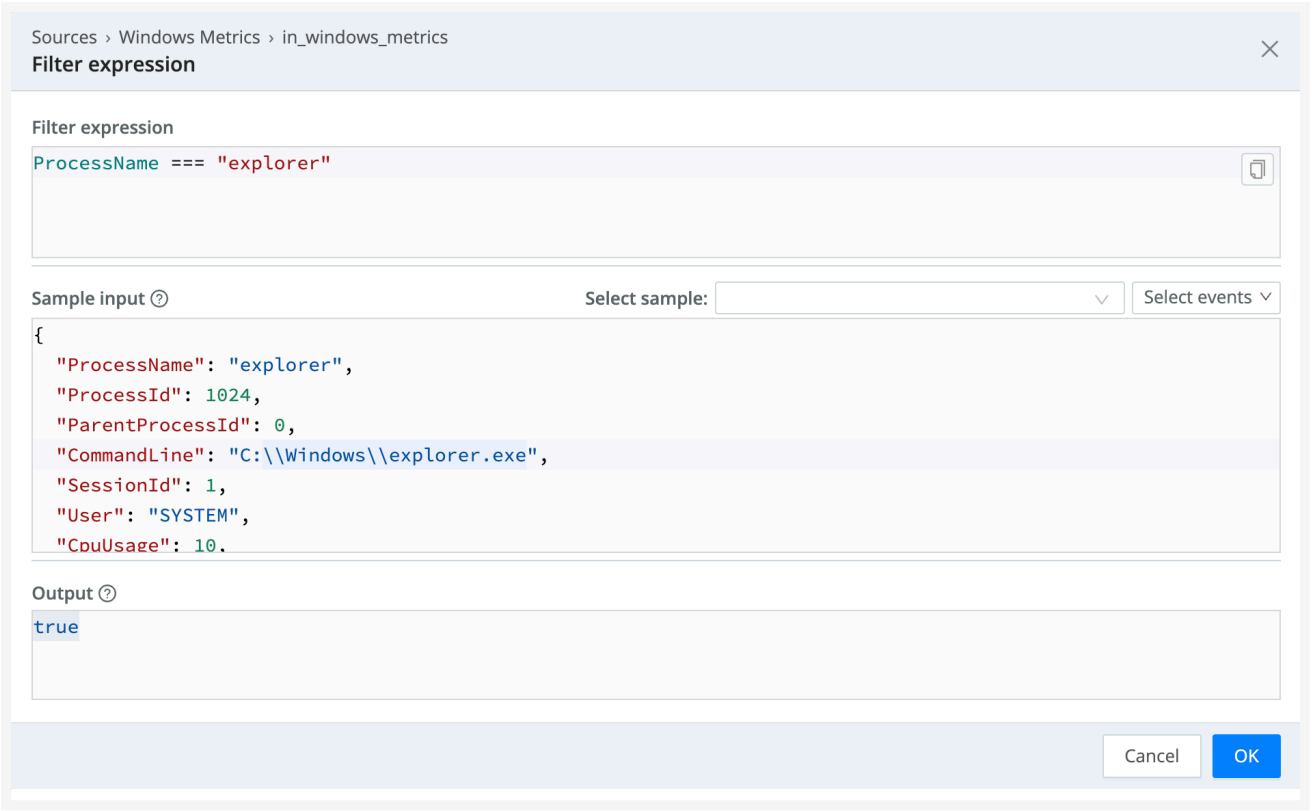
The **Filter expression** field expects a specific syntax in order to apply the filter to the processes. These expressions evaluate to either `true` or `false`. See Build Custom Logic to Route and Process Your Data: Filter Expressions for more information.

Collecting Metrics

Once you have at least one Process Set created and saved, Cribl Edge will begin collecting process metrics at the interval defined in the **Polling interval** field (**General Settings** menu).

To view the status of the Collector and total events collected, click the **Status** tab in the Windows Metrics Source.

To view a live capture of individual metrics gathered from processes that match the Process Set, click the **Live Data** tab. The Process Set that owns each metric is represented by the `__process_set` internal field.



Supported Processes

To view the complete table of supported Windows process metrics, their descriptions, types, and dimensions, see Process-Specific Metrics.

Using Advanced Mode

To test your filter expression against a sample input, click the **Advanced mode** button within the **Filter expression** field. The **Filter expression** modal will open.

Here, you can paste in your filter expression, select a sample JSON input from the drop-down (or enter your own directly in the **Sample input** field), and select a specific event to test against.

The **Advanced mode** window, for process-specific metrics

The **Output** will show you if the filter expression returns any matching processes, based on the filter expressions and JSON input.

GPU Metrics

GPU Metrics track the usage of Nvidia GPUs.

Use the buttons to select a level of detail.

- **Basic** enables capturing basic metrics, such as temperature, GPU utilization, and memory utilization.
- **All** enables full, detailed metrics.
- **Custom** enables the following toggles:
  - **Per GPU metrics** collects metrics per individual GPU.
  - **Detailed metrics** collects metrics for all known GPU metrics.
- **Disabled** means that no metrics will be generated.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Select a **Pipeline** (or Pack) from the drop-down to process this Source's data. Required to configure this Source via **Data Routes**; optional to configure via **Collect**/**QuickConnect**.

Disk Spooling

Enable disk persistence: Whether to save metrics to disk. When toggled on, exposes this section's remaining fields.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`).

Max data size: Maximum disk space the persistent metrics can consume. Once reached, Cribl Edge will delete older data. Example values: `420 MB`, `4 GB`. Default value: `100 MB`.

Max data age: How long to retain data. Once reached, Cribl Edge will delete older data. Example values: `2h`, `4d`. Default value: `24h` (24 hours).

Compression: Optionally compress the data before sending. Defaults to `gzip` compression. Select `none` to send uncompressed data.

Path location: Path to write metrics to. Default value is `$CRIBL_HOME/state/windows_metrics`.

Advanced Settings

Use Windows Tools: Toggled off by default.

> **Deprecation Notice**
>
> This legacy setting will be removed in a future release. We highly recommend keeping this option disabled and using the newer native capabilities, which are faster and more reliable.

- If toggled off, the Windows Metrics Source interacts directly with the Windows Management Instrumentation (WMI) API, resulting in faster metrics collection.
- If toggled on, the Windows Metrics Source will collect events using Powershell cmdlets.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

12.2.6. Apple Unified Logs Source

Cribl Edge supports collecting Apple Unified Logs on macOS.

Type: **Pull** | TLS Support: **N/A** | Event Breaker Support: **No**

This Source is available only on Cribl Edge Nodes running on macOS.

Apple's Unified Logging system writes structured log entries from the operating system and applications to a central store. You can use the Apple Unified Logs Source to stream those entries into Cribl Edge for processing and forwarding.

The Apple Unified Logs Source applies an NSPredicate filter to scope collection to specific subsystems, categories, or processes. The Source polls for new entries at a 5 second interval and delivers them as structured events for further processing and forwarding.

Configure Cribl Edge to Collect Apple Unified Logs

1. On the top bar, select **Products**, then select **Cribl Edge**. Under **Fleets**, select a Fleet. You have two options:
    - To configure via QuickConnect, navigate to **Collect**. Select **Add Source**, then select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **More** > **Sources**. Select the Source you want, then select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Predicate**: Enter an NSPredicate expression to filter log entries. For example:
        - `subsystem == "com.example.app"` - collect entries from a specific subsystem.
        - `category == "network"` - collect entries from a specific category.
        - `process == "Safari"` - collect entries from a specific process.
        - `subsystem == "com.example.app" AND category == "network"` - combine conditions with `AND` or `OR`.

      We recommend you use indexed fields (such as `subsystem`, `category`, `process`) whenever possible to take advantage of significantly better performance.
      See Common Log Types and Predicates for more examples of predicate expressions.

3. Next, you can configure the following **Optional Settings**:
    - **Read mode**: Select **From last entry** (the default) to read only new events. Select **Entire Log** to read all of the historical events and new events.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Send to Routes: Enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

QuickConnect: Send this Source's data to one or more Destinations via independent, direct connections.

Common Log Types and Predicates

Use the following predicates to filter common types of logs.

Log type	Predicate
Network framework	`subsystem == "com.apple.network"`
Wi-Fi	`subsystem == "com.apple.wifi"`
Bluetooth	`subsystem == "com.apple.bluetooth"`
Security framework	`subsystem == "com.apple.security"`
Authorization daemon	`subsystem == "com.apple.authd"`
HTTP networking	`subsystem == "com.apple.CFNetwork"`
DNS resolution	`process == "mDNSResponder"`
Push notifications	`subsystem == "com.apple.apsd"`
Disk arbitration	`subsystem == "com.apple.diskarbitration"`
Power management	`process == "powerd"`
Display server	`process == "WindowServer"`
Spotlight indexing	`subsystem == "com.apple.spotlight"`
Time Machine	`subsystem == "com.apple.TimeMachine"`

12.2.7. AppScope Source

AppScope is deprecated and will be removed in a future release. Don't use AppScope in production and ensure it is not part of your data flow configuration. For details, please read the announcement in Cribl Community Slack.

12.2.8. Cloudflare Source

The Cloudflare Source receives logs and events directly from Cloudflare Logpush using the HTTP Event Collector (HEC) protocol. This Source is designed for seamless integration with the Cloudflare push API, supporting both structured and raw event formats.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

Configure a Cloudflare Source

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP on which to listen for HTTP(S) data. Such as: `localhost` or `0.0.0.0`. Supports IPv4 and IPv6 addresses.
    - **Port**: Enter the port number.
    - **HEC endpoint**: Absolute path on which to listen for the Cloudflare HTTP Event Collector API requests. Defaults to `/services/collector`. This single endpoint supports JSON events via `/event` and raw events via `/raw`.
3. Next, you can configure the following **Optional Settings**:
    - **Allowed Indexes**: List the values allowed in the HEC event index field. Allows wildcards. Leave blank to skip validation.
    - **Tags**: Add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing, Auth tokens, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled: Defaults to toggled on.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`. Defaults to `$CRIBL_HOME/local/cribl/auth/certs/default.crt` when TLS is enabled.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. Defaults to `$CRIBL_HOME/local/cribl/auth/certs/default.key` when TLS is enabled.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (such as the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Event Breakers

Cloudflare Source Event Breakers only function with the `/raw` endpoint. The `/event` endpoint operates on the assumption that the data they receive is already properly formatted into individual events and therefore do not utilize Event Breakers.

- `/raw`: Event Breakers split incoming raw, unstructured data into distinct events before processing them through Pipelines.
- `/event`: Event Breakers are not applied since data is already segmented in JSON format.

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to determine the field's value (can be a constant).

Fields specified on the **Fields** tab will normally override fields of the same name in events. But you can specify that fields in events should override these fields' values.

In particular, where incoming events have no `index` field, this Source adds one with the literal value `default`. You can override this value by using **Add Field** to specify an `index` field, and then setting its **Value** to an expression of the following form: `index == 'default' ? 'myIndex' : index`

Fields here are evaluated and applied **after** any fields specified in the Auth Tokens section.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Auth Tokens

Provides the authentication token required to access this Source's data. Ensure the token is valid and has the necessary permissions for data retrieval.

Not providing a token allows **unauthorized access**.

Authentication method: Choose between manually entering a **Token** or selecting a stored **Secret**. If you opt for manual entry, type the token directly or **Generate** a new one. For added security, use the secrets store to select a stored **Token (text secret)** or **Create** a new one.

Enable token: Controls the status of the specified authentication token. When toggled on, the specified auth token is active and can be used for client access. If toggled off, the token is disabled, causing it to be skipped and ignored during initialization. This means that any client attempting to use a disabled token will not be granted access.

Disabling a token can be helpful when you need to temporarily stop receiving data from a particular service or application. Disabling a token prevents the service or application from sending data to your endpoint without having to completely delete the token.

See also Periodic Logging for information on how auth tokens affect product logging.

Description: Optional (but recommended), the description for this token. Although this field is optional, the token description becomes the display name for the token. You can select this display name to expand or collapse the token details.

Allowed indexes: Optionally, specify which indexes are permissible for events ingested using this token. Supports multiple index values and wildcards.

Fields: Fields to add to events referencing this token. Each field is a **Name/Value** pair.

Fields specified on the **Auth Tokens** tab will normally override fields of the same name in events. But you can specify that fields in events should override these fields' values.

In particular, where incoming events have no `index` field, this Source adds one with the literal value `default`. You can override this value by using **Add Field** to specify an `index` field, and then setting its **Value** to an expression of the following form: `index == 'default' ? 'myIndex' : index`

Fields here are evaluated and applied **before** any fields specified in the Fields section.

Advanced Settings

Emit per-token request metrics: Toggle on to emit per-token `<prefix>.http.perToken` and summary `<prefix>.http.summary` request metrics. This enables Periodic Logging.

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

CORS allowed origins: If you need to enable cross-origin resource sharing, use this field to specify the HTTP origins to which Cribl Edge should send `Access-Control-Allow-*` headers. You can enter multiple domains and use wildcards. This and its companion **CORS allowed headers** option should seldom be needed - see Working with CORS Headers for details.

CORS allowed headers: List HTTP headers that Cribl Edge will send in a CORS preflight response to your configured **CORS allowed origins** as `Access-Control-Allow-Headers`. Enter `*` to allow all headers.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) by the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__hecToken`
- `__inputId`
- `__ctrlFields`
- `__srcIpPort` - See Overriding `__srcIpPort` with Client IP/Port for details.
- `__TZ`

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the client sending data to this Source.

When any proxies (including load balancers) lie between the client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Working with CORS Headers

The **CORS allowed origins** and **CORS allowed headers** settings are needed **only** when you want JavaScript code running in a web browser to send events to the Source. In this (uncommon) scenario, the code in question sends a preflight request that includes CORS (Cross-Origin Resource Sharing) headers, and the Source includes CORS headers in its response.

If the settings (and thus the CORS headers in the response) are correct, the browser will allow the code in question to complete requests to the Source - that is, allow the code to read the Source's responses. (These settings are optional because for some web applications it's sufficient to send requests **without** reading responses.)

The CORS header dance begins when the web browser sends a request with a header stating its origin. What happens next depends on how you've configured the CORS header settings, as explained in the following tables. (For these examples, we'll assume an origin of `https://mycoolwebapp:3001`.)

CORS allowed origins value	What Source does	Does Browser then allow code to read response?
`*`	Send `Access-Control-Allow-Origin: *` header.	Yes
Multiple wildcard values	If origin value matches any wildcard, send `Access-Control-Allow-Origin: https://mycoolwebapp:3001` header.	Yes
Nothing (not configured)	Send neither an `Access-Control-Allow-Origin` nor an `Access-Control-Allow-Headers` header.	No

The web browser's request might also include an `Access-Control-Request-Headers` header that lists one or more headers that it wants to use in a subsequent `POST` request (that is, the "actual" as opposed to preflight request). The Source can then respond with an `Access-Control-Allow-Headers` header **if and only if** it's also sending the `Access-Control-Allow-Origin` header.

CORS allowed headers value	What Source does	Does Browser then allow code to read response?
`*`	Send `Access-Control-Allow-Headers` header with the same list the client sent.	Yes
Multiple wildcard values	If any headers from the client's list match wildcards, send `Access-Control-Allow-Headers` header listing the matching headers.	Yes
Nothing (not configured)	Do not send an `Access-Control-Allow-Headers` header.	Probably not

Periodic Logging

Cribl Edge emits metrics about incoming requests when **Advanced Settings > Emit per-token request metrics** is enabled. These metrics can be routed to a Destination by enabling the Cribl Metrics Source. There are two categories of metrics: per-token metrics provide details for each configured token, while summary metrics aggregate data across all tokens. If no tokens are configured, only summary metrics will be emitted.

Per-token metric names will be prefixed by `<basePrefix>.http.perToken.`, where `<basePrefix>` is the configured base prefix for the Cribl Metrics Source. The available metric names are listed below, excluding the prefix. As these are counter-type metrics, they will not be emitted if the value is zero.

- `bytesReceived`
- `numRequests`

- `numEvents`
- `numErrors` *Note: this is cumulative of specific error types below as well as a catch-all for other types*
- `numParserErrors`
- `numToDisabledToken`

The summary metric names will be prefixed by `<basePrefix>.http.summary.` where `<basePrefix>` is the configured base prefix for the Cribl Metrics Source. The available metric names are listed below, excluding the prefix. As these are counter-type metrics, they will not be emitted if the value is zero.

- `bytesReceived`
- `numRequests`
- `numEvents`
- `numErrors` *Note: this is cumulative of specific error types below as well as a catch-all for other types*
- `numParserErrors`
- `numToDisabledToken`
- `numAuthFailures`
- `numToWrongUrl`
- `numAckReqs`
- `numReqsAcked`

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka

Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Common Issues

Dropping request because token invalid",“authToken”: “Bas…Njc=”

12.2.9. Datadog Agent Source

Datadog Agent is open-source software that monitors the host on which it runs. Acting as a DogStatsD server, Datadog Agent also aggregates metrics from other processes or containers on the host.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

Looking for the Datadog Agent Source in **Cribl Search**? See Ingest Datadog Agent Data into Cribl Search.

Cribl Edge can ingest the following from Datadog Agent, in bundled form:

- Logs.
- Metrics (gauge, rate, counter, and histogram).
- Service checks.
- Agent metadata and other events emitted from the `/intake/` endpoint.

APM data: In addition to the data types listed above, this Source supports agent-routed APM, including traces, APM client stats, and remote-configuration and telemetry data. To route APM data from Datadog Agent to this Source, set `DD_APM_DD_URL` to your Cribl Edge Datadog Agent Source address. This Source supports both the `AgentPayload` protobuf format (agents v6.33+/v7.33+) and the legacy `TracePayload` format (agents older than v6.33 or v7.33). Datadog tracing libraries (`dd-trace`) can also send traces and APM stats directly to this Source. For the full list of supported endpoints, see APM Endpoints and the Datadog tracing library documentation.

On the system(s) that you want to monitor, you'll need to install Datadog Agent and configure it to send data to Cribl Edge. Cribl Edge can parse, filter, and enrich that data, and then send it to any supported Destination, including a Cribl Edge Datadog Destination. (By default, Datadog Agent sends data only to Datadog.)

For inbound log data, this Source supports `gzip`, `identity`, and `zstd` compression. For all other data types (metrics, service checks, agent metadata, and events), this Source supports `deflate` and `zstd` compression.

Configure Datadog to use Datadog API v1

This Source communicates with the Datadog API. Although v2 is the latest version of this API, this Source uses v1, which Datadog still supports.

To configure your Datadog Agent to work with this Source, ensure that in the `datadog.yaml` file, `use_v2_api.series` is set to `false`. Otherwise, when Datadog Agent sends metrics, Cribl Edge will not receive them, and `API Key invalid, dropping transaction` errors will appear in the Datadog Agent logs.

> Potential Cribl Edge support for Datadog API v2 is being tracked as **CRIBL-18281** in Known Issues.

Configure Cribl Edge to Ingest Datadog Agent Output

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for Datadog Agent data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
    - **Global Sampling Rate**: A number from `0.0` to `1.0` (default: `1.0`) that Cribl Edge returns as a sampling hint to connected Datadog tracers. The hint is delivered in the `rate_by_service` response and applies to any service and environment not covered by a per-service rule. For caveats on when tracers override this hint, see Effected Sampling Rate.
    - **Per-Service Sampling Rules**: A table of service-specific sampling rate overrides. Each row specifies a **Service**, an **Environment**, and a **Rate** (0.0–1.0). Rows can be added, edited, and removed. Per-service rules take precedence over the global sampling rate for matching service/environment combinations.
4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.

- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be

affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Active request limit (on-prem only): Maximum number of active requests per Worker Process. Use `0` for unlimited.

Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

Extract metrics: Toggle on to extract each incoming metric to multiple events, one per data point. This works well when sending metrics to a `statsd`-type output. If sending metrics to DatadogHQ or any destination that accepts arbitrary JSON, leave toggled off (default).

Forward API key validation requests: Toggle on to send key validation requests from Datadog Agent to the Datadog API. If toggled off (the default), Stream handles key validation requests by always responding that the key is valid.

Reject unauthorized certificates: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Default is toggled on. Available when **Forward API key validation requests** is toggled on.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__agent_api_key`
- `__agent_event_type`
- `__final`
- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__inputId`
- `__tracer_meta` - Present on APM trace events. Contains tracing metadata including `agent_version` (the Datadog Agent version parsed from the `User-Agent` header, such as `7.45.1`).
- `__srcIpPort` - See details below.
- `_time`

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Datadog Agent sending data to this Source.

When any proxies (including load balancers) lie between the Datadog Agent and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Sending Datadog Agent Data to Cribl Edge

Before you begin this section, you should have Datadog Agent running on one or more hosts.

To enable Datadog Agent to send data to Cribl Edge, you'll set the following environment variables:

- `DD_DD_URL`: The URL or IP address and port of your Datadog Agent Source in Cribl Edge.
- `DD_LOGS_CONFIG_LOGS_DD_URL`: The same value as above, assuming log collection is enabled on Datadog Agent.
- `DD_LOGS_CONFIG_USE_HTTP`: Set to `true`. Cribl Edge ingests Datadog Agent logs over HTTP only; ingesting logs over TCP is not supported.

Set these environment variables in one of two ways: (1) through a `docker run` command, or (2) by editing the `datadog.yaml` configuration file that your Datadog Agent uses.

Using the `docker run` Command

Here's an example `docker run` that sets the environment variables described above, along with others required for Datadog Agent but not relevant to Cribl Edge. Replace the example values with values appropriate for your environment.

```
docker run --rm --name dd-agent
  -e DD_API_KEY=6d1ephx1w55p978i6d1ephx1w55p978i \
  -e DD_SKIP_SSL_VALIDATION=true \
  -e DD_DD_URL="http://0.0.0.0:8080" \
  -e DD_LOGS_ENABLED=true \
  -e DD_LOGS_CONFIG_LOGS_DD_URL="0.0.0.0:8080" \
  -e DD_LOGS_CONFIG_USE_HTTP=true \
  -e DD_LOGS_CONFIG_LOGS_NO_SSL=true \
  -e DD_LOGS_CONFIG_CONTAINER_COLLECT_ALL=true \
  -e DD_DOGSTATSD_NON_LOCAL_TRAFFIC="true" \
  gcr.io/datadoghq/agent:7
```

Copy

Using a Config File

Instead of using environment variables, you can set the Cribl Edge-related values in your Datadog Agent's `datadog.yaml` config file.

See the documentation links in the example config file that Datadog maintains online; and, the docs that describe filesystem locations relevant to getting Datadog Agent to configure itself with the desired `datadog.yaml` file.

Managing What Data Goes Where

The different kinds of information that Datadog Agents emit - logs, metrics, service checks, agent metadata, and APM data - are not completely independent when you send them to Cribl Edge Datadog Agent Source. The reference to "bundling" near the top of this page introduced this situation in simplified form. The table below explains the relevant constraints for each type of information that Datadog Agents emit, along with the Datadog environment variables that control them.

Type(s) of Information	Dependencies and/or Limitations	Environment Variable
Logs	Independent of other types.	`DD_LOGS_CONFIG_DD_URL`
Metrics, Events, Service Checks, and Metadata	Always sent together.	`DD_DD_URL`
APM Data (traces, stats, remote config/telemetry)	Set `DD_APM_DD_URL` to your Cribl Edge Datadog Agent Source address to route agent APM data to Cribl Edge. This Source supports both the `AgentPayload` protobuf format (agents v6.33+/v7.33+) and the legacy `TracePayload` format (agents older than v6.33 or v7.33). Alternatively, configure your Datadog tracing library (`dd-trace`) to send traces and APM stats directly to this Source. See APM Endpoints for the full list of supported endpoints.	`DD_APM_DD_URL`

APM Endpoints

When Datadog Agent or a `dd-trace` library is configured to send APM data to this Source, Cribl Edge accepts requests at the following endpoints:

Traces

Endpoint	Format	When used
`/v0.3/traces`	MessagePack	Legacy tracers
`/v0.4/traces`	MessagePack	Standard trace API
`/v0.5/traces`	MessagePack (string-table encoded)	Standard trace API
`/api/v0.2/traces`	Protobuf (`AgentPayload`)	Datadog Agent v6.33+/v7.33+

APM client stats

Endpoint	When used
`/v0.6/stats`	`dd-trace` library stats
`/api/v0.2/stats`	Agent-forwarded stats

Remote configuration and telemetry

The Source also accepts remote-configuration and APM telemetry requests so agents pointed at it with `DD_APM_DD_URL` don't error. These requests are forwarded to Datadog only when **Forward API key validation requests** is toggled on in Advanced Settings; otherwise the Source acknowledges and discards them.

Managing API Keys

Suppose your data flow runs from Datadog Agents, to Cribl Edge Datadog Agent Sources, to Cribl Edge Datadog Destinations, to Datadog accounts. You'll need to decide **how many** of each of these elements there are to define the data flow you want. You will also set (or override) **Datadog API keys** to support the desired data flow. For some data flows, you'll need the **General Settings** > **Allow API key from events** toggle in the Cribl Edge Datadog Destination.

Another possibility is that you want data to flow to some Destination other than a Cribl Edge Datadog Destination. If that's the case, try adapting the examples below to your use case. Please connect with us on the `Cribl Community` Slack if you have questions.

Data Flow Examples

The examples which follow start simple and become more complex in terms of desired data flow, and, consequently, of Cribl Edge configuration.

One Agent to One Account

- You're running one Datadog Agent on one host.
- You want the output of the Agent sent to a single Datadog account.
- You only need one API key.
- You configure that single API key on your Cribl Edge Datadog Destination.

Many Agents to One Account

- You're running Datadog Agents on a fleet of hosts.
- You want to consolidate all the output of the Agents into a single Datadog account.
- You only need one API key. This is no different from the simpler one-to-one scenario above.
- You configure that single API key on your Cribl Edge Datadog Destination.

- No matter which host the data originates from, your Cribl Edge Datadog Destination sends it to Datadog using that single API key.

Many Agents to Many Accounts

- You're running Datadog Agents on a fleet of hosts.
- You want the output of the Agents from some hosts to flow into one Datadog account, and the output from other hosts to flow into a different Datadog account.
    - This may need to scale up to multiple accounts, if, for example, you are managing data from several different customers, or from several different organizations within your company.
- You need one API key **for each** Datadog account.
- In the Cribl Edge Datadog Destination, toggle **General Settings** > **Allow API key from events** on.
- Here's what happens:
    - Datadog Agent always sends an API key when it communicates with the Cribl Edge Datadog Agent Source. Agents within different subgroups of hosts will send different API keys, as described above.
    - Cribl Edge Datadog Agent Source passes the API key from the Agent to the Cribl Edge Datadog Destination as an internal field.
    - Cribl Edge Datadog Destination uses that API key to direct its output to the correct Datadog account. If need be, you can configure the Destination to override the passed-in API key with a different one. This comes in handy when you know that your Agent(s) are using invalid API keys. You can even override **all** passed-in API keys.

Verifying that Data is Flowing

Once you have configured your Datadog Agent(s) as described above, and they have begun sending data:

- Try viewing the incoming data in the **Live Data** tab in your Cribl Edge Datadog Agent Source.
- If you have a Cribl Edge Datadog Destination set up, connect your Cribl Edge Datadog Agent Source to it via a **QuickConnect Passthru**, and verify that the same data shows up in the Destination's **Live Data** tab.
    - Another possibility is that you want your Cribl Edge Datadog Agent Source to connect to some Destination other than a Cribl Edge Datadog Destination. That's beyond the scope of this example, but verifying data flow should be similar.
- If the Cribl Edge Datadog Destination is configured to send data to a Datadog instance, verify that the same data shows up there, in the appropriate form, according to the transformations you've configured in Cribl Edge.
- If you have a many-to-many data flow as described above, verify that output is being correctly split among the possible Datadog accounts at the end of the data flow.

Assuming that data is behaving as expected, you can proceed to the best part, namely adding one or more Pipelines between Datadog Agent Source and Datadog Destination, to transform the data however you wish. Given the varied nature of what Datadog Agents collect, there should be ample opportunities to make the data leaner and more usable.

Effected Sampling Rate

When you point Datadog tracers at a Cribl Edge Datadog Agent Source instead of a Datadog Agent, Cribl Edge returns a sampling hint to those tracers using the same `rate_by_service` mechanism that a Datadog Agent uses. You configure that hint through the **Global Sampling Rate** and **Per-Service Sampling Rules** settings. Tracers apply this suggestion when making their keep/drop decision.

Because the suggested rate is the lowest-priority sampling control in Datadog's model, any higher-priority setting overrides it. When that happens, Cribl Edge forwards the sampling decision your tracer already made. It does not re-sample or override your traces, and no data is dropped because of Cribl Edge.

Case 1: Sampling configured in Datadog (Remote Configuration)

If you set ingestion sampling rates or rules from the Datadog UI, those take immediate effect and override the rate Cribl Edge suggests. Your traces are still forwarded; the keep/drop rate follows your Datadog UI configuration.

Case 2: Sampling configured in your application

If your application sets its own sampling rate or rules, those local settings take precedence over the rate Cribl Edge suggests. Adjust them in your application to change the behavior.

Case 3: Tracers that do not apply agent-suggested rates

Some tracers do not apply a rate suggested by the agent. This matches the behavior you would see when connected to a Datadog Agent directly.

In each of the cases above, Cribl Edge honors the sampling decision already made upstream and forwards your traces accordingly. To change how many traces are kept, adjust sampling at its source.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Common Issue

12.2.10. Elasticsearch API Source

Cribl Edge supports receiving data over HTTP/S using the Elasticsearch Bulk API.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

For examples of receiving data from popular senders via this API, see Configuring Elastic Beats below.

Looking for the Elasticsearch API Source in **Cribl Search**? See Ingest Elasticsearch Data into Cribl Search.

Configure Cribl Edge to Receive Elasticsearch Bulk API Data over HTTP(S)

Cribl Edge ships with an Elasticsearch API Source preconfigured to listen on Port 9200. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle on to enable the Source.
    - **Input ID**: Enter a unique name to identify this Syslog Source definition. The default Source is prefilled with the value `in_elastic`. which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP on which to listen for Elasticsearch data. (For example, `localhost` or `0.0.0.0`.)
    - **Port**: Enter the port number to listen on.

- **Elasticsearch API endpoint** (for Bulk API): Absolute path on which to listen for Elasticsearch API requests. Defaults to `/`. Cribl Edge automatically appends `_bulk`, so (for example) `/myPath` becomes `/myPath/_bulk`. Requests could then be made to either `/myPath/_bulk` or `/myPath/<myIndexName>/_bulk`. Other entries are faked as success.

3. Next, you can configure the following **Optional Settings**:
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

In the **Authentication type** drop-down, select one of the following options:

- **None**: Don't use authentication.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials. Click **Generate** if you need a new password.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.
- **Auth Tokens**: Use HTTP token authentication with tokens stored in this Source's configuration. Select **Add Token** and, in the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header. Select **Generate** if you need a new token. Select **Add Token** to specify more tokens.
- **Auth Tokens (text secret)**: Use HTTP token authentication with bearer tokens referenced from the secrets store rather than entered in this Source's configuration. Select **Add Token**, then in **Token secret (text secret)** choose **Select local secret** or **Select global secret**. Select a stored text secret, or select **Create** to store a new, reusable secret. Optionally enter a **Description**. See Create and Manage Legacy Secrets and Add and Use Global Secrets. Select **Add Token** to specify more tokens.
  This option does not import tokens you already entered under **Auth Tokens**. Recreate those values as stored secrets if you switch.

  Edge Nodes running Cribl Edge version 4.19.2 and older do not support stored secrets for auth tokens on this Source. Before you downgrade those nodes, switch this Source back to **Auth Tokens** (or another supported method). Leaving **Auth Tokens (text secret)** in place prevents this Source from authenticating or starting on the older version.

See also Periodic Logging for information on how auth tokens affect product logging.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.
>
> All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

> **Deprecation Notice**
>
> To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On**

mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

> When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

> Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:
>
> - Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
> - Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.
>
> Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Enable proxy mode: If toggled on, see Proxy Mode below for the resulting options.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. By default, Cribl Edge's responses to HTTP requests include the `X-elastic-product` header, with an `Elasticsearch` value. (This is required by certain clients, including some Elastic Beats.)

API version: To upstream Elastic Beats, this Cribl Edge Source will appear as an Elasticsearch instance matching the version that you set in this drop-down:

- `6.8.4` - Retained for backward compatibility.
- `8.3.2` - This default entry matches Elasticsearch's current `8.3.x` versions.
- `Custom` - Opens an HTTP response object in the **Custom API Version** editor. This object replicates what an Elasticsearch server would send in its HTTP responses to a client. You can edit the `version : number`, and any other fields, as required to satisfy the Elastic Beat sending data to this Source. (This `Custom` option supports future Elasticsearch releases, as long as Elasticsearch keeps the same response-object structure.)

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Proxy Mode

Enabling proxy mode allows Cribl Edge to proxy non-Bulk API requests to a downstream Elasticsearch server. This can be useful when integrating with Elasticsearch API senders like Elastic Endgame agents, which send requests that Cribl Edge does not natively support. Toggle **Enable proxy mode** on to expose the following controls.

Proxy URL: URL of the Elasticsearch server that will proxy non-bulk requests, for example: `http://elastic:9200`.

Reject unauthorized certificates: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Default is toggled on.

Remove headers: Enter any headers that you want removed from proxied requests. Press `Tab` or `Return` to separate header names.

Proxy request timeout: How long, in seconds, to wait for a proxy request to complete before aborting it. Defaults to `60` seconds; minimum timeout is `1` second.

To understand how **Proxy request timeout** interacts with the `X-Forwarded-For` header, see Overriding `__srcIpPort` with Client IP/Port.

Authentication method: Select one of the following options.

- **None**: Don't use authentication.
- **Manual**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Secret**: This option exposes a **Credentials secret** drop-down, in which you can select a stored secret that references the credentials described above. A **Create** link is available to store a new, reusable secret.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge

performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Field Normalization

When ingesting data from Elasticsearch, this Source performs the following field normalization:

- Renames `@timestamp` to `_time`, maintaining millisecond precision.
- Renames `host.name` to `host`.
- Stores original `host.name` in `__host` to retain all host-related information.

The Elasticsearch Destination does the reverse, and it also recognizes the presence of `__host`.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__host`
- `__id`
- `__index`
- `__inputId`
- `__pipeline` - If present in the Elasticsearch `event.action` field of the event. See also how to override the pipeline attribute.
- `__srcIpPort` - See details below.
- `__type`

Overriding the Pipeline Attribute in the Elasticsearch and Elastic Cloud Destinations

The Elasticsearch Source will record the pipeline attribute received in a variable named `__pipeline`, if pipeline was presented in the Source event. If you want to forward the pipeline from the Source event to an Elasticsearch or Elastic Cloud Destination, set up the **Elastic pipeline** in one of the following ways.

This expression will use the value of `__pipeline` or default to `'myPipeline'` if `__pipeline` is missing:

```
__pipeline || 'myPipeline'
```

An alternative is to pass the pipeline if present, or otherwise omit it:

```
__pipeline ? __pipeline : undefined
```

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Elasticsearch client sending data to this Source.

When any proxies (including load balancers) lie between the Elasticsearch client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Configuring Elastic Beats

Beats are open-source data shippers that act as agents, sending data to Elasticsearch (or to other services, in this case Cribl Edge). The Beats most popular with Cribl users are Filebeat and Winlogbeat.

To set up a Beat to send data to Cribl Edge, edit the Beat's YAML configuration file: `filebeat.yml` for Filebeat, `winlogbeat.yml` for Winlogbeat, and so on. In the config file, you'll specify your Cribl Edge Elasticsearch Source endpoint as the Beat's Elasticsearch output. To the Beat, Cribl Edge will appear as an instance of Elasticsearch.

If you're using HTTP token authentication (which is disabled by default, both on-prem and on Cribl.Cloud): First, set the token. Then add the following to the Beat config file under `output.elasticsearch.headers`, substituting your token for `myToken42`:

```
output.elasticsearch:
  headers:
    Authorization: "myToken42"
```

Copy

Configuring an Elastic Agent

An Elastic Agent is single agent for logs, metrics, security data, and threat prevention that sends data to Elasticsearch (or to other services, in this case Cribl Edge).

When you are sending from an Elastic Agent to Cribl Edge, the `elastic-agent.yml` file doesn't pay any attention to the settings for `output.elasticsarch.allow_older_versions: true`. As a result, the Elasticsearch API Source will not get any data.

To set it up correctly, go to the **Advanced Settings** tab, and change the **API Version** to `Custom`. In the **Custom API Version** editor, edit the `version : number` to match the version of the Elastic Agent you are using. This should allow the data to start flowing to the Source.

Periodic Logging

Cribl Edge logs metrics about incoming requests and ingested events once per minute.

If one or more auth tokens are configured and enabled, Cribl Edge logs requests and events for each enabled auth token individually. Since the tokens themselves are redacted for security, Cribl Edge logs the initial text of the token description to help you identify which token a given log is for.

If no auth token is configured and enabled, Cribl Edge simply logs overall statistics about incoming requests and ingested events.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker process.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

Common Issue

12.2.11. HTTP/S (Bulk API) Source

Cribl Edge supports receiving data over HTTP/S from Cribl Bulk API, Splunk HEC, and Elastic Bulk API endpoints.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

Configure Cribl Edge to Receive Data over HTTP(S)

Cribl Edge ships with an HTTP Source preconfigured to listen on Port 10080, and on several default endpoints. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `http`, which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP on which to listen for HTTP(S) data. (For example, `localhost` or `0.0.0.0`.)
    - **Port**: Enter the port number to listen on.
3. Under **Authentication**, enter the **Auth tokens**:
    - **Token**: Shared secrets to be provided by any client (`Authorization: <token>`). Click **Generate** to create a new secret. If empty, unauthorized access **will be permitted**.
    - **Description**: Optionally, enter a description.
    - **Fields**: Fields to add to events referencing this token. Each field is a **Name/Value** pair, where **Value** is a JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.) For details, see Authentication Fields.

