1. Introduction 15
1.1. About Cribl Stream 15
1.2. Basic Concepts 17
1.3. Cribl.Cloud vs. Self-Hosted 22
1.4. Cribl Stream Tour 27
1.5. Getting Started Guide 48
1.6. Distributed Quick Start 67
2. Cribl.Cloud 94
2.1. Initial Cribl.Cloud Setup 96
2.2. Managing Cribl.Cloud 98
2.3. Cribl.Cloud Billing 100
2.4. Managing Cribl.Cloud Members 104
2.5. Managing Cribl.Cloud Worker Groups 108
2.6. Connect On-Premises Leaders to Cribl.Cloud Billing 112
2.7. Enterprise Cloud 117
3. Planning and Sizing 121
3.1. Deploying Cribl Stream Software 121
3.1.1. Deployment Planning 121
3.1.2. Sizing and Scaling 124
3.1.3. Architectural Considerations 134
3.1.4. Ports 143
3.2. On-Prem Deployment 147
3.2.1. Deployment Types 147
3.2.2. OS and System Requirements 149
3.2.3. Single-Instance/Basic Deployment 153
3.2.4. Run Cribl Stream 154
3.2.5. Configure Cribl Stream for Non-Root User 161
3.2.6. Distributed Deployment 163
3.2.6.1. Set Up Leader and Worker Nodes 170
3.2.6.2. Manage Worker Groups 175
3.2.6.3. Map Workers to Worker Groups 178
3.2.6.4. Manage Config Bundles 180
3.2.6.5. Deploy Stream Configurations 182
3.2.6.6. Persistent Socket Connections 184
3.2.7. Splunk App Deployment 185
3.2.8. Bootstrap Workers from Leader 188

3.2.9. Leader High Availability/Failover 199
3.2.10. Converting a Single Instance to Distributed Deployment 206
3.3. Orchestrated Deployment 208
3.3.1. Kubernetes/Helm Deployment 208
3.3.2. Kubernetes Worker Deployment 222
3.3.3. Considerations for Cribl Stream on Kubernetes 229
3.4. Docker Deployment 233
4. CrowdStream 238
5. Reference Architectures 255
5.1. All-in-One Reference Architecture 256
5.2. Multiple Agents Reference Architecture 258
5.3. Comprehensive Reference Architecture 268
5.4. Comprehensive Hybrid Cloud Reference Architecture 271
6. QuickConnect 273
7. Workspaces 279
7.1. Configuring Workspaces 283
8. Projects 285
8.1. Configure Projects 289
8.2. Configure Subscriptions 294
8.3. Add Users to Projects 297
9. Administering 300
9.1. Licensing 300
9.2. Version Control 307
9.3. GitOps 327
9.4. Worker Group Settings 340
9.5. Notifications Overview 347
9.5.1. Source-State Notifications 351
9.5.2. Destination-State Notifications 355
9.5.3. License-Expiration Notifications 360
9.5.4. Email Notifications 362
9.5.5. Notification Targets 366
9.5.5.1. Webhook Notification Targets 368
9.5.5.2. PagerDuty Notification Targets 375
9.5.5.3. Slack Notification Targets 377
9.5.5.4. AWS SNS Notification Targets 379
9.5.5.5. Email Notification Targets 383
9.6. Customizing the Interface 386

9.6.1. Custom Banners 386
9.6.2. Custom Login Page 387
9.7. Scripts 388
9.8. Upgrade 390
9.9. Uninstalling 404
10. Access Management 405
10.1. Authentication 407
10.2. Members and Permissions 414
10.3. Teams 420
10.4. Local Users 421
10.5. Roles 423
10.6. Cribl.Cloud SSO 432
10.6.1. SSO 432
10.6.1.1. Cribl.Cloud SSO Setup 432
10.6.1.2. Configuring SSO groups 433
10.6.1.3. SSO with Okta and OIDC (Cribl.Cloud) 436
10.6.1.4. SSO with Microsoft Entra ID and SAML (Cribl.Cloud) 440
10.6.1.5. SSO with Okta and SAML (Cribl.Cloud) 445
10.6.1.6. SSO Troubleshooting in Cribl.Cloud 449
10.6.2. On-Prem SSO 450
10.6.2.1. SSO with Okta and OIDC (On-Prem) 450
10.6.2.2. SSO with Okta and SAML (On-Prem) 456
10.6.2.3. SSO with Microsoft Entra ID and SAML (On-Prem) 461
10.6.2.4. SSO with Microsoft Entra ID and OIDC (On-Prem) 465
11. Securing 469
11.1. Secure Your Cribl.Cloud Deployment 469
11.2. Secure Your On-Prem/Hybrid Deployment 472
11.3. Secure Leader/Worker Nodes Communication 478
11.3.1. How to Secure the Auth Token for the Leader Node 483
11.3.2. TLS Defaults and System-wide Settings 486
11.3.3. Securing Cribl.Cloud with TLS and Mutual TLS 489
11.3.4. Configure mTLS Authentication On-Prem 491
11.3.5. Secure Leader Using an Existing TLS/SSL Certificate and Key 494
11.3.6. Configure TLS for API and UI Access 496
11.3.7. Secure Cribl Stream Sources and Destinations with Certificates 498
11.3.8. Configure System Proxy 500
11.3.9. Configure SOCKS Proxy 507