4. Next, you can configure the following **Optional Settings**:
    - **Cribl HTTP event API**: Base path on which to listen for Cribl HTTP API requests. To construct the actual endpoint, Cribl Edge will append `/_bulk` to this path. For example, with the default value of `/cribl`, your senders should send events to a `/cribl/_bulk` path. Use an empty string to disable.
    - **Elastic API endpoint** (for Bulk API): Base path on which to listen for Elasticsearch API requests. For details, see Elastic API Endpiont.
    - **Splunk HEC endpoint**: Absolute path on which to listen for Splunk HTTP Event Collector (HEC) API requests. Use an empty string to disable. Default entry is `/services/collector`. For details, see Splunk HEC Endpoint.
    - **Enable Splunk HEC acknowledgements**: Whether to enable Splunk HEC acknowledgements. Default is toggled off.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Elastic API Endpoint

Currently, the only supported option is the default `/elastic`, to which Cribl Edge will append `/_bulk`. So, your senders should send events to an `/elastic/_bulk` path. Other entries are faked as success. Use an empty string to disable.

Cribl generally recommends that you use the dedicated Elasticsearch API Source instead of this endpoint. The Elastic API implementation here is provided for backward compatibility, and for users who want to ingest multiple inputs on one HTTP/S port.

Splunk HEC Endpoint

This Splunk HEC implementation is an **event** (such as, not **raw**) endpoint. For details, see Splunk's documentation. To send data to it from a HEC client, use either `/services/collector` or `/services/collector/event`. (See the examples below.)

The system default Event Breaker is automatically applied, which enforces a limit of 51,200 bytes per event.

Cribl generally recommends that you use the dedicated Splunk HEC Source instead of this endpoint. The Splunk HEC implementation here is provided for backward compatibility, and for users who want to ingest multiple inputs on one HTTP/S port.

Authentication Fields

By default, fields specified here will override fields of the same name in incoming events. However, you can customize this behavior to allow event fields to take precedence. For example, to allow the event's `index` field to take precedence, you could use this expression: `` `event.index || 'defaultIndex'` ``.

Fields add context to events based on the token used. This can be useful for tagging events with metadata such as source or environment, enhancing security by avoiding direct use of authorization values in Routes and Pipelines.

See also Periodic Logging for information on how auth tokens affect product logging.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter:

`worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Auth Tokens

Provides the authentication token required to access this Source's data. Ensure the token is valid and has the necessary permissions for data retrieval.

Not providing a token allows **unauthorized access**.

Clients must include shared secrets in their request headers as `Authorization: <token>` to authenticate. Cribl validates the token upon receiving the request, ensuring secure and authenticated access.

Authentication method: Choose between manually entering a **Token** or selecting a stored **Secret**. If you opt for manual entry, type the token directly or **Generate** a new one. For added security, use the secrets store to select a stored **Token (text secret)** or **Create** a new one.

Fields: Fields to add to events referencing this token. Each field is a **Name/Value** pair, where **Value** is a JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

By default, fields specified here will override fields of the same name in incoming events. However, you can customize this behavior to allow event fields to take precedence. For example, to allow the event's `index` field to take precedence, you could use this expression: `` `event.index || 'defaultIndex'` ``.

Fields add context to events based on the token used. This can be useful for tagging events with metadata such as source or environment, enhancing security by avoiding direct use of authorization values in Routes and Pipelines.

See also Periodic Logging for information on how auth tokens affect product logging. –>

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.

- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be

affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` - Added only when **Advanced Settings** > **Capture request headers** is toggled on.
- `__inputId`
- `__hecToken`
- `__srcIpPort` - See details below.
- `__host` (Elastic In)
- `__id` (Elastic In)
- `__index` (Elastic In)
- `__type` (Elastic In)

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the client sending data to this Source.

When any proxies (including load balancers) lie between the HTTP client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original HTTP client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Format and Endpoint

Cribl Edge expects HTTP(S) events to be formatted as one JSON record per event. Here are two event records:

Sample Event Format

```
{"_time":1541280341, "_raw":"this is a sample event ", "host":"myHost", "source":"myS
{"_time":1541280341, "host":"myOtherHost", "source":"myOtherSource", "_raw": "{\"mess
```

Copy

Note 1: Events can be sent as separate POSTs, but Cribl **highly** recommends combining multiple events in newline-delimited groups, and POSTing them together.

Note 2: If an HTTP(S) source is routed to a Splunk destination, fields within the JSON payload are mapped to Splunk fields. Fields that do not have corresponding (native) Splunk fields become index-time fields. For example, let's assume we have a HTTP(S) event like this:

`{"_time":1541280341, "host":"myHost", "source":"mySource", "_raw":"this is a sample event ", "fieldA":"valueA"}`

Here, `_time`, `host` and `source` become their corresponding fields in Splunk. The value of `_raw` becomes the actual body of the event, and `fieldA` becomes an index-time field. (`fieldA::valueA`).

Examples

The examples in this section demonstrate sending HTTP data into a Bulk HTTP Source configured to listen on port `10080`. The token is set to `myToken42` and included in the `Authorization` header of requests.

Cribl Endpoint - Single Event

Cribl Endpoint, Single Event Example

```
curl -k "http://<myCriblHost>:10080/cribl/_bulk" \
-H "Authorization: myToken42" \
-d '{"_raw":"this is a sample event ", "host":"myHost", "source":"mySource", "fieldA'
```

Copy

Cribl Endpoint - Multiple Events

Cribl Endpoint, Multiple Events Example

```
curl -k "http://<myCriblHost>:10080/cribl/_bulk" \
-H "Authorization: myToken42" \
-d $'{"_raw":"this is a sample event ", "host":"myHost", "source":"mySource", "fieldA
{"_raw":"this is another sample event ", "host":"myOtherHost", "source":"myOtherSourc
```

Copy

Splunk HEC Event Endpoints

For Splunk HEC, the token specification can be either `Splunk <token>` or `<token>`.

Splunk HEC Event Endpoint, /services/collector/event Example

```
curl -k "http://<myCriblHost>:10080/services/collector/event" \
-H "Authorization: myToken42" \
-d '{"event":"this is a sample event ", "host":"myHost", "source":"mySource", "fieldA
```

Copy

Splunk HEC Event Endpoint, /services/collector Example

```
curl -k "http://<myCriblHost>:10080/services/collector" \
-H "Authorization: myToken42" \
-d '{"event":"this is a sample event ", "host":"myHost", "source":"mySource", "fieldA
```

Copy

Cribl.Cloud - Single Event

Replace `<organizationId>` with your Cribl.Cloud Organization ID.

Cribl.Cloud, Single Event Example

```
curl -k "https://default.main.<organizationId>.cribl.cloud:10080/cribl/_bulk" \
-H "Authorization: myToken42" \
-d '{"_raw":"this is a sample event ", "host":"myHost", "source":"mySource", "fieldA'
```

Copy

For Cribl.Cloud Enterprise plans, replace `default` in the request URL with the name of the Fleet that you want to send to.

Periodic Logging

Cribl Edge logs metrics about incoming requests and ingested events once per minute.

If one or more auth tokens are configured and enabled, Cribl Edge logs requests and events for each enabled auth token individually. Since the tokens themselves are redacted for security, Cribl Edge logs the initial text of the token description to help you identify which token a given log is for.

If no auth token is configured and enabled, Cribl Edge simply logs overall statistics about incoming requests and ingested events.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker process.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki,

Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy) while data does not arrive or is rejected downstream. Destination logs may show no errors, or you may see TLS certificate or hostname validation failures, or authentication errors such as `invalid audience`.

To avoid the conflict, use an Eval Function in a Pipeline to remove `__headers` before the Destination. To keep the captured headers under another name, add a field that copies `__headers`, then remove `__headers` (the Rename Function cannot operate on fields whose names begin with `__`). If TLS or certificate errors appear and `__headers` contains a `host` value, you can also toggle **Validate server certs** off on the Destination. That weakens TLS verification, so use it only after you confirm the conflict is the cause.

12.2.12. Raw HTTP/S Source

Cribl Edge supports receiving raw HTTP data. The Raw HTTP Source listens on a specific port, captures every HTTP request to that port, and creates a corresponding event that it pushes to its configured Event Breakers.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

Looking for the Raw HTTP Source in **Cribl Search**? See Ingest Raw HTTP Data into Cribl Search.

Configure Cribl Edge to Receive Raw HTTP Data

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Raw HTTP Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the address to bind on. Defaults to `0.0.0.0` (all addresses).
    - **Port**: Enter the port number to listen on. For Cribl.Cloud, use the `20000` - `20010` port range.
3. Under **Authentication**, enter the **Auth tokens**:
    - **Token**: Shared secrets to be provided by any client. Click **Generate** to create a new secret. If empty, permits open access.
    - **Description**: Optionally, enter a description.
    - **Fields**: Fields to add to events referencing this token. Each field is a **Name/Value** pair, where **Value** is a JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.) For details, see Authentication Fields.
4. Next, you can configure the following **Optional Settings**:

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Authentication Fields

By default, fields specified here will override fields of the same name in incoming events. However, you can customize this behavior to allow event fields to take precedence. For example, to allow the event's `index` field to take precedence, you could use this expression: `` `event.index || 'defaultIndex'` ``.

Fields add context to events based on the token used. This can be useful for tagging events with metadata such as source or environment, enhancing security by avoiding direct use of authorization values in Routes and Pipelines.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you

disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.

- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Auth Tokens

Provides the authentication token required to access this Source's data. Ensure the token is valid and has the necessary permissions for data retrieval.

Not providing a token allows **unauthorized access**.

Clients must include shared secrets in their request headers as `Authorization: <token>` to authenticate. Cribl validates the token upon receiving the request, ensuring secure and authenticated access.

Authentication method: Choose between manually entering a **Token** or selecting a stored **Secret**. If you opt for manual entry, type the token directly or **Generate** a new one. For added security, use the secrets store to select a stored **Token (text secret)** or **Create** a new one.

Fields: Fields to add to events referencing this token. Each field is a **Name/Value** pair, where **Value** is a JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

By default, fields specified here will override fields of the same name in incoming events. However, you can customize this behavior to allow event fields to take precedence. For example, to allow the event's `index` field to take precedence, you could use this expression: `` `event.index || 'defaultIndex'` ``.

Fields add context to events based on the token used. This can be useful for tagging events with metadata such as source or environment, enhancing security by avoiding direct use of authorization values in Routes and Pipelines. –>

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.
>
> All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

> **Deprecation Notice**
>
> To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On**

mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

Advanced Settings

Show originating IP: Toggle on when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle on to add request headers to events, in the `__headers` field.

> When **Capture request headers** is enabled, this Source stores request headers in the `__headers` field. Some Destinations also read `__headers` for outbound behavior. HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM use it to inject dynamic request headers. Kafka Destinations use it for message headers. Other Destinations that read `__headers` can be affected the same way. Forwarding captured events to these Destinations without removing `__headers` can cause TLS validation failures or expose inbound authentication headers. Use an Eval Function in a Pipeline to remove `__headers` (or copy it to another field name, then remove `__headers`) before the Destination. See `__headers` field conflicts.

Health check endpoint: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Allowed URI paths: List of URI paths accepted by this input. Supports wildcards, for example, `/api/v*/hook`. Defaults to `*`, which allows all paths.

Allowed HTTP methods: List of HTTP methods accepted by this input. Supports wildcards, for example, `P*`, `GET`. Defaults to `*`, which allows all methods.

Active request limit (on-prem only): Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.
- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Requests-per-socket limit: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Edge will reuse connections. The shorter the timeout, the closer Cribl Edge gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

CORS allowed origins: List HTTP origins to which Cribl Edge should send CORS response headers. You can enter multiple domains and use wildcards. If you configure headers but leave origins empty, Cribl Edge defaults origins to `*`. **IP allowlist** and **IP denylist** rules are applied before CORS. Requests blocked by IP rules do not receive CORS headers. CORS is enabled when either **CORS allowed origins** or **CORS allowed headers** is non-empty. Leave both empty to disable CORS. See Working with CORS Headers.

CORS allowed headers: List HTTP headers that Cribl Edge will allow in a CORS preflight response. Enter `*` to allow all headers. If you configure origins but leave headers empty, Cribl Edge defaults headers to `*`.

CORS allowed methods: List HTTP methods that Cribl Edge allows on CORS preflight responses. Defaults to `OPTIONS` and `POST`.

CORS exposed headers: Optionally list response headers that browsers are allowed to access.

CORS include credentials: Toggle on to include credentials in cross-origin requests. Defaults to toggled off. Per the CORS specification, Cribl Edge does not include credentials when **CORS allowed origins** is set to `*`.

CORS max age (seconds): Optionally set how long browsers should cache the preflight response.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long

connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields for this Source:

- `__channel`
- `__headers` - Automatically includes any headers sent with request.
- `__inputId`
- `__srcIpPort` - See details below.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the HTTP client sending data to this Source.

When any proxies (including load balancers) lie between the HTTP client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is toggled off, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is toggled on, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Working with CORS Headers

Configure the CORS fields in **Advanced Settings** when JavaScript code running in a web browser needs to send events to the Raw HTTP Source, for example browser-based OTLP/HTTP telemetry. In this scenario, the browser sends a preflight request that includes CORS headers, and the Raw HTTP Source includes CORS headers in its response.

If the settings (and thus the CORS headers in the response) are correct, the browser allows the code to complete requests to the Raw HTTP Source, that is, to read the Source's responses. These settings are optional because some web applications can send requests without reading responses.

CORS is enabled when either **CORS allowed origins** or **CORS allowed headers** is non-empty. There is no separate enable toggle.

When CORS is enabled:

- `OPTIONS` preflight requests return `204` and bypass authentication, method, and content-type checks.
- **IP allowlist** and **IP denylist** still apply first. Requests rejected by IP rules do not receive CORS headers.

The CORS header exchange begins when the browser sends a request with an Origin header. What happens next depends on how you've configured the CORS settings, as explained in the tables below. (For these examples, assume an origin of `https://mycoolwebapp:3001`.)

CORS allowed origins value	What Raw HTTP Source does	Does browser then allow code to read response?
`*`	Send `Access-Control-Allow-Origin: *` header.	Yes
Multiple wildcard values	If origin value matches any wildcard, send `Access-Control-Allow-Origin: https://mycoolwebapp:3001` header.	Yes
Nothing (not configured), but headers are configured	Default allowed origins to `*` and send `Access-Control-Allow-Origin: *` header.	Yes
Nothing (not configured), and	Send neither an `Access-Control-Allow-Origin` nor an `Access-Control-Allow-Headers` header.	No

CORS allowed origins value	What Raw HTTP Source does	Does browser then allow code to read response?
headers also empty		

The browser's request might also include an `Access-Control-Request-Headers` header that lists one or more headers that it wants to use in a subsequent `POST` request (the actual request, as opposed to the preflight). The Raw HTTP Source can then respond with an `Access-Control-Allow-Headers` header **if and only if** it's also sending the `Access-Control-Allow-Origin` header.

CORS allowed headers value	What Raw HTTP Source does	Does browser then allow code to read response?
`*`	Send `Access-Control-Allow-Headers` header with the same list the client sent.	Yes
Multiple wildcard values	If any headers from the client's list match wildcards, send `Access-Control-Allow-Headers` header listing the matching headers.	Yes
Nothing (not configured), but origins are configured	Default allowed headers to `*` and echo the client's requested headers.	Yes
Nothing (not configured), and origins also empty	Do not send an `Access-Control-Allow-Headers` header.	No

Examples

The examples in this section demonstrate sending HTTP data into a Raw HTTP Source. The token is set to `myToken42` and included in the `Authorization` header of requests.

Cribl Endpoint - Single Event

Replace `<myCriblHost>` with your Public Ingress address.

Cribl Endpoint, Single Event Example

```
curl -k "http://<myCriblHost>:10050/postPath" \
-H "Authorization: myToken42" \
-H "Content-Type: application/json" \
-d '{"_raw":"this is a sample event", "host":"myHost", "source":"mySource", "fieldA":
```

Copy

Cribl Endpoint - Multiple Events

Replace `<myCriblHost>` with your Public Ingress address.

Cribl Endpoint, Multiple Events Example

```
curl -k "http://<myCriblHost>:10050/postPath" \
-H "Authorization: myToken42" \
-H "Content-Type: application/json" \
-d $'{"_raw":"this is a sample event", "host":"myHost", "source":"mySource", "fieldA'
{"_raw":"this is another sample event", "host":"myOtherHost", "source":"myOtherSource
```

Copy

Cribl.Cloud - Single Event

Replace `<Your-Org-ID>` with your Cribl.Cloud Organization ID. Cribl.Cloud makes the `20000 - 20010` port range available for configuring Sources that don't have a default port, like the Raw HTTP Source.

Cribl.Cloud, Single Event Example

```
curl -k "http://default.main.<Your-Org-ID>.cribl.cloud:20001" \
-H "Authorization: myToken42" \
-d '{"_raw":"this is a sample event"}'
```

Copy

For Cribl.Cloud Enterprise plans, replace `default` in the request URL with the name of the Fleet that you want to send to.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

`__headers` Field Conflicts with Destinations

When **Capture request headers** is enabled, this Source writes inbound headers to the `__headers` field. Some Destinations also use `__headers` for outbound HTTP headers or related TLS behavior, so the fields can interfere silently. Destinations that read `__headers` include HTTP Destinations such as Webhook, Loki, Microsoft Sentinel, Dynatrace HTTP, and Cortex XSIAM, which use it for dynamic request headers, and Kafka Destinations, which use it for message headers. Other Destinations that read `__headers` can be affected the same way.

In that case, events can leave Cribl Edge successfully (Source, Route, and Destination metrics look healthy)

12.2.13. Metrics Source

Cribl Edge supports receiving metrics in these wire formats/protocols: StatsD, StatsD Extended, and Graphite. Automatic protocol detection happens on the first line received over a TCP connection or a UDP packet. Lines not matching the detected protocol are dropped.

Type: **Push** | TLS Support: **No** | Event Breaker Support: **No**

Cribl Edge Workers support System Metrics only when running on Linux, not on Windows.

Configure Cribl Edge to Receive Metrics

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
    - **UDP port**: Enter the UDP port number to listen on. Not required if listening on TCP.For detail, see UDP Port Considerations.
    - **TCP port**: Enter the TCP port number to listen on. Not required if listening on UDP.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

UDP Port Considerations

Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This results from restrictions of the UDP protocol. To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP senders. Cribl also recommends tuning the OS UDP buffer size.

TLS Settings (TCP Only)

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Enable Proxy Protocol: Toggle on if the connection is proxied by a device that supports Proxy Protocol v1 or v2.

IP allowlist regex: Regex matching IP addresses that are allowed to send data. Defaults to `.*` (i.e., all IPs.)

Buffer size limit (events): Maximum number of events to buffer when downstream is blocking. Defaults to `1000`.

UDP socket buffer size (bytes): Optionally, set the SO_RCVBUF socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Min: `256`. Max: `4294967295`.

It may also be necessary to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__srcIpPort`
- `__metricsInType`

Metric Event Schema and Destination Support

Metric data is read into the following event schema:

```
_metric - the metric name
_metric_type - the type of the metric (gauge, counter, timer)
_value - the value of the metric
_time - metric_time or Date.now()/1000
dim1 - value of dimension1
dim2 - value of dimension2
....
```

Copy

Cribl Edge places sufficient information into a field called `__criblMetric` to enable these events to be properly serialized out to any metric outputs (independent of the input type).

The following Destinations natively support the `__criblMetric` field:

- Splunk
- Splunk HEC
- InfluxDB
- Statsd
- Statsd Extended
- Graphite

Data Format/Protocol Examples

StatsD

Format: `MetricName:value|type`

StatsD Example

```
metric1:100|g
metric2:200|ms
metric.dot.3:300.16|c
```

Copy

See the StatsD repo.

StatsD Extended

Format: `MetricName:value|type|#dim=value,dim2=value`

StatsD Extended Example

```
metric1:100|g|#dim1:val1,dim2:val2,dim3:val3
metric2:200|ms|#dim1:val1,dim2:val2,dim3:val3
metric.dot.3:300.16|c|#dim1:val1,dim2:val2,dim3:val3
```

Copy

Graphite

Format: `MetricName[;dim1=val1[;dim2=val2]] value time`

Graphite Example with Dimensions

```
metric1;dim1=val1;dim2=val2 100 9999
metric2;dim1=val1;dim2=val2 200 9999
metric.dot.3;dim1=val1;dim2=val2 300.16 9999.16
```

Copy

Graphite Example without Dimensions

```
metric1 100 9999
metric2 200 9999
metric.dot.3 300.16 9999.16
```

Copy

See the Graphite (also known as Carbon) plaintext protocol.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

12.2.14. OpenTelemetry (OTel) Source

Cribl Edge supports receiving trace, metric, and log events from OTLP-compliant senders.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

Looking for the OpenTelemetry Source in **Cribl Search**? See Ingest OpenTelemetry Data into Cribl Search.

Supported and Unsupported Input Data

The OpenTelemetry (OTel) Source supports receiving:

- Compressed inbound data (with DEFLATE or gzip compression), as well as uncompressed data.
- Telemetry data over either of the transports that the OpenTelemetry Protocol (OTLP) describes: gRPC or HTTP. OTLP defines Protocol buffer (Protobuf) schemas for its payloads (requests and responses). With the HTTP transport, this Source supports Binary Protobuf and JSON Protobuf encoding.

The Source does not expose an encoding setting. When **Protocol** is `HTTP`, it selects the encoding from the request `Content-Type`:

- `application/x-protobuf`: Binary Protobuf.
- `application/json`: JSON Protobuf. Use this encoding when your sender is configured to emit OTLP as JSON rather than as binary Protobuf.

JSON Protobuf requires **OTLP version** `1.3.1`. If **OTLP version** is `0.10.0`, the Source rejects JSON requests with HTTP `501`. Invalid JSON, malformed OTLP payloads, and unsupported HTTP paths return HTTP `400`. Other unsupported `Content-Type` values return HTTP `501`.

JSON and binary payloads are decoded into the same internal events, so Routes and Pipelines behave the same regardless of encoding.

The OpenTelemetry Project's Signals documentation provides these hierarchical definitions of Cribl Edge's supported trace and metric event types:

- A **trace** tracks the progression of a single request.
    - Each trace is a tree of **spans**.
    - A span object represents the work being done by the individual services, or components, involved in a request as that request flows through a system.
- A **metric** provides aggreggated statistical information.
    - A metric contains individual measurements called **data points**.

- A **log** provides a recording of an event.
    - See the OTLP Logs Function topic for an explanation of OTLP logs structure.

Breaking Changes Between OTLP 0.19.0 and 1.3.1

With version 0.19.0, the OTLP Protobuf spec introduced breaking changes in its field names. This means that if you created Routes or Pipelines that work with OTLP version 0.10.0, they may break when you use them with OTLP 1.3.1.

To use Routes or Pipelines created before Cribl Edge 4.7 with OTLP 1.3.1, you must check their filters and logic for any use of obsolete field names, and modify them accordingly,

Configure an OTel Source

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Unique ID for this Source. For example, `OTel042`.
    - **Description**: Optionally, enter a description.
    - **OTLP version**: The drop-down offers `0.10.0` and `1.3.1` (default).
    - **Protocol**: Use the drop-down to choose the protocol matching the data you will ingest: gRPC (default), or `HTTP`.
    - **Address**: Enter the hostname/IP to listen on. Defaults to `0.0.0.0` (all addresses, IPv4 format).
    - **Port**: By default, OTel applications send output to port `4317` when using the gRPC protocol, and port `4318` when using HTTP. This setting defaults to `4317` - you must change it if you set **Protocol** (below) to `HTTP`, or you want Cribl Edge to collect data from an OTel application that is using a different port.

      Port `4318` is not available on Cribl-managed Worker Groups in Cribl.Cloud.
    - The **Extract spans**, **Extract metrics**, and **Extract logs** settings are specific to the OpenTelemetry Source. By default, these options are toggled off, allowing Cribl Edge to act as a pass-through that

generates a single event for each incoming OTel payload. This is useful when you want to forward complete OTel events to downstream systems, such as persistent storage, without breaking them apart. You can enable these settings to extract and process individual records from within OTel events:

- **Extract spans**: Generates an individual event for each span contained in an OTLP traces export payload. A single OTLP traces payload (batch) typically includes many spans.
- **Extract metrics**: Generates an individual event for each data point in a metric event. OTel metrics often contain multiple data points per event.
- **Extract logs**: Available only when **OTLP version** is set to `1.3.1`. Generates an individual event for each log record. Cribl recommends enabling this option to simplify log transformation and manipulation.

- **Tags**: Optionally, add tags to help filter and group Sources within Cribl Edge's UI. Tags are not included in the event data. Separate tag names using a tab or hard return.

3. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the following sections.
4. Select **Save**, then **Commit & Deploy**.

Authentication

Under **Auth methods**, select **Add Method** for each authentication method you want to configure, and then choose an **Authentication type**. If you don't configure any methods, the Source permits unauthenticated access.

- **Token**: Enter the bearer token that senders must include when connecting to this Source.
- **Token (secret)**: Provide a bearer token referenced by a secret. Select a stored text secret in the resulting **Token secret** drop-down, or select **Create** to configure a new secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.
- **OAuth**: Validate bearer JSON Web Tokens (JWTs) against signing keys from a JSON Web Key Set (JWKS) endpoint. Configure these settings:
  - **Issuer**: Expected token issuer. The value must match the JWT's `iss` claim.
  - **JWKS URI**: URL of the JWKS endpoint from which the Source retrieves public signing keys.
  - **Audience**: Expected token audience. The value must match the JWT's `aud` claim.
  - **Required scopes**: Optionally, add scopes that the JWT must grant. The Source checks the token's `scope` or `scp` claim.

On Cribl-managed Worker Groups in Cribl.Cloud, the **JWKS URI** host must be publicly reachable. The Source rejects a JWKS endpoint that resolves to a private or link-local address.

Configure Sender Credentials

When configuring an upstream OTLP sender (such as the OpenTelemetry Collector, Azure Monitor, or an application SDK), map your **Authentication** selection to the key-value pair the sender asks for. When **General Settings** > **Protocol** is set to `HTTP`, senders include credentials in HTTP request headers. When **Protocol** is set to `gRPC`, senders include credentials as gRPC Metadata entries. Metadata entries are key-value pairs that work similarly to HTTP headers.

Authentication	Key	Value
No authentication methods configured	N/A	N/A
Token or **Token (secret)**	`authorization`	`Bearer <your-configured-token>`
Basic or **Basic (credentials secret)**	`authorization`	`Basic <base64-encoded-username:password>`
OAuth	`authorization`	`Bearer <JWT>`

Use lowercase `authorization` for the key. The key and value are the same for both transports.

Multiple Authentication Methods

You can configure more than one authentication method on a single Source, in any combination. For example, you can accept a static auth token from a legacy sender while requiring OAuth from the rest. The Source accepts a request whose credentials match any enabled method, so different senders can send data to the same Source using different credentials.

Select **Add Method** for each sender that should authenticate to this Source, or select **Clone** on an existing method to copy its settings. Each method has an **Enable** toggle, so you can retire a credential without deleting its configuration.

Configure multiple methods when you want to:

- Receive OTLP data from multiple applications, services, projects, or tenants through one Source.
- Assign different credentials to each sender.
- Add sender-specific metadata that you can use later in Routes or Pipelines.

Authentication Fields

Use **Fields** on an authentication method to associate that method with sender metadata, such as an application, project, environment, or tenant.

This is useful when multiple senders share one OTel Source and you want to:

- Route events differently by sender.
- Apply different Pipelines based on the sending app or project.
- Search or analyze OTel data by sender-specific metadata.

For example, you might give one method a Field such as `app=checkout` and another a Field such as `app=payments`.

Each Field is a name/value pair. When a sender authenticates with a given method, Cribl Edge adds that method's Fields to the resulting events.

TLS Settings (Server Side)

> In OTel terminology, your Cribl Edge OTel Source will receive OTel data from a **Collector** running on a local **agent**. In Cribl Edge's terminology, the Collector is the **client** and the OTel Source is the **server**. This is why this Source's UI identifies the Source's TLS Settings as "server-side."
>
> For more about this client-server relationship, see the TLS Configuration Example below.
>
> On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below,

use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can

work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

When **General Settings** > **Protocol** is set to `gRPC`, the UI displays one additional setting:

- **Active connection limit**: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set `0` for unlimited connections.
- **Environment**: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

When **General Settings** > **Protocol** is set to `HTTP`, the UI displays these additional settings:

- **Health check endpoint**: Toggle on to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:
  - `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
  - `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.
- **Active request limit (on-prem only)**: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Raising this limit can increase throughput by allowing more concurrent data requests, but increases resource usage and load on both your Cribl Edge infrastructure and on downstream Destinations. Before raising this limit, ensure:

- Your Cribl Edge deployment has sufficient capacity to support higher request concurrency, including CPU, memory, or number of Worker Processes.

- Downstream Destinations are correctly sized and tuned to accept the higher data ingest rate, preventing backpressure. See Manage Backpressure for more information.

Improper sizing on either side can result in dropped events, delayed processing, or overall system instability.

- **Requests-per-socket limit**: The maximum number of requests Cribl Edge should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.
- **Socket timeout (seconds)**: How long Cribl Edge should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.
- **Request timeout (seconds)**: How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.
- **Keep-alive timeout (seconds)**: After the last response is sent, Cribl Edge will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).
- **IP allowlist regex**: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).
- **IP denylist regex**: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).
- **Environment**: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

Cross-Origin Resource Sharing (CORS) lets a browser send OTLP/HTTP to this Source. CORS is enabled when either **CORS allowed origins** or **CORS allowed headers** is non-empty. Leave both empty to disable CORS. If you set one and leave the other empty, Cribl Edge defaults the empty setting to `*`. **IP allowlist** and **IP denylist** rules are applied before CORS. Requests blocked by those rules do not receive CORS headers.

- **CORS allowed origins**: List the HTTP origins to which Cribl Edge sends CORS response headers. You can enter multiple domains and use wildcards.
- **CORS allowed headers**: List the HTTP headers that Cribl Edge allows in a CORS preflight response. Enter `*` to allow all headers.
- **CORS allowed methods**: List HTTP methods that Cribl Edge allows on CORS preflight responses. Defaults to `OPTIONS` and `POST`.
- **CORS exposed headers**: Optionally list response headers that browsers are allowed to access.
- **CORS include credentials**: Toggle on to include credentials in cross-origin requests. Defaults to toggled off. Per the CORS specification, Cribl Edge does not include credentials when **CORS allowed origins** is set to `*`.

- **CORS max age (seconds)**: Optionally set how long browsers should cache the preflight response.

Balancing Connection Reuse Against Request Distribution

Requests-per-socket limit allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Edge uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Edge sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Edge has asked it to do and tries to send another HTTP request over the existing connection, Cribl Edge will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Edge Node processes by Cribl Edge:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Edge Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Edge performs better when the workload is distributed across multiple Edge Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Requests-per-socket limit** to force the client to create a new connection sooner. This way, more data can be spread over more Edge Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Requests-per-socket limit**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Edge Node processes, yielding better performance from Cribl Edge.

A final point to consider is that one Cribl Edge Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Requests-per-socket limit**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

OTel internal fields are metadata fields added to events processed by the OTel Source. These fields provide essential context about the event's origin and processing details and can be referenced in filters, Routes, and Pipelines to apply specific logic based on the event's metadata. These fields are not included in the final output unless explicitly configured at the Pipeline or Destination stage.

Fields for this Source:

- `__otlp.version` - The OTLP version used to parse the event. For example, `0.10.0` or `1.3.1`. This helps ensure compatibility with upstream systems and configurations.
- `__otlp.type` - The type of telemetry data. For example, `logs`, `metrics`, or `traces`. This is crucial for distinguishing between different signal types in Pipelines.
- `__otlp.extracted` - A boolean flag that denotes whether individual records were extracted from a batch event. If `true`, the event represents an extracted record. This behavior is directly governed by the **Extract spans**, **Extract metrics**, and **Extract logs** general settings of the OTel Source.

TLS Configuration Example

Here's a simple example for using TLS to secure the communication between an OpenTelemetry client and your Cribl Edge OTel Source.

1. Choose or generate a certificate and key. If you need to generate a certificate/key pair, you can adapt the following OpenSSL command:

   ```
   openssl req -nodes -new -x509 -newkey rsa:2048 -keyout myKey.pem -out myCert.pem
   ```

   Copy

   This example command will generate both a self-signed cert named `myCert.pem` (certified for 420 days), and an unencrypted, 2048-bit RSA private key named `myKey.pem`.

2. Configure the **TLS Settings (Server Side)**. Toggle **Enabled** on. In **Server Certificate**, select a certificate from the **Certificate** dropdown, or select **Create** to create a new certificate. You can also manually enter **Private key path** and **Certificate path**. Leave **Authenticate client (mutual auth)** toggled off.
3. Configure the OTel client. See the OTel Collector TLS Configuration Settings README for an explanation of the relevant settings. The config file might be named `otel-config.yaml`, `otel-local-config.yaml`, or just `config.yaml`, depending on your environment. This YAML file will have an `exporters` section, which you must edit to include an `otlp` sub-section, as follows:

- Add an `endpoint` whose value is the IP address of either (a) the Cribl Edge Edge Node on which your OTel Source is running, or (b) the IP address of the load balancer for the relevant Fleet. In the example snippet below, this is the `<Cribl_IP_address>`. Specify the port on which Cribl Edge's OTel Source is listening; port `4317` is the OTLP default for gRPC (`4318` for HTTP).
- Set `tls` > `insecure` to `false`. This matches your setting **TLS Settings (Server Side)** > **Enabled** to toggled on for the Cribl Edge OTel Source.
- Set `tls` > `insecure_skip_verify` to `true`. This matches your setting **TLS Settings (Server Side)** > **Authenticate client (mutual auth)** to toggled off for the Cribl Edge OTel Source. Setting `insecure_skip_verify` to `true` is also required if you're using a self-signed certificate.

Here's how the section you edited should look:

```
exporters:
  otlp:
    endpoint: "https://<Cribl_IP_address>:4317"
    tls:
      insecure: false
      insecure_skip_verify: true
```

Copy

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

When your upstream sender is the OpenTelemetry Collector and its logs show the error `Exporting failed.`

12.2.15. SNMP Trap Source

Cribl Edge supports receiving data from SNMP Traps.

Type: **Push** | TLS Support: **NO** | Event Breaker Support: **No**

Configure Cribl Edge to Receive SNMP Traps

Cribl Edge, except in Cribl.Cloud, ships with an SNMP Trap Source preconfigured to listen on port `9162`. You can clone or directly modify this Source to further configure it, and then enable it.

In Cribl Edge, configure SNMP Traps:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. The default Source is prefilled with the value `in_snmp_trap`. which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Address to bind on. Defaults to `0.0.0.0` (all addresses).
    - **UDP Port**: Port on which to receive SNMP traps. Defaults to `162`.

      Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This results from restrictions of the UDP protocol.

      To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP senders. Cribl also recommends tuning the OS UDP buffer size.
3. Next, you can configure the following **Optional Settings**:

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication Settings

SNMPv3 authentication provides secure access to devices through optional user authentication and decryption of incoming data packets. Cribl Edge lets you choose any of the following levels of security:

- User name checking without authentication.
- User authentication without privacy.
- User authentication with privacy.

SNMPv3 authentication: Toggle on to enable SNMPv3 authentication and reveal authentication parameters. Default is toggled off.

Allow unmatched traps: Toggle on to pass through traps that don't match any of the configured users. Cribl Edge will not attempt to authenticate or decrypt these traps. When toggled off (default), Cribl Edge drops traps without a correctly configured user name.

v3 Name: Enter the SNMPv3 user name (required). Multiple users are supported.

You must configure at least one user to enable SNMPv3 authentication. If desired, you can enter separate user credentials for each SNMPv3 user. The authentication protocol, authentication key, privacy protocol, and privacy key can be unique for each user.

For authentication to succeed, the user name and authentication protocol and key must match in the Source and the sending device configuration.

For decryption to succeed, the user name, authentication protocol and key, and the privacy protocol and key must match in the Source and the sending device configuration.

Authentication protocol: Select the authentication protocol required for your use case. If you select `None`, Cribl Edge will only check the user name without authenticating the user or decrypting the data. Otherwise, Cribl Edge uses the authentication protocol you specify and the key you provide to authenticate the user.

Options include:

- `None`
- `MD5`
- `SHA1`

- SHA224
- SHA256
- SHA384
- SHA512

v3 authentication key: Enter the authentication key.

Choosing an authentication protocol also allows you to select an optional privacy protocol to decrypt incoming packets.

Cribl Edge logs authentication failures at the `debug` level.

Privacy protocol: Select the privacy protocol required for your use case. If you select `None`, Cribl Edge authenticates the user without decrypting the incoming data. Otherwise, Cribl Edge uses the privacy protocol you specify and the key you provide to decrypt the data.

Options include:

- `None`
- `AES128`
- `AES256b (Blumenthal)`
- `AES2556r (Reeder)`

For every successfully decrypted trap, Cribl Edge adds `__didDecrypt: true` to the Event. Cribl Edge logs decryption failures at the `debug` level.

v3 privacy key: Enter the privacy key.

Add user: Click to add a new set of user credentials for SNMPv3 authentication.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Include varbind types: Toggle on to include varbind types in the `varbinds` field on each event. This is required for the SNMP Trap Serialize Function to serialize compliant events into SNMP traps before sending them to an SNMP Trap Destination. The field is parsed to an array of objects like, `[{oid: string, value: any, type: number}]`. Off by default.

IP allowlist regex: Regex matching IP addresses that are allowed to send data. Defaults to `.*`, that is, all IPs.

Buffer size limit (events): Maximum number of events to buffer when downstream is blocking. Defaults to `1000`.

UDP socket buffer size (bytes): Optionally, set the SO_RCVBUF socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Min: `256`. Max: `4294967295`.

It may also be necessary to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__didDecrypt`: Set to `true` for every trap that is successfully decrypted.
- `__final`
- `__inputId`
- `__snmpRaw`: Buffer containing Raw SNMP packet
- `__snmpVersion`: Acceptable values are `0`, `2` , or `3`. These respectively indicate SNMP v1, v2c, and v3.
- `__srcIpPort` : In this particular Source, this field uses a pipe (|) symbol to separate the source IP address and the port, in this format: `event.__srcIpPort = ${rInfo.address}|${rInfo.port};`
- `_time`

Considerations for Working with SNMP Trap Data

- It's possible to work with SNMP metadata (that is, we'll decode the packet). Options include dropping, routing, and so on.
- SNMP packets can be forwarded to other SNMP destinations. However, the contents of the incoming packet **cannot** be modified - that is, we'll forward the packets verbatim as they came in.
- SNMP packets can be forwarded to non-SNMP destinations (for example, Splunk, Syslog, S3, and so on).
- Non-SNMP input data **cannot** be sent to SNMP destinations.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate

12.2.16. Syslog Source

The Syslog Source receives syslog data (UDP/TCP) from various devices. Syslog messages are parsed into structured fields or stored in a raw format if unrecognized. For high-volume scenarios, TCP load balancing distributes data, optimizing performance and minimizing CPU strain.

Compatible RFCs:

- Supports structured syslog data defined by RFC 3164 and RFC 5424, which can include timestamps, facility codes, severities, and message content for detailed analysis.
- Processes message-length prefixes specified in RFC 5425 and RFC 6587, ensuring complete and accurate data transmission.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

For details on how to replace your syslog server with Cribl Edge, and for configuration examples, see these resources:

- Syslog Best Practices.
- Syslog to Cribl Stream Reference Architecture.
- Palo Alto Syslog to Cribl.Cloud.
- CEF/LEEF Syslog Pack.
- Exabeam Pack for Palo Alto Networks NGFW.

Looking for the Syslog Source in **Cribl Search**? See Ingest Syslog Messages into Cribl Search.

Configure Cribl Edge to Receive Data over Syslog

Cribl Edge ships with a Syslog Source preconfigured to listen for both UDP and TCP traffic on Port 9514. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.

- To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.

2. In the **New Source** modal, configure the following under **General Settings**:
   - **Input ID**: Enter a unique name to identify this Syslog Source definition. The default Source is prefilled with the value `in_syslog_default`. which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.

The default filter expression from the **Input ID** field, `__inputId.startsWith('syslog:in_syslog:')` includes a trailing colon, which is omitted in the **Preview Full** mode of Data Preview. Therefore, when testing Routes and Pipelines, adjust your filter by removing the colon to match **Preview Full**. This issue is limited to testing and does not affect normal data processing.

   - **Description**: Optionally, enter a description.
   - **Address**: Enter the hostname/IP on which to listen for data. For example, `localhost` or `0.0.0.0`. For details, see IP Address Considerations.
   - **UDP port**: Enter the UDP port number to listen on. Not required if listening on TCP. The maximum supported inbound UDP message size is 16,384 bytes. For details, see UDP Port Considerations.
   - **TCP port**: Enter the TCP port number to listen on. Not required if listening on UDP.
3. Next, you can configure the following **Optional Settings**:
   - **Fields to keep**: List of fields from source data to retain and pass through. Supports wildcards. Defaults to `*` wildcard, meaning keep all fields. Fields **not** specified here (by wildcard or specific name) will be removed from the event.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in the Cribl Edge UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS, Persistent Queue, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

IP Address Considerations

Cribl recommends that you change the **Address** setting from its default `0.0.0.0` only if you know precisely why you're doing so. There are very few use cases where changing this broad default makes sense. All your Worker Nodes in each Worker Group receive this config, and no two Nodes should have the same IPs, other than `0.0.0.0` or `127.0.0.1`. The `0.0.0.0` tells the system to listen to all interfaces and addresses. A `127.0.0.1` entry means listen **only** on `localhost`.

UDP Port Considerations

Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This is due to the UDP protocol's restrictions. To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP senders. Cribl also recommends tuning the OS UDP buffer size.

Listening on Port 514

For Syslog devices that are hardcoded to send to port 514, you can listen on this port on Cribl.Cloud, which otherwise is normally available only with privileged access. To do this, enable the built-in `in_syslog_default` Syslog Source, which forwards traffic from port 514 to 10514.

Note that traffic on port 514 is unencrypted. This means that using this port may result in collecting fake or undesirable data. Enable the `in_syslog_default` Source only if you are aware of this risk.

TLS Settings (TCP Only)

On Cribl.Cloud, you can enable TLS using Cribl-provided certificates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.

- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.
>
> All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge

applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

On this tab, you can enrich fields with added fields, and attach a pre-processing Pipeline to condition inbound syslog data.

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

Advanced Settings

Enable proxy protocol: Toggle on if the connection is proxied by a device that supports PROXY protocol v1 or v2. This setting applies only to TCP connections.

- **Enable enhanced TLS handshake for proxy protocol**: Toggle on to make TLS handshakes compatible with the PROXY protocol v1 and v2. When enabled, PROXY headers are parsed during the TLS handshake, reliably preserving the original source IP and port even for encrypted traffic routed through proxies or load balancers that prepend these headers.

> **Proxy protocol with UDP syslog**
>
> This setting does not preserve the original source IP for UDP syslog traffic that includes a PROXY protocol header (for example, traffic forwarded by NGINX). As a workaround, toggle on **Single msg per UDP** and attach a pre-processing Pipeline that extracts the original source IP from the event. With this workaround, Cribl Edge does not automatically parse syslog fields such as message, severity, and facility.

Single msg per UDP: Toggle on to treat received UDP packet data as a full syslog message. If toggled off (default) Cribl Edge will treat newlines within the packet as event delimiters.

Allow non-standard app name: Toggle on to allow hyphens to appear in an RFC 3164-formatted Syslog message's `TAG` section. For details, see TAG Section Processing.

Enable TCP load balancing: Toggle on if you want the Source to load balance traffic across all Worker Processes, as explained in TCP Load Balancing. This setting is available only in Cribl Stream single-instance and Distributed deployments and when a **TCP port** is configured.

IP allowlist regex: Regex matching IP addresses that are permitted to send data. Defaults to `.*` (that is, all IPs).

Active connection limit: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set `0` for unlimited connections.

TCP socket idle timeout (seconds): The duration that Cribl Edge will wait for activity on an idle TCP socket before closing the connection. Disabled when set to `0`, the default.

TCP forced socket termination timeout (seconds): The extra time the server waits before forcibly closing a socket that has been idle (**TCP socket idle timeout**) or exceeded its maximum lifespan (**TCP socket max lifespan**) but has not yet properly closed. This prevents resource leaks caused by unresponsive clients or network issues. Configure based on network latency and client behavior. Default: `30` seconds. Set to `0` to disable.

TCP socket max lifespan (seconds): The duration that a socket is allowed to remain open, regardless of activity. This setting prevents resource exhaustion (such as TCP pinning) by limiting the lifespan of connections. Configure based on expected connection durations and resource availability. Disabled when set to `0`, the default.

Buffer size limit (events): Maximum number of events to buffer when downstream is blocking. The buffer is only in memory. (This setting is applicable only to UDP syslog.) Events dropped because they exceed this buffer are logged as dropped in `stats` messages.

UDP socket buffer size (bytes): Optionally, set the SO_RCVBUF socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Min: `256`. Max: `4294967295`.

You might also need to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Default timezone: Timezone to assign to timestamps that omit timezone info. Accept the default `Local` value, or use the drop-down list to select a specific timezone by city name or GMT/UTC offset.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

TCP Load Balancing

This feature is available for Cribl Stream deployments running in either single-instance or Distributed mode. The UI displays the setting when a **TCP port** is configured.

> In single-instance mode, enabling TCP load balancing still starts a dedicated Load Balancer Worker Process. Ensure the host has enough CPU capacity to run the Load Balancer plus the configured Worker Processes.

When the Syslog Source receives a high volume of data over TCP, a single Worker Process can place excessive CPU load on its Cribl Stream Worker Node, while remaining Worker Processes on the same node mostly sit idle. This undesirable condition is called "TCP pinning" because the high volume of traffic "pins" a single TCP connection.

To alleviate TCP pinning, try toggling **Advanced Settings** > **Enable TCP load balancing** on. The Syslog Source will then load balance traffic across all Worker Processes.

When TCP load balancing is enabled, the Worker Node forks a special Worker Process dedicated to load balancing; creates sockets for communication between the load balancer and the regular Worker Processes; and, makes TCP load balancing metrics available.

The Load Balancing Process

The Worker Node forks a new, special **Load Balancer** Worker Process that distributes incoming syslog data among the other Worker Processes. For customer-managed (hybrid or on-prem) Fleets, consider reducing the Process count by 1, if possible. This will leave a core free to run the load balancer process.

If you want to verify that the load balancer Worker Process exists, teleport into the relevant Worker and in the **Worker Processes** tab you will see a Worker Process with `LB` in its name.

To view logs from the Leader UI, navigate to **Monitoring** > **Logs** > `<Worker Node ID>` > **Load Balancer**.

Worker Process Socket Files

The load balancer Worker Process sends data to the regular Worker Processes over inter-process communication (IPC) sockets. This means that in the `state` directory, there is a socket file for each load balancer Worker Process and each Worker Process.

By default, the socket files are linked to `state`, from the Cribl `tmp` directory. For customer-managed (hybrid or on-prem) Stream Worker Groups, you can specify a directory other than `tmp` for these links. Cribl recommends that you do **not** use this option, but if you find it necessary, navigate to **Worker Group/Fleet Settings** > **General Settings** > **Sockets** to configure as desired.

TCP Load Balancing Metrics

Metrics specific to TCP load balancing become available.

- `lb.bytes_out` - Total bytes processed by the load balancer Worker Process, by Source.
- `lb.writable_sockets` - Total unblocked Worker Process sockets, by Source.
- `lb.blocked_sockets` - Total blocked Worker Process sockets, by Source.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source data via the Routing table.

Select **QuickConnect** to send the data from this Source to one or more Destinations via independent, direct connections.

TAG Section Processing

Cribl Edge will try to parse `appname` out of a syslog message's `TAG` section, even when the message is not RFC 5424-formatted.

This practice means that the `TAG` section can contain any alphanumeric character or an underscore (`_`). When the **Allow-non-standard app name** option is enabled, Cribl Edge will also process hyphens that appear in an RFC 3164-formatted Syslog message's `TAG` section. If Cribl Edge encounters a hyphenated `appname`, it will continue processing to find `procid`. (This setting has no effect on RFC 5424-formatted messages.)

If the `TAG` section contains any non-alphanumeric character, Cribl Edge will treat that character as the termination of the `TAG` section, and as the starting character of the `CONTENT` section.

CONTENT Section Processing

Cribl Edge will try to parse `procid` from the beginning of the `CONTENT` section if this section is directly after the `TAG` section, and if it either follows a `:` or is surrounded by `[]`. This process occurs regardless of the **Allow-non-standard app name** setting.

What Fields to Expect

To create fields, the Syslog Source requires messages to comply with RFC 3164 or RFC 5424. If messages sent to the Source comply with neither of these RFCs, you'll see the following fields:

- `_raw`: Contains the whole message, but no other fields broken out.
- `_time`: Contains the time the message was received by Cribl Edge.
- `__srcIpPort <udp|tcp>:<port>`: See Internal Fields.
- `__syslogFail`: See Internal Fields.
- `host`: IP address of the device sending the incoming message.

If messages sent to the Source comply with either RFC 3164 or RFC 5424, fields that the RFC deems guaranteed will always be there, but fields deemed optional might or might not be. Once Cribl Edge parses the required fields and any optional fields, what remains is the actual message.

To see this in real life, install the `cribl-syslog-input` Pack and preview the `RFC5424-RFC3164.log` sample file.

RFC Name for Field	Cribl Name for Field	Guaranteed?	Notes
`PRI`	`facility`, `facilityName`, `severity`, `severityName`	Yes	`PRI` is a bitwise representation of Facility and Severity, which is how Cribl Edge can derive values for all four of its fields.
`TIMESTAMP`	`_time`	Yes	This field's format differs depending on which RFC the messages adhere to. Cribl Edge converts it to Unix time.
`HOSTNAME`	`host`	Yes	
`APP-NAME`	`appname`	No	
`PROCID`	`procid`	No	
`MSGID`	`msgid`	No	
`STRUCTURED-DATA`	`structuredData`	No	
`MSG`	`message`	Yes	

Event Size and Storage

By default, a Syslog Source produces eight parsed fields: `_time`, `appname`, `facility` (numeric), `facilityName` (text), `host`, `message`, `severity` (numeric), and `severityName` (text). This improves readability but does not reduce event volume. It also introduces redundancy, numeric and text pairs for `facility` and `severity`.

If you keep all of the default fields (the default behavior), events written to downstream storage are larger than the original raw syslog line because the original message is accompanied by additional fields. For short messages, this overhead can be significant relative to the raw size and could roughly double the stored size. For larger messages, the percentage increase is lower.

To control size growth, configure trimming at the Source or in a Pipeline:

- Adjust the Source **Fields to keep** setting to include only the fields you require. By default, all fields are kept.
- Use a Pipeline to remove redundant/unnecessary fields and, if appropriate, shrink outbound `_raw` to only the message component.

For a walk-through of optimization steps and expected results, see Syslog Best Practices: The Goal–Optimizing Syslog Events.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but are accessible and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__srcIpPort <udp|tcp>:<port>`: Identifies the port of the sending socket.
- `__syslogFail: true` for data that fails RFC 3164/5424 validation as syslog format.

`stats` Log Message

In Cribl Edge 4.2.2 and newer, `stats` log messages report the number of events received, buffered, or dropped for exceeding the maximum Cribl buffer size. By default, these messages are logged every 60 seconds. These values also appear in **Sources** > **Syslog** > <Source_name> > **Status**, in the **UDP** row.

UDP Tuning

This section applies only to UDP-based syslog ingest with on-prem or hybrid Cribl Stream Worker Groups or Cribl Edge Fleets. It does not apply to TCP-based syslog, nor to Cribl-managed Stream Workers in Cribl.Cloud, where Cribl will manage UDP tuning for you.

Incoming UDP traffic is put into a buffer by the Linux kernel. Cribl will drain from that buffer as resources are available. At lower throughput levels, and with plenty of available processes, this isn't an issue. As you scale up, however, the default size of that buffer is very likely too small.

Monitoring Buffer Size and Packet Errors

You can check the current buffer size with the following command:

```
$ sysctl net.core.rmem_max
```

Copy

A typical value of about 200 KB is far too small for an even moderately busy syslog server.

You can check the health of UDP with the following command. Check the `packet receive errors` line.

```
$ netstat -su
```

Copy

If `packet receive errors` is more than zero, you have lost events, which is a particularly serious problem if the number of errors is increasing rapidly. This means you need to increase your `net.core.rmem_max` setting (covered later in this section).

Commands to Update Settings

You can update the live settings. But you'll also need to change the boot-time setting, so that next time you reboot, everything is ready to roll.

Live change, setting to 25 MB:

```
$ sysctl -w net.core.rmem_max=26214400
net.core.rmem_max = 26214400
$ sysctl -w net.core.rmem_default=26214400
net.core.rmem_default = 26214400
```

Copy

For the permanent settings change, add the following lines to `/etc/sysctl.conf`:

```
net.core.rmem_max=26214400
net.core.rmem_default=26214400
```

Copy

We recommend that you track a few things related to UDP receiving:

- The `netstat -su` command, watching for errors.
- The **Status** tab in the Syslog Source. In particular, watch for dropped messages. They could indicate you need a bigger buffer under **Advanced Settings** (default: 1000 events). They could also indicate your Worker is encountering pressure further down the Pipeline.
- Especially if you increase your kernel receive buffer as above, watch your Worker processes' memory usage.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Source Integrations: Syslog short course. To

12.2.17. TCP JSON Source

Cribl Edge can receive newline-delimited JSON data over TCP.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

Looking for the TCP JSON Source in **Cribl Search**? See Ingest JSON Events via TCP into Cribl Search.

The TCP JSON Source is part of Cribl Edge's default configuration. If you delete it, Cribl Edge will re-create it when defaults are applied again (for example, when you create a new Fleet or deploy a configuration bundle). To prevent it from receiving data, disable it instead of deleting it.

Configure Cribl Edge to Receive TCP JSON Data

Cribl Edge ships with a TCP JSON Source preconfigured to listen on Port 10070. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `in_tcp_json`, which can't be changed via the UI. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for TCP JSON data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Use this default option to enter the shared secret that clients must provide in the `authToken` header field. Exposes an **Auth token** field for this purpose. (If left blank, unauthorized access will be permitted.) A **Generate** link is available if you need a new secret.

- **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the `authToken` header field value described above. The secret can reside in Cribl Edge's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need a new secret.

4. Next, you can configure the following **Optional Settings**:
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.
- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.

- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.
>
> All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

Advanced Settings

Enable proxy protocol: Toggle on if the connection is proxied by a device that supports proxy protocol v1 or v2.

Enable load balancing (Cribl Stream only): Toggle on to distribute the data from incoming TCP connections across multiple Worker Processes. This improves performance compared to the default of having all data from an incoming connection processed on a single Worker Process.

- This spins up an extra Worker Process (named `wLB` in **Settings** > **Processes**) on the Worker Node, which handles splitting data from incoming TCP connections across all other Worker Processes.
- When enabled, the option to include common fields in the JSON header is not supported. This means fields specified under `fields` in the JSON header are not automatically added to all events.

Load balancing is available in Cribl Stream single-instance and Distributed deployments when a TCP port is configured.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (such as, all IPs).

Active connection limit: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set to `0` for unlimited connections.

Socket idle timeout (seconds): The duration that Cribl Edge will wait for activity on an idle TCP socket before closing the connection. Disabled when set to `0`, the default.

Forced socket termination timeout (seconds): The extra time the server waits before forcibly closing a socket that has been idle (**TCP socket idle timeout**) or exceeded its maximum lifespan (**TCP socket max lifespan**) but has not yet properly closed. This prevents resource leaks caused by unresponsive clients or network issues. Configure based on network latency and client behavior. Default: `30` seconds. Set to `0` to disable.

Socket max lifespan (seconds): The duration that a socket is allowed to remain open, regardless of activity. This setting prevents resource exhaustion (such as TCP pinning) by limiting the lifespan of connections. Configure based on expected connection durations and resource availability. Disabled when set to `0`, the default.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the configuration will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Field for this Source:

- `__inputId`
- `__srcIpPort`

Format

Cribl Edge expects TCP JSON events in newline-delimited JSON format:

1. A header line. Can be empty - for example, `{}`. If **authToken** is enabled (see above) it should be included here as a field called `authToken`. When `authToken` is **not** set, the header line is **optional**. In this case, the first line will be treated as an event if does not look like a header record.
   In addition, if events need to contain common fields, they can be included here under `fields`. In the example below, `region` and `AZ` will be automatically added to all events.

   When you enable **Enable load balancing (Cribl Stream only)** under Advanced Settings, the Source will no longer support common fields in the JSON header. Consequently, any fields you define in the JSON header `fields` object will not be automatically propagated to each event.

2. A JSON event/record per line.

   Sample TCP JSON Events

   ```
   {"authToken":"myToken42", "fields": {"region": "us-east-1", "AZ":"az1"}}

   {"_raw":"this is a sample event ", "host":"myHost", "source":"mySource", "fieldA
   {"host":"myOtherHost", "source":"myOtherSource", "_raw": "{\"message\":\"Somethi
   ```

   Copy

TCP JSON Field Mapping to Splunk

If a TCP JSON Source is routed to a Splunk destination, fields within the JSON payload are mapped to Splunk fields. Fields that do not have corresponding (native) Splunk fields become index-time fields. For example, let's assume we have a TCP JSON event as below:

```
{"_time":1541280341, "host":"myHost", "source":"mySource", "_raw":"this is a sample event ", "fieldA":"valueA"}
```

Here, `_time`, `host`, and `source` become their corresponding fields in Splunk. The value of `_raw` becomes the actual body of the event, and `fieldA` becomes an index-time field (`fieldA::`valueA``).

Examples

Testing TCP JSON In

This first example simply tests that data is flowing in through the Source:

1. Configure Cribl Edge to listen on port `10001` for TCP JSON. Set `authToken` to `myToken42`.
2. Create a file called `test.json` with the payload above.
3. Send it over to your Cribl Edge host: `cat test.json | nc <myCriblHost> 10001`

Cribl Edge to Cribl.Cloud

This second example demonstrates using TCP JSON to send data from one Cribl Edge instance to a downstream Cribl.Cloud instance. We assume that the downstream Cloud instance uses Cribl.Cloud's **default** TCP JSON Source configuration.

So all the configuration happens on the upstream instance's TCP JSON Destination. Replace the `<organizationId>` placeholder with the Org ID from your Cribl.Cloud portal.

TCP JSON Destination Configuration

On the upstream Cribl Edge instance's Destination, set the following field values to match the target Cloud instance's defaults:

General Settings

Address: `default.main.<organizationId>.cribl.cloud` - you can simply copy/paste your Cribl.Cloud portal's **Ingest Endpoint** here. With a Cribl.Cloud Enterprise plan, generalize the `default.main` substring in this URL to `<groupName>.main` when sending to other Fleets.

Port: `10070`

TLS Settings (Client Side)

Use TLS: Toggle on

Validate server certs: Toggle on

Periodic Logging

Cribl Edge logs metrics about incoming requests and ingested events once per minute.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker Process.

This kind of periodic logging helps you determine whether a Source is in fact still healthy even when no data is coming in.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

12.2.18. TCP (Raw) Source

Cribl Edge supports receiving of data over TCP. (See examples and header options below.)

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

Looking for the TCP (Raw) Source in **Cribl Search**? See Ingest Raw TCP Data into Cribl Search.

The TCP (Raw) Source is part of Cribl Edge's default configuration. If you delete it, Cribl Edge will re-create it when defaults are applied again (for example, when you create a new Fleet or deploy a configuration bundle). To prevent it from receiving data, disable it instead of deleting it.

Configure Cribl Edge to Receive TCP Data

Cribl Edge ships with a TCP Source preconfigured to listen on Port 10060. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this TCP Source definition. If you clone this Source, Cribl Edge will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for raw TCP data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter port number.
    - **Enable header**: Toggle on to indicate that client will pass a header record with every new connection. The header can contain an `authToken`, and an object with a list of fields and values to add to every event. These fields can be used to simplify Event Breaker selection, routing, and so forth. Header format: `{ "authToken" : "myToken", "fields": { "field1": "value1", "field2": "value2" }}`.

- **Authentication method**: Select **Manual** to enter an auth token directly, or **Secret** to use a text secret to authenticate.
  - **Auth token**: If you selected **Manual**, enter an auth token, or select **Generate** to automatically generate a token. If empty, unauthorized access is permitted.
  - **Auth token (text secret)**: If you selected **Secret**, enter a shared secret to be provided by any client (in `authToken` header field). Select **Create** to create a new secret. If empty, unauthorized access will be permitted.

3. Next, you can configure the following **Optional Settings**:
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS Settings, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

On Cribl.Cloud, you can enable TLS using Cribl-provided certficates if desired.

Enabled: Defaults to toggled off.

Server Certificate

Select a certificate from the store to auto-fill the paths below, or enter them manually.

Certificate: Name of the predefined certificate.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Mutual Authentication (mTLS)

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Default is toggled off. When toggled on:

- **Trusted client CA path**: Server path containing CA certificates (in PEM format) to use when verifying client certificates. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the client's identity. This is typically the root CA that anchors the client's certificate chain. If you

disable **Authenticate client (mutual auth)**, this field is hidden in the UI, but any value already saved remains on disk.

- **Validate client certificates**: Reject certificates that are not authorized by a CA in the **Trusted client CA path**, or by another trusted CA (for example, the system's CA). Default is toggled on.
- **Common name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) The CN and SAN fields in the client certificate are matched against this regex. Clients are rejected unless at least one match is found. If the subject attribute contains Subject Alternative Name (SAN) entries, the Source checks the regex against all of those but ignores the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source checks the regex against the single name in the CN.

TLS Version

Reject clients using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

> **Deprecation Notice**
>
> To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:
>
> - Monitor your persistent queue usage so that you can allocate enough disk space.
> - Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
> - Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

> **Deprecation Notice**
>
> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Custom Command

In this section, you can pass the data from this input to an external command for processing before the data continues downstream.

Enabled: Default is toggled off. When toggled on:

Command: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).

Arguments: Click **Add Argument** to add each argument for the command. You can drag arguments vertically to resequence them.

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

Advanced Settings

Enable proxy protocol: Toggle on if the connection is proxied by a device that supports Proxy Protocol v1 or v2. When this setting is enabled, the `__srcIpPort` internal field will show the original source IP address and port. When it is disabled, the `__srcIpPort` field will show the IP address and port of the proxy that forwarded the connection.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (i.e,. all IPs).

Active connection limit: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set `0` for unlimited connections.

Socket idle timeout (seconds): The duration that Cribl Edge will wait for activity on an idle TCP socket before closing the connection. Disabled when set to `0`, the default.

Forced socket termination timeout (seconds): The extra time the server waits before forcibly closing a socket that has been idle (**TCP socket idle timeout**) or exceeded its maximum lifespan (**TCP socket max lifespan**) but has not yet properly closed. This prevents resource leaks caused by unresponsive clients or network issues. Configure based on network latency and client behavior. Default: `30` seconds. Set to `0` to disable.

Socket max lifespan (seconds): The duration that a socket is allowed to remain open, regardless of activity. This setting prevents resource exhaustion (such as TCP pinning) by limiting the lifespan of connections. Configure based on expected connection durations and resource availability. Disabled when set to `0`, the default.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields accessible for this Source:

- `__inputId`
- `__srcIpPort`
- `__channel`

TCP Source Examples

Every new TCP connection may contain an **optional** header line, with an `authToken` and a list of fields and values to add to every event. To use the Cribl Edge Cloud sample, copy the `<token_value>` out of your Cribl Edge Cloud TCP Source.

Sample test.raw (on-prem) | Sample test.raw (Cribl.Cloud)

```
{"authToken":"myToken42", "fields": {"region": "us-east-1", "AZ":"az1"}}

this is event number 1
this is event number 2
```

Copy

Enabling the Example - Cribl Edge

1. Configure Cribl Edge to listen on port `7777` for raw TCP. Set `authToken` to `myToken42`.
2. Create a file called `test.raw`, with the payload above.
3. Send it over to your Cribl Edge host, using this command: `cat test.raw | nc <myCriblHost> 7777`

Enabling the Example - Cribl.Cloud

Use netcat with `--ssl` and `--ssl-verify`:

Command-line test

```
cat test.raw | nc --ssl --ssl-verify default.main.<organizationId>.cribl.cloud 10060
```

Copy

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to `<groupName>.main` when sending to other Fleets.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate,

12.2.19. UDP (Raw) Source

The UDP (Raw) Source allows Cribl Edge to ingest unparsed, asynchronous data streams. Because UDP (User Datagram Protocol) is a connectionless protocol, this Source is primarily used for high-velocity telemetry where low latency is prioritized over guaranteed delivery or for data streams where the overhead of TCP handshakes would impact performance.

While the UDP (Raw) Source is highly flexible, it should be treated as a fallback for non-standard data. For common network telemetry needs, use Sources such as the Syslog, NetFlow & IPFIX, or SNMP Trap first.

For important information about using the UDP (Raw) Source more effectively, see:

- Better Practices
- UDP Tuning

Type: **Push** | TLS Support: **NO** | Event Breaker Support: **NO**

Configure Cribl Edge to Receive Raw UDP Data

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this raw UDP Source definition.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen for raw UDP data. For example: `localhost`, `0.0.0.0`, or `::`.
    - **Port**: Enter the port number.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Edge's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.

5. Select **Save**, then **Commit & Deploy**.

> Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This results from restrictions of the UDP protocol.
>
> To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP sender. Cribl also recommends tuning the OS UDP buffer size.

Persistent Queue Settings

In the **Persistent Queue Settings** tab, you can optionally specify persistent queue storage, using the following controls. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Source Persistent Queues

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Enable persistent queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and the queue does not perform any compression. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.
>
> All other settings described in this section apply to on-prem and hybrid deployments only.

Enable persistent queue: Default is toggled off. When toggled on:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to the Cribl Edge data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from the Cribl Edge data processing engine. `Smart` mode only engages when necessary, such as when a downstream Destination becomes blocked *and* the **Buffer size limit** reaches its limit. When persistent queue is set to `Smart` mode, Cribl Edge attempts to flush the queue when every new event arrives. The only time events stay in the buffer is when a downstream Destination becomes blocked.

Deprecation Notice

To improve data integrity, **Smart** mode is deprecated for Source persistent queue on hybrid and on-prem deployments. In January 2027, affected configurations will automatically migrate to **Always On** mode. Consider updating existing configurations to **Always On** mode prior to the automatic migration date. Before changing the configuration:

- Monitor your persistent queue usage so that you can allocate enough disk space.
- Before making changes to your persistent queue, remember to drain the queues first to avoid orphaned data.
- Verify that data routing and filtering behaves as expected in a test environment before rolling out the new configuration to production.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Commit frequency: The number of events to send downstream before committing that Cribl Edge has read them. Defaults to `42`.

File size limit: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Edge applies the default `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source stops queueing data and applies the **Queue-full behavior**. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** in Group or Fleet settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Edge appends `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file closes. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity.

- **Block** (Default): Does not accept new data until the queue has capacity. When the sender supports backpressure signaling, Cribl Edge returns block signals to the sender.
- **Drop new data**: Discards incoming events while leaving the contents of the persistent queue unchanged.

In Cribl Edge 4.1 and newer, the Source persistent queue default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Optimize Source Persistent Queues.

You can optimize Workers' startup connections and CPU load at **Group/Fleet settings** > Worker Processes.

Processing Settings

Fields

In this section, you can define new fields or modify existing ones using JavaScript expressions, similar to the Eval function.

- The **Field Name** can either be a new field (unique within the event) or an existing field name to modify its value.
- The **Value** is a JavaScript expression (enclosed in quotes or backticks) to compute the field's value (can be a constant). Select this field's advanced mode icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.

This flexibility means you can:

- Add new fields to enrich the event.
- Modify existing fields by overwriting their values.
- Compute logic or transformations using JavaScript expressions.

Pre-Processing

Auto parse: Toggle on to detect each event's Datatype and extract top-level fields from `_raw` before Source **Fields** and before the pre-processing Pipeline or Pack. The toggle is off by default. Because **Fields** runs after automatic parsing, values you add there take precedence over same-named fields extracted from `_raw`. For Datatypes that automatic parsing can detect, see the List of Stock v2 Datatypes. For field behavior, prevention of duplicate parsing, and performance considerations, see Automatic Parsing.

Pipeline: Select an existing Pipeline or Pack to process data from this Source before routing.

Advanced Settings

Single msg per UDP: Toggle on if each UDP message should be treated as an independent event. Toggle off (default) if the message should be broken on newlines to create multiple events.

Ingest raw bytes: Toggle on to add a `__rawBytes` field to each event containing an array of the bytes received as the UDP message.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (i.e, all IPs).

Buffer size limit (events): Maximum number of events to buffer when downstream is blocking. The buffer is only in memory.

UDP socket buffer size (bytes): Optionally, set the SO_RCVBUF socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Min: `256`. Max: `4294967295`.

It may also be necessary to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

What Fields to Expect

The Raw UDP Source does minimal processing of the incoming UDP messages to remain consistent with the internal Cribl event model. For each UDP message received on the socket, you can expect an event with the following fields:

- `_raw`: Contains the UTF-8 representation of the entire message received (if **Single msg per UDP** is toggled on), or of the given line that was split out of the message.

- `_time`: Timestamp in Unix time (seconds) at which the message was received by Cribl Edge.
- `source`: A string in the form `udp|<remote IP address>|<remote port>`, indicating the remote sender.
- `host`: The hostname of the machine running Cribl Edge that ingested this event.

Also, the internal fields listed below will be present.

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields accessible for this Source:

- `__inputId`
- `__srcIpPort`
- `__rawBytes`: When **Ingest raw bytes** is toggled on, this field will be an array containing the bytes of the UDP message.

Better Practices

High-throughput UDP ingestion is uniquely sensitive to Linux kernel limitations. Unlike TCP, adding more Worker Processes to a single Edge Node does not linearly improve UDP performance. Under high stress (particularly with small, high-frequency events like Syslog), excessive Worker Process counts can cause kernel-level socket contention, visible as elevated `ksoftirqd` CPU usage.

Scale Horizontally

Instead of using a few extra-large Edge Nodes with high Worker Process counts, scale out using more Edge Nodes with a moderate number of Worker Processes. For many environments, a footprint of 2–3 Edge Nodes with fewer than 10 Worker Processes per Node provides a stable balance.

Use the minimum number of Worker Processes required to sustain your throughput. Increasing Worker Process counts beyond the point of saturation can lead to a disproportionate jump in CPU overhead.

Isolate UDP Traffic

Isolate high-volume UDP Sources into their own dedicated Fleet. Since TCP scales effectively with larger Edge Nodes and higher Worker Process counts, keeping TCP and UDP on separate Fleets allows you to tune each according to their specific scaling behaviors without one starving the other for kernel resources.

OS and Network Tuning

The bottleneck for UDP is often the OS kernel, not the Cribl Edge application logic.

- **Kernel Buffers:** Consider tuning `net.core.rmem_max` to increase the size of the receive buffers, which helps prevent packet loss during bursts.
- **Advanced NIC Tuning:** Features like RSS (Receive Side Scaling) or RPS (Receive Packet Steering) can help distribute interrupt load across CPU cores, though results vary by hardware and environment.

These limitations are driven by how the Linux kernel distributes UDP packets and handles interrupts. While OS-level tuning may improve performance, the most reliable strategy remains horizontal scaling across smaller, dedicated nodes.

UDP Tuning

For guidance on handling UDP data during backpressure events, see UDP Sources and Backpressure.

Incoming UDP traffic is put into a buffer by the Linux kernel. Cribl Edge will drain from that buffer as resources are available. At lower throughput levels, and with plenty of available processes, this isn't an issue. As you scale up, however, the default size of that buffer may be too small.

You can check the current buffer size with:

```
$ sysctl net.core.rmem_max
```

Copy

A typical value of about 200 KB is far too small for an even moderately busy Syslog server. You can check the health of UDP with the following command. Check the `packet receive errors` line.

```
$ netstat -su
```

Copy

If `packet receive errors` is more than zero, you have lost events, which is a particularly serious problem if the number of errors is increasing rapidly. This means youneed to increase your `net.core.rmem_max` setting (see earlier).

You can update the live settings, but you'll also need to change the boot-time setting so next time you reboot everything is ready to roll.

Live change, setting to 25 MB:

```
$ sysctl -w net.core.rmem_max=26214400
net.core.rmem_max = 26214400
$ sysctl -w net.core.rmem_default=26214400
net.core.rmem_default = 26214400
```

Copy

For the permanent settings change, add the following lines to `/etc/sysctl.conf`:

```
net.core.rmem_max=26214400
net.core.rmem_default=26214400
```

Copy

We recommend you track a few things related to UDP receiving:

- The `netstat -su` command, watching for errors.
- The **Status** tab in the UDP (Raw) Source. In particular, watch for dropped messages. They could indicate you need a bigger buffer under **Advanced Settings** (default: 1000 events). They could also indicate your Worker is encountering pressure further down the Pipeline.
- Especially if you increase your kernel receive buffer as above, watch your Worker processes' memory usage.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

12.3. Destinations

Cribl Edge can send transformed data to various Destinations, including Cribl HTTP, Cribl TCP, Elasticsearch, Amazon Kinesis, Amazon S3 and other object stores, Prometheus and compatible services, InfluxDB, Splunk, Snowflake, Databricks, TCP JSON, and many others.

Destinations can write data to either IPv4 or IPv6 addresses.

Destination are grouped into categories that define how they handle unreachable outputs (backpressure events) and their load-balancing capabilities.

Destination Categories

Destinations can be divided into streaming and non-streaming: those that accept events in real time, and those that batch them from a staging directory.

Other than that, each Destination can belong to one of the following (non-exclusive) categories:

- Filesystem-based
- Load-balanced

Streaming and Non-Streaming Destinations

Streaming and non-streaming Destination differ in the way they receive events:

- Streaming Destinations accept events in real time.
- Non-streaming Destinations receive events in batches from a staging directory.

Non-Streaming Destinations

Non-streaming Destinations make use of the staging directory, and have specific behavior regarding batching events into files.

Staging Directory

With non-streaming Destinations, Cribl Edge uses a staging directory in the local filesystem to format and write outputted events before sending them to configured Destinations. After a set of conditions is met, data is compressed and then moved to the final Destination.

To reduce costs when the staging directory is also the final directory, Cribl Edge avoids iterating through all the files within a directory by keeping an inventory of open (in progress) files in the staging directory's root. At startup, Cribl Edge will check for any leftover files in progress from prior sessions, and will ensure that they're moved to their final Destination. The process of moving to the final Destination is delayed after startup (default delay: 30 seconds). Processing of these files is paced at one file per service period (which defaults to 1 second).

Batching Conditions

In non-streaming delivery, a file is closed and rolled out when it reaches its configured maximum:

- Size
- Open time
- Idle time

If a new file needs to be open, Cribl Edge will enforce the maximum number of open files by closing files in the order in which they were opened.

Filesystem-based Destinations

Some Destinations are Filesystem-based, which means they receive files on disk from a staging directory and batch them in a queue. When a batch of events is ready for transmission, Cribl Edge closes the file, optionally compresses it, and transmits the file to the downstream service. Filesystem-based Destinations do not support persistent queues.

Load-balanced Destinations

Certain Destinations offer built-in load-balancing capabilities.

Available Destinations

Cribl Edge supports the following Destinations. You can configure proxy servers for all HTTP-based Destinations.

Destination	Protocol	Streaming	Filesystem-Based	Load-Balanced
Amazon S3 Compatible Stores	HTTP/S	Non-streaming		
Amazon CloudWatch Logs	HTTP/S	Non-streaming		
Data Lakes > Amazon Security Lake	HTTP/S	Non-Streaming		
Amazon Kinesis Data Streams	HTTP/S	Streaming		
Amazon MSK	TCP	Streaming		
Amazon SQS	HTTP/S	Streaming		
Azure Blob Storage	HTTPS only	Non-Streaming		

Destination	Protocol	Streaming	Filesystem-Based	Load-Balanced
Azure Data Explorer	HTTPS only	Streaming or non-streaming		
Azure Event Hubs	TCP	Streaming		
Azure Monitor Logs	HTTPS only	Streaming		
Microsoft Sentinel	HTTP/S	Streaming		
ClickHouse	HTTP/S	Streaming		
Cortex XSIAM	HTTP/S	Streaming		
Confluent Cloud	TCP	Streaming		
CrowdStrike Falcon LogScale	HTTPS only	Streaming		
CrowdStrike Falcon Next-Gen SIEM	HTTPS only	Streaming		
Datadog	HTTPS only	Streaming		
Databricks		Non-Streaming		
Dynatrace HTTP	HTTP/S	Streaming		
Dynatrace OTLP	HTTP/S	Streaming		
Elastic Cloud	HTTPS only	Streaming		
Elasticsearch	HTTP/S	Streaming		
Exabeam	HTTP/S	Non-Streaming		
Filesystem/NFS		Non-Streaming		
Google Cloud Chronicle API	HTTPS only	Streaming		
Google Cloud Logging	HTTPS only	Streaming		
Google Cloud Pub/Sub	HTTPS only	Streaming		
Google Cloud Storage	HTTPS only	Non-Streaming		
Google SecOps	HTTPS only	Streaming		

Destination	Protocol	Streaming	Filesystem-Based	Load-Balanced
Grafana Cloud	HTTP/S	Streaming		
Graphite	TCP or UDP	Streaming		
Honeycomb	HTTPS only	Streaming		
IBM Cloud Object Storage	HTTP/S	Non-Streaming		
InfluxDB	HTTP/S	Streaming		
Kafka	TCP	Streaming		
Loki	HTTP/S	Streaming		
Microsoft Fabric Real-Time Intelligence	TCP	Streaming		
MinIO	HTTP/S	Non-Streaming		
New Relic Events	HTTPS only	Streaming		
New Relic Logs & Metrics	HTTPS only	Streaming		
OpenTelemetry (OTel)	gRPC or HTTP/S	Streaming		
Prometheus	HTTP/S	Streaming		
SentinelOne AI SIEM	HTTP/S	Streaming		
SentinelOne DataSet	HTTPS only	Streaming		
ServiceNow Cloud Observability	gRPC or HTTP/S	Streaming		
SignalFx	HTTPS only	Streaming		
SNMP Trap	UDP	Streaming		
Splunk HEC	HTTP/S	Streaming		
Splunk Load Balanced	TCP	Streaming		
Splunk Single Instance	TCP	Streaming		
StatsD	TCP or UDP	Streaming		

Destination	Protocol	Streaming	Filesystem-Based	Load-Balanced
StatsD Extended	TCP or UDP	Streaming		
Sumo Logic	HTTP/S	Streaming		
Syslog	TCP or UDP	Streaming		(TCP only)
TCP JSON	TCP	Streaming		
Wavefront	HTTPS only	Streaming		
Webhook	HTTP/S	Streaming		

You can adapt the Amazon S3 Compatible Stores Destination to send data to downstream services like Databricks and Snowflake, for which Cribl Edge currently has no preconfigured Destination. For details, please contact Cribl Support.

Internal Destinations

Internal Destinations are special-purpose Destinations that route data within your Cribl Edge deployment, or among Edge Nodes across distributed or hybrid Cribl.Cloud deployments. The following internal Destinations are available:

- Default: Specify a default output from among your configured Destinations.
- Output Router: A "meta-Destination." Configure rules that route data to multiple configured Destinations.
- DevNull: Simply drops events. Preconfigured and active when you install Cribl Edge, so it requires no configuration. Useful for testing.
- Cribl HTTP: Send data among peer Edge Nodes over HTTP. Streaming and load-balanced.
- Cribl TCP: Send data among peer Edge Nodes over TCP. Streaming and load-balanced.
- Cribl Search: Send data from Edge Fleets directly to Cribl Search over HTTP. Streaming and load-balanced.
- **SpaceOut**: This experimental Destination is undocumented. Be careful!

Connecting to Cribl Stream

Always use Cribl TCP or Cribl HTTP as the Destinations to send data to Cribl Stream. Otherwise, you might see duplication of certain data (such as host). Also, data sent to Cribl Stream via TCP/HTTP is not counted against your ingest data quota.

See Cribl Edge to Cribl Stream for more information.

Data Delivery to Unreachable Destinations

Cribl Edge attempts to deliver data to all Destinations that are configured to receive it at least once. When a Destination is unreachable, there are three possible behaviors:

- **Block** - Cribl Edge will block incoming events.
- **Drop** - Cribl Edge will drop events addressed to that Destination.
- **Queue** - To prevent data loss, Cribl Edge will write events to a **persistent queue** disk buffer, then forward them when a Destination becomes available. (Available on several streaming Destinations.)

For further information about backpressure (a situation when a Destination receives more data than it can send), see Destination Backpressure Triggers.

You can configure your desired behavior through a Destination's **Backpressure Behavior** drop-down. Where other options are not displayed, Cribl Edge's default behavior is **Block**. For details about all the above behaviors and options, see Persistent Queues.

To learn how backpressure affects upstream Sources when persistent queue is not enabled, see Backpressure Impacts to Sources.

How Destinations Count Bytes Sent

Cribl Destinations record bytes sent per event by setting an internal field, `__outLen`, at the point where the Destination serializes or writes the payload for delivery. The calculation varies by Destination type. `__outLen` reflects uncompressed bytes. Compression is applied after `__outLen` is set, so metrics represent logical (uncompressed) size rather than on-the-wire compressed size.

These values feed `total.out_bytes`. This metric counts bytes the Destination accepted for delivery. Retry and failed delivery attempts do not increment it, so `total.out_bytes` can be lower than bytes actually transmitted to the downstream system.

Some Destinations can operate in multiple transport/mode categories. For example, Azure Data Explorer supports both streaming and batching, and OpenTelemetry and Dynatrace OTLP support HTTP and gRPC. These Destinations have clarifications in parenthesis in the `Destinations` column of the Byte Calculations table.

Byte Calculations

Destination Category	Byte Calculations	Destinations
HTTP and API-based Destinations	Measures the size of the data payload sent in the HTTP request (the	Amazon CloudWatch Logs, Azure Data Explorer (streaming mode), CrowdStrike Next-Gen SIEM, Cribl HTTP, Dynatrace (HTTP), Dynatrace (OTLP

Destination Category	Byte Calculations	Destinations
	uncompressed event data), calculated either event-by-event or during batch creation.	HTTP), Elastic, Elastic Cloud, Exabeam, Grafana Cloud, Google Cloud Logging, Google Pub/Sub, Honeycomb, Humio (HEC), InfluxDB, Microsoft Fabric, Microsoft Sentinel, New Relic (Events), OpenTelemetry (HTTP), SentinelOne AI SIEM, ServiceNow, Splunk HEC, Subscription, Wavefront
Batched HTTP serialization	Measures the event size during batch assembly. The final byte count is assigned from the size of the event's data within the batched request body.	Azure Monitor Logs, ClickHouse, Datadog, DataSet, Google Cloud Chronicle, Grafana Loki, Palo Alto Cortex XSIAM, Sumo Logic, Webhook
Object storage	Measures the size of the content before compression and writing to the storage medium.	Amazon S3, Amazon Security Lake, Azure Blob Storage, Azure Data Explorer (batching mode), Cloudflare R2, Cribl Lake, Databricks, Disk Spool, DL S3, Filesystem, Google Cloud Storage, MinIO, Ring
TCP-based outputs	Measures the actual bytes written to the TCP network buffer for each event.	Cribl TCP, Graphite, Syslog (TCP), TCP JSON
Splunk Forwarder (S2S)	Measures the raw byte size for data events. Metric events are counted as a fixed 150 bytes each.	Splunk (Load Balanced), Splunk (S2S)
OpenTelemetry (OTLP/gRPC)	Measures the size of the data after it has been formatted (serialized) into the protobuf structure for gRPC transmission.	Dynatrace (OTLP gRPC), OpenTelemetry (OTLP gRPC)
Streaming and message queues	Measures the total size of the message, including the key, value (payload), and any headers.	Amazon Kinesis Data Streams, Amazon MSK, Amazon SQS, Apache Kafka, Azure Event Hubs, Confluent Cloud
Metrics line senders	Measures the byte size of the formatted metric line at the moment it is prepared for output.	StatsD Extended, StatsD
Metrics platforms	Measures the size based on the metric components and series metadata, as defined by the specific platform.	New Relic (Metrics), Prometheus, SignalFx

12.3.1. Manage Destinations

For each Destination **type**, you can create multiple definitions, each with different settings, to handle delivering data to different outputs with differing requirements.

Once a Destination definition is created, enabled and set up to receive data, you can verify that data is flowing correctly, and monitor the Destination status to check for issues.

Create a Destination

You can create a new Destination in two ways: by using QuickConnect or Routing.

For configuration settings specific to each Destination, check that Destination's documentation.

Create a Destination with QuickConnect

To create a new Destination via QuickConnect:

1. If you are on a Distributed deployment, first select **Fleets** in the sidebar and choose a Fleet.
2. Select **Collect**.
3. Select **Add Destination** at right, and select the Destination you want from the list.

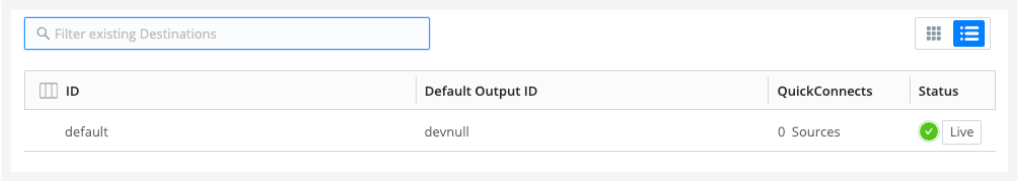
For configuration settings specific to each Destination, check that Destination's documentation. After you've set up the Destination, you can verify its data flow.

Create a Destination with Routes

To create a new Destination via Routing:

1. If you are on a Distributed deployment, first select **Fleets** in the sidebar and choose a Fleet.
2. Select **More**, and then **Destinations**.
3. Select the Destination you want.
4. Select **Add Destination** to open a **New Destination** modal.

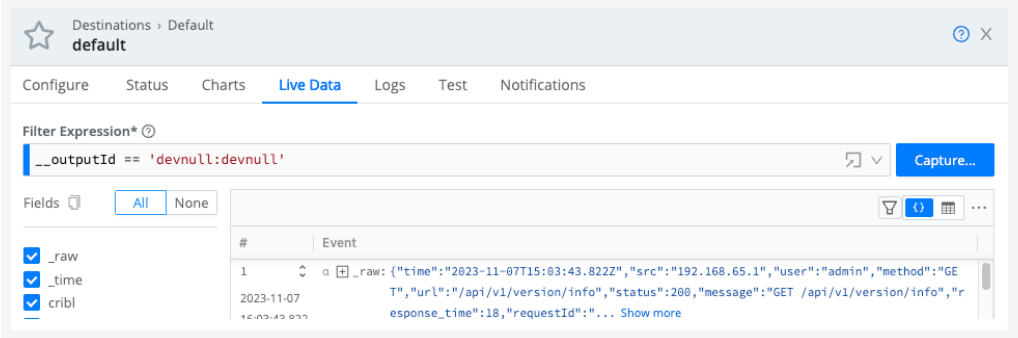
For configuration settings specific to each Destination, check that Destination's documentation. After you've set up the Destination, you can verify its data flow.



Edit Destination Settings with JSON

To edit any Destination's definition in a JSON text editor, select **Manage as JSON** at the bottom of the Destination modal. You can directly edit multiple values, and you can use the **Import** and **Export** buttons to copy and modify existing Destination configurations as `.json` files.

When JSON configuration contains sensitive information, it is redacted during export.



Capture Outgoing Data

To capture data from a single enabled Destination, you can bypass the Data Preview pane and instead capture directly from the list of Destinations. Select the **Live** button beside the Destination you want to capture.

Destination > Live button

You can also start an immediate capture from within an enabled Destination's config modal, by selecting the modal's **Live Data** tab.

Destination modal > Live Data tab

Verify Data Flow

Use the **Test** tab in the Destination's configuration modal to validate the configuration and connectivity of your Destination. A test sends sample events through the Destination to ensure it is correctly set up and can communicate with the downstream receiver.

You can choose from the available sample events or enter your own events, formatted as a JSON array.

Monitor Destination Status

You can get a quick overview of Destination health status by referring to their status icons.

Additionally, each Destination's configuration modal offers two tabs for monitoring: Status and Charts.

Destination Status Icons

Destination status icons are available on the **More** > **Destinations** page and for each individual Destination in the list for a specific Destination type.

The icons have the following meanings:

Icon	Meaning
	Healthy. Operating correctly.
	Warning. Experiencing issues. The Destination is not functioning fully. Specific conditions will depend on the Destination type.
	Critical. Experiencing critical issues. Drill down to the Destination's Status tab to find out the details.
	Disabled. The Destination is configured, but not enabled.
	No health metrics available. This may mean that a Destination is enabled, but has not been deployed yet.
	Inactive. When using GitOps, a Destination appears `Inactive` if its **Environment** field (configured under **Advanced Settings**) does not match the currently active environment determined by the deployed Git branch. This ensures integrations only activate in their designated environments, preventing unintended data flow or misconfiguration.

Destination Status Tab

The **Status** tab provides details about the Edge Nodes in the Fleet and their status. An icon next to each Edge Node uses color to clearly signal its health:

-  : All systems go! Your Edge Node is operating normally.
-  : Attention needed. There's a potential issue with this Edge Node.
-  : Stop! This Edge Node has encountered a critical error.

The way you view Edge Node statuses depends on the size of your Fleet:

- **Fewer than 1000 Edge Nodes**: All Edge Nodes are conveniently displayed on the Status tab, along with their statuses. Use the **Status** checkboxes at the top to filter the list by health (healthy, warning, error).

Clicking on any Edge Node row dives deeper, providing specific details to help diagnose issues. The specific set of information provided depends on the Destination type. Keep in mind that this data only reflects process `0` for each Edge Node.

- **More than 1000 Edge Nodes**: With a larger Fleet, you can select a specific Edge Node from the drop-down menu (showing up to 100 Nodes). You can search by `hostname` or `GUID` to find a specific Node. You can also use the **Status** checkboxes to filter which Edge Nodes appear in the drop-down list.

The content of the **Status** tab is loaded live when you open it and only displayed when all the data is ready. With a lot of busy Edge Nodes in a group, or Nodes located far from the Leader, there may be a delay before you see any information.

The statistics presented are reset when the Edge Node restarts.

Destination Health

Cribl Edge evaluates Destination health based on recent delivery outcomes that Edge Nodes report through internal metrics to the Leader.

A Destination changes from **Healthy** when health checks over a recent time window start to show any of the following patterns:

- **Connection and protocol problems:** Repeated connection failures, DNS/TLS errors, or authentication failures between Edge Nodes and the Destination that prevent it from accepting data.
- **HTTP-style delivery failures:** A rising rate of retryable HTTP errors from the downstream service (for example, `5xx` responses, `429` throttling, or request timeouts) as reflected in the Destination's metrics and logs.
- **Backpressure and persistent queue stress:** Backpressure engaging and persistent-queue metrics indicating that the Destination cannot keep up and data is being buffered or blocked.
- **Multi-endpoint imbalance:** For multi-endpoint Destinations such as Splunk Load Balanced or Output Router, a large fraction of senders entering an error state.

There is no fixed hold time for clearing a warning or error state. Once the underlying errors stop and the next health metrics update from the Edge Nodes reflects recovery, the Destination returns to **Healthy** automatically. The exact thresholds and error conditions can vary by destination type, but they always derive from the same internal health metrics.

You can track transitions over time using health metrics (for example, `health.outputs`) in your monitoring system.

Destination Charts Tab

The **Charts** tab presents a visual representation of Destination activity using internal metrics. Unlike the status tab, this data is read almost instantly and does not reset when restarting an Edge Node.

At the top of the modal, a time range picker controls which time window the charts display:

- The picker offers the same presets as the main Monitoring time selector (for example, `5 min`, `15 min`, `1 hour`, `6 hours`, `1 day`).
- When you open the Destination I/O metrics modal from **Monitoring**, the charts inherit the current Monitoring time range.
- When you open the modal from other areas of the UI (for example from **Data** > **Destinations** or directly from a Destination configuration modal), the Charts tab defaults to `10 minutes`, matching the previous behavior.
- Changing the time range in the modal only affects that modal and is not persistent. It does not change the global time range on the originating page (for example, the **Monitoring** overview or the page-level time picker).

Use this picker to zoom in on short spikes or expand to longer windows when you're troubleshooting Destination performance or throughput issues.

The following data is available:

- Total events out
- Average throughput (events per second)
- Total events dropped
- Total bytes out
- Average throughput (bytes per second)
- Backpressure
- Throttling Events

Total bytes out counts bytes the Destination accepted for delivery. It does not include retry or failed delivery attempts, so it can be lower than the bytes actually transmitted to the downstream system.

This data (in contrast with the status tab) is read almost instantly and does not reset when restarting an Edge Node.

12.3.2. Internal

You can send data from Cribl Edge to the following internal receivers:

Destination	Description
Cribl HTTP	Send data between peer Nodes via HTTP
Cribl TCP	Send data between peer Nodes via raw TCP
Cribl Search	Send data to Cribl Search via HTTP
Disk Spool	Spool incoming event data and hold it in a consistent location
Default	Specify a default output from among your Destinations
DevNull	Drop events when testing Pipelines and Routes
Output Router	Routes data to Destinations based on defined rules

12.3.2.1. Cribl HTTP Destination

The Cribl HTTP Destination sends data to a Cribl HTTP Source. Relaying data between a Cribl HTTP Destination and Cribl HTTP Source pair prevents double-billing: You won't incur any additional charges or credit usage after initial ingest to the first Fleet (depending on your Leader setup - see Transfer Data Between Workspaces or Environments for more details).

It's common to send data from Cribl Edge to a Cribl Stream Worker Group using this kind of pairing.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

For guidance on when to choose this Source versus the Cribl TCP Destination, see Interoperation Protocols.

For supported Cribl Stream and Cribl Edge combinations, auth tokens, and transports, see Cribl-to-Cribl compatibility matrix.

Within Cribl Stream, the Cribl HTTP Destination is available only in Distributed deployments. In single-instance mode, or for testing, you can use the Webhook Destination instead. However, this substitution will not facilitate sending all internal fields, as described below.

How It Works

You can use the Cribl HTTP Destination to transfer data between Edge Nodes and Workers. If the Cribl HTTP Destination sends data to its Cribl HTTP Source counterpart on another Worker, you're billed for ingress only once - when Cribl first receives the data.

Using a Cribl HTTP Destination/Source pair, you're not charged for subsequent data sent to:

- Workers that share a Leader.
- Workers that don't share a Leader, but are configured in Cribl.Cloud Workspaces within the same Organization.
- Workers that do not share a Leader, but that do have the exact same on-prem license installed.

This use case is common in hybrid Cribl.Cloud deployments, where a customer-managed (hybrid) Worker Node sends data to a Worker in Cribl.Cloud for additional processing and routing to Destinations. However, the Cribl HTTP Destination/Source pair can similarly reduce your metered data ingress in other scenarios, such as on-prem Edge to on-prem Stream.

As one usage example, assume that you want to send data from one Node deployed on-prem, to another that is deployed in Cribl.Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl.Cloud.
- Create an on-prem Cribl HTTP Destination.
- Create a Cribl HTTP Source, on the target Stream Worker Group or Edge Fleet in Cribl.Cloud.
- For an on-prem Node configure a File System Collector to send data to the Cribl HTTP Destination, and from there to the Cribl HTTP Source in Cribl.Cloud.
- On Cribl-managed Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl HTTP Destination and the Cribl HTTP Source it's sending data to, or enabled on both. Otherwise, no data will flow. On Cribl.Cloud instances, the Cribl HTTP Source ships with TLS enabled by default. In addition, the **Minimum TLS version** and **Maximum TLS version** on the Destination must be compatible with the corresponding settings on the Source. Mismatched version ranges will also prevent data from flowing. For details, see Match TLS Versions Between Source and Destination.

Configure a Cribl HTTP Destination

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: When toggled off (default), if you notice that Cribl Edge is not sending data to all possible IP addresses, enable **Advanced Settings** > **Round-robin DNS**. When toggled on, see Load Balancing Settings below.
    - **Cribl endpoint**: URL of the Worker that hosts the peer Cribl HTTP Source.
        - For Cribl-managed Cribl.Cloud Workers, use the ingest address defined for `in_cribl_http` in **Workspace > Data Sources > Sources Enabled by Default**. Select the Worker Group from the **Group** drop-down, locate the `in_cribl_http` Source and copy its **Ingest Address**. If you are using a custom Cribl HTTP Source, replace the port in the ingest address with the port you configured for your Source.
        - For customer-managed (hybrid) Workers, or in an on-prem deployment, use the **Address** and **Port** configured on that Source, for example, `http://localhost:10200`.

The **Cribl endpoint** field appears only when you toggle **Load balancing** off. Its value must resolve to the same host and **Port** as the peer Cribl HTTP Source to which you're sending, using the Cloud or on-prem pattern above.

3. Next, you can configure the following **Optional Settings**:
    - **Compression**: Codec to use to compress the data before sending. Defaults to `Gzip`.
    - **Throttling**: Throttle rate per Worker Process, in bytes per second. Defaults to `0` in Cribl Stream, meaning no throttling, and to `256 KB` in Cribl Edge. Multiple-byte units such as KB, MB, GB, and so forth, are also allowed - for example, `42 MB`. When throttling is engaged, your **Backpressure behavior** selection determines whether Cribl Edge will handle excess data by blocking it, dropping it, or queueing it to disk. You can use this setting to limit the risk of overwhelming your deployment when sending high volumes of data from Cribl Edge to Cribl Stream.
    - **Backpressure behavior**: Specifies whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`. See Persistent Queue Settings below.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any TLS settings, Persistent Queue, Retries, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Load Balancing Settings

Enabling the **Load balancing** toggle displays the following controls.

Load balancing requires each Edge Node to resolve the endpoint hostnames. If you send data through an HTTP proxy that alone can resolve those hostnames, toggle **Load balancing** off and let the proxy resolve the endpoint and balance traffic across its IPs. See Configure System Proxy.

Exclude Current Host IPs: Displays under **Optional Setting** when **Load balancing** is toggled on. This toggle determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Defaults to No, which keeps the current host available for load balancing.

Cribl Worker Endpoints: In this table, you specify a set of Cribl Workers on which to load-balance data. To specify more Workers on new rows, click **Add Endpoint**. Each row provides the following fields.

Cribl Endpoint: Enter the URL of a Worker to send events to.

Each URL must follow the same rules as **Cribl endpoint** in General Settings: **Cribl.Cloud** entries use `https://` with the **Public Ingress address** and Source **Port**; **on-prem or self-managed** entries use the Worker **Address** and **Port** configured on the peer Cribl HTTP Source.

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (> `0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Edge will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

TLS Settings (Client Side)

Use TLS: Defaults to toggled off.

Server Validation

Configure how this client verifies the remote server's identity.

Validate server certs: Reject certificates that are **not** authorized by a CA in the **Trusted server CA path**, nor by another trusted CA (for example, the system's CA). Default is toggled on.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. Must be a host name, not an IP address.

Trusted server CA path: Path on the Edge Node containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the server's identity. This is typically the root CA that anchors the server's certificate chain.

Mutual Authentication (mTLS)

Certificate: Name of the predefined certificate. Selecting a certificate auto-fills the mutual-auth paths below.

Certificate path (mutual auth): Path on the Edge Node containing certificates (in PEM format) to use for client authentication. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on the Edge Node containing the private key (in PEM format) to use for client authentication. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

TLS Version

Reject connections using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.

- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

Honor Retry-After header: Toggle on to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream/Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. Any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. Toggle off to ignore all `Retry-After` headers.

Default Retry Behavior: By default, Cribl Stream/Edge applies predefined retry strategies for certain failed requests to the Destination using an exponential backoff algorithm. You can override these settings by manually configuring the retry behavior for a particular error code.

Destinations created before the 4.16.0 release do not support the default `4xx` series retry behavior. If your Destination was created prior to this release and you'd like it to support the behavior, reconfigure the Destination.

To retry requests, Cribl Stream/Edge applies the following rules by default:

Status Code	Action
Any in the `1xx`, `3xx` series	Drop the request
`401`, `403`, `408`, `429` errors	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached
Any other `4xx` series	Drop the request
Any in the `5xx` series	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached

By default, any `429 (Too Many Requests)` response that is not listed in the retry settings is treated as a non-retryable `4xx` error and dropped. If you want `429` responses retried, ensure `429` is included in the **Settings for failed HTTP requests**.

Settings for failed HTTP requests: You can also manually configure Cribl Stream/Edge to automatically retry requests that receive particular HTTP response status codes.

Upon receiving a response code that's on the list, Cribl Stream/Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream/Edge continues retrying the request without increasing the time between retries any further.

If the sender (which manages the connection to the Destination) is at capacity, it will not accept any incoming events. These incoming events originate internally from a previous stage of the data flow when Destinations send outbound requests to their respective external services, and they include retry requests and new requests. Any events that were already in transit when the sender reached capacity will continue to be processed downstream.

Sender capacity is freed up when an outgoing request succeeds or encounters a non-retryable error. When the sender has available capacity again, it will resume accepting incoming events. This capacity management is influenced by the number of active connections and configured limits, such as concurrency and buffer sizes. If a Pipeline sends events faster than the Destination can process, the buffers may fill up, leading to backpressure and `Sender at capacity` warnings. This backpressure prevents the sender from accepting additional requests until capacity is restored.

For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: Toggle on to automatically retry requests that have timed out and display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Auth Token

This section is only available for on-prem environments that have a Connected Environment. It is intended for use when migrating data from an on-prem environment to a Cribl.Cloud environment.

If you previously had an on-prem deployment of Cribl and you are moving forward with a Cloud-first or Cloud only solution, you can use connected environments to onboard your data from on-prem Edge Nodes to their counterpart Cribl.Cloud Edge Nodes. See Migrate Data from On-Prem to Cribl.Cloud for implementation details.

Advanced Settings

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to toggled on. This setting is also configurable in **TLS Settings (Client Side)**. If you enable Client-Side TLS, the validation rules defined there will override this setting.

Round-robin DNS: Toggle on to enable round-robin DNS lookup across multiple IP addresses, IPv4 and IPv6. When a DNS server resolves a Fully Qualified Domain Name (FQDN) to multiple IP addresses, Cribl Edge will sequentially use each address in the order they are returned by the DNS server for subsequent connection attempts. Only displayed when the General Settings tab's **Load balancing** option is disabled.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Exclude fields: Fields to exclude from the event. This Destination excludes `__kube_*`, `__metadata`, `__winEvent`, and `__raw` by default and forwards all other Internal Fields. For more information about

`__winEvent`, see the Windows Event Logs Source topic.

If you are running Cribl Edge 4.0.x (or earlier) and are using the Kubernetes Metrics Source with this Destination, consider excluding the following fields to reduce event size:

`!__inputId,!__outputId,!__criblMetrics,__*` .

The contents of `__raw` are often redundant with the `_raw` field's contents, so this Destination excludes `__raw` by default. If you need to forward `__raw`, remove it from **Exclude fields**.

Auth Token TTL minutes: The number of minutes before the internally generated authentication token expires, valid values between 1 and 60.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

The following options are added if you enable the General Settings tab's **Load balancing** option:

DNS resolution period (seconds): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from A records. Defaults to `600` seconds.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds. (Note that If multiple receivers are behind a hostname - i.e., multiple A records - all resolved IPs will inherit the weight of the host, unless each IP is specified separately. In Cribl Stream load balancing, IP settings take priority over those from hostnames.)

Internal Fields Loopback to Sources

The Cribl HTTP and Cribl TCP Destinations differ from all other Destinations in the way they handle internal fields: They normally send data back to their respective Cribl Sources - where Cribl internal fields, metrics, and sender-generated fields can all be useful.

These Destinations forward all internal fields by default, except for any that you exclude in **Advanced Settings** > **Exclude fields**.

As examples, if the following fields are present on an event forwarded by a Cribl HTTP or Cribl TCP Destination, they'll be accessible in the ingesting Cribl HTTP/TCP Source: `__criblMetrics`, `__srcIpPort`, `__inputId`, and `__outputId`.

12.3.2.2. Cribl TCP Destination

The Cribl TCP Destination sends data to a Cribl TCP Source. Relaying data between a Cribl TCP Destination and Cribl TCP Source pair prevents double-billing: You won't incur any additional charges or credit usage after initial ingest to the first Fleet (depending on your Leader setup - see Transfer Data Between Workspaces or Environments for more details).

It's common to send data from Cribl Edge to a Cribl Stream Worker Group using this kind of pairing.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

For guidance on when to choose this Source versus the Cribl HTTP Destination, see the Full Suite Reference Architecture.

For supported Stream and Edge combinations, auth tokens, and transports, see Cribl-to-Cribl compatibility matrix.

Within Cribl Stream, the Cribl TCP Destination is available only in Distributed deployments. In single-instance mode, or for testing, you can use the TCP JSON Destination instead. However, this substitution will not facilitate sending all internal fields, as described below.

How It Works

You can use the Cribl TCP Destination to transfer data between Edge Nodes and Workers. If the Cribl TCP Destination sends data to its Cribl TCP Source counterpart, you're billed for ingress only once - when Cribl first receives the data.

Using a Cribl HTTP Destination/Source pair, you're not charged for subsequent data sent to:

- Workers that share a Leader.
- Workers that don't share a Leader, but are configured in Cribl.Cloud Workspaces within the same Organization.
- Workers that do not share a Leader, but that do have the exact same on-prem license installed.

This use case is common in hybrid Cribl.Cloud deployments, where a customer-managed (hybrid) Worker Node sends data to a Worker in Cribl.Cloud for additional processing and routing to Destinations. However, the Cribl TCP Destination/Source pair can similarly reduce your metered data ingress in other scenarios, such as on-prem Cribl Edge to on-prem Cribl Stream.

As one usage example, assume that you want to send data from one Node deployed on-prem, to another that is deployed in Cribl.Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl.Cloud.
- Create an on-prem Cribl TCP Destination.
- Create a Cribl TCP Source, on the target Cribl Stream Worker Group or Cribl Edge Fleet in Cribl.Cloud.
- For an on-prem Node configure a File System Collector to send data to the Cribl TCP Destination, and from there to the Cribl TCP Source in Cribl.Cloud.
- On Cribl-managed Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl TCP Destination and the Cribl TCP Source it's sending data to, or enabled on both. Otherwise, no data will flow. On Cribl.Cloud instances, the Cribl TCP Source ships with TLS enabled by default.

Configuration Requirements

The key points about configuring this architecture are:

- When you configure the Cribl TCP Destination, its **Address** and **Port** values must point to the **Address** and **Port** you've configured on the Cribl TCP Source.
- Cribl 3.5.4 was a breakpoint in Cribl TCP Leader/Worker communications. Nodes running the Cribl TCP Source on Cribl 3.5.4 and newer can send data only to Nodes running v.3.5.4 and newer. Nodes running the Cribl TCP Source on Cribl 3.5.3 and older can send data only to Nodes running v.3.5.3 and older.

Configure a Cribl TCP Destination

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: When toggled on, see Load Balancing Settings below.

The following two fields appear **only** if **Load balancing** is toggled off (default), and must match the **Address** and **Port** you've configured on the peer Cribl TCP Source to which you're

> sending.

- **Address**: Hostname of the receiver.
- **Port**: Port number to connect to on the host, for example, `10300`.

3. Next, you can configure the following **Optional Settings**:
   - **Compression**: Codec to use to compress the data before sending. Defaults to `Gzip`.
   - **Throttling**: Throttle rate, in bytes per second. Defaults to `0`, meaning no throttling. Multiple-byte units such as KB, MB, and so forth, are also allowed - for example, `42 MB`. When throttling is engaged, your **Backpressure behavior** selection determines whether Cribl Edge will handle excess data by blocking it, dropping it, or queueing it to disk. When used in conjunction with **Connection limit**, the throttling rate is applied per connection. For instance, if **Connection limit** is set to `2` and throttling is set to `3 MB`, each of the two connections can send data at a rate of up to 3 MB per second, resulting in a total potential throughput of 6 MB per second across both connections.
   - **Backpressure behavior**: Specifies whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`. See Persistent Queue Settings below.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any TLS settings, Persistent Queue, Timeout, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Load Balancing Settings

Enabling the **Load balancing** toggle displays the following controls:

Exclude Current Host IPs

Displays under **Optional Setting** when **Load balancing** is toggled on. This toggle determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Default is toggled off, which keeps the current host available for load balancing.

Destinations

The **Destinations** table is where you specify a set of receivers on which to load-balance data. Click **Add Destination** to specify more receivers on new rows. Each row provides the following fields:

Address: Hostname of a receiver. Optionally, you can paste in a comma-separated list, in `<host>:<port>` format.

Port: Port number to send data to on the host.

Each **Address**/**Port** combination must match the **Address** and **Port** configured on a peer TCP Source to which you're sending.

TLS: Whether to inherit TLS configs from group setting, or disable TLS. Defaults to `inherit`.

TLS servername: Servername to use if establishing a TLS connection. If not specified, defaults to connection host (if not an IP); otherwise, uses the global TLS settings.

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (> `0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Edge will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but

decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

> **Deprecation Notice**
>
> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

> Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

TLS Settings (Client Side)

Use TLS: Defaults to toggled off.

Server Validation

Configure how this client verifies the remote server's identity.

Validate server certs: Reject certificates that are **not** authorized by a CA in the **Trusted server CA path**, nor by another trusted CA (for example, the system's CA). Default is toggled on.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. Must be a host name, not an IP address.

Trusted server CA path: Path on the Edge Node containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the server's identity. This is typically the root CA that anchors the server's certificate chain.

Mutual Authentication (mTLS)

Certificate: Name of the predefined certificate. Selecting a certificate auto-fills the mutual-auth paths below.

Certificate path (mutual auth): Path on the Edge Node containing certificates (in PEM format) to use for client authentication. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on the Edge Node containing the private key (in PEM format) to use for client authentication. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

TLS Version

Reject connections using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Timeout Settings

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish before retrying. Defaults to `10000`.

Write timeout: Amount of time (in milliseconds) to wait for a write to complete before assuming connection is dead. Defaults to `60000`.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Auth Token

This section is only available for on-prem environments that have a Connected Environment. It is intended for use when migrating data from an on-prem environment to a Cribl.Cloud environment.

If you previously had an on-prem deployment of Cribl and you are moving forward with a Cloud-first or Cloud only solution, you can use connected environments to onboard your data from on-prem Edge Nodes to their counterpart Cribl.Cloud Edge Nodes. See Migrate Data from On-Prem to Cribl.Cloud for implementation details.

Advanced Settings

Auth Token TTL minutes: The number of minutes before the internally generated authentication token expires, valid values between 1 and 60.

Exclude fields: Fields to exclude from the event. This Destination excludes `__kube_*`, `__metadata`, `__winEvent`, and `__raw` by default and forwards all other Internal Fields. For more information about `__winEvent`, see the Windows Event Logs Source topic.

If you are running Cribl Edge 4.0.x (or earlier) and are using the Kubernetes Metrics Source with this Destination, consider excluding the following fields to reduce event size:

`!__inputId,!__outputId,!__criblMetrics,__*` .

The contents of `__raw` are often redundant with the `_raw` field's contents, so this Destination excludes `__raw` by default. If you need to forward `__raw`, remove it from **Exclude fields**.

Log failed requests to disk: Toggling on makes the payload of the most recently failed request available for inspection. See Inspect Payload to Troubleshoot Closed Connections below.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

The following options are added if you enable the General Settings tab's **Load balancing** option:

DNS resolution period (seconds): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from A records. Defaults to `600` seconds.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds. (Note that If multiple receivers are behind a hostname - i.e., multiple A records - all resolved IPs will inherit the weight of the host, unless each IP is specified separately. In Cribl Stream load balancing, IP settings take priority over those from hostnames.)

Max connections: Constrains the number of concurrent receiver connections, per Worker Process, to limit memory utilization. If set to a number > `0`, then on every DNS resolution period, Cribl Edge will randomly select this subset of discovered IPs to connect to. Cribl Edge will rotate IPs in future resolution periods - monitoring weight and historical data, to ensure fair load balancing of events among IPs.

Inspect Payload to Troubleshoot Closed Connections

When a downstream receiver closes connections from this Destination (or just stops responding), inspecting the payload of the most recently failed request can help you find the cause. For example:

- Suppose you send an event whose size is larger than the downstream receiver can handle.
- Suppose you send an event that has a `number` field, but the value exceeds the highest number that the downstream receiver can handle.

When **Log failed requests to disk** is enabled, you can inspect the last failed request payload. Here is how:

1. In the Destination UI, navigate to the **Logs** tab.
2. Find a log entry with a `connection error` message.
3. Expand the log entry.
4. If the message includes the phrase `See payload file for more info`, note the path in the `file` field on the next line.

Now you have the path to the directory where Cribl Edge is storing the payload from the last failed request.

Internal Fields Loopback to Sources

The Cribl TCP and Cribl HTTP Destinations differ from all other Destinations in the way they handle internal fields: They normally send data back to their respective Cribl Sources - where Cribl internal fields, metrics, and sender-generated fields can all be useful.

These Destinations forward all internal fields by default, except for any that you exclude in **Advanced Settings** > **Exclude fields**.

As examples, if the following fields are present on an event forwarded by a Cribl HTTP or Cribl TCP Destination,

12.3.2.3. Cribl Search Destination

The Cribl Search Destination enables Cribl Edge to send logs and native metrics directly to Cribl Search over a dedicated, internal HTTP path.

Use the Cribl Search Destination when you want to send data from:

- Fleets to Cribl Search running in the same Cribl.Cloud organization.
- Fleets to a connected Cribl.Cloud environment that hosts Cribl Search.
- Fleets to Cribl Search as an ingestion endpoint, instead of configuring generic Cribl HTTP Destinations by hand.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

For Cribl Stream Worker Groups that are managed in Cribl.Cloud and sending to Cribl Search in the same Organization, TLS for Cribl-to-Cribl traffic is managed automatically. You do not configure TLS settings directly on this Destination.

How It Works

With the Cribl Search Destination:

- The Destination serializes events using the same HTTP payload format as Cribl HTTP.
- Events are delivered over HTTP to a Cribl HTTP Source in the Cribl.Cloud environment that hosts Cribl Search. That Source is preconfigured to forward all received events into Cribl Search's ingestion pipeline.
    - That Cribl HTTP Source typically runs in a different Fleet than the one where you configured the Cribl Search Destination, and it serves as the HTTP entry point for Cribl Search ingestion.
- The **Send as** setting determines whether the Destination sends logs, native metrics, or both. Native metric events contain a nonempty `__criblMetrics` array. You can create native metric events with the Publish Metrics Function.
- Cribl Search routes native metric events to the metrics store and all other events to log search. Metric events aren't also stored as logs.
- Cribl Search parses log events through Datatyping and stores them in Search Datasets on a lakehouse engine. Search normalizes native metric events and stores them in the `metrics` Dataset for a lakehouse engine.
- After Search stores native metrics, you can query and visualize them in Metrics Explorer.
- If events are already parsed before they reach this Destination, set the `datatype` and `isParsed` event fields so Cribl Search does not reparse `_raw`. If you pick the target Dataset upstream, also set `dataset`. These are event fields, not Destination settings.

For field behavior and configuration options, see Override Cribl Search Processing and Assign Datatypes in Cribl Stream.

Data Transfer Behavior

You can use the Cribl Search Destination to transfer data between Fleets and Cribl Search without incurring additional ingest charges, as long as it sends data to a Cribl HTTP Source that acts as the entry point for Cribl Search ingestion, and your deployment meets the eligibility rules in Transfer Data Between Workspaces or Environments.

If the Cribl Search Destination sends data to its Cribl HTTP Source counterpart for Search on another Edge Node, you're billed for ingress only once when Cribl first receives the data. Using a Cribl Search Destination and Cribl HTTP Source pair, you're not charged for subsequent data sent to:

- Edge Nodes that share a Leader.
- Edge Nodes that don't share a Leader but are configured in Cribl.Cloud Workspaces within the same Organization.
- Edge Nodes that do not share a Leader but that have the exact same on-prem license installed.

How Lakehouse Engine Billing Sees This Data

The receiving Cribl Search lakehouse engine meters ingest at the engine, after Cribl Edge processes the data. If your Pipeline parses raw events into JSON or CSV, enriches them with extra fields, or keeps a copy of `_raw`, the engine can see noticeably more bytes than Cribl Edge's upstream ingest counter shows.

If you don't need Cribl Edge processing before storage, you can skip this Destination and **send data directly to a lakehouse engine** using one of Cribl Search's native Sources, such as Syslog, Splunk HEC, OpenTelemetry, or Raw HTTP. That keeps the engine's ingest count aligned with the raw data volume you expect. Search also parses incoming events through Auto-Datatyping and Custom Datatypes v2, so in many cases Cribl Edge processing isn't needed.

For details, see the Cribl Search docs: Ingest Is Measured at the Engine.

Prerequisites

Before configuring the Cribl Search Destination:

- You must have Cribl Search enabled in a Cribl.Cloud organization, with at least one Lakehouse Engine configured to ingest data from the Cribl HTTP Source used by this Destination.
- For cross-environment or cross-Workspace paths (for example, on-prem Stream to Cloud Search), both environments must be on paid plans and eligible for free data transfer via Cribl TCP/HTTP.
    - For those paths, configure Cribl-to-Cribl authentication using Auth Tokens on both the Cribl HTTP Source in Cribl.Cloud that receives events for Cribl Search, and on the on-prem Cribl Search

Destination as described in Transfer Data Between Workspaces or Environments.

For Worker Groups running in Cribl.Cloud and sending to Cribl Search in the same Organization, the Cribl Search Destination uses the existing Cribl-to-Cribl authentication path automatically. No additional tokens are required.

Configuration Requirements

The Cribl Search Destination's **Cribl endpoint** must point to the **Address** and **Port** configured on the corresponding Cribl HTTP Source that serves as the HTTP entry point for Cribl Search in the target Fleet.

Configure a Cribl Search Destination

1. On the top bar, select **Products**, and then select Cribl Edge. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** (Stream) or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination modal**, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original Output ID.
    - **Description**: Optionally, enter a description.
    - **Cribl endpoint**: URL of the Cribl HTTP Source that receives events for Cribl Search. In Cribl.Cloud this is auto-populated as `https://search.<workspace>.<organizationId>.cribl.cloud:10200`. In self-managed or connected environments, use the host and port from your Cribl HTTP Source.
3. Next, you can configure the following **Optional Settings**:
    - **Throttling**: Throttle rate per Worker Process, in bytes per second. Defaults to `0`, meaning no throttling. Multiple-byte units such as KB, MB, GB, and so forth, are also allowed (for example, 42 MB). When throttling is engaged, your backpressure behavior selection determines whether Cribl Edge will handle excess data by blocking it, dropping it, or queueing it to disk.
    - **Backpressure behavior**: Specifies whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to **Block**. See Persistent Queue Settings below.
    - **Send as**: Select how to route events in Cribl Search:
        - **Logs** sends everything to log search, including metric events.
        - **Metrics** routes metric events to the metric store and drops everything else.

        - **Logs and Metrics** routes metric events to the metric store and sends the rest to log search. Metric routing requires the receiving Cribl Search Source to be enabled for metrics storage. If it is not, metric events are discarded rather than stored as logs.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the Destinations page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any Processing Settings, Auth Tokens, and Advanced Settings settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output. Use this Pipeline to set the `datatype`, `isParsed`, and `dataset` override fields. See Override Cribl Search Processing, Automatic Parsing, and Assign Datatypes in Cribl Stream.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

Honor Retry-After header: Toggle on to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream/Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. Any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. Toggle off to ignore all `Retry-After` headers.

Default Retry Behavior: By default, Cribl Stream/Edge applies predefined retry strategies for certain failed requests to the Destination using an exponential backoff algorithm. You can override these settings by manually configuring the retry behavior for a particular error code.

Destinations created before the 4.16.0 release do not support the default `4xx` series retry behavior. If your Destination was created prior to this release and you'd like it to support the behavior, reconfigure the Destination.

To retry requests, Cribl Stream/Edge applies the following rules by default:

Status Code	Action
Any in the `1xx`, `3xx` series	Drop the request
`401`, `403`, `408`, `429` errors	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached
Any other `4xx` series	Drop the request
Any in the `5xx` series	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached

By default, any `429 (Too Many Requests)` response that is not listed in the retry settings is treated as a non-retryable `4xx` error and dropped. If you want `429` responses retried, ensure `429` is included in the

Settings for failed HTTP requests.

Settings for failed HTTP requests: You can also manually configure Cribl Stream/Edge to automatically retry requests that receive particular HTTP response status codes.

Upon receiving a response code that's on the list, Cribl Stream/Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream/Edge continues retrying the request without increasing the time between retries any further.

If the sender (which manages the connection to the Destination) is at capacity, it will not accept any incoming events. These incoming events originate internally from a previous stage of the data flow when Destinations send outbound requests to their respective external services, and they include retry requests and new requests. Any events that were already in transit when the sender reached capacity will continue to be processed downstream.

Sender capacity is freed up when an outgoing request succeeds or encounters a non-retryable error. When the sender has available capacity again, it will resume accepting incoming events. This capacity management is influenced by the number of active connections and configured limits, such as concurrency and buffer sizes. If a Pipeline sends events faster than the Destination can process, the buffers may fill up, leading to backpressure and `Sender at capacity` warnings. This backpressure prevents the sender from accepting additional requests until capacity is restored.

For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: Toggle on to automatically retry requests that have timed out and display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.

- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Auth Tokens

This section is only available for on-prem environments that have a Connected Environment. It is intended for use when migrating data from an on-prem environment to a Cribl.Cloud environment.

If you previously had an on-prem deployment of Cribl and you are moving forward with a Cloud-first or Cloud only solution, you can use connected environments to onboard your data from on-prem Worker Nodes to their counterpart Cribl.Cloud Worker Nodes. See Migrate Data from On-Prem to Cribl.Cloud for implementation details.

Advanced Settings

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Internal Fields Loopback to Sources

Because the Cribl Search Destination is implemented as a Cribl HTTP Destination, it shares the same internal-fields behavior as the Cribl HTTP and Cribl TCP Destinations. These Destinations normally send data back to their respective Cribl Sources, where Cribl internal fields, metrics, and sender-generated fields can be useful. They forward all internal fields by default. This Destination does not expose the **Exclude fields** control that appears on the Cribl HTTP Destination Advanced Settings. To drop fields before sending, add an Eval Function to the Pipeline and list them in **Remove fields**. For example, if `__criblMetrics`, `__srcIpPort`,

`__inputId`, or `__outputId` are present on an event forwarded by the Cribl Search Destination, they'll be accessible in the ingesting Cribl HTTP Source.

Proxying Requests

12.3.2.4. Disk Spool Destination

The **Disk Spool** Destination writes recent events to disk, so you can spool incoming event data and save it in a predefined file path location. This consistent path can help you find data when you use generic Cribl Search Datasets.

Type: **Internal** | TLS Support: **N/A** | PQ Support: **No**

Configure Cribl Edge to Spool Event Data

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Disk Spool Destination definition.
    - **Description**: Optionally, enter a description.
3. Next, you can configure the following **Optional Settings**:
    - **Bucket time span**: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`). Consider the volume of the data source, as high-volume logs can fill a disk up quickly if you enter a long time span.
    - **Data size limit**: This is the maximum amount of disk space that spooled data is allowed to consume. Once data reaches this amount, Edge will delete data starting with the oldest buckets.
    - **Data age limit**: The duration of time for which Cribl Edge will retain data. Edge will delete data that exceeds the max age entered in this field. Example values are `2h`, `4d`. The default value is 24 hours (`24h`).
    - **Compression**: The codec that Edge uses to compress the data. The default is `gzip`.
    - **Partitioning expression**: The JavaScript expression that defines how Edge partitions and organizes files into time bucket directories. The default is date-based. If this field is left blank, Cribl Edge will fall back to the event's `__partition` field value (if present), or otherwise to the root directory of the Output Location and Staging Location.
    - **Tags**: Add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Processing and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

> **Use Case Example**: When you partition incoming events, Search can find them more efficiently. Imagine you've configured three Sources, each sending event data to the Disk Spool Destination. Enter the partitioning expression `__inputId`. Now you can send data from the three different Sources to individual subdirectories under the spool's time bucket directories.

For help with writing partitioning expressions, check out Improving Partitioning Expressions.

Processing Settings

Post-Processing

Pipeline: The Pipeline that will process the data before sending it out.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Advanced Settings

Environment: If you're using GitOps, use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Collect Event Data

Once your Destination is configured, you can begin sending data to it from any Source. We recommend only connecting Sources that do not support disk spooling at the Source level. When you have disk spooling enabled at the Source *and* you connect the Source to the Disk Spool Destination, event data is duplicated and sent into two different spools.

When you have the Disk Spool Destination configured and Sources connected to it, check that data is flowing using the **Live Data** tab in the Disk Spool Destination.

Next, use Cribl Search to locate spooled data.

Searching for Spooled Data

Disk spooling allows you to store recent events to disk, and makes them available to find with Cribl Search. Typically, data from Edge is sent to and stored directly in a Destination. By caching data in a spool, you can perform data queries in real time without needing to connect to the data's final destination.

For example, let's say you're an IT administrator who is troubleshooting issues with a specific Edge Node. Rather than navigating away from Edge to access the software that's hosting all the Edge data and looking through logs, you can stay in Cribl Edge and run a Search query, returning data for a specific Node over a duration of time you define.

To find spooled data, make sure you have at least one Source connected to the Disk Spool Destination, then open Cribl Search.

1. In the search query box, type `dataset="cribl_edge_spool"` to return all events currently in the spool.
2. Use statements, scope, and processing operators to refine your spooled data. Check out Build a Search for more information and examples.

12.3.2.5. Default Destination

The **Default** Destination simply enables you to specify a default output from among your already-configured Destinations.

Type: Internal | TLS Support: N/A | PQ Support: N/A

Configure Cribl Edge's Default Destination

In Cribl Edge configure Default.

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). A **Default** Destination is preconfigured and ready to use in the right **Destinations** column. Hover over the tile and click its **Configure** button to proceed.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. From the resulting **Destinations** page, click anywhere on the `default` row to proceed.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: This is prefilled with the default value `default`, which cannot be changed via the UI.
    - **Default Output ID** drop-down to select one of your configured Destinations.
3. Select **Save**, then **Commit & Deploy**.

Preventing Circular References

If you've configured an Output Router Destination with a branch that points to this Default Destination (`default:default`), you cannot select that Output Router here. This restriction prevents a circular dependency.

12.3.2.6. DevNull Destination

The DevNull Destination simply drops events. Cribl provides this as a basic output to test Pipelines and Routes.

Type: Internal | TLS Support: N/A | PQ Support: N/A

Configure Cribl Edge to Forward to DevNull

DevNull requires no configuration: A DevNull Destination is preconfigured and active as soon as you install Cribl Edge. To verify this, follow the direction below.

On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:

- To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). A **DevNull** Destination is preconfigured and ready to use in the right **Destinations** column.
- To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. From the resulting **Destinations** page, click anywhere on the `devnull` row to proceed.

12.3.2.7. Output Router Destination

The Output Router Destination enables dynamic, rule-based routing of events to one or more downstream Destinations. It acts as a meta-destination, evaluating each event against an ordered set of filter rules (JavaScript expressions) to determine the appropriate Destinations (outputs).

This is useful where routing decisions depend on event content, such as sending security logs to a SIEM and application logs to cloud storage, all from a single Pipeline.

How It Fits Into the Data Flow

- **Source ingestion**: Events are ingested from Sources.
- **Pre-processing Pipelines**: Pre-processing Pipelines attached to Sources run first. Fields created or modified here are available for routing and Output Router rule evaluation.
- **Route Pipelines**: If configured, regular Pipelines attached to Routes process events next. Fields set here are also available to Output Router rules.
- **Output Router**: The Output Router evaluates its rules (**Filter expressions**) against each event using fields from pre-processing and Route Pipelines. Matching rules determine which Destinations receive the event. If multiple rules match and final is `false`, the event is cloned and sent to all matching Destinations.

  Events that do not match a rule are sent to the Default Destination.
- **Destination(s)**: Events are delivered to the selected Destinations.
- **Post-processing Pipelines**: Post-processing Pipelines attached to Destinations run last, after routing. Fields created or modified here are not available to Output Router rules.

Backpressure and Persistent Queue Behavior

The Output Router is a meta-destination that evaluates rules and forwards events to downstream Destinations. It does not provide its own persistent queue. Backpressure behavior is controlled by each downstream Destination.

If multiple rules match (with **Final** toggled off), Cribl Edge clones the event and sends it to each matching Destination. If one of those Destinations is configured to **Block**, it can block delivery for that event across all Destinations. If one is configured for **Persistent Queue**, Cribl Edge can buffer that copy of the event locally while other healthy Destinations continue to receive data, until the queue fills or the downstream Destination recovers.

For more information, see About Persistent Queues.

Type: Internal | TLS Support: N/A | PQ Support: N/A

Configure an Output Router Destination

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Router name**: Enter a unique name to identify this Router definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Rules**: A list of event routing rules. Rules are evaluated in order, top-down. For details, see Rules.
3. You can configure the following **Optional Settings**:
    - **System fields**: A list of fields to automatically add to events that use this Destination. For details, see System Fields.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. On the **Advanced Settings** tab you can configure an **Environment** if you're using GitOps. Optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.
5. Select **Save**, then **Commit & Deploy**.

Rules

Rules route events by examining event content. These rules are processed sequentially from top to bottom.

Filter expression: A JavaScript expression to select events to route to Destinations. Filter expressions evaluate event fields after pre-processing (input conditioning at the Source) and after any Route Pipeline processing, but before any post-processing (output conditioning at the Destination). Fields created or modified in pre-processing or Route Pipelines are available to Output Router filter expressions. Fields created or modified during post-processing are not available, as post-processing occurs after routing decisions are made.

Use the expression `true` to match any remaining events you want sent, like in this example.

Output: The Destination to send matching events to. This can be any configured Destination, except for another Output Router or a Default Destination that points back to an Output Router.

Description: Optionally, enter a description of this rule's purpose.

Final: By default (toggled on), event routing stops after this rule matches. Toggle off if you want the event to be evaluated against other rules lower in the stack, allowing cloning to multiple Destinations.

System Fields

By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Example

Scenario:

- Send all events where `host` starts with `66` to Destination `San Francisco`.
- From the rest of the events: Send all events with `method` field `POST` or `GET` to both `Seattle` and `Los Angeles` (i.e., clone them).
- Send the remaining events to `New York City`.

Router Name: **router66**

Filter Expression	Output	Final
`host.startsWith('66')`	**San Francisco**	Yes
`method=='POST' || method=='GET`	**Seattle**	No

Filter Expression	Output	Final
`method=='POST' || method=='GET'`	**Los Angeles**	Yes
`true`	**New York**	Yes

12.3.3. Amazon

You can send data from Cribl Edge to the following Amazon services:

Destination	Description
Amazon CloudWatch Logs	Send data to Amazon CloudWatch Logs
Amazon Kinesis Data Streams	Deliver data to an Amazon Kinesis Data Stream
Amazon S3 Compatible Stores	Send data to Amazon S3 or to an S3-compatible store
Amazon SQS	Send events to Amazon Simple Queuing Service
Amazon Security Lake	Send OCSF data to Amazon Security Lake in Parquet format

12.3.3.1. Amazon CloudWatch Logs Destination

Cribl Edge supports sending data to Amazon CloudWatch Logs. Cribl Edge does **not** have to run on AWS in order to deliver data to CloudWatch Logs.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

IAM Permissions

Ensure your AWS IAM user or role has the following permissions:

- `logs:CreateLogGroup` - Allows the creation of new log groups in CloudWatch Logs.
- `logs:CreateLogStream` - Permits the creation of new log streams within a log group.
- `logs:PutLogEvents` - Enables the insertion of log events into a log stream.

Configure Cribl Edge to Output to Amazon CloudWatch Logs

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this CloudWatch definition.
    - **Description**: Optionally, enter a description.
    - **Log group name**: CloudWatch log group to associate events with.
    - **Log stream prefix**: Prefix for CloudWatch log stream name. This prefix will be used to generate a unique log stream name per Cribl Edge instance. (For example, `myStream_myHost_myOutputId`.)
    - **Region**: AWS Region where the CloudWatch Logs group is located.
3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`. When this field is set to `queue`, see Persistent Queue Settings for details.

- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Authentication, Assume Role, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.

Mode	Description
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

> Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
2. **IAM Identity Center (SSO)**: Loaded from AWS IAM Identity Center configuration.
3. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
4. **IAM Roles for Amazon EC2/ECS**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance or ECS container.

5. **JSON File on Disk**: Loaded from a JSON file on disk.
6. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

Azure-based Cribl.Cloud Worker Groups do not have AWS credentials, so **Auto** finds none and authentication fails. On an Azure-based Worker Group, select another authentication method and supply your own AWS credentials.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Edge's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using **Assume Role** to access resources in a different Region than Cribl Edge, you can target the AWS Security Token Service (STS) endpoint specific to that Region by using the `CRIBL_AWS_STS_REGION` environment variable on your Edge Node. To specify a custom STS endpoint, set the `CRIBL_AWS_STS_ENDPOINT` environment variable. If both are set, `CRIBL_AWS_STS_ENDPOINT` takes precedence. Setting an invalid Region or endpoint results in a fallback to the global STS endpoint.

Enable for CloudWatch Logs: Toggle on to use Assume Role credentials to access CloudWatch Logs.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Advanced Settings

Endpoint: CloudWatch Logs service endpoint. If empty, defaults to AWS' Region-specific endpoint. Otherwise, use this field to point to a CloudWatchLogs-compatible endpoint.

To proxy outbound HTTP/S requests, see System Proxy Configuration.

Queue size limit: Maximum number of queued batches before blocking. Defaults to `5`.

Record size limit (KB, uncompressed): Maximum size of each individual record before compression. For non-compressible data, 1MB (the default) is the maximum recommended size.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum.

Reuse connections: Whether to reuse connections between requests. Toggling on (default) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to toggled on.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

How the Amazon CloudWatch Logs Destination Batches Events

Amazon CloudWatch Logs specifies that a batch of log events in a single request cannot span more than 24 hours.

When the Amazon CloudWatch Logs Destination transmits a batch of events, it notes the most recent event in the batch (by date-time) and drops all events in the batch that are 24 hours older (or more) than the most recent event.

To monitor dropped events, check **Out of Range Dropped Event Count** under **Status**. Alternately, you can monitor a debug log action to flag how many events are being dropped in a batch.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

12.3.3.2. Amazon Kinesis Data Streams Destination

Cribl Edge can output events to **Amazon Kinesis Data Streams** records of up to 1MB uncompressed. Cribl Edge does **not** have to run on AWS in order to deliver data to a Kinesis Data Stream.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Meeting the Needs of Different Downstream Receivers

You can use this Destination to send data to different kinds of downstream receivers that have different expectations. In all cases what the Destination sends out are Kinesis Records. This works because the Amazon Kinesis Data Streams Service is flexible about what is actually in a Record, as the two following use cases show.

Sending Multiple Events within One Record

When used to feed data into Amazon Data Firehose, this Destination will start with multiple events as NDJSON, gzip-compress them together into a blob, and send that as a single Kinesis Record. This uses the Kinesis PutRecord API call to send the combined events in a single Record.

Amazon Data Firehose will gunzip-uncompress the Record and split the NDJSON out into individual events again. There are also other downstream receivers besides Amazon Data Firehose that can do the same thing.

This approach requires either:

- **Advanced Settings** > **Compression** set to `Gzip`, **or**
- **Advanced Settings** > **Send batched** toggled on.

Meanwhile, if you want Cribl Edge to be the consumer, on the Kinesis Streams Source, set **Record data format** to `Cribl`. See the format details below.

Sending One Event Per Record

In contrast to the first use case, some downstream receivers require a Kinesis Record to contain exactly one Cribl event. Here, this Destination uses the Kinesis PutRecords API call to send multiple events in a single API call, but where each event has a Record to itself. (Note the difference between `PutRecord` in the previous use case and `PutRecords` in this one.)

This approach requires:

- **Advanced Settings** > **Compression** set to `None`, **and**
- **Advanced Settings** > **Send batched** toggled off.

Meanwhile, if you want Cribl Edge to be the consumer, on the Kinesis Streams Source, set **Record data format** to `Newline JSON`. See the format details below.

Amazon Kinesis Data Streams Permissions

The following permissions are needed to write to an Amazon Kinesis Stream:

Shard Verification (Determining Stream Availability):

- `kinesis:ListShards` - Required by default to use the ListShards API. This API offers higher rate limits for shard verification.
- `kinesis:DescribeStream` - Required instead of `kinesis:ListShards` if the **ListShards API** advanced setting is toggled off.

Data Writing (Sending Data to the Stream):

- `kinesis:PutRecord` - Required for Gzip compression or batching (when **Advanced Settings** > **Compression** is set to `Gzip` or **Advanced Settings** > **Send batched** is toggled on).
- `kinesis:PutRecords` - Required for non-batched mode (when **Advanced Settings** > **Send batched** is toggled off).

Configure Cribl Edge to Output to Amazon Kinesis Data Streams

In Cribl Edge, configure Amazon CloudWatch Kinesis Data Streams:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Kinesis definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Stream name**: Enter the name of the Kinesis Data Stream (not ARN) to which to send events.
    - **Region**: Select the AWS Region where your Kinesis Data Stream is located. If your Region isn't listed, you can manually enter it. Additionally, you can specify the service endpoint in the **Endpoint** field

under Advanced Settings.

3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`. When this field is set to `queue`, see Persistent Queue Settings for details.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any Authentication, Assume Role, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Authentication

Use the **Authentication Method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
2. **IAM Identity Center (SSO)**: Loaded from AWS IAM Identity Center configuration.
3. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).

4. **IAM Roles for Amazon EC2/ECS**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance or ECS container.
5. **JSON File on Disk**: Loaded from a JSON file on disk.
6. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

Azure-based Cribl.Cloud Worker Groups do not have AWS credentials, so **Auto** finds none and authentication fails. On an Azure-based Worker Group, select another authentication method and supply your own AWS credentials.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

For details, see AWS' Actions, resources, and condition keys for Amazon Kinesis Data Streams documentation.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Edge's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using **Assume Role** to access resources in a different Region than Cribl Edge, you can target the AWS Security Token Service (STS) endpoint specific to that Region by using the `CRIBL_AWS_STS_REGION`

environment variable on your Edge Node. To specify a custom STS endpoint, set the `CRIBL_AWS_STS_ENDPOINT` environment variable. If both are set, `CRIBL_AWS_STS_ENDPOINT` takes precedence. Setting an invalid Region or endpoint results in a fallback to the global STS endpoint.

Enable for Kinesis Streams: Toggle on to use Assume Role credentials to access Kinesis Streams.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Advanced Settings

Endpoint: Kinesis Stream service endpoint. If empty, the endpoint will be automatically constructed from the Region.

To proxy outbound HTTP/S requests, see System Proxy Configuration.

Signature version: Signature version to use for signing Kinesis Stream requests. Defaults to `v4`.

Put request concurrency: Maximum number of ongoing put requests before blocking. Defaults to `5`.

Record size limit (KB, uncompressed): Maximum size of each individual record before compression. For non-compressible data, 1MB (the default) is the maximum recommended size.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum.

Compression: Type of compression to use on records being sent downstream. Defaults to `Gzip`, and when set to `None`, displays the following control:

Send batched: Whether to send multiple events batched as a single NDJSON Kinesis record (the default) or send each event as its own Kinesis record, serialized as JSON. When toggled off, displays the following control:

- **Records-per-flush limit**: Maximum number of records to send in a single request to the Amazon Kinesis Data Streams Service PutRecords API endpoint.

ListShards API: The ListShards API is used by default for Kinesis Stream shard verification. This provides significantly higher rate limits (1,000 calls/second/stream), minimizing throttling and improving data delivery speed and reliability, particularly in high-throughput environments.

- Using ListShards requires your IAM policy to have the `kinesis:ListShards` action to grant access. See Controlling Access to Amazon Kinesis Data Streams Resources Using IAM.
- Toggle off to use the DescribeStream API, which has lower rate limits (10 calls/second/account) and increased susceptibility to throttling.

Reuse connections: Whether to reuse connections between requests. Toggling on (default) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to toggled on.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Record Formats in Detail

When sending multiple events within one record, the Record format will be as follows:

- A header line provides information about the payload (the one supported type is shown below).
- Each Kinesis record will contain multiple events serialized as Newline-Delimited JSON (NDJSON).
- Record payloads (including header and body) will be gzip-compressed if **Advanced Settings > Compression** is set to `Gzip`.

Sample Kinesis Record

```
{"format":"ndjson","count":8,"size":3960}
{"_raw":"07-03-2018 18:33:51.136 -0700 ERROR TcpOutputFd - Read error. Connection res
{"_raw":"07-03-2018 18:33:51.136 -0700 INFO  TcpOutputProc - Connection to 127.0.0.1:
...
```

Copy

When sending one event per Record, the Record format will be as follows:

- No header will be included.
- Each Kinesis record will contain a single event serialized as JSON (**not** NDJSON).
- Record payloads will not be compressed.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

12.3.3.3. Amazon S3 Compatible Stores Destination

S3 is a non-streaming Destination type. Cribl Edge does **not** have to run on AWS to deliver data to S3. Stores that are S3-compatible will also work with this Destination type. The Destination can write to buckets that have S3 Object Lock enabled.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

For guidance in configuring adaptations to S3-compatible stores, contact Cribl Support. For general guidance, see our Amazon S3 Better Practices guide. To replay data you've previously exported to S3-compatible stores, see our Using S3 Storage and Replay guide and our interactive Data Collection & Replay sandbox.

Configure Cribl Edge to Output to S3 Destinations

In Cribl Edge, configure Amazon S3:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this S3 definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **S3 bucket name**: Name of the destination S3 Bucket. This value can be a constant, or a JavaScript expression that will be evaluated only at init time. For example, referencing a Global Variable: `myBucket-${C.vars.myVar}`.

      Event-level variables are not available for JavaScript expressions. This is because the bucket name is evaluated only at Destination initialization. If you want to use event-level variables in file paths, Cribl recommends specifying them in the **Partitioning Expression** field (described below), because this is evaluated for each file.
    - **Staging location**: Filesystem location in which to locally buffer files before compressing and moving to final destination. Cribl recommends that this location be stable and high-performance.

The **Staging location** field is not displayed or available on Cribl.Cloud-managed Edge Nodes.

- **Key prefix**: Root directory to prepend to path before uploading. Enter either a constant, or a JS expression (enclosed in single quotes, double quotes, or backticks) that will be evaluated only at init time.
- **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (supported only on Linux, not Windows) exposes a **Parquet Settings** left tab, where you **must** configure certain options in order to export data in Parquet format.

3. Next, you can configure the following **Optional Settings**:

- **Region**: Region where the S3 bucket is located.

You must grant your IAM role or user the `GetBucketLocation` permission to the S3 bucket when no **Region** is selected. See Amazon S3 Permissions for an example.

- **Partitioning expression**: JavaScript expression that defines how files are partitioned and organized. Default is date-based. If blank, Cribl Edge will fall back to the event's `__partition` field value (if present); or otherwise to the root directory of the **Output Location** and **Staging Location**.
- **Compression**: Data compression format used before moving to final destination. Defaults to `gzip` (recommended). This setting is not available when **Data format** is set to `Parquet`.
- **File name prefix expression**: The output filename prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
- **File name suffix expression**: The output filename suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ""}` ``, where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.

To prevent files from being overwritten, Cribl appends a random sequence of 6 characters to the end of their names. This also applies to prefix and suffix expressions in file names.

For example, if you set the **File name prefix expression** to `CriblExec` and set the **File name suffix expression** to `.csv`, the file name might display as `CriblExec-adPRWM.csv` with `adPRWM` appended.

- **Backpressure behavior**: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Authentication, Assume Role, Processing, Parquet, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication method** drop-down to select one of these options:

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
2. **IAM Identity Center (SSO)**: Loaded from AWS IAM Identity Center configuration.
3. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
4. **IAM Roles for Amazon EC2/ECS**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance or ECS container.
5. **JSON File on Disk**: Loaded from a JSON file on disk.
6. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

Azure-based Cribl.Cloud Worker Groups do not have AWS credentials, so **Auto** finds none and authentication fails. On an Azure-based Worker Group, select another authentication method and supply your own AWS credentials.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

The values for **Access key** and **Secret key** can be a constant or a JavaScript expression. Store credentials as secrets and reference them with `C.Secret()`: use `` `${C.Secret('myKeyPair', 'keypair').apiKey}` `` for the access key and `` `${C.Secret('myKeyPair', 'keypair').secretKey}` `` for the secret key.

Enclose values that contain special characters (like `/`) or JavaScript expressions in single quotes or backticks.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Edge's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using **Assume Role** to access resources in a different Region than Cribl Edge, you can target the AWS Security Token Service (STS) endpoint specific to that Region by using the `CRIBL_AWS_STS_REGION` environment variable on your Edge Node. To specify a custom STS endpoint, set the `CRIBL_AWS_STS_ENDPOINT` environment variable. If both are set, `CRIBL_AWS_STS_ENDPOINT` takes precedence. Setting an invalid Region or endpoint results in a fallback to the global STS endpoint.

Enable for S3: Toggle on to use Assume Role credentials to access S3.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID in order to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields

include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Edge CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Parquet Schemas for pointers on how to avoid problems such as data mismatches.
- In Cribl Edge 4.3 and newer, the S3 Collector supports ingesting data in the Parquet format. Therefore, data that you export in Parquet format can be replayed via the Collector.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Edge writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported, and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: Set the target memory size for page segments. Generally, set lower values to improve reading speed, or set higher values to improve compression. Value must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle on to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics - these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Advanced Settings

File size limit (MB): Maximum uncompressed output file size. Files of this size will be closed and moved to final output location. Defaults to `32`.

File open time limit (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Idle time limit (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Defaults to `30`.

Open file limit: Maximum number of files to keep open concurrently. When this limit is exceeded, on any individual Worker Process, Cribl Edge will close the oldest open files, and move them to the final output location. Defaults to `100`.

Cribl Edge will close files when **any** of the four above conditions is met.

Compression level: Specifies the level of compression to apply before moving files to the final destination. Higher compression levels reduce file size but increase CPU usage. Choose from `Best Speed`, `Normal`, or `Best Compression`. The default level, `Best Speed`, will prioritize faster compression over smaller file sizes.

Staging file limit: Maximum number of files that the Destination will allow to wait for upload before it applies backpressure. Defaults to `100`; minimum is `10`; maximum is `4200`. For context, see Troubleshooting below.

Concurrent file parts limit: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send the whole file at once. When set to `2` or above, IAM permissions must include those required for multipart uploads. Defaults to `4`; highest allowed value is `10`.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined **Min free disk space** amount.

Add Output ID: When toggled on (default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

> For a Destination originally configured in a Cribl Edge version below 2.4.0, the **Add Output ID** behavior will be switched **off** on the backend, regardless of this toggle's state. This is to avoid losing any files pending in the original staging directory, upon Cribl Edge upgrade and restart. To enable this option for such Destinations, Cribl's recommended migration path is:
>
> - Clone the Destination.
> - Redirect the Routes referencing the original Destination to instead reference the new, cloned Destination.
>
> This way, the original Destination will process pending files (after an idle timeout), and the new, cloned Destination will process newly arriving events with **Add output ID** enabled.

Remove empty staging directories: When toggled on (the default), Cribl Edge deletes empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).
- **Directory batch size**: Specifies how many directories are scanned per batch during automatic cleanup of empty staging directories. Set between `10` and `10000`, defaults to `1000`. Higher values speed up cleanup but increase memory usage.

Force close on shutdown: Toggle on to force all staged files to close during an orderly shutdown. This triggers immediate upload or finalization of any in-progress files, regardless of **Idle time**, **File open time**, or **File size** limits. Use this option to minimize data loss risk in ephemeral or auto-scaling environments. This could result in a higher number of small files, as files are closed before reaching their configured thresholds. Ensure your Worker Group or Fleet **Drain timeout** is set high enough to allow all staged data to be finalized before shutdown completes.

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Endpoint: S3 service endpoint. If empty, Cribl Edge will automatically construct the endpoint from the AWS Region. To access the AWS S3 endpoints, use the path-style URL format. You don't need to specify the bucket name in the URL, because Cribl Edge will automatically add it to the URL path. For details, see AWS' Path-Style Requests topic.

Object ACL: Object ACL (Access Control List) to assign to uploaded objects.

Storage class: Select a storage class for uploaded objects. Defaults to `Standard`. The other options are: `Reduced Redundancy Storage`; `Standard, Infrequent Access`; `One Zone, Infrequent Access`; `Intelligent Tiering`; `Glacier Flexible Retrieval`; `Glacier Instant Retrieval`; or `Glacier Deep Archive`.

Server-side encryption: Encryption type for uploaded objects - used to enable encryption on data at rest. Defaults to no encryption; the other options are `Amazon S3 Managed Key` or `AWS KMS Managed Key`.

> AWS S3 always encrypts data in transit using HTTPS, with default one-way authentication from server to clients. With other S3-compatible stores (such as our native MinIO Destination), use an `https://` URL to invoke in-transit encryption. Two-way authentication is not required to get encryption, and requires clients to possess a certificate.

Signature version: Signature version to use for signing S3 requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. Toggling on (default) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to toggled on.

Verify if bucket exists: Toggle off if you can access files within the bucket, but not the bucket itself. This resolves errors of the form: `error initializing...Bucket does not exist`. For context, see Troubleshooting below.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

IAM Permissions

The following permissions are needed to write to an Amazon S3 bucket:

- `s3:GetBucketLocation` - Needed if **Region** is not configured.
- `s3:ListBucket` - Needed unless **Verify if bucket exists** is toggled off.
- `s3:PutObject`

If your Destination needs to do multipart uploads to S3, two more permissions are needed:

- `kms:GenerateDataKey`
- `kms:Decrypt`

See the AWS documentation.

Temporary Access via SSO Provider

You can use Okta or SAML to provide access to S3 buckets using temporary security credentials.

Internal Fields

Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Destination Integrations: S3 short course. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses - but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

Common Issues

"InvalidClientTokenId" or "The security token included in the request is invalid"

Can occur when using `AssumeRole` to access resources in a non-default AWS region (for example, `eu-central-2` / Zurich). This happens because:

- Instance profile credentials are typically minted by the global STS endpoint.
- Non-default regions (those disabled by default on AWS accounts) do not accept STS tokens minted by the global endpoint.

Recommendation

Set the `CRIBL_AWS_STS_REGION` environment variable to a default region that will accept your source credentials (for example, `eu-central-1` or `eu-west-1`), or set `CRIBL_AWS_STS_ENDPOINT` explicitly (for example, `https://sts.eu-west-1.amazonaws.com`).

Tokens minted by a regional STS endpoint are valid in any region, including non-default regions. For more information, see Troubleshooting STS in Non-Default AWS Regions.

"Bucket does not exist - self signed certificate"

Example Error Text:

```
message: Bucket does not exist - self signed certificate
stack: Error: self signed certificate
    at TLSSocket.onConnectSecure (node:_tls_wrap_1535:34)
    at TLSSocket.emit (node:events:513:28)
    at TLSSocket.emit (node:events:489:12)
    at TLSSocket._fini... Show more
tmpPath: /opt/cribl/s3_bucket/cribl/2023/03/28/CriblOut-XTNGh5.0.json.tmp
```

Copy

Can occur when:

- the Destination uses a self-signed cert that has not yet been trusted by Cribl Stream.
- the user does not have appropriate permissions to view the bucket.
- the authentication token generated by your computer has a timestamp that is out of sync with the server's time, resulting in an authentication failure.

Recommendation

Disable **Advanced Settings** > **Reject unauthorized certificates** or; get the sender's cert and add it to the `NODE_EXTRA_CA_CERTS` path for validation; or verify that the user has appropriate permissions.

Misconfigured or Nonexistent Buckets

If the S3 bucket that the Destination is trying to send files to does not exist or is misconfigured, the Destination logs will reflect the following pattern:

1. Upon initialization, the Destination will log an error that says the bucket cannot be found. This error will not be logged if **Advanced Settings** > **Verify if bucket exists** is turned off.
2. Every time the Destination "rolls" a new file out of staging to try to upload it to S3, the Destination will log an error, until the number of files rolled exceeds the value of **Advanced Settings** > **Max files to stage**.

Once the Destination has begun to apply backpressure:

- The Destination will log a backpressure warning.
- Events will stop flowing through the Destination.
- The Destination will stop creating staging files.

12.3.3.4. Amazon SQS Destination

Cribl Edge supports sending events to Amazon Simple Queuing Service.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Edge to Send Data to Amazon SQS

In Cribl Edge, configure Amazon SQS:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this SQS Destination.
    - **Description**: Optionally, enter a description.
    - **Queue name**: The name, URL, or ARN of the SQS queue to send events to. This value must be a JavaScript expression (which can evaluate to a constant), enclosed in single quotes, double quotes, or backticks. To specify a non-AWS URL, use the format: `'{url}/<queueName>'`. (For example, `':port/<myQueueName>'`.)
    - **Queue type**: The queue type used (or created). Defaults to `Standard`. `FIFO` (First In, First Out) is the other option.
3. Next, you can configure the following **Optional Settings**:
    - **Message group ID**: This parameter applies only to queues of type FIFO. Enter the tag that specifies that a message belongs to a specific message group. (Messages belonging to the same message group are processed in FIFO order.) Defaults to `cribl`. Use event field `__messageGroupId` to override this value.
    - **Create queue**: Specifies whether to create the queue if it does not exist. Defaults to toggled on.
    - **Region**: Region where SQS queue is located.
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`. When this field is set to `queue`, see Persistent Queue Settings for details.

- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Authentication, Assume Role, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.

Mode	Description
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

> Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
2. **IAM Identity Center (SSO)**: Loaded from AWS IAM Identity Center configuration.
3. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
4. **IAM Roles for Amazon EC2/ECS**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance or ECS container.

5. **JSON File on Disk**: Loaded from a JSON file on disk.
6. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

Azure-based Cribl.Cloud Worker Groups do not have AWS credentials, so **Auto** finds none and authentication fails. On an Azure-based Worker Group, select another authentication method and supply your own AWS credentials.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Edge's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using **Assume Role** to access resources in a different Region than Cribl Edge, you can target the AWS Security Token Service (STS) endpoint specific to that Region by using the `CRIBL_AWS_STS_REGION` environment variable on your Edge Node. To specify a custom STS endpoint, set the `CRIBL_AWS_STS_ENDPOINT` environment variable. If both are set, `CRIBL_AWS_STS_ENDPOINT` takes precedence. Setting an invalid Region or endpoint results in a fallback to the global STS endpoint.

Enable for SQS: Toggle on to use Assume Role credentials to access SQS.

AWS account ID: Enter the SQS queue owner's AWS account ID. Leave empty if the SQS queue is in the same AWS account where this Cribl Edge instance is located.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Advanced Settings

Endpoint: SQS service endpoint. If empty, the endpoint will be automatically constructed from the Region.

Signature version: Signature version to use for signing SQS requests. Defaults to `v4`.

Queue size limit: Maximum number of queued batches before blocking. Defaults to `100`.

Record size limit (KB): Maximum size of each individual record. Per the SQS spec, the maximum allowed value is 256 KB. (the default).

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Concurrent request limit: The maximum number of in-progress API requests before backpressure is applied. Defaults to `10`.

Reuse connections: Whether to reuse connections between requests. Toggling on (default) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to toggled on.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

SQS Permissions

The following permissions are needed to write to an SQS queue:

- `sqs:ListQueues`
- `sqs:SendMessage`
- `sqs:SendMessageBatch`
- `sqs:CreateQueue`
- `sqs:GetQueueAttributes`
- `sqs:SetQueueAttributes`
- `sqs:GetQueueUrl`

Internal Fields

Cribl Edge uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields for this Destination:

- `__messageGroupId`
- `__sqsMsgAttrs`
- `__sqsSysAttrs`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

12.3.3.5. Amazon Security Lake Destination

This Destination delivers data to Amazon Security Lake, a fully-managed security data lake service backed by Amazon S3 buckets.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

This Destination is unavailable on Windows and macOS.

Security Lake ingests events described by the Open Cybersecurity Schema Framework (OCSF) and conveyed as Parquet files. This Destination sends the Parquet files in batches. Cribl Edge does not read or replay the data sent to Security Lake.

A Complete Setup Scenario

Cribl recommends that you start with the Amazon Security Lake Integration topic, which will guide you through the following steps in the correct order:

1. Set up Amazon Security Lake.
2. Set up Cribl Stream.
3. Create an Amazon Security Lake custom source, This is an S3 bucket dedicated to a single OCSF event class.
4. Create a Cribl Amazon Security Lake Destination.
5. Connect a Cribl Source to the Amazon Security Lake Destination.
6. Send data to Amazon Security Lake.

As outlined above, you'll create and configure this Destination as the fourth of the six overall steps. The Integration topic covers the key points about configuring this Destination. Refer back to this reference topic, as needed, for details about any given setting. Some of the instructions below assume that you have recorded IDs, values, etc., from procedures you've already completed according to the Integration topic.

Although Cribl Edge does **not** need to be deployed in Cribl.Cloud in order to deliver data to Amazon Security Lake, setup procedures on Cribl>Cloud will differ from those documented here. To learn more, please contact Cribl via the `#packs` channel of Cribl Community Slack.

Configure Cribl Edge to Output to Amazon Security Lake

In Cribl Edge, configure Amazon Security Lake:

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:

    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.

2. In the **New Destination** modal, configure the following under **General Settings**: -**Output ID**: Enter a unique name to identify this Amazon Security Lake Destination definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.

    - **Description**: Optionally, enter a description.
    - **S3 bucket name**: Name of the destination S3 Bucket you created when setting up Amazon Security Lake. This value can be a constant, or a JavaScript expression that will be evaluated only at init time. For example, referencing a Global Variable: `myBucket-${C.vars.myVar}`.

      Event-level variables are not available for JavaScript expressions. This is because the bucket name is evaluated only at Destination initialization.

    - **Region**: Region where the Amazon Security Lake is located.
    - **Account ID**: The ID of the AWS Account whose admin enabled Amazon Security Lake.
    - **Custom source name**: The name of the custom source you created in Amazon Security Lake to receive data from this Destination.
    - **Staging location**: Filesystem location in which to locally buffer files before compressing and moving to final destination. Cribl recommends that this location be stable and high-performance.

      The **Staging location** field is not displayed or available on Cribl.Cloud-managed Edge Nodes.

3. Next, you can configure the following **Optional Settings**:

    - **File name prefix expression**: The output filename prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
    - **Backpressure behavior**: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Authentication, Assume Role, Processing, Parquet, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

For the **Authentication Method**, you **must** leave the default **Auto** method selected.

This method uses the AWS instance's metadata service to automatically obtain short-lived credentials from the IAM role attached to an EC2 instance. The attached IAM role grants Cribl Edge Edge Nodes access to authorized AWS resources. Can also use the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. Works only when running on AWS.

Assume Role

For these settings, you'll enter values that you noted when creating the custom source in Security Lake.

AssumeRole ARN: The custom source's **Provider role ARN**.

External ID: In the custom source, this is the value of the `ExternalId` element of the trust relationship JSON object.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output. Use the drop-down to select the Pack you installed when setting up Cribl Edge.

System fields: A list of fields to automatically add to events that use this output. By default, no system fields are added. Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.

- `cribl_mode` - Distributed mode of the instance that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Edge CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Parquet Schemas for pointers on how to avoid problems such as data mismatches.
- In Cribl Edge 4.3 and newer, the S3 Collector supports ingesting data in the Parquet format. Therefore, data that you export in Parquet format can be replayed via the Collector.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Edge writes. When toggled off (the default), exposes the following additional field:

Parquet schema: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported, and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: Ideal memory size for page segments. For example, 1 MB or 128 MB. Generally, lower values improve reading speed, while higher values improve compression. Imposes a target, not a strict limit; the final size of a row group may be larger or smaller. Defaults to 1 MB.

Log invalid rows: Toggle on to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics – these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Advanced Settings

File size limit (MB): Maximum uncompressed output file size. Files of this size will be closed and moved to final output location. Defaults to `32`.

File open time limit (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Idle time limit (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Defaults to `30`.

Open file limit: Maximum number of files to keep open concurrently. When this limit is exceeded, on any individual Edge Node Process, Cribl Edge will close the oldest open files, and move them to the final output location. Defaults to `100`.

Cribl Edge will close files when **any** of the four above conditions is met.

Concurrent file parts limit: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send the whole file at once. When set to `2` or above, IAM permissions must include those required for multipart uploads. Defaults to `4`; highest allowed value is `10`.

Add Output ID: When toggled on (default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

Remove empty staging directories: When toggled on (the default), Cribl Edge deletes empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).
- **Directory batch size**: Specifies how many directories are scanned per batch during automatic cleanup of empty staging directories. Set between `10` and `10000`, defaults to `1000`. Higher values speed up cleanup but increase memory usage.

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging

due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Endpoint: Security Lake service endpoint. If empty, defaults to AWS' Region-specific endpoint. Otherwise, it must point to Security Lake-compatible endpoint.

Object ACL: Object ACL (Access Control List) to assign to uploaded objects.

Storage class: Select a storage class for uploaded objects. Defaults to `Standard`. The other options are: `Reduced Redundancy Storage`; `Standard, Infrequent Access`; `One Zone, Infrequent Access`; `Intelligent Tiering`; `Glacier`; or `Deep Archive`.

Server-side encryption: Encryption type for uploaded objects - used to enable encryption on data at rest. Defaults to no encryption; the other options are `Amazon S3 Managed Key` or `AWS KMS Managed Key`.

Amazon S3 always encrypts data in transit using HTTPS, with default one-way authentication from server to clients. Two-way authentication is not required to get encryption, and requires clients to possess a certificate.

Signature version: Signature version to use for signing Security Lake requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. Toggling on (default) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to toggled on.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

IAM Permissions

The following permissions are always needed to write to an Amazon S3 bucket:

- `s3:ListBucket`
- `s3:GetBucketLocation`
- `s3:PutObject`

If your Destination needs to do multipart uploads to S3, two more permissions are needed:

- `kms:GenerateDataKey`
- `kms:Decrypt`

See the AWS documentation.

Creating and Modifying Parquet Schemas

When you need to add a new Parquet schema or modify an existing one:

1. Navigate to the Parquet Schema Library, located at **Processing** > **Knowledge** > **Parquet Schemas**.
2. Create or modify the schema, as described in Parquet Schemas.

Cribl strongly recommends that to modify an existing schema, you first clone it and give the clone its own distinct name.

3. Return to this Destination, and select the new or modified schema in the **Parquet schema** drop-down.
4. Click **Save**.

Cloning First is Safer Than Just Modifying

Modifying an existing schema in the Schema Library does **not** propagate your modifications to the Destination's copy of the schema.

- Cloning and renaming schemas is the safest approach, because in Step 3 above, it removes any doubt that your Destination will now use the newly-modified version of your schema.
- If you do **not** clone and rename the schema (i.e., you leave the schema name unchanged), you still must re-select the schema in the Destination's **Parquet schema** drop-down, and click **Save**, to bring the modified version into the Destination.

Internal Fields

Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Troubleshooting Resources

Cribl University offers an Advanced Troubleshooting > Destination Integrations: S3 short course. Since Amazon Security Lake relies on S3 buckets, what you learn from the course can augment your Security Lake skills.

To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link.

You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses - but Cribl's training is always free of charge.)

12.3.4. Azure

You can send data from Cribl Edge to the following Azure services:

Destination	Description
Azure Blob Storage	Deliver data to Azure Blog Storage or Azure Data Lake Storage Gen2
Azure Data Explorer	Send batched or streaming data to the Azure Data Explorer managed data analytics service
Azure Event Hubs	Send data to Azure Event Hubs
Azure Monitor Logs	Send data to Azure Monitor Logs
Microsoft Sentinel	Send Log and Metric Events to Microsoft Sentinel SIEM

12.3.4.1. Azure Blob Storage Destination

Cribl Edge supports sending data to (and replaying specific events from) both Azure Blob Storage, and Azure Data Lake Storage Gen2, which implements a hierarchical namespace over blob data. This Destination can deliver data to Azure whether Cribl Edge is running on Azure, another cloud platform, or on-prem.

To use Azure Data Lake Storage Gen2 with this Destination, configure an Azure Storage account with hierarchical namespace enabled and use the standard connection string format. No additional settings are required to target Azure Data Lake Storage Gen2.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

For configuration examples, see Resources below.

Configure Cribl Edge to Output to Azure Blob Storage

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition.
    - **Description**: Optionally, enter a description.
    - **Container name**: Specify the Azure Blob Storage container name. Containers organize blobs, similar to directories in a file system. Container names can include only lowercase letters, numbers, and hyphens.
        - For dynamic container names, provide a JavaScript expression within quotes or backticks, for example, `` `myContainer-${C.env["CRIBL_WORKER_ID"]}` ``. This expression is evaluated at initialization, resolving environment or runtime variables. Only simple concatenations and references to global variables are supported.
    - **Blob prefix**: Root directory to prepend to path before uploading.
    - **Staging location**: Local filesystem location in which to buffer files before compressing and moving them to the final destination. Cribl recommends that this location be stable and high-performance. Default is `$CRIBL_HOME/state/outputs/staging`.

In Cribl Stream, the **Staging location** field is not displayed or available on Cribl.Cloud-managed Worker Groups.

- **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (supported only on Linux, not Windows) exposes a **Parquet Settings** left tab, where you **must** configure certain options in order to export data in Parquet format.

3. Under **Authentication**, select an **Authentication method** from the dropdown:
   - **Manual**: Use this default option to enter your Azure Storage connection string directly. Exposes a **Connection string** field for this purpose. (If left blank, Cribl Edge will fall back to `env.AZURE_STORAGE_CONNECTION_STRING`.)
   - **Secret**: This option exposes a **Connection string (text secret)** drop-down, in which you can select a stored secret that references an Azure Storage connection string. A **Create** link is available to store a new, reusable secret. For details, see Connection String Format.
   - **Client secret**: This option allows you to use the Azure service principal's client secret to authenticate, and exposes Azure service principal settings.
   - **Certificate**: This option allows you to use a certificate registered with the Azure service principal to authenticate, and exposes Azure service principal settings.
4. Next, you can configure the following **Optional Settings**:
   - **Create container**: Toggle on to create the configured container in Azure Blob Storage if one does not already exist. Hierarchical namespaces are typically used when working with Azure Data Lake Storage Gen2. When the target storage account has hierarchical namespace enabled, any container created by this Destination will therefore be an ADLS Gen2 container by default.
   - **Partitioning expression**: JavaScript expression that defines how files are partitioned and organized. Default is date-based. If blank, Cribl Edge will fall back to the event's `__partition` field value (if present); or otherwise to the root directory of the **Output Location** and **Staging Location**.
   - **Compression**: Data compression format used before moving to final destination. Defaults to `gzip` (recommended). This setting is not available when **Data format** is set to `Parquet`.
   - **File name prefix expression**: The output file name prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
   - **File name suffix expression**: The output file name suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ""}` ``, where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.

To prevent files from being overwritten, Cribl appends a random sequence of 6 characters to the end of their names. This also applies to prefix and suffix expressions in file names.

> For example, if you set the **File name prefix expression** to `CriblExec` and set the **File name suffix expression** to `.csv`, the file name might display as `CriblExec-adPRWM.csv` with `adPRWM` appended.

- **Backpressure behavior**: Whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the Processing, Parquet Settings, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Connection String Format

Manual and **Secret** authentication methods use an Azure Storage connection string in this format:

```
DefaultEndpointsProtocol=[http|https];AccountName=<your-account-name>;AccountKey=<you
```

Copy

A fictitious example, using Microsoft's recommended HTTPS option, is:

```
DefaultEndpointsProtocol=https;AccountName=storagesample;AccountKey=12345678...32;Enc
```

Copy

> For Azure Data Lake Storage Gen2 accounts, use the same connection string pattern as for standard Azure Blob Storage.

Service Principal Settings

Client secret and **Certificate** authentication methods expose the following additional settings:

- **Storage account name**: Enter the name of your Azure Storage Account.
- **Tenant ID**: Enter the service principal's tenant ID.
- **Client ID**: Enter the service principal's client ID.

- **Client secret (text secret)** (with **Client secret** method selected): Select a text secret containing the client secret, or create a new one.
- **Certificate** (with **Certificate** method selected): Select the certificate you registered as credentials for your app in the Azure portal, or create a new one.
- **Azure Cloud**: Select the Azure cloud environment to use, `Azure Public Cloud` (default), `Azure China`, or `Azure Government`. The **Endpoint suffix** advanced setting is available if you need to override the default values.
    - Selecting `Azure China` sets the authority host to `login.chinacloudapi.cn` and the endpoint suffix to `core.chinacloudapi.cn`.
    - Selecting `Azure Government` sets the authority host to `login.microsoftonline.us` and the endpoint suffix to `core.usgovcloudapi.net`.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Edge CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Parquet Schemas for pointers on how to avoid problems such as data mismatches.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Edge writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported, and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: Set the target memory size for page segments. Generally, set lower values to improve reading speed, or set higher values to improve compression. Value must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle on to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics - these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, and so on.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Advanced Settings

File size limit (MB): Maximum uncompressed output file size. Files reaching this size will be closed and moved to the final output location. Defaults to `32`.

File open time limit (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Idle time limit (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Default: `30`.

Open file limit: Maximum number of files to keep open concurrently. When exceeded, the oldest open files will be closed and moved to final output location. Default: `100`.

Cribl Edge will close files when **either** of the `File size limit (MB)` or the `Max file open time (sec)` conditions are met.

Concurrent file parts limit: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send one part at a time - that is, to upload the file's contents sequentially. Defaults to `1`; highest allowed value is `10`.

Blob access tier: Select the access tier for storing your data in Azure Blob Storage. Defaults to `Default account access tier`. Options include:

- `Hot tier` for frequently accessed data.
- `Cool tier` for infrequent access.
- `Cold tier` for rarely accessed data.
- `Archive tier` for data that can tolerate retrieval delays.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined Min free disk space amount.

Add Output ID: When toggled on (default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

For a Destination originally configured in a Cribl Edge version below 2.4.0, the **Add Output ID** behavior will be switched **off** on the backend, regardless of this toggle's state. This is to avoid losing any files pending in the original staging directory, upon Cribl Edge upgrade and restart. To enable this option for such Destinations, Cribl's recommended migration path is:

- Clone the Destination.
- Redirect the Routes referencing the original Destination to instead reference the new, cloned Destination.

This way, the original Destination will process pending files (after an idle timeout), and the new, cloned Destination will process newly arriving events with **Add output ID** enabled.

Remove empty staging directories: When toggled on (the default), Cribl Edge deletes empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this

additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).
- **Directory batch size**: Specifies how many directories are scanned per batch during automatic cleanup of empty staging directories. Set between `10` and `10000`, defaults to `1000`. Higher values speed up cleanup but increase memory usage.

Force close on shutdown: Toggle on to force all staged files to close during an orderly shutdown. This triggers immediate upload or finalization of any in-progress files, regardless of **Idle time**, **File open time**, or **File size** limits. Use this option to minimize data loss risk in ephemeral or auto-scaling environments. This could result in a higher number of small files, as files are closed before reaching their configured thresholds. Ensure your Worker Group or Fleet **Drain timeout** is set high enough to allow all staged data to be finalized before shutdown completes.

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Endpoint suffix: (Optional) Overrides the default endpoint suffix set by the **Azure Cloud** setting. Use this only if you need to connect to a custom or non-standard Azure Blob Storage endpoint.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Azure Permissions

When configuring an Azure Destination in Cribl Edge, you must grant the necessary permissions for it to interact with your Azure environment. Cribl recommends creating an Azure service principal with the minimum required permissions using Azure role-based access control (Azure RBAC). This approach ensures Cribl Edge has a dedicated identity with precisely the access it needs, following the principle of least privilege.

The minimum permissions required for Destinations are:

- **Storage Blob Data Contributor**

See Permissions for calling data operations in the official Microsoft documentation for more information.

Internal Fields

Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Resources

For examples of configuring Cribl Edge to interoperate with Azure services, see these guides:

- Preparing the Azure Workspace.
- SSO with Microsoft Entra ID (Cribl.Cloud).
- SSO with Microsoft Entra ID (On-Prem).

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

12.3.4.2. Azure Data Explorer Destination

Cribl Edge supports sending data to the Azure Data Explorer (ADX) managed data analytics service; you can then run Kusto queries against the data. This Destination can deliver data to Azure whether Cribl Edge is running on Azure, another cloud platform, or on-prem.

ADX stores log data in databases, which in turn contain one or more of the tables defined in the Azure namespace. You must create a separate Cribl Edge ADX Destination for each table that will store your data.

Type: Non-Streaming **or** Streaming (configurable) | TLS Support: Yes | PQ Support: No

For configuration examples, see Resources below.

Prerequisites

Before you configure the Destination, you need to collect some information from your Azure deployment. Start from **Home** (`portal.azure.com`), then navigate to the locations described below and collect the items specified.

Information About Your ADX Cluster

From **Home**, navigate to:

Azure Data Explorer Clusters > `your_Azure_cluster_name` > **Overview** > **Essentials**

- Copy the **URI**. In Cribl Edge, this will be the value for **General Settings** > **Cluster base URI**. Make a copy of the URI with `/.default` appended - this will be the value of **Authentication Settings** > **Scope**.
- Copy the **Data Ingestion URI**. In Cribl Edge, this will be the value for **General Settings** > **Ingestion service URI**.

Information About Your Azure Database

From **Home**, navigate to:

Azure Data Explorer Clusters > `your_Azure_cluster_name` | **Databases** > `database_name` | **Query**

- Note the name of your desired target table - this table name will be the value of **General Settings** > **Table name**.

Information About Your Azure App

First, from **Home**, navigate to:

App registrations > `your_Azure_app_name` | **Overview** | **Essentials**

- Copy the **Application (client) ID** - this will be the value of **Authentication Settings** > **Client ID**.
- Copy the **Directory (tenant) ID** - this will be the value of **Authentication Settings** > **Tenant ID**.

Nex, from **Home**, navigate to:

App registrations > `your_Azure_app_name` | **Certificates & secrets**

Now what you do depends on which method for **Authentication** you plan to use in Cribl Edge.

To use the Client secret method

- In the **Client secrets** tab, click **New client secret** and copy the **Value** of the new secret. In Cribl Edge, this will be the value of **Client secret**.

To use the Client secret (text secret) method

- In the **Client secrets** tab, click **New client secret** and copy the **Value** of the new secret. In Cribl Edge, this will be the value of **Create new secret** > **Value**.

To use the Certificate method

After you have generated a certificate and keys (if you do this later on in the configuration process, return to this section then):

- In the **Certificates** tab, click **Upload Certificate**. In the resulting drawer, follow the prompts to upload your certificate, and click **Add** to close the drawer.

The chosen certificate will then appear in the **Certificates** tab's list.

Data Mapping Prerequisites

Finally, you might need to note or copy data mapping information to obtain values for some of the **General Settings**.

ADX uses a data mapping to map fields from incoming data to fields in the target table. To see the data mapping, you'll run a Kusto query against your target table.

Here's the query syntax:

```
.show table EntityName ingestion MappingKind mapping MappingName
```

Copy

Here's an example query:

```
.show table SyslogTable ingestion json mapping "SyslogMapping"
```

Copy

The Kusto query that originally created this mapping would look like this:

```
.create table SyslogTable ingestion json mapping "SyslogMapping"
```

Copy

In Cribl Edge, you can use the names of mappings like the above example in the **General Settings** > **Data mapping** field. Alternatively, you can create a mapping without naming it, then copy and paste it (as a JSON object) into the Cribl Edge UI. To do this, toggle **General Settings** > **Mapping object** on. This hides the default **Data mapping** text field and opens a text window that expects JSON.

Configure Cribl Edge to Output to Azure Data Explorer

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition.
    - **Description**: Optionally, enter a description.
    - **Ingestion mode**: Use the buttons to select **Batching** mode (the default) or **Streaming** mode. For details, see Ingestion Mode.
    - **Cluster base URI**: Enter the base URI for your ADX cluster.
    - **Ingestion service URI**: Displayed only in **Batching** mode. Enter the Ingestion Service URI for your ADX cluster.
    - **Database name**: Enter the name of the ADX database where the target table resides.
    - **Table name**: Enter the name of the target table.
    - **Validate database settings**: When you save or start the Destination, validates the database name and credentials that you have entered in these settings. Also validates the table name, except

when **Add mapping object** (below) is on. Defaults to toggled on. Toggle off if your Azure app does not have **both** the **Database Viewer** and the **Table Viewer** role.

- **Add mapping object**: Displayed only in **Batching** mode, this control is toggled off by default. Toggle on when you want to paste in a data mapping as a JSON object, instead of using a named data mapping. See Data Mapping Prerequisites above.
- **Data mapping**: If **Add mapping object** is off, enter the name of the desired data mapping. If **Add mapping object** is on, enter the desired data mapping as a JSON object.
- **Compression**: By default, this Destination compresses data using `gzip`; otherwise it sends the data uncompressed. This setting is not available when **Data format** is set to `Parquet`.
- **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (available only in **Batching** mode, and supported only on Linux, not Windows) exposes a **Parquet Settings** tab, where you select the Parquet schema.
- **Backpressure behavior**: Whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`. When **Ingestion mode** is set to **Streaming** mode, the **Persistent Queue** option becomes available. See **Persistent Queue Settings** below.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

3. Optionally, you can adjust the Authentication, Persistent Queue, Processing, Parquet, and Advanced settings outlined in the sections below.
4. Select **Save**, then **Commit & Deploy**.

Ingestion Mode

This Destination supports two ingestion modes:

- **Batching** (the default) stages data in a storage container from which ADX pulls batches of data, then writes them to the target ADX table. Batching works well when the Destination needs to ingest large amounts of data in short periods of time.
- **Streaming** sends data as HTTP request payloads, directly to the target ADX table, without staging them in a container first. Streaming can achieve lower latency than batching, as long as the data that the Destination ingests arrives in relatively small amounts. When in this mode, the Retries section (left tab) becomes available.

Authentication Settings

Microsoft Entra ID authentication endpoint: From the drop-down, select the Microsoft Entra ID endpoint that provides authentication tokens. To understand the available choices, see the Microsoft Entra documentation.

Tenant ID: Directory ID (tenant identifier) in Microsoft Entra ID.

Client ID: `client_id` to pass in the OAuth request parameter.

Scope: Scope to pass in the OAuth request parameter.

Use the **Authentication method** buttons to select one of these options:

- **Client secret**: Use this default option to enter the client secret that you generated for your app in the Azure portal.
- **Client secret (text secret)**: Use this option to select or create a stored text secret.
- **Certificate**: Use this option to select the certificate whose public key you register (or will register) for your app in the Azure portal. Or, create a new one.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when **Ingestion mode** is set to **Streaming** and the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues (dPQ)
- Destination Backpressure Triggers

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.

Mode	Description
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Stream or Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Stream/Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

> Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.

- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Edge CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Parquet Schemas for pointers on how to avoid problems such as data mismatches.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Edge writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: The target memory size for page segments. Generally, lower values improve reading speed, while higher values improve compression. Must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle on to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics - these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Retries

This tab is displayed when **General Settings** > **Ingestion mode** is set to **Streaming** mode.

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Edge applies the following rules:

Status Code	Action
`408, 429, 503, 504, 520.`	Retry the request.
Any other status code.	Drop the request.

Upon receiving a response code that's on the list, Cribl Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Edge continues retrying the request without increasing the time between retries any further.

By default, `429 (Too Many Requests)` is the only response code configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

The controls on this tab vary depending on the **Ingestion mode** selected on the **General Settings** tab. Below you'll find one dedicated section for the Batching, and another for the Streaming controls.

Only the **Environment** control, at the bottom of the tab, is common to both:

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Advanced Settings for Batching Mode

Flush immediately: Toggle on to bypass the data management service's aggregation mechanism. See the ADX documentation.

Retain blob on success: By default, Cribl Edge deletes each data blob once ingestion is complete. Toggle this on if you prefer to retain blobs instead.

Extent tags: Optionally, add strings or tags to partitions of the target table - Azure calls these extents or data shards.

Enforce uniqueness via tag values: Use the **Add value** button to specify a list of `ingest-by` values. Cribl Edge will then check the `ingest-by` tags of incoming extents and discard those whose values match a listed value. This mechanism for avoiding ingesting duplicate extents uses the `ingestIfNotExists` property, as described in the ADX documentation.

Report level: Level for ingestion status reporting. Options are `DoNotReport`, `FailuresOnly` (the default), and `FailuresAndSuccesses`.

Report method: Target for ingestion status reporting. Options are `Queue` (the default), `Table`, and `QueueAndTable`.

Additional fields: Optionally, enter additional configuration properties to send to the ingestion service.

Staging location: Local filesystem location in which to buffer files before compressing and moving them to the final destination. Cribl recommends that this location be stable and high-performance. Defaults to `/tmp`.

File name suffix expression: The output filename suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks.

Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ""}` ``, where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.

To prevent files from being overwritten, Cribl appends a random sequence of 6 characters to the end of their names. This also applies to prefix and suffix expressions in file names.

For example, if you set the **File name prefix expression** to `CriblExec` and set the **File name suffix expression** to `.csv`, the file name might display as `CriblExec-adPRWM.csv` with `adPRWM` appended.

File size limit (MB): Maximum uncompressed output file size. Files reaching this size will be closed and moved to the storage container. Defaults to `32`.

File open time limit (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to the storage container. Defaults to `300` seconds (5 minutes).

Idle time limit (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to the storage container. Default: `30`.

Open file limit: Maximum number of files to keep open concurrently. When exceeded, the oldest open files will be closed and moved to the storage container. Default: `100`.

Concurrent file parts limit: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send one part at a time - that is, to upload the file's contents sequentially. Defaults to `1`; highest allowed value is `10`.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined Min free disk space amount.

Add output ID: Toggle on if you want Cribl Edge to append the Destination name to staging directory pathnames. This can make it easier to organize and troubleshoot when you have multiple Destinations populating staging directories.

Remove empty staging directories: When toggled on (the default), Cribl Edge deletes empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).
- **Directory batch size**: Specifies how many directories are scanned per batch during automatic cleanup of empty staging directories. Set between `10` and `10000`, defaults to `1000`. Higher values speed up cleanup but increase memory usage.

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Advanced Settings for Streaming Mode

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Edge hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Events-per-request limit: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Validate server certs: When toggled on (default) Cribl Edge will reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (such as the system's CA, for example).

Round-robin DNS: Toggle on to enable round-robin DNS lookup across multiple IP addresses, IPv4 and IPv6. When a DNS server resolves a Fully Qualified Domain Name (FQDN) to multiple IP addresses, Cribl Edge will

sequentially use each address in the order they are returned by the DNS server for subsequent connection attempts.

Keep alive: By default, Cribl Edge sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Edge to close the connection immediately after sending a request.

Azure Permissions

When configuring an Azure Destination in Cribl Edge, you must grant the necessary permissions for it to interact with your Azure environment. Cribl recommends creating an Azure service principal with the minimum required permissions using Azure role-based access control (Azure RBAC). This approach ensures Cribl Edge has a dedicated identity with precisely the access it needs, following the principle of least privilege.

The minimum permissions required for Destinations are:

- **Database Ingestor:** For the database being written to.
- **Database Viewer:** Required if **Validate database settings** is enabled.

OR

- **Table Ingestor:** For the table being written to.
- **Database Viewer:** Required if **Validate database settings** is enabled.

See Manage Azure Data Explorer cluster permissions and Manage Azure Data Explorer database permissions in the Azure portal in the official Microsoft documentation for more information.

Internal Fields

Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Resources

For examples of configuring Cribl Edge to interoperate with Azure services, see these guides:

- Preparing the Azure Workspace.

- SSO with Microsoft Entra ID (Cribl.Cloud).
- SSO with Microsoft Entra ID (On-Prem).

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

12.3.4.3. Azure Event Hubs Destination

Cribl Edge supports sending data to Azure Event Hubs using the Kafka protocol.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Azure Event Hubs uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Edge must send events directly to receivers. You might need to adjust your firewall rules to allow this traffic.

For configuration examples, see Resources below.

See Microsoft's Compare Azure Event Hubs Tiers topic to configure tiers whose features and quotas match your desired data volume and throughput.

Configuring Cribl Edge to Output to Azure Event Hubs

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Azure Event Hubs definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Brokers**: List of Event Hub Kafka brokers to connect to. (For example, `yourdomain.servicebus.windows.net:9093`.) Find the hostname in Shared Access Policies, in the host portion of the primary or secondary connection string. If omitted, the port will default to `9093`.
    - **Event Hub name**: The name of the Event Hub (a.k.a., Kafka Topic) on which to publish events. Can be overwritten using the `__topicOut` field.
3. Next, you can configure the following **Optional Settings**:
    - **Acknowledgments**: Control the number of required acknowledgments. Defaults to `Leader`. Setting this control to `Leader` or `All` may significantly slow throughput. If the impact is too great for your use case, set this control to `None`.

- **Record data format**: Format to use to serialize events before writing to the Event Hub Kafka brokers. Defaults to `JSON`.
  - `JSON` serializes the entire event from your Pipeline, including all metadata and enriched fields, into a single JSON object.
  - `Field _raw` sends only the contents of the `_raw` field as the payload. This option provides maximum throughput and minimal overhead.
- **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the TLS, Authentication, Persistent Queue, Processing, Parquet, Retries and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Client Side)

Use TLS: Defaults to toggled on.

Validate server certs: Reject certificates that are **not** authorized by a trusted CA (for example, the system's CA). Default is toggled on.

Authentication

Authentication parameters to use when connecting to brokers. Using TLS is highly recommended.

Enabled: If toggled on (default), this section's remaining settings are displayed, and all are required settings.

SASL mechanism: SASL (Simple Authentication and Security Layer) authentication mechanism to use with Kafka brokers. Defaults to `PLAIN`, which exposes Basic Authentication options that rely on Azure Event Hubs connection strings. Select `OAUTHBEARER` to enable OAuth Authentication via a different set of options.

Basic Authentication

Selecting the `PLAIN` SASL mechanism provides the options listed in this section.

Username: The username for authentication. For Event Hubs, this should always be `$ConnectionString`.

Authentication method: Use the buttons to select one of these options:

- **Manual**: Use this default option to enter the primary or secondary connection string from the Event Hubs workspace. Exposes a **Password** field for this purpose.

- **Secret**: This option exposes a **Password (text secret)** drop-down, in which you can select a stored secret that references an Event Hubs connection string. The secret can reside in Cribl Edge's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need a new secret.

Connection String Format

Either authentication method above uses an Azure Event Hubs connection string in this format:

```
Endpoint=sb://<FQDN>/;SharedAccessKeyName=<your-shared-access-key-name>;SharedAccessKey=<your-shared-access-key-value>
```

A fictitious example is:

```
Endpoint=sb://dummynamespace.servicebus.windows.net/;SharedAccessKeyName=DummyAccessKeyN
```

OAuth Authentication

Selecting the `OAUTHBEARER` SASL mechanism provides the options listed in this section.

Microsoft Entra ID authentication endpoint: Specifies the Microsoft Entra ID endpoint from which to acquire authentication tokens. Defaults to `https://login.microsoftonline.com`. You can instead select `https://login.microsoftonline.us` or `https://login.partner.microsoftonline.cn`.

Client ID: Enter the `client_id` to pass in the OAuth request parameter.

Tenant identifier: Enter your Microsoft Entra ID subscription's directory ID (tenant ID).

Scope: Enter the scope to pass in the OAuth request parameter. This will be of the form: `https://<Event-Hubs-Namespace-Host-name>/.default`. (For example, for an Event Hubs Namespace > Host name: `goatyoga.servicebus.windows.net`, **Scope**: `https://goatyoga.servicebus.windows.net/.default`.)

Authentication method: Use the buttons to select one of these options:

- **Manual**: This default option exposes a **Client secret** field, in which to directly enter the `client_secret` to pass in the OAuth request parameter.
- **Secret**: Exposes a **Client secret (text secret)** drop-down, in which you can select a stored secret that references the `client_secret`. A **Create** link is available to define a new secret.
- **Certificate**: Exposes a **Certificate** drop-down, in which you can select a stored certificate. A **Create** link is available to define a new cert.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination

has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater

than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this

mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Retry limit: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2`–`20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Record size limit (KB, uncompressed): Maximum size (KB) of each record batch before compression. Setting should be < `message.max.bytes` settings in Kafka brokers. Defaults to `768`.

Events-per-batch limit: Maximum number of events in a batch before forcing a flush. Defaults to `1000`.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Connection timeout (ms): Maximum time to wait for a successful connection. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour).

Request timeout (ms): Maximum time to wait for a successful request. Defaults to `60000` ms (1 minute).

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Edge initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Destination from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Destination to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Working with Event Timestamps

By default, when an incoming event reaches this Destination, the underlying Kafka JS library adds a `timestamp` field set to the current time at that moment. The library gets the current time from the `Date.now()` JavaScript method. Events that this Destination sends to downstream Kafka receivers include this `timestamp` field.

Some production situations require the `timestamp` value to be the time an incoming event was originally created by an upstream sender, not the current time of its arrival at this Destination. For example, suppose the events were originally created over a wide time range, and arrive at the Destination hours or days later. In this case, the original creation time might be important to retain in events Cribl Edge sends to downstream Kafka receivers.

Here is how to satisfy such a requirement:

1. In a Pipeline that routes events to this Destination, use an Eval Function to add a field named `__kafkaTime` and write the incoming event's original creation time into that field. The value of `__kafkaTime` **must** be in Unix time (either seconds or milliseconds - both will work). For context, see this explanation of the related fields `_time` and `__origTime`.
2. This Destination will recognize the `__kafkaTime` field and write its value into the `timestamp` field. (This is similar to the way you can use the `__topicOut` field to overwrite a topic setting, as described above.)

If the `__kafkaTime` field is **not** present, the Destination will apply the default behavior (using `Date.now()`) described previously.

Azure Permissions

When configuring an Azure Destination in Cribl Edge, you must grant the necessary permissions for it to interact with your Azure environment. Cribl recommends creating an Azure service principal with the minimum required permissions using Azure role-based access control (Azure RBAC). This approach ensures Cribl Edge has a dedicated identity with precisely the access it needs, following the principle of least privilege.

The minimum permissions required for Destinations are:

- **Azure Event Hubs Data Sender**

See Authorize access to Azure Event Hubs resources using Microsoft Entra ID in the official Microsoft documentation for more information.

Internal Fields

Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__topicOut`
- `__key`
- `__headers`
- `__keySchemaIdOut`
- `__valueSchemaIdOut`

Resources

For examples of configuring Cribl Edge to interoperate with Azure services, see these guides:

- Preparing the Azure Workspace.
- SSO with Microsoft Entra ID (Cribl.Cloud).
- SSO with Microsoft Entra ID (On-Prem).

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Destination Integrations: Azure Event Hubs short course. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation,

12.3.4.4. Azure Monitor Logs Destination

The Azure Monitor Log Destination is now deprecated. The replacement for routing data to the Microsoft Log Analytics platform is the Microsoft Sentinel Destination. This change aligns with the Microsoft recommendation to use the Azure Monitor Logs Ingestion API, which the Microsoft Sentinel Destination is built upon.

Microsoft is retiring the legacy HTTP Data Collector API on September 14, 2026. For details, see the Microsoft deprecation notice: Send log data to Azure Monitor by using the HTTP Data Collector API (deprecated).

Cribl Edge supports sending data to Azure Monitor Logs.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

For configuration examples, see Resources below.

Configure Cribl Edge to Output to Azure Monitor Logs

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Azure Monitor Logs definition.
    - **Description**: Optionally, enter a description.
    - **Log type**: The Record Type of events sent to this LogAnalytics workspace. Defaults to `Cribl`. Use only letters, numbers, and `_` characters. (See Microsoft's Azure Monitor documentation.) Can be overwritten by an event's `__logType` field.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Displays fields in which to enter your Azure Log Analytics **Workspace ID** and your Primary or Secondary Shared **Workspace key**. See the Azure Monitor documentation.

- **Secret**: This option exposes a **Secret key pair** drop-down, in which you can select a stored secret that references the credentials described above. A **Create** link is available to store a new, reusable secret.

4. Next, you can configure the following **Optional Settings**:
   - **DNS name of API endpoint**: Enter the DNS name of the Log API endpoint that sends log data to a Log Analytics workspace in Azure Monitor. Defaults to: `.ods.opinsights.azure.com.` Cribl Edge will add a prefix and suffix around this DNS name, to construct a URI in this format: `https://<Workspace_ID><your_DNS_name>/api/logs?api-version=<API version>`.
   - **Resource ID**: Resource ID of the Azure resource to associate the data with. This populates the `_ResourceId` property, and allows the data to be included in resource-centric queries. (Optional, but if this field is not specified, the data will not be included in resource-centric queries.)
   - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at

> the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

> If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

Honor Retry-After header: Toggle on to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream/Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. Any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. Toggle off to ignore all `Retry-After` headers.

Default Retry Behavior: By default, Cribl Stream/Edge applies predefined retry strategies for certain failed requests to the Destination using an exponential backoff algorithm. You can override these settings by manually configuring the retry behavior for a particular error code.

Destinations created before the 4.16.0 release do not support the default `4xx` series retry behavior. If your Destination was created prior to this release and you'd like it to support the behavior, reconfigure the Destination.

To retry requests, Cribl Stream/Edge applies the following rules by default:

Status Code	Action
Any in the `1xx`, `3xx` series	Drop the request

Status Code	Action
`401`, `403`, `408`, `429` errors	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached
Any other `4xx` series	Drop the request
Any in the `5xx` series	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached

By default, any `429 (Too Many Requests)` response that is not listed in the retry settings is treated as a non-retryable `4xx` error and dropped. If you want `429` responses retried, ensure `429` is included in the **Settings for failed HTTP requests**.

Settings for failed HTTP requests: You can also manually configure Cribl Stream/Edge to automatically retry requests that receive particular HTTP response status codes.

Upon receiving a response code that's on the list, Cribl Stream/Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream/Edge continues retrying the request without increasing the time between retries any further.

If the sender (which manages the connection to the Destination) is at capacity, it will not accept any incoming events. These incoming events originate internally from a previous stage of the data flow when Destinations send outbound requests to their respective external services, and they include retry requests and new requests. Any events that were already in transit when the sender reached capacity will continue to be processed downstream.

Sender capacity is freed up when an outgoing request succeeds or encounters a non-retryable error. When the sender has available capacity again, it will resume accepting incoming events. This capacity management is influenced by the number of active connections and configured limits, such as concurrency and buffer sizes. If a Pipeline sends events faster than the Destination can process, the buffers may fill up, leading to backpressure and `Sender at capacity` warnings. This backpressure prevents the sender from accepting additional requests until capacity is restored.

For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.

- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: Toggle on to automatically retry requests that have timed out and display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle on to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle on to enable round-robin DNS lookup across multiple IP addresses, IPv4 and IPv6. When a DNS server resolves a Fully Qualified Domain Name (FQDN) to multiple IP addresses, Cribl Edge will sequentially use each address in the order they are returned by the DNS server for subsequent connection attempts.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Edge hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `1024` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Events-per-request limit: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Edge will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Azure Monitor Limitations

The Azure Monitor Logs architecture limits the number of columns per table, characters per column name, and other parameters. For details, see Microsoft's Azure Monitor Service Limits topic.

Azure will drop logs if your data exceeds these limits. To diagnose this, you can search in the Azure Data Explorer console with a query like this:

```
Operation | summarize count() by Detail
```

...for error messages of this form:

```
Data of type <type> was dropped: The number of custom fields <number> is above the limit of 500 fields per data type.
```

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Edge will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular Destination when there is a constant flow of events.
- If keepalives are not supported by the server (or if the server closes a pooled connection while idle), a new connection will be established for the next request.
- When resolving the Destination's hostname, Cribl Edge will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between destination cluster nodes.

Azure Permissions

Azure Monitor Logs does not require any specific permissions.

Resources

For examples of configuring Cribl Edge to interoperate with Azure services, see these guides:

- Preparing the Azure Workspace.
- SSO with Microsoft Entra ID (Cribl.Cloud).
- SSO with Microsoft Entra ID (On-Prem).

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

12.3.4.5. Microsoft Sentinel Destination

Cribl Edge can send log and metric events to the Microsoft Sentinel SIEM. This Destination encrypts and sends events via the HTTPS protocol. The supported environments include:

- Azure Public Cloud
- Azure US Government Cloud
- Microsoft Azure operated by 21Vianet

Type: Streaming | TLS Support: No | PQ Support: Yes

For a walk-through of configuring this Destination with Microsoft Sentinel, see our Microsoft Sentinel SIEM Integration guide. Also see these Packs on the Cribl Packs Dispensary, which provide processing Pipelines that you can import and adapt to your needs:

- Microsoft Sentinel Pack.
- Microsoft Sentinel Syslog Pack.
- Microsoft Sentinel Common Security Log Pack.

Ensure that the field names in your data match the schema defined in the Data Collection Rule (DCR) for Microsoft Sentinel. The DCR specifies the expected structure, including field names and types. Mismatched field names can cause dropped events. This Destination sends out individual top-level fields, not a combined `_raw` (or similar) field.

Prerequisites

Before configuring your Microsoft Sentinel Destination(s), you have to prepare the Azure workspace, create data collection rules (DCRs), and obtain the ingestion URL that will receive the data from your Destination(s).

Complete these preparatory steps, which are described in Microsoft Sentinel Integration, before configuring the Microsoft Sentinel Destination. That topic explains the overall Sentinel/Cribl workflow, provides necessary context, and shows you how to obtain the values you'll need to configure the Destination.

If you intend to send multiple event types, or tables, to Sentinel, you'll need a separate Destination for each event type. There are three approaches to configure this:

- **Multiple Destinations**: Configure separate Microsoft Sentinel Destinations, each with its own URL, and use Routes to direct data to the appropriate Destination.
- **Multiple Destinations and a Output Router**: Use an Output Router to split events from a single Source into multiple Destinations, each corresponding to a specific table.

- **Single Destination and overwriting the URL in a Pipeline**: Configure a single Microsoft Sentinel Destination and dynamically overwrite the URL within Pipelines using the `__url` internal field to direct events to the correct table.

Behind the scenes, this Destination uses the Azure Monitor Logs Ingestion API.

Configure Cribl Edge to Output to Microsoft Sentinel

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this HTTP output definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Endpoint configuration**: Use the buttons to select **URL** or **ID**. This specifies the method for configuring the endpoint. For details, see Endpoint Configuration Options
3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication Settings, Processing, Retries and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Endpoint Configuration Options

For Syslog, Cribl recommends starting from the Syslog DCR template in the Cribl-Microsoft GitHub repository. This template defines a stream name of `Custom-Syslog` and routes data into the Sentinel Syslog table.

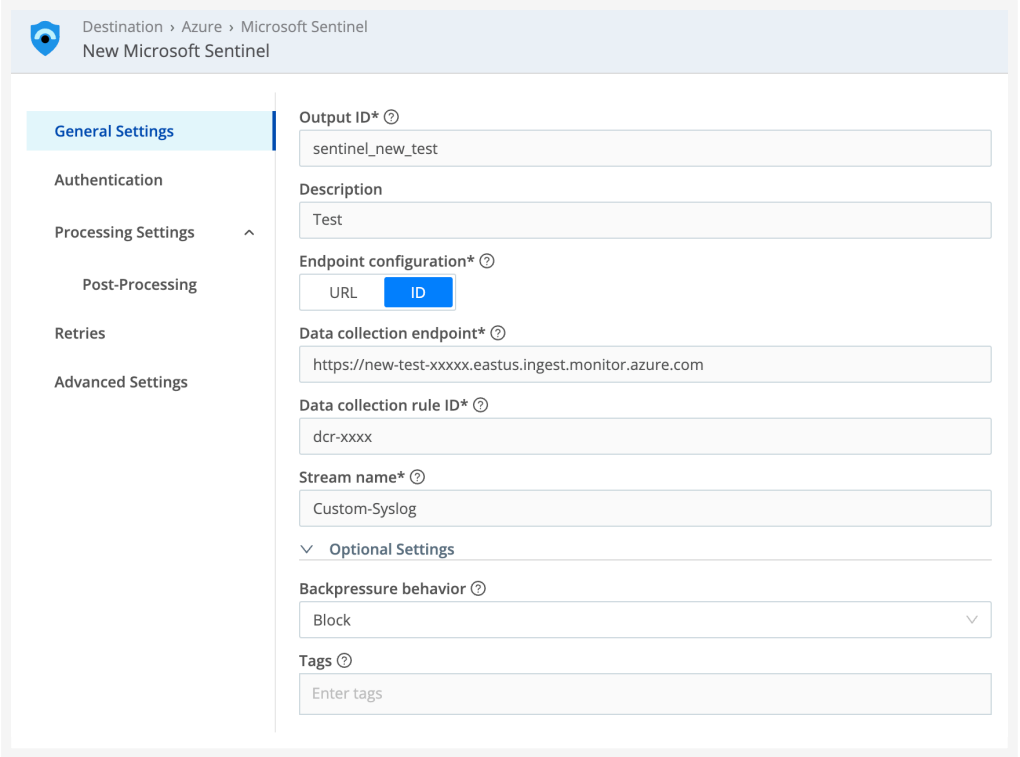
After you create a data collection rule (DCR) from this template in Azure, you will use its values when configuring the Microsoft Sentinel Destination.

Note that the Syslog template is provided under the `DataCollectionRules` path and is intended for the **DCR kind:direct** approach, matching the corresponding method described in preparing the Azure workspace for Cribl integrations. If your deployment instead uses a Data Collection Endpoint (DCE), use the DCE-based template from the same repository and follow the DCE path in the guide.

The **Endpoint configuration** setting offers the following options:

- **URL** - lets you directly enter the data collection endpoint. This method is the simplest way of configuring the endpoint. See Preparing Your Azure Environment for more information.
- **ID** - lets you enter individual IDs that Cribl Edge uses to create the URL used as the data collection endpoint.

Selecting `URL` exposes the following field.



URL: Endpoint URL to send events to. The internal field `__url`, where present in events, will override the `URL` and `ID` values. See Internal Fields below.

Selecting `ID` exposes the following fields.

Data collection endpoint: The Azure `LogsIngestion` URL in the format `https://<endpoint-name>.<identifier>.<region>.ingest.monitor.azure.com`.

Data collection rule ID: Immutable ID for the DCR.

Stream name: Name of the Sentinel table in which to store events. For DCR-based ingestion, this value must exactly match the stream/table name defined in the Azure DCR template, not the friendly table name shown in the Sentinel UI. For the Cribl Syslog template, the correct stream/table name is `Custom-Syslog`. If Stream name does not exactly match the table name in the template, data may fail to land in the expected Sentinel table.

Microsoft Sentinel Destination settings

Optional Settings

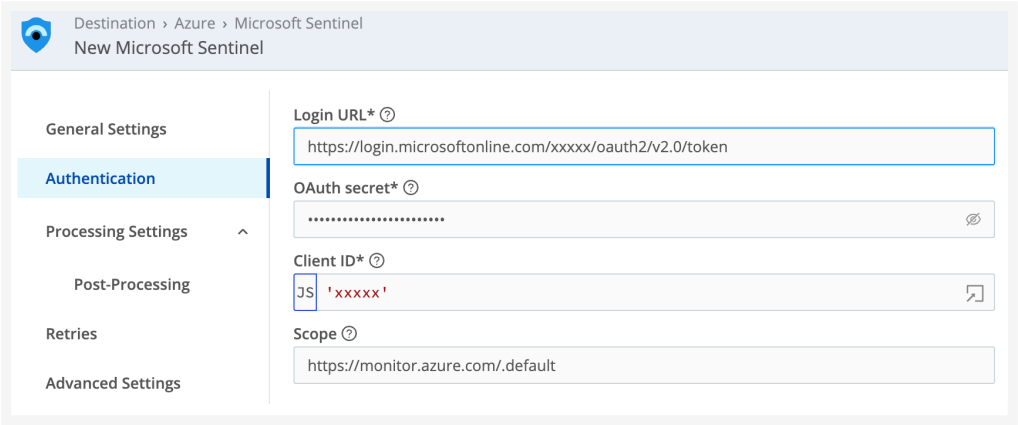
Authentication Settings

In Cribl Stream, open your **Microsoft Sentinel Destination** and select **Authentication**. Fill in the fields as follows:

Login URL: Endpoint for the OAuth API call. Use the OAuth2 token endpoint that matches your cloud shown in the Azure **Endpoints** view for your Microsoft Entra app.

Typical formats are:

- Azure Public Cloud: `https://login.microsoftonline.com/<tenant-id>/oauth2/v2.0/token`
- Azure US Government Cloud: `https://login.microsoftonline.us/<tenant-id>/oauth2/v2.0/token`
- Microsoft Azure operated by 21Vianet: `https://login.chinacloudapi.cn/<tenant-id>/oauth2/v2.0/token`



OAuth secret source: Select how to provide the client secret value you created for the app:

- **Inline**: Enter the secret directly in **OAuth secret**. This is the default.
- **Secret**: Use **OAuth secret (text secret)** to select a local or global stored text secret, or select **Create text secret**.

Client ID: JavaScript expression used to compute the application (client) ID for the Azure application. Can be a constant.

Scope: The OAuth scope to the appropriate endpoint URL for your Azure environment. This ensures that your OAuth tokens are valid and that your data is correctly ingested into Microsoft Sentinel. This setting should match the specific endpoint for your Azure environment:

- Azure Public Cloud (default): `https://monitor.azure.com/.default`
- Azure US Government Cloud: `https://monitor.azure.us/.default`
- Microsoft Azure operated by 21Vianet: `https://monitor.azure.cn/.default`

Microsoft Sentinel Destination auth settings

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at

> the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

> If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

Honor Retry-After header: Toggle on to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream/Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. Any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. Toggle off to ignore all `Retry-After` headers.

Default Retry Behavior: By default, Cribl Stream/Edge applies predefined retry strategies for certain failed requests to the Destination using an exponential backoff algorithm. You can override these settings by manually configuring the retry behavior for a particular error code.

To retry requests, Cribl Stream/Edge applies the following rules by default:

Status Code	Action
Any in the `1xx`, `3xx` series	Drop the request
`408`, `429` errors	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached
Any other `4xx` series	Drop the request

Status Code	Action
Any `5xx` series	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached

By default, any `429 (Too Many Requests)` response that is not listed in the retry settings is treated as a non-retryable `4xx` error and dropped. If you want `429` responses retried, ensure `429` is included in the **Settings for failed HTTP requests**.

Settings for failed HTTP requests: You can also manually configure Cribl Stream/Edge to automatically retry requests that receive particular HTTP response status codes.

Upon receiving a response code that's on the list, Cribl Stream/Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream/Edge continues retrying the request without increasing the time between retries any further.

If the sender (which manages the connection to the Destination) is at capacity, it will not accept any incoming events. These incoming events originate internally from a previous stage of the data flow when Destinations send outbound requests to their respective external services, and they include retry requests and new requests. Any events that were already in transit when the sender reached capacity will continue to be processed downstream.

Sender capacity is freed up when an outgoing request succeeds or encounters a non-retryable error. When the sender has available capacity again, it will resume accepting incoming events. This capacity management is influenced by the number of active connections and configured limits, such as concurrency and buffer sizes. If a Pipeline sends events faster than the Destination can process, the buffers may fill up, leading to backpressure and `Sender at capacity` warnings. This backpressure prevents the sender from accepting additional requests until capacity is restored.

For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: Toggle on to automatically retry requests that have timed out and display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Toggle off if you want Cribl Edge to accept such certificates. Defaults to toggled on.

Round-robin DNS: Toggle on to enable round-robin DNS lookup across multiple IP addresses, IPv4 and IPv6. When a DNS server resolves a Fully Qualified Domain Name (FQDN) to multiple IP addresses, Cribl Edge will sequentially use each address in the order they are returned by the DNS server for subsequent connection attempts.

Compress: By default, Cribl Edge enables gzip-compress to compress the payload body before sending. Toggle this off if you want Cribl Edge not to gzip-compress the payload body.

Keep alive: By default, Cribl Edge sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Edge to close the connection immediately after sending a request.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Edge hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `1000` KB, the maximum allowed size of API call. Be aware that high values can cause high memory usage per Worker Node, especially if a dynamically constructed URL (see Internal Fields) causes this Destination to send events to more than one URL. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow

larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Body size limit** settings.

Events-per-request limit: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass to all events as additional HTTP headers. Values will be sent encrypted. You can also add headers dynamically on a per-event basis in the `__headers` field. See Internal Fields below.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Edge will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__criblMetrics`
- `__url`
- `__headers`

If an event contains the internal field `__criblMetrics`, Cribl Edge will send it to the HTTP endpoint as a metric event. Otherwise, Cribl Edge will send it as a log event.

If an event contains the internal field `__url`, that field's value will override the **General Settings** > **URL** value. This way, you can determine the endpoint URL dynamically.

For example, you could create a Pipeline containing an Eval Function that adds the `__url` field, and connect that Pipeline to your Microsoft Sentinel Destination. Configure the Eval Function to set `__url`'s value to a URL that varies depending on a global variable, or on some property of the event, or on some other dynamically-generated value that meets your needs.

If an event contains the internal field `__headers`, that field's value will be a JSON object containing Name-value pairs, each of which defines a header. By creating Pipelines that set the value of `__headers` according to conditions that you specify, you can add headers dynamically.

For example, you could create a Pipeline containing Eval Functions that add the `__headers` field, and connect that Pipeline to your Microsoft Sentinel Destination. Configure the Eval Functions to set `__headers` values to Name-value pairs that vary depending on some properties of the event, or on dynamically-generated values that meet your needs.

Here's an overview of how to add headers:

- To add "dynamic" (a.k.a. "custom") headers to some events but not others, use the `__headers` field.
- To define headers to add to **all** events, use **Advanced Settings** > **Extra HTTP Headers**.
- An event can include headers added by both methods. So if you use `__headers` to add `{ "api-key": "foo" }` and **Extra HTTP Headers** to add `{ "goat": "Kid A" }`, you'll get both headers.
- Headers added via the `__headers` field take precedence. So if you use `__headers` to add `{ "api-key": "foo" }` and **Extra HTTP Headers** to add `{ "api-key": "bar" }`, you'll get only one header, and that will be `{ "api-key": "foo" }`.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Edge will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, it will throw away the connection and attempt a new one. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), Cribl Edge will establish a new connection for the next request.
- When resolving the Destination's hostname, Cribl Edge will pick the first IP in the list for use in the next

12.3.5. Elastic

You can send data from Cribl Edge to the following Elastic services:

Destination	Description
Elasticsearch	Send events to an Elasticsearch cluster using the Bulk API
Elastic Cloud	Send events to Elastic Cloud

12.3.5.1. Elasticsearch Destination

Cribl Edge can send events to an Elasticsearch cluster using the Bulk API. As of v.3.3, Cribl Edge supports Elastic data streams.

Use the Elastic Cloud Destination if you are exclusively targeting Elastic Cloud and prefer a simpler, optimized configuration process.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

For an example of using Cribl Edge to parse and enrich inbound events for Elasticsearch, see our Splunk to Elasticsearch topic.

Configure Cribl Edge to Output to Elasticsearch

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Elasticsearch Destination definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: Toggle on (default) to specify multiple bulk API URLs and load weights. If toggled off and you notice that Cribl Edge is not sending data to all possible IP addresses, enable **Advanced Settings** > **Round-robin DNS**.
    - **Bulk API URL or Cloud ID**: Specify either an Elasticsearch cluster or Elastic Cloud deployment to send events to. For an Elasticsearch cluster, enter a URL (for example, `http://<myElasticCluster>:9200/_bulk`). For an Elastic Cloud deployment, enter its Cloud ID. This setting is not available when **Load balancing** is enabled.
    - **Index or data stream**: Enter a JavaScript expression that evaluates to the name of the Elastic data stream or Elastic index where you want events to go. The expression is evaluated for each event, can evaluate to a constant value, and must be enclosed in quotes or backticks. An event's `__index` field can overwrite the index or data stream name.

3. Under **Authentication**, toggle **Authentication enabled** on to display **Authentication method** dropdown. Select one of these options:
    - **Manual**: Enter your credentials directly in the resulting **Username** and **Password** fields.
    - **Secret**: Exposes a **Credentials secret** drop-down, in which you can select a stored secret that references the credentials described above. A **Create** link is available to store a new, reusable secret.
    - **Manual API Key**: Exposes an **API key** field to directly enter your Elasticsearch API key.
    - **Secret API Key**: Exposes an **API key (text secret)** drop-down, in which you can select a stored text secret that references your Elasticsearch API key. A **Create** link is available to store a new, reusable secret.
4. Next, you can configure the following **Optional Settings**:
    - **Exclude current host IPs**: This toggle appears when **Load balancing** is toggled on. It determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Default is toggled off, which keeps the current host available for load balancing.
    - **Type**: Specify document type to use for events. An event's `__type` field can overwrite this value.
    - **Backpressure behavior**: Specify whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Bulk API URLs

Use the **Bulk API URLs** table to specify a known set of receivers on which to load-balance data. To specify more receivers on new rows, click **Add URL**. Each row provides the following fields:

URL: Specify the URL to an Elastic node to send events to - for example, `http://elastic:9200/_bulk`

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (> `0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Edge will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

When you first enable load balancing, or if you edit the load weight once your data is load-balanced, give the logic time to settle. The changes might take a few seconds to register.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.

- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

Honor Retry-After header: Toggle on to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream/Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. Any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. Toggle off to ignore all `Retry-After` headers.

Default Retry Behavior: By default, Cribl Stream/Edge applies predefined retry strategies for certain failed requests to the Destination using an exponential backoff algorithm. You can override these settings by manually configuring the retry behavior for a particular error code.

Destinations created before the 4.16.0 release do not support the default `4xx` series retry behavior. If your Destination was created prior to this release and you'd like it to support the behavior, reconfigure the Destination.

To retry requests, Cribl Stream/Edge applies the following rules by default:

Status Code	Action
Any in the `1xx`, `3xx` series	Drop the request
`401`, `403`, `408`, `429` errors	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached
Any other `4xx` series	Drop the request
Any in the `5xx` series	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached

By default, any `429 (Too Many Requests)` response that is not listed in the retry settings is treated as a non-retryable `4xx` error and dropped. If you want `429` responses retried, ensure `429` is included in the **Settings for failed HTTP requests**.

Settings for failed HTTP requests: You can also manually configure Cribl Stream/Edge to automatically retry requests that receive particular HTTP response status codes.

Upon receiving a response code that's on the list, Cribl Stream/Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream/Edge continues retrying the request without increasing the time between retries any further.

If the sender (which manages the connection to the Destination) is at capacity, it will not accept any incoming events. These incoming events originate internally from a previous stage of the data flow when Destinations send outbound requests to their respective external services, and they include retry requests and new requests. Any events that were already in transit when the sender reached capacity will continue to be processed downstream.

Sender capacity is freed up when an outgoing request succeeds or encounters a non-retryable error. When the sender has available capacity again, it will resume accepting incoming events. This capacity management is influenced by the number of active connections and configured limits, such as concurrency and buffer sizes. If a Pipeline sends events faster than the Destination can process, the buffers may fill up, leading to backpressure and `Sender at capacity` warnings. This backpressure prevents the sender from accepting additional requests until capacity is restored.

For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: Toggle on to automatically retry requests that have timed out and display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a trusted CA (for example, the system's CA). Default is toggled on.

Round-robin DNS: Toggle on to enable round-robin DNS lookup across multiple IP addresses, IPv4 and IPv6. When a DNS server resolves a Fully Qualified Domain Name (FQDN) to multiple IP addresses, Cribl Edge will sequentially use each address in the order they are returned by the DNS server for subsequent connection attempts. (This option is visible only when the **General Settings** > **Load balancing** option is toggled off.)

Compress: Compresses the payload body before sending. Default is toggled on (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Edge hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Events-per-request limit: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (s): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Extra parameters: Name-value pairs to pass as additional parameters. If you are using Elastic ingest pipelines, specify an extra parameter whose name is `pipeline` and whose value is the name of your pipeline, similar to these examples.

Elastic version: Determines how to format events. For Elastic Cloud, you must explicitly set version `7.x`. For other Elasticsearch clusters, the `Auto` default will discover the downstream Elasticsearch version automatically, but you have the option to explicitly set version `6.x` or `7.x`.

Elastic pipeline: To send data to an Elastic Ingest pipeline, optionally enter that pipeline's name as a constant. Or, enter a JavaScript expression that evaluates outgoing events and sends matching events to the desired Elastic Ingest pipeline(s). Cribl Edge will first interpret your entry as a constant and try to find a matching value in the event. If it finds no matching value, it will evaluate your **Elastic pipeline** entry as an expression.

For example, the expression `sourcetype=='access_common'?'cribl_pipeline':undefined` matches events whose `sourcetype` is `access_common`, and sends them to an Elastic Ingest pipeline named `cribl_pipeline`.

You can also specify the name of the pipeline in an event field. For example, `myPipelineField` would use the value from the event's `myPipelineField` property (if present) to identify the Elastic Ingest pipeline to process the event. Alternately, the expression `myPipelineField != null ? myPipelineField : undefined`

would also identify this field. If the event does not contain such a field, `myPipelineField != null ? myPipelineField : 'theDefaultIndex'` will provide a default index. With this approach, you can override the Elastic Ingest pipeline at the event level.

See also the Elasticsearch Source documentation.

The next two fields appear only when you toggle **Load balancing** on in the **General Settings**.

DNS resolution period (seconds): Re-resolve any hostnames each time this interval recurs, and pick up destinations from the A records. Defaults to `600` seconds.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds.

Include document_id: Toggle off to omit the `document_id` field when sending events to an Elastic TSDS (time series data stream).

Write action: Action to use when writing events. Set this option to `Create` (default) when writing to a data stream, which is append-only. Set this option to `Index` only when you write directly to an index and need to update existing records. `Index` will fail if you use it to write to a data stream.

Failed request logging mode: Determines which data is logged when a request fails. Use the drop-down to select one of these options:

- `None` (default).
- `Payload`.
- `Payload + Headers`. Use the **Safe Headers** field below to specify the headers to log. If you leave that field empty, all headers are redacted, even with this setting.

Safe headers: List the headers you want to log, in plain text.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Recommended Settings

The following tables provide recommended destination settings for production deployments, organized by deployment type. These values are tuned for high-throughput ingestion and aligned with Elastic Agent tuning presets. Apply the full set of values for your deployment type. Do not mix values between deployment types.

One Cribl Edge Worker Process handles data from many sources simultaneously, so concurrency and batch sizes need to be higher than what you would configure for a single Elastic Agent.

On-Prem (Bare Metal / VM)

For self-hosted Elasticsearch clusters with dedicated ingest nodes, this configuration aligns with the Elastic Agent Throughput preset.

Setting	Value
Validate server certs	On
Compress	On
Request timeout	`120` seconds
Request concurrency	`12`
Body size limit (KB)	`15360` KB
Events-per-request limit	`8000`
Flush period (s)	`30` seconds

Dedicated ingest nodes handle the higher concurrency well. The 15 MB **Body size limit (KB)** sits comfortably under Elasticsearch's 100 MB default `http.max_content_length`. Without a cloud load balancer in the path, connections stay stable. A 30-second **Flush period (s)** keeps data fresher than the default for observability use cases.

ECK (Elastic Cloud on Kubernetes)

For Elasticsearch clusters running on Kubernetes through ECK, this configuration aligns with a guarded Throughput preset.

Setting	Value
Validate server certs	On
Compress	On
Request timeout	`120` seconds
Request concurrency	`10`
Body size limit (KB)	`10240` KB
Events-per-request limit	`6000`
Flush period (s)	`30` seconds

Load the ECK CA certificate into Cribl Edge and keep **Validate server certs** enabled. Kubernetes Ingress controllers can enforce their own body size limits, so 10 MB is a safe default for **Body size limit (KB)**. The lower **Request concurrency** accommodates pod scheduling during rolling upgrades. For **Bulk API URL or Cloud ID**, use the stable ECK Kubernetes Service address instead of individual Elasticsearch pod IP addresses. The Service handles routing requests to the pods.

Field Normalization

When sending data to Elasticsearch, this Destination applies the following field normalization to align with the Elasticsearch schema:

- Renames `_time` to `@timestamp`, maintaining millisecond precision.
- Renames `host` to `host.name`.

See also our Elasticsearch Source documentation's **Field Normalization** section.

Internal Fields

Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__id`
- `__type`
- `__index`
- `__host`

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Edge will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), a new connection will be established for the next request.
- When resolving the Destination's hostname with load balancing disabled, Cribl Edge will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between Elasticsearch cluster nodes.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly

12.3.5.2. Elastic Cloud Destination

Cribl Edge can send events to Elastic Cloud.

Use the Elasticsearch Destination if you need flexibility to support both self-hosted and Elastic Cloud deployments and require advanced configuration options.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

For an example of using Cribl Edge to parse and enrich inbound events for Elasticsearch, see our Splunk to Elasticsearch topic.

Configure Cribl Edge to Output to Elastic Cloud

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Elastic Cloud Destination definition.
    - **Description**: Optionally, enter a description.
    - **Cloud ID**: Enter the Cloud ID of the Elastic Cloud environment where you want to send events. You'll find it on the Deployments overview page of your Elastic Cloud environment.
    - **Data stream or index**: Enter a JavaScript expression that evaluates to the name of the Elastic data stream or Elastic index where you want events to go. The expression is evaluated for each event, can evaluate to a constant value, and must be enclosed in quotes or backticks. An event's `__index` field can overwrite the index or data stream name.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Enter your credentials directly in the resulting **Username** and **Password** fields.
    - **Secret**: Exposes a **Credentials secret** drop-down, in which you can select a stored secret that references the credentials described above. A **Create** link is available to store a new, reusable secret.
    - **Manual API Key**: Exposes an **API key** field to directly enter your Elasticsearch API key.

- **Secret API Key**: Exposes an **API key (text secret)** drop-down, in which you can select a stored text secret that references your Elasticsearch API key. A **Create** link is available to store a new, reusable secret.

4. Next, you can configure the following **Optional Settings**:
   - **Backpressure behavior**: Specify whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but

decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

> **Deprecation Notice**
>
> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

> Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

Honor Retry-After header: Toggle on to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream/Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. Any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. Toggle off to ignore all `Retry-After` headers.

Default Retry Behavior: By default, Cribl Stream/Edge applies predefined retry strategies for certain failed requests to the Destination using an exponential backoff algorithm. You can override these settings by manually configuring the retry behavior for a particular error code.

Destinations created before the 4.16.0 release do not support the default `4xx` series retry behavior. If your Destination was created prior to this release and you'd like it to support the behavior, reconfigure the Destination.

To retry requests, Cribl Stream/Edge applies the following rules by default:

Status Code	Action
Any in the `1xx`, `3xx` series	Drop the request
`401`, `403`, `408`, `429` errors	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached
Any other `4xx` series	Drop the request
Any in the `5xx` series	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached

By default, any `429 (Too Many Requests)` response that is not listed in the retry settings is treated as a non-retryable `4xx` error and dropped. If you want `429` responses retried, ensure `429` is included in the

Settings for failed HTTP requests.

Settings for failed HTTP requests: You can also manually configure Cribl Stream/Edge to automatically retry requests that receive particular HTTP response status codes.

Upon receiving a response code that's on the list, Cribl Stream/Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream/Edge continues retrying the request without increasing the time between retries any further.

If the sender (which manages the connection to the Destination) is at capacity, it will not accept any incoming events. These incoming events originate internally from a previous stage of the data flow when Destinations send outbound requests to their respective external services, and they include retry requests and new requests. Any events that were already in transit when the sender reached capacity will continue to be processed downstream.

Sender capacity is freed up when an outgoing request succeeds or encounters a non-retryable error. When the sender has available capacity again, it will resume accepting incoming events. This capacity management is influenced by the number of active connections and configured limits, such as concurrency and buffer sizes. If a Pipeline sends events faster than the Destination can process, the buffers may fill up, leading to backpressure and `Sender at capacity` warnings. This backpressure prevents the sender from accepting additional requests until capacity is restored.

For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: Toggle on to automatically retry requests that have timed out and display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.

- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Edge hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Events-per-request limit: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (s): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Extra parameters: Name-value pairs to pass as additional parameters. If you are using Elastic ingest pipelines, specify an extra parameter whose name is `pipeline` and whose value is the name of your pipeline, similar to these examples.

Elastic pipeline: Enter the name of the Elastic ingest pipeline (optional). You can use an expression to override the pipeline attribute received from the Elasticsearch Source.

Include document_id: Toggle off to omit the `document_id` field when sending events to an Elastic TSDS (time series data stream).

Failed request logging mode: Determines which data is logged when a request fails. Use the drop-down to select one of these options:

- `None` (default).
- `Payload`.
- `Payload + Headers`. Use the **Safe Headers** field below to specify the headers to log. If you leave that field empty, all headers are redacted, even with this setting.

Safe headers: List the headers you want to log, in plain text.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Recommended Settings

The following table provides recommended destination settings for Elastic Cloud Serverless deployments. These values are tuned to work with the serverless autoscaler and aligned with the Elastic Agent Scale preset.

Always use the Elastic Cloud Destination for Serverless deployments. The Elasticsearch Destination does not work with Serverless due to TLS and authentication incompatibilities.

Serverless

Setting	Value
Request timeout	`60` seconds
Request concurrency	`4`
Body size limit (KB)	`5120` KB
Events-per-request limit	`3000`
Flush period (s)	`60` seconds

Keep **Request concurrency** low to avoid outpacing the autoscaler before it has warm shards. The shorter **Request timeout** surfaces HTTP 429 responses quickly instead of waiting out a slow request. A 60-second **Flush period (s)** balances batching efficiency against data freshness. On Serverless, compression reduces both bandwidth usage and ECU consumption.

HTTP 429 responses during autoscaler ramp-up are expected. Enable retries with exponential backoff and do not treat 429 as a fatal error. During cold start (new data stream, first hour of ingestion), consider dropping **Request concurrency** to `2` and **Body size limit (KB)** to `2048` KB until the autoscaler has warm shards, then restore the values above.

Field Normalization

This Destination normalizes the following fields:

- `_time` becomes `@timestamp` at millisecond resolultion.
- `host.name` is set to `host`.

See also our Elasticsearch Source documentation's **Field Normalization** section.

Internal Fields

Cribl Edge uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__id`
- `__type`
- `__index`
- `__host`

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Edge will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), a new connection will be established for the next request.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

12.3.6. Google Cloud

You can send data from Cribl Edge to the following Google Cloud services:

Destination	Description
Google BigQuery	Send data directly to Google BigQuery
Google SecOps	Send data to Google Security Operations (SecOps)
Google Cloud Chronicle API	Send to Google Cloud Chronicle API
Google Cloud Logging	Send data to Google Cloud Logging
Google Cloud Observability	Send logs, metrics, and traces to Google Cloud Observability
Google Cloud Pub/Sub	Send data to Google Cloud Pub/Sub
Google Cloud Storage	Send data to Google Cloud Storage

12.3.6.1. Google BigQuery Destination

Cribl Edge supports sending data directly to Google BigQuery using the BigQuery Storage Write API. This eliminates the need to stage data in Google Cloud Storage first, reducing end-to-end latency significantly.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Edge to Output to Google BigQuery

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this BigQuery destination. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Project ID**: The Google Cloud project that contains the target BigQuery dataset.
    - **Dataset ID**: The BigQuery dataset to write to.
    - **Table ID**: The BigQuery table to write to. The table must already exist; Cribl Edge does not create tables automatically.
3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, Persistent Queue, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication method** drop-down to select one of these options:

- **Auto**: Uses Google Application Default Credentials (ADC) with no manual configuration. Cribl Edge checks the following credential sources in order:

  1. The `GOOGLE_APPLICATION_CREDENTIALS` environment variable, which should point to a service account key file or contain the credentials JSON directly.
  2. Credentials attached to the Google Cloud instance (workload identity federation or the instance metadata server).

  Use this option when running Cribl Edge on Google Cloud infrastructure or when credentials are managed externally.

- **Secret**: Select a stored text secret containing the service account credentials JSON. Use the **Create** link to store a new, reusable secret.

The **Manual** option (entering credentials inline) is not available for this Destination. Store service account credentials as a secret and use the **Secret** option instead.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

> If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

> **Deprecation Notice**
>
> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

> Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Advanced Settings

Timestamp column: Name of the BigQuery column that receives event timestamps. When set, Cribl Edge converts each event's `_time` field (Unix epoch, in seconds) to a BigQuery `TIMESTAMP` value (microsecond precision) and writes it to this column. The column must exist in the table schema and be of type `TIMESTAMP`. If the column name differs from `_time`, the `_time` field is omitted from the row. Use this setting when the table is partitioned by a timestamp column.

Queue size limit: Maximum number of batches that can queue before Cribl Edge applies backpressure. Defaults to `100`. Minimum: `1`.

Batch size limit (KB): Maximum size of a single append request sent to BigQuery. BigQuery enforces a 10 MB per-request limit. Defaults to `1024` KB. Minimum: `1`, Maximum: `10240`.

Flush period (sec): Maximum time to wait before sending a batch when the configured **Batch size limit** has not been reached. Defaults to `1` second. Minimum: `1`.

Concurrent request limit: Maximum number of in-progress API requests before Cribl Edge applies backpressure. Defaults to `5`. Minimum: `1`, Maximum: `100`.

Max send retries: Maximum number of retries per batch for retryable failures before the batch is dropped. Set to `0` to retry indefinitely. Defaults to `0`. Minimum: `0`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Delivery Semantics

Cribl Edge writes to BigQuery using the BigQuery Storage Write API default write stream, which provides **at-least-once** delivery. Rows may be duplicated in the event of a retry. If your downstream queries are sensitive to duplicates, use a deduplication key in your table design or query logic.

Event-to-Row Mapping

When Cribl Edge writes an event to BigQuery, it maps each event field to a column in the target table:

- All event fields are included as columns, **except** fields with names that start with `__` (internal Cribl Edge metadata fields).
- If **Timestamp column** is configured, the event's `_time` field is written to that column as a BigQuery `TIMESTAMP`. If the column name differs from `_time`, the `_time` field itself is omitted from the row.
- The target table schema is fetched at initialization. Columns present in the event but absent from the table schema are silently dropped by BigQuery.

Google Cloud Roles and Permissions

Your Google Cloud service account must have at least the following IAM roles on the target dataset:

- `roles/bigquery.dataEditor` — grants `bigquery.tables.updateData` and `bigquery.tables.get`, which are the only permissions required by the Storage Write API.

For details on granting this role, see the Google Cloud documentation on BigQuery access control.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

12.3.6.2. Google Security Operations (SecOps) Destination

Cribl Edge supports sending data to Security Operations (SecOps), a cloud service for retaining, analyzing, and searching enterprise security and network telemetry data. This service was formerly known as Google Chronicle.

If you plan to use **V2** of the Google Security Operations API, you need your Google service account credentials to define a Google SecOps Destination.

If you plan to use **V1** of the Google Security Operations API, Cribl recommends using Google service account credentials for authentication, but alternatively, you can opt to use an API key from Google.

To add labels to individual events instead of at the batch level, you can use the Google Cloud Chronicle API Destination.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Options for Sending Data to SecOps

When sending data to SecOps, you have two primary methods, each with its own advantages:

- **Sending Unstructured Data for SecOps Parsing**: This is ideal for well-known data types. You send your raw, unstructured data, and SecOps uses its built-in parsers to transform it into the Unified Data Model (UDM). However, this approach can lead to parsing errors and troubleshooting if you're dealing with less common or proprietary data types.
- **Sending Pre-Structured UDM Data**: This method bypasses SecOps's parsing process entirely. It's especially beneficial for less-usual or unique, proprietary data types that might confuse SecOps's parsers. By sending data that's already structured as UDM, you gain greater control and flexibility over how your data lands in SecOps. The trade-off is that you "own" the data transformation process, using Pipelines and Functions to convert your initial unstructured data to UDM before sending it to SecOps.
- **Sending Pre-Structured UDM Entity Data**: This is an extension of the **Pre-Structured UDM Data** option, specifically for sending entity data to the `v2/entities:batchCreate` endpoint. This data is used to enrich logs and provide additional context on events. Like sending UDM logs, you must format your events to conform to the UDM entity schema before sending them to SecOps.

Do not place UDM fields like `metadata`, `principal`, and `network` inside `_raw`. These fields must exist as top-level fields in the event payload.

Working with Unstructured Log Types

Google SecOps supports a dynamic list of unstructured log types that evolves over time. There are two configuration settings for managing log type assignments:

- **Default log type**: Cribl Edge periodically updates its **Default log type** dropdown with the latest list from Google.
- **Custom log types**: If a log type you need isn't in the default dropdown, or if you're using an older, removed log type, you can define and manage it in the **Custom log types** table under **Optional Settings**.

For Google's latest list of supported log types, see the Google SecOps SIEM reference or send a `GET` request to `https://malachiteingestion-pa.googleapis.com/v1/logtypes`.

How Log Types are Assigned

- **Event-specific**: When processing an event, Cribl Edge first checks if the event has a `__logType` field. If this field is present, its value determines the log type for that event.
- **Default**: If the event lacks a `__logType` field, Cribl Edge assigns the log type specified in the **Default log type** drop-down.
- **Custom**: If the **Default log type** is set to `Custom`, Cribl Edge will use the first custom log type listed in the **Custom log types** table. Reorder the custom log types in the table using the grab handles to prioritize which custom log type should be used as the default.
    - If the **Default log type** is set to a specific log type (not `Custom`), the custom log types defined in the **Custom log types** table will not be used as defaults. However, you can still use these custom log types by explicitly setting the `__logType` field in your events to one of the custom log types.

Configure Cribl Edge to Output to SecOps

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this SecOps output definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.

- **API version**: The version of the Google Security Operations Ingestion API you want the Destination to use when communicating with SecOps. Defaults to `V2`.
- **Send events as**: Choose how you want the Destination to send data to SecOps. The options are: **Unstructured** and **UDM**. See Options for Sending Data to SecOps to learn about the differences between working with `Unstructured` and already-structured `UDM` data.

3. Next, configure the settings that appear based on your **API version** and **Send events** as selections. For detail, see the API Version and Output Format Options section.
4. Next, you can configure the following **Optional Settings**: (The following settings are available regardless of how **General Settings** > **Send events as** is set.)
   - **Region**: The Google SecOps regional endpoint to send events to.
   - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Authentication, Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

API Version and Output Format Options

The settings that appear in the **New Destination** modal depend on your selections for **API version** and **Send events as**. The following sections describe how these choices affect the available configuration options.

For Google SecOps unstructured parsers, set the Destination **Log text field** to `_raw`. This ensures that the payload body is the raw log line and that fields like `message_trace_id` are at the payload root.

API version: V2 (Default)

The API version `V2` is the recommended version for most use cases.

- If you choose **Send events as**: `UDM`, an additional **UDM type** option displays. You must select either `Logs` for standard log data or `Entities` for entity-specific data.
- If you choose **Send events as**: `Unstructured`, the following settings appear under **General Settings**:
  - **Default log type**: Select a log type to assign to events that lack a `__logType` field.
  - **Customer ID**: A unique identifier (UUID) corresponding to a particular SecOps instance.

  The following are **Optional Settings**:

- **Custom log types**: For each log type you want to define, select **Add type** and enter values for **Log type** and **Description** in the resulting table row. See Working with Unstructured Log Types above for more details.
- **Namespace**: Configure an environment namespace to identify logs' originating data domain. You can use this as a tag when indexing and/or enriching data. The `__namespace` event field, if present, will overwrite this.
- **Custom labels**: Define labels for the Destination to add to events. These are used by Google SecOps for features such as data RBAC and filtering. See how to configure data RBAC for reference lists. Select **Add label** to create a new label and specify it as a key-value pair.
- **Log text field**: Set to the event field containing the raw log string (commonly `_raw`). If left blank, the Destination sends a JSON representation of the whole event. Use this when you want Google to parse the raw line itself rather than JSON you provide.

API version V1

THe API version `V1` is a legacy version. We recommend using `V2` for all new deployments, but `V1` is available for backward compatibility with existing configurations or for environments that have specific requirements that prevent them from using `V2`.

- If you choose **Send events as**: `UDM`, no additional settings appear, but the **Custom labels** setting is available.
- If you choose **Send events as**: `Unstructured`, the following settings appear under **General Settings**:
  - **Default log type**: Select a log type for events that lack a `__logType` field.

  The following are **Optional Settings**:
  - **Custom log types**: For each log type you want to define, select **Add type** and enter values for **Log type** and **Description** in the resulting table row. See Working with Unstructured Log Types above for more details.
  - **Namespace**: Configure an environment namespace to identify logs' originating data domain. You can use this as a tag when indexing and/or enriching data. The `__namespace` event field, if present, will overwrite this.
  - **Customer ID**: A unique identifier (UUID) corresponding to a particular SecOps instance.
  - **Custom labels**: Define labels for the Destination to add to events. These are used by Google SecOps for features such as data RBAC and filtering. See how to configure data RBAC for reference lists. Select **Add label** to create a new label and specify it as a key-value pair.
  - **Log text field**: Set to the event field containing the raw log string (commonly `_raw`). If left blank, the Destination sends a JSON representation of the whole event. Use this when you want Google to parse the raw line itself rather than JSON you provide.

Authentication

To complete this part of the Destination definition, you will need either a Google Security Operations API key or your Google SecOps service account credentials. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.

Use the **Authentication method** to select an option. Whether you have set **General Settings** > **API version** to `V2` or `V1` determines what options are displayed.

For API version `V2`, the options are:

- **Service Account Credentials**: This option exposes a field where you can enter your Google SecOps service account directly.
- **Service Account Credentials Secret**: This option exposes a drop-down, in which you can select a stored secret that references your Google SecOps service account. A **Create** link is available to store a new, reusable secret.

For API version `V1`, the options include the two listed above plus two more:

- **API key**: This option exposes a field where you can enter your Google Security Operations API key.
- **API Key Secret**: This option exposes a drop-down, in which you can select a stored secret that references your Google Security Operations API key. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

> On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-

> enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

> If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.

- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

> **Deprecation Notice**
>
> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

> Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: In this section's **Pipeline** drop-down list, you can select a single existing Pipeline or Pack to process data from this input before the data is sent through the Routes.

System fields: Specify any fields you want Cribl Edge to automatically add to events using this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Wildcards are supported. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Edge applies the following rules:

Status Code	Action
Any in the `1xx`, `3xx`, or `4xx` series	Drop the request
Any in the `5xx` series	Retry the request

Upon receiving a response code that's on the list, Cribl Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Edge continues retrying the request without increasing the time between retries any further.

If the sender (which manages the connection to the Destination) is at capacity, it will not accept any incoming events. These incoming events originate internally from a previous stage of the data flow when Destinations send outbound requests to their respective external services, and they include retry requests and new requests. Any events that were already in transit when the sender reached capacity will continue to be processed downstream.

Sender capacity is freed up when an outgoing request succeeds or encounters a non-retryable error. When the sender has available capacity again, it will resume accepting incoming events. This capacity management is influenced by the number of active connections and configured limits, such as concurrency and buffer sizes. If a Pipeline sends events faster than the Destination can process, the buffers may fill up, leading to backpressure and `Sender at capacity` warnings. This backpressure prevents the sender from accepting additional requests until capacity is restored.

By default, `429 (Too Many Requests)` and `503 (Service Unavailable)` are the only response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `30000` (30 seconds).
- **Backoff multiplier**: The base for the exponential backoff algorithm; defaults to `1`. A value of `2` means that Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Edge should apply for its final retry, in milliseconds. Defaults to `30000` (30 seconds); minimum is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to toggled on.

Round-robin DNS: Toggle on to enable round-robin DNS lookup across multiple IP addresses, IPv4 and IPv6. When a DNS server resolves a Fully Qualified Domain Name (FQDN) to multiple IP addresses, Cribl Edge will sequentially use each address in the order they are returned by the DNS server for subsequent connection attempts.

Compress: Toggle on (default) to compress the payload body before sending.

Request timeout: Enter an amount of time, in seconds, to wait for a request to complete before aborting it. Defaults to `90`.

Request concurrency: Enter the maximum number of ongoing requests to allow before blocking.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `1024` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to five times the max body size (if set). If `0`, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Body size limit** settings.

Events-per-request limit: Enter the maximum number of events to include in the request body. Defaults to `0` (unlimited).

Flush period (sec): Enter the maximum time to allow between requests. Be aware that small values could cause the payload size to be smaller than the configured **Body size limit**.

Extra HTTP Headers: Select **Add Header** to insert extra headers as **Name/Value** pairs. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Edge will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

12.3.6.3. Google Cloud Chronicle API Destination

The **Google Cloud Chronicle API** Destination sends data to Google Cloud Chronicle using the v1alpha `ImportLogs` ingestion method. The Destination sends your raw, unstructured data, and Chronicle API uses its built-in parsers to transform it into the Unified Data Model (UDM).

Using the **Google Cloud Chronicle API** Destination, in contrast to the Google Security Operations (SecOps) Destination, lets you add labels to individual events, not only at the batch level, and take advantage of the improved performance and scaling offered by Chronicle API.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Working with Unstructured Log Types

Google Cloud Chronicle API supports a dynamic list of unstructured log types that evolves over time.

The **Default log type** setting lets you select the log type to send. To send a log of an unsupported type, type your custom log type into this field.

For Google's latest list of supported log types, see the Supported log types and default parsers in Google Cloud documentation to learn more about the specific log types.

How Log Types are Assigned

- **Event-specific**: When processing an event, Cribl Edge first checks if the event has a `__logType` field. If this field is present, its value determines the log type for that event.
- **Default**: If the event lacks a `__logType` field, Cribl Edge assigns the log type specified in the **Default log type** drop-down.
- **Custom**: If you entered a custom log name into **Default log type**, Cribl Edge will use this type.

Configure a Google Cloud Chronicle API Destination

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.

2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Default log type**: Select or type in the default log type value to assign to events that lack a `__logType` field. See Working with Unstructured Log Types for more information.
    - **GCP project ID**: Enter the Google Cloud Platform (GCP) project ID to send events to. You can find the project ID on the Google Cloud Welcome page.
    - **GCP instance**: Enter ID of the GCP instance to send events to. This is the Chronicle customer UUID.
    - **Region**: Select the regional endpoint to send events to.
    - **Log text field**: Optionally, select the name of the event field that contains the log text to send. If not specified, Cribl Edge sends a JSON representation of the whole event.
3. Next, you can configure the following **Optional Settings**:
    - **Namespace**: User-configured environment namespace to identify the data domain from which the logs originated. This namespace is used as a tag to identify the appropriate data domain for indexing and enrichment functionality. The `__namespace` event field, if present, will overwrite this.
    - **Custom labels**: Custom labels to be added to every event. Custom labels are a Google SecOps feature used for data role-based access control (data RBAC) and other purposes. See the Google SecOps documentation. Click **Add label** to create a new label and specify it as a key-value pair.
        - **Enable RBAC**: Toggle on to designate a the custom label for RBAC and filtering, allowing granular multi-tenant data management directly within Chronicle. The label is flagged in the event payload, and Chronicle enforces access boundaries based on its value. This enables per-event RBAC, so you can dynamically tag events and restrict visibility to authorized roles without duplicating Destinations or relying on parser extensions. The label must resolve for all events in a batch.
    - **Backpressure behavior**: How to handle events when all receivers are exerting backpressure.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Service Account Credentials**: This option exposes a field where you can enter your Google SecOps service account directly.
    - **Service Account Credentials Secret**: This option exposes a drop-down, in which you can select a stored secret that references your Google SecOps service account. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older

than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Retries

Honor Retry-After header: Toggle on to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream/Edge limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. Any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. Toggle off to ignore all `Retry-After` headers.

Default Retry Behavior: By default, Cribl Stream/Edge applies predefined retry strategies for certain failed requests to the Destination using an exponential backoff algorithm. You can override these settings by manually configuring the retry behavior for a particular error code.

Destinations created before the 4.16.0 release do not support the default `4xx` series retry behavior. If your Destination was created prior to this release and you'd like it to support the behavior, reconfigure the Destination.

To retry requests, Cribl Stream/Edge applies the following rules by default:

Status Code	Action
Any in the `1xx`, `3xx` series	Drop the request
`401`, `403`, `408`, `429` errors	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached
Any other `4xx` series	Drop the request
Any in the `5xx` series	Retry in memory or persistent queue if enabled, and initiate backpressure after limit is reached

By default, any `429 (Too Many Requests)` response that is not listed in the retry settings is treated as a non-retryable `4xx` error and dropped. If you want `429` responses retried, ensure `429` is included in the **Settings for failed HTTP requests**.

Settings for failed HTTP requests: You can also manually configure Cribl Stream/Edge to automatically retry requests that receive particular HTTP response status codes.

Upon receiving a response code that's on the list, Cribl Stream/Edge first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream/Edge continues retrying the request without increasing the time between retries any further.

If the sender (which manages the connection to the Destination) is at capacity, it will not accept any incoming events. These incoming events originate internally from a previous stage of the data flow when Destinations send outbound requests to their respective external services, and they include retry requests and new

requests. Any events that were already in transit when the sender reached capacity will continue to be processed downstream.

Sender capacity is freed up when an outgoing request succeeds or encounters a non-retryable error. When the sender has available capacity again, it will resume accepting incoming events. This capacity management is influenced by the number of active connections and configured limits, such as concurrency and buffer sizes. If a Pipeline sends events faster than the Destination can process, the buffers may fill up, leading to backpressure and `Sender at capacity` warnings. This backpressure prevents the sender from accepting additional requests until capacity is restored.

For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: Toggle on to automatically retry requests that have timed out and display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream/Edge will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream/Edge should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Defaults to toggled on.

Round-robin DNS: Toggle on to enable round-robin DNS lookup across multiple IP addresses, IPv4 and IPv6. When a DNS server resolves a Fully Qualified Domain Name (FQDN) to multiple IP addresses, Cribl Edge will sequentially use each address in the order they are returned by the DNS server for subsequent connection attempts.

Compress: Toggle on (default) to compress the payload body before sending.

Endpoint: The Chronicle API service endpoint. If empty, this defaults to the endpoint in the **Region** field. Otherwise, it must point to a Chronicle API-compatible endpoint (for example, https://custom-endpoint.googleapis.com).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Edge hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`. Each request can potentially hit a different HEC receiver.

Body size limit (KB): Maximum size, in KB, of the request body. Defaults to `5120`. Lowering the size can potentially result in more parallel requests and also cause outbound requests to be made sooner.

Events-per-request limit: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than the configured **Body size limit**. Defaults to `5`.

- Retries happen on this flush interval.
- Any HTTP response code in the `2xx` range is considered success.
- Any response code in the `5xx` range is considered a retryable error, which will not trigger persistent queue (PQ) usage.
- Any other response code will trigger PQ (if PQ is configured as the Backpressure behavior).

Extra HTTP headers: Select **Add Header** to add **Name**/**Value** pairs to pass as additional HTTP headers. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Edge will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

12.3.6.4. Google Cloud Logging Destination

Cribl Edge supports sending log data to Google Cloud Logging, a real-time log storage and management service with search, analysis and alerting.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Edge to Output to Google Cloud Logging

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Google Cloud Logging definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Log location type**: Select an option from the dropdown to determine where your log entries are categorized. Choose **Project**, **organization**, **Billing Account**, or **Folder**. For details, see Log Location Types.
    - **Log name expression**: Enter a JavaScript expression to compute the log name's value.
    - **Validate and correct log name**: Toggle on to ensure that log names are sanitized and truncated for compliance and reliability. Log name expression characters that do not meet Google requirements are replaced by an underscore `_`. Additionally, the log name is truncated to a maximum of 512 characters, which is the upper limit enforced by Google Cloud Logging. Without sanitization, Google Cloud Logging will reject requests with invalid log names, resulting in dropped events and potential data loss.
3. Under **Field Mappings**, configure the following:
    - **Payload format**: Select an option from the dropdown specify how data is structured within a log entry. Choose `Text` or `JSON`. For details, see Field Mappings

      This Destination compresses all payloads, using gzip.

- **Log labels**: Click **Add label** to apply one or more labels to log entries. On each row of the resulting table, define each label with:
- **Label**: Arbitrary name for the label.
- **Value**: JavaScript expression to compute the label's value.
- **Resource type expression**: JavaScript expression to compute the field value for the managed resource type. Must evaluate to one of the monitored resource types listed here. If not specified, falls back to `global`.
- **Resource labels**: Click **Add label** to apply one or more labels to the managed resource. For details, see Resource Labels.
- **Severity expression**: JavaScript expression to compute the severity field's value. Must evaluate to one of the `LogSeverity` values listed here. Case-insensitive. If not specified, falls back to `DEFAULT`.
- **Insert ID expression**: JavaScript expression to compute the insert ID field's value.

4. Next, you can configure the following **Optional Settings**:
   - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. To add **Indexed Fields** to your LogEntry objects, provide JavaScript expressions to populate fields beyond the standard LogEntry structure, enabling richer analysis and correlation within Chronicle. For each field you want to index, provide a JavaScript expression. Ensure the expression's result matches the expected data type defined in the LogEntry documentation. Mismatched types prevent the field from appearing in Chronicle.
   - You can configure the following indexed fields using JavaScript expressions: **Trace expression**, **Span ID expression**, **Trace sampled expression**, **HTTP Request**, **Operation**, **Source Location**, and **Log Split**.

The LogEntry object's `timestamp` field is populated from the event's `_time` field.

6. Optionally, you can adjust the Authentication, Processing, and Advanced settings outlined in the sections below.
7. Select **Save**, then **Commit & Deploy**.

Log Location Types

Log Location Types allow you to categorize your log entries based on organizational structures. Choose one of the following options to associate log entries with a specific project, organization, billing account, or folder:

- `Project`: Displays a **Project ID expression** field. Here, enter a JavaScript expression to compute the value of the project ID to associate log entries with.
- `Organization`: Displays a **Organization ID expression** field. Enter a JS expression to compute the value of the organization ID to associate log entries with.
- `Billing Account`: Displays a **Billing account ID expression** field. Enter a JS expression to compute the value of the billing account ID to associate log entries with.
- `Folder`: Displays a **Folder expression** field. Enter a JS expression to compute the value of the folder ID to associate log entries with.

Field Mappings

Field Mappings specify how log entries should be structured. Choose one of the following options:

- `Text`: This default option displays a **Payload text expression** field. Here, enter JavaScript expression to compute the payload's value. Must evaluate to a JavaScript string value; if validation fails, this will default to a JSON string representation of the event.
- `JSON`: Displays a **Payload object expression** field. Enter a JS expression to compute the payload's value. Must evaluate to a JavaScript object value; if validation fails, this will default to the entire event.

Resource Labels

Each **Resource label** must correspond to a valid label for the resource type you've specified in the **Resource type expression**, or else Google Cloud Logging will drop it. On each row of the resulting table, define each label with:

- **Label**: Arbitrary name for the label.
- **Value**: JavaScript expression to compute the label's value.

Authentication

Use the **Authentication method** drop-down to select one of these options:

- **Auto**: This option uses the `GOOGLE_APPLICATION_CREDENTIALS` environment variable, and requires no configuration here.
- **Manual**: This default option displays a **Service account credentials** field for you to enter the contents of your service account credentials file (a set of JSON keys), as downloaded from Google Cloud. To insert the file itself, click the upload button at this field's upper right. As an alternative, you can use environment variables, as outlined here.
- **Secret**: This option exposes a drop-down in which you can select a stored secret that references the service account credentials described above. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older

than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Advanced Settings

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish before retrying. Defaults to `10000` (10 sec.).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30` sec.

Body size limit (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Body size limit** settings.

Events-per-request limit: Maximum number of events to include in the request body. Defaults to `0` (unlimited).

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` sec.

Throttle request rate: Enter a maximum number of requests to send per second, as necessary to comply with Google Cloud's API limits. This field defaults to empty (no throttling), and accepts throttling rates as high as `2000` requests per second.

Environment: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

Google Cloud Roles and Permissions

Your Google Cloud service account must have at least the following role:

- `Logs Writer`

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

12.3.6.5. Google Cloud Observability Destination

The Google Cloud Observability Destination enables integration with Google Cloud Observability. This Destination routes observability data, including logs, metrics, and traces, to Google Cloud using the OpenTelemetry Protocol (OTLP).

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Prerequisites

Before you configure this Destination, ensure the following:

- Identify the Google Cloud project that should receive logs, metrics, and traces.
- Enable the following Google Cloud APIs in that project:
  - Telemetry API (`telemetry.googleapis.com`)
  - Cloud Logging API (`logging.googleapis.com`)
  - Cloud Monitoring API (`monitoring.googleapis.com`)
  - Cloud Trace API (`cloudtrace.googleapis.com`)
- Grant the Google identity used by this Destination permission to write telemetry. At minimum, assign the Cloud Telemetry Writer role (`roles/telemetry.writer`). See Google Cloud Roles and Permissions for details.

Configuring a Google Cloud Observability Destination

In Cribl Edge, set up a Google Cloud Observability Destination.

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
   - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select **Google Cloud** > **Observability**, choosing either **Select Existing** or **Add New**.
   - To configure via the Routes, select **Data** > **Destinations** (Stream) or **More** > **Destinations** (Edge). Select **Google Cloud** > **Observability**, then select **Add Destination** to open a **New Destination** modal.
2. In the Destination modal, configure the following under **General Settings**:
   - **Output ID**: Enter a unique name to identify this output definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.

- **Endpoint**: Read-only. Fixed to `telemetry.googleapis.com:443`. This is the Telemetry (OTLP) API endpoint for Google Cloud Observability. All three signals share this transport. The OTLP service path determines whether the call lands on traces, metrics, or logs.
- **Backpressure behavior**: Optionally, set whether to `Block`, `Drop`, or send to **Persistent Queue** when all receivers are exerting backpressure.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

3. Optionally, configure any Authentication, TLS, Persistent Queue, Processing, and Advanced settings outlined in the sections below.
4. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Google authentication method** drop-down to select one of these options:

- **Auto**: Uses Google Application Default Credentials (ADC). Cribl Edge uses the `GOOGLE_APPLICATION_CREDENTIALS` environment variable when it is set to a service account key file or inline credentials. When that variable is unset or invalid, Cribl Edge falls back to other ADC locations described in Google's documentation. On Google Compute Engine VMs, you can also use credentials attached to the instance.
- **Secret**: Select a stored secret that references Google service account credentials. A **Create** link is available to store a new, reusable secret.

If you authenticate with user credentials through ADC (for example, after running `gcloud auth application-default login`), add **Advanced Settings** > **Metadata** with **Key** `x-goog-user-project` and **Value** set to the Google Cloud project ID that should receive billing and quota attribution.

TLS Settings (Client Side)

Use TLS: Defaults to toggled off.

Server Validation

Configure how this client verifies the remote server's identity.

Validate server certs: Reject certificates that are **not** authorized by a CA in the **Trusted server CA path**, nor by another trusted CA (for example, the system's CA). Default is toggled on.

Trusted server CA path: Path on the Edge Node containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`. The certificate(s) to trust as the chain root when verifying the

server's identity. This is typically the root CA that anchors the server's certificate chain.

Mutual Authentication (mTLS)

Certificate: Name of the predefined certificate. Selecting a certificate auto-fills the mutual-auth paths below.

Certificate path (mutual auth): Path on the Edge Node containing certificates (in PEM format) to use for client authentication. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on the Edge Node containing the private key (in PEM format) to use for client authentication. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

TLS Version

Reject connections using TLS versions below or above these thresholds.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections. Selecting `TLSv1` or `TLSv1.1` shows a deprecation warning.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-

> enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

> If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.

- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

> **Deprecation Notice**
>
> The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

> Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output - both metric events, as dimensions, and log events, as labels. By default, includes `cribl_pipe` (Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Advanced Settings

Preserve native AnyValue wrappers: Toggle on to serialize values that are already in OTLP AnyValue form (for example, `{ "string_value": "..." }`) directly, instead of wrapping them as key-value maps. When toggled off, Cribl Edge treats those wrappers as plain objects, which can leave wrapper names such as `string_value` as literal field names in the output. Defaults to toggled on.

If your Pipeline uses the OTLP Logs Function before this Destination, enable **Preserve native AnyValue wrappers** on both the Function and the Destination. Enabling it on only one side can still leave wrapper names such as `string_value` as literal field names in the output.

Connection timeout: Amount of time (milliseconds) to wait for the connection to establish before retrying. Defaults to `10000`.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30` sec.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Keep alive time (seconds): How often the sender should ping the peer to keep the connection alive. Defaults to `30`.

Body size limit (KB): Maximum size of the request body sent to Google Cloud Observability. Defaults to `2048` KB. The minimum is `1024` KB and the maximum is `10240` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Body size limit** value until downstream receivers reliably accept all events.

Events-per-request limit: Maximum number of events to include in each gRPC request. Defaults to `0` (unlimited). Use this setting to stay within Google Cloud Observability request limits. For metrics, combine it with the OTLP Metrics function **Batch size** setting.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than the configured **Body size limit**. Defaults to `1` sec.

Metadata: Extra information to send with each gRPC request. Select **Add Metadata** to add each item as a **Key-Value** pair. The **Key** field is arbitrary. The **Value** field is a JavaScript expression that is evaluated just once, when this Destination is initialized. If you pass credentials as metadata, Cribl recommends using C.Secret().

Use dynamic metadata: Toggle on to enable per-event dynamic metadata on outbound gRPC requests. When enabled, Cribl Edge reads metadata key-value pairs from the field specified in **Dynamic metadata field** on each event. It injects them into the gRPC request metadata and batches together events that share the same metadata values. Dynamic metadata entries override any static **Metadata** entries with matching keys. Default is off.

Dynamic metadata field: The event field that contains the metadata key-value pairs to inject into outbound gRPC request metadata. Visible only when **Use dynamic metadata** is enabled. Defaults to `__headersOut`.

Environment: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

Protocol and Transport Support

This Destination always sends observability data using the OpenTelemetry Protocol (OTLP) v1.3.1 over gRPC to `telemetry.googleapis.com:443`. These transport settings are fixed and are not shown in the configuration UI. OTLP defines Protocol buffer (Protobuf) schemas for its payloads (requests and responses).

When configuring Pipelines (including pre-processing and post-processing Pipelines), you need to ensure that events sent to this Destination conform to the relevant Protobuf specification.

- For traces, opentelemetry/proto/trace/v1/trace.proto
- For metrics, opentelemetry/proto/metrics/v1/metrics.proto
- For logs, opentelemetry/proto/logs/v1/logs.proto

This Destination will drop non-conforming events. If the Destination encounters a parsing error when trying to convert an event to OTLP, it discards the event and Cribl Edge logs the error.

For metric naming and label constraints enforced by Google Cloud Observability, see OTLP metric ingestion overview.

OTLP Resource Attributes

Google Cloud Observability maps OTLP resource attributes to monitored resource types and labels for logs, metrics, and traces. The required attributes depend on the signal type and the source environment (for example, Compute Engine, GKE, or on-premises hosts).

Use Pipelines to add or transform resource attributes before events reach this Destination. For workloads running in Google Cloud, you can also attach resource attributes at the Collector or SDK layer using a Google Cloud resource detector.

At minimum, ensure that telemetry includes a project identifier such as `gcp.project_id` or `project_id` so Google Cloud Observability can route data to the correct project. See Google's Write OTLP logs to the Telemetry API topic for examples.

Google Cloud Roles and Permissions

The Google identity used by this Destination needs permission to write telemetry to your Google Cloud project. Grant at least the Cloud Telemetry Writer role (`roles/telemetry.writer`), which includes:

- `logging.logEntries.create`
- `monitoring.timeSeries.create`
- `telemetry.traces.write`

Enable the Telemetry API (`telemetry.googleapis.com`), Cloud Logging API (`logging.googleapis.com`), Cloud Monitoring API (`monitoring.googleapis.com`), and Cloud Trace API (`cloudtrace.googleapis.com`) in the target project.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

12.3.6.6. Google Cloud Pub/Sub Destination

Cribl Edge supports sending data to Google Cloud Pub/Sub, a managed real-time messaging service for sending and receiving messages between applications.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Prerequisites

When working with Google Cloud Pub/Sub, you need to know:

- The project where your credentials originated.
- The project that contains any topic you want to work with.

If the desired topic resides in the same project where your credentials originated, describe it using either its short name **or** its fully-qualified name.

If the desired topic resides in a different project than the one where your credentials originated, you **must** describe it using its fully-qualified name.

Here's an example of a fully-qualified topic name: `projects/my-project-id/topics/my-topic-id`.

The short name for the same topic would be: `my-topic-id`.

Configure Cribl Edge to Output to Pub/Sub

1. On the top bar, select **Products**, and then select **Cribl Edge**. Under **Fleets**, select a Fleet. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Pub/Sub output definition. If you clone this Destination, Cribl Edge will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Topic ID**: ID of the Pub/Sub topic to send events to. This static initial configuration of the topic is required; but you can optionally also override it dynamically on a per-event basis.

3. Next, you can configure the following **Optional Settings**:

- **Create topic**: Toggle on if you want Cribl Edge to create the topic on Pub/Sub if it does not exist.
- **Ordered delivery**: Toggle on if you want Cribl Edge to send events in the order that they arrived in the queue. For ordered delivery to work correctly, ensure that both the process receiving events and the subscription from which messages are read have ordered delivery enabled.
- **Region**: Region to publish messages to. Select `default` to allow Google to auto-select the nearest region. (If you've enabled **Ordered delivery**, the selected region must be allowed by message storage policy.)
- **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Persistent Queue, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication method** drop-down to select one of these options:

- **Auto**: This option uses the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to provide the location of a credential JSON file. The environment variable can also be set directly in JSON format. When this option is set, Cribl Edge will first check whether the `GOOGLE_APPLICATION_CREDENTIALS` environment variable exists and properly set with valid credentials. If this environmental variable is missing or incorrect, Cribl Edge checks for credentials in two additional fallback locations, as described in the official Google Cloud documentation: How Application Default Credentials works. In addition to using the `GOOGLE_APPLICATION_CREDENTIALS` environment variable, you can use credentials attached to your Google Cloud instance.
- **Manual**: This default option displays a **Service account credentials** field for you to enter the contents of your service account credentials file (a set of JSON keys), as downloaded from Google Cloud.
  To insert the file itself, select the upload button at this field's upper right. As an alternative, you can use environment variables, as outlined here.
- **Secret**: This option exposes a drop-down in which you can select a stored secret that references the service account credentials described above. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

The **Persistent Queue Settings** tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**. Persistent queue buffers and preserves incoming events when a downstream Destination

has an outage or experiences backpressure.

Before enabling persistent queue, learn more about persistent queue behavior and how to optimize it with your system:

- About Persistent Queues
- Optimize Destination Persistent Queues
- About Destination Backpressure Triggers

Some of these settings might not appear if you set the persistent queue storage mode to `Network filesystem` or `AWS S3` at the Worker Group level (**Worker Group Settings** > **System** > **PQ Storage**). When using these storage types, this behavior is managed at the Worker Group level. See Worker Group PQ Storage Fields for more information.

On Cribl-managed Cloud Workers (with an Enterprise plan), this tab exposes only the **Mode** and **Backpressure duration limit** settings and the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Edge blocks outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk when the Destination is unavailable or in an error state.
Backpressure	Queues and stores data to a disk when it detects backpressure from the Destination until the backpressure event resolves.
Always On	Cribl Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

If a Worker/Edge Node starts with an invalid **Mode** setting, it automatically switches to **Error** mode. This might happen if the Worker/Edge Node is running a version that does not support other modes (older than 4.9.0), or if it encounters a nonexistent value in YAML configuration files.

File size limit: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `10 MB`. When you save the configuration, **File size limit** must be greater

than or equal to **Buffer size limit (bytes)**. Cribl Edge rejects invalid combinations.

Queue size limit: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Worker Process PQ size limit** on the Worker Group/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Edge appends `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Buffer size limit (bytes): The maximum memory to buffer events before flushing them to persistent queue on disk. Enter a value with a unit suffix. For example: `64KB`, `1MB`, or `10MB`. Spaces between the number and unit are allowed (such as `64 KB`). Units are case-insensitive. Plain byte values (like `65536`) are accepted, but decimals (like `0.5MB`) are not. The valid range is `64KB` to `10MB`. Values outside this range are rounded to the nearest limit. Defaults to `1MB`.

Deprecation Notice

The **Buffer size limit (bytes)** setting replaces the deprecated **Buffer size limit (events)** setting as of version 4.18.0 to provide more predictable memory management. For upgraded Worker Groups and Fleets, the new byte-based limit defaults to `1MB`. Update your configurations to use the byte-based limit to ensure optimal memory stability.

Backpressure duration limit: Displays when **Mode** is set to `Backpressure`. Controls how long (in seconds) a Destination must experience backpressure before Cribl Edge queues data to persistent storage. Defaults to `30` seconds. Lowering this limit strengthens data loss prevention, while raising it helps prevent unnecessary queue activation in environments with frequent, short network interruptions.

Strict ordering: Toggle on (default) to enable FIFO (first in, first out) event forwarding, ensuring Cribl Edge sends earlier queued events first when receivers recover. The persistent queue flushes every 10 seconds in this

mode. Toggle off to prioritize new events over queued events, configure a custom drain rate for the queue, and display this option:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, select this button if you want to delete the files that are currently queued for delivery to this Destination. If you select this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. This button only appears after you define the **Output ID**.

Use the **Clear Persistent Queue** button with caution to avoid data loss. See How to Safely Disable and Clear Persistent Queues for more information.

Processing Settings

Post-Processing

Pipeline: Pipeline or Pack to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Edge Pipeline that processed the event). Supports wildcards. Available fields include:

- `cribl_host` - Edge Node that processed the event.
- `cribl_input` - Source that processed the event.
- `cribl_output` - Destination that processed the event.
- `cribl_pipe` - Pipeline that processed the event.
- `cribl_route` - Route (or QuickConnect) that processed the event.
- `cribl_wp` - Worker Process that processed the event.
- `cribl_group` - Fleet that processed the event.
- `cribl_mode` - Distributed mode of the instance that processed the event.

Advanced Settings

Batch size: The maximum number of items the Google API should batch before it sends them to the topic. Defaults to `10` items.

Batch timeout (ms): The maximum interval (in milliseconds) that the Google API should wait to send a batch (if the configured **Batch size** limit has not been reached).. Defaults to `100` ms.

Queue size limit: Maximum number of queued batches before blocking. Defaults to `100`.

Batch size limit (KB): Maximum size for each sent batch. Defaults to `256` KB.

Flush period (sec): Enter the maximum time to allow between requests (in seconds). Low values could cause the payload size to be smaller than the configured **Batch size limit (KB)**. Defaults to `1` second.

Concurrent request limit: The maximum number of in-progress API requests before Cribl Edge applies backpressure. Defaults to `10`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Google Cloud Roles and Permissions

Your Google Cloud service account should have at least the following roles on topics:

- `roles/pubsub.publisher`
- `roles/pubsub.viewer` or `roles/viewer`

To enable Cribl Edge's **Create topic** option, your service account should have one of the following (or higher) roles:

- `roles/pubsub.editor`
- `roles/editor`

Either `editor` role confers multiple permissions, including those from the lower `viewer`, `subscriber`, and `publisher` roles. For additional details, see the Google Cloud Access Control topic.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Let's Change the Topic

The Pub/Sub Destination supports alternate topics specified at the event level in the `__topicOut` field. So (for example) if a Pub/Sub Destination is configured to send to main topic `topic1`, and Cribl Edge receives an event with `__topicOut: topic2`, then Cribl Edge will override the main topic and send this event to `topic2`.

However, a topic specified in the event's `__topicOut` field must already exist on Pub/Sub. If it does not, Cribl Edge cannot dynamically create the topic, and will drop the event. On the Destination's **Status** tab, the

Dropped metric tracks the number of events dropped because a specified alternate topic did not exist.

(This example uses the short topic name, and that works as long as the topic resides in the project where your GCP credentials originated. If the topic resides in a different project, you must use the fully-qualified topic name, for example `__topicOut: projects/<my-project-id>/topics/topic2`.)