11.4. Manage Secrets and Keys 509
11.4.1. Create and Manage Encryption Keys 509
11.4.2. Create and Manage Secrets in Cribl Stream 511
11.4.3. Configure KMS 513
11.5. Compliance 519
11.5.1. FIPS Mode 519
11.5.2. Running Cribl Stream on a Hardened OS 525
11.5.3. SELinux (Enforcing Mode) Configuration 528
12. Monitoring 534
12.1. Internal Metrics 554
12.2. Internal Logs 563
13. Working With Data 569
13.1. Event Model 569
13.2. Event Processing Order 572
13.3. Routes 574
13.4. Pipelines 580
13.4.1. Create Pipelines Using Cribl Copilot 587
13.5. Packs 590
13.5.1. Packs Publication Standards 609
13.6. Use Datagens 618
13.7. Data Preview 623
13.8. Data Onboarding 638
14. Functions 642
14.1. Auto Timestamp 647
14.2. Aggregations 652
14.3. CEF Serializer 661
14.4. Chain 663
14.5. Clone 665
14.6. Code 667
14.7. Comment 670
14.8. DNS Lookup 671
14.9. Drop 676
14.10. Dynamic Sampling 677
14.11. Eval 680
14.12. Event Breaker 684
14.13. Flatten 687
14.14. GeoIP 690

14.15. Grok 693
14.16. JSON Unroll 695
14.17. Lookup 697
14.18. Mask 703
14.19. Numerify 709
14.20. OTLP Logs 711
14.21. OTLP Metrics 721
14.22. OTLP Traces 746
14.23. Parser 753
14.24. Publish Metrics 764
14.25. Redis 770
14.26. Regex Extract 782
14.27. Regex Filter 786
14.28. Rename 787
14.29. Rollup Metrics 790
14.30. Sampling 792
14.31. Serialize 794
14.32. SNMP Trap Serialize 797
14.33. Suppress 800
14.34. Tee 803
14.35. Unroll 806
14.36. XML Unroll 808
14.37. Prometheus Publisher (deprecated) 812
14.38. Reverse DNS (deprecated) 814
14.39. Trim Timestamp (deprecated) 816
15. Integrations 818
15.1. Sources Overview 819
15.1.1. Collector Sources 828
15.1.1.1. Azure Blob Storage Collector 834
15.1.1.2. Cribl Lake Collector 841
15.1.1.3. Database Collector 844
15.1.1.4. File System/NFS Collector 853
15.1.1.5. Google Cloud Storage Collector 857
15.1.1.6. Health Check Collector 864
15.1.1.7. REST / API Endpoint Collector 877
15.1.1.8. S3 Collector 907
15.1.1.9. Script Collector 916
15.1.1.10. Splunk Search Collector 922

15.1.1.11. Manage Collector State in Database and REST API Collectors 929
15.1.1.12. Schedule and Run Collector Jobs 932
15.1.1.13. Job Limits 942
15.1.1.14. Using Collectors 945
15.1.1.14.1. Using S3 Storage and Replay 945
15.1.1.14.2. Using REST/API Collectors 952
15.1.1.14.3. Lacework API Collection 981
15.1.1.14.4. Microsoft Graph API Collection 988
15.1.1.14.5. ServiceNow API Collection 993
15.1.1.14.6. Creating a Custom Collector 999
15.1.2. Amazon 1029
15.1.2.1. Amazon Data Firehose Source 1029
15.1.2.2. Amazon Kinesis Data Streams Source 1037
15.1.2.3. Amazon S3 Source 1044
15.1.2.4. Amazon Security Lake Source 1057
15.1.2.5. Amazon SQS Source 1066
15.1.3. Azure 1072
15.1.3.1. Azure Blob Storage Source 1072
15.1.3.2. Azure Event Hubs Source 1084
15.1.4. Google Cloud 1093
15.1.4.1. Google Cloud Pub/Sub Source 1093
15.1.5. Kafka 1098
15.1.5.1. Kafka Source 1098
15.1.5.2. Confluent Cloud Source 1109
15.1.5.3. Amazon MSK Source 1119
15.1.6. Office 365 1129
15.1.6.1. Office 365 Activity Source 1129
15.1.6.2. Office 365 Message Trace Source 1139
15.1.6.3. Office 365 Services Source 1147
15.1.7. Prometheus 1154
15.1.7.1. Prometheus Scraper Source 1154
15.1.7.2. Prometheus Remote Write Source 1162
15.1.7.3. Grafana Source 1170
15.1.7.4. Loki Source 1178
15.1.8. Splunk 1186
15.1.8.1. Splunk HEC Source 1186
15.1.8.2. Splunk Search Source 1201

15.1.8.3. Splunk TCP Source 1207
15.1.9. Internal 1216
15.1.9.1. Cribl Internal Source 1216
15.1.9.2. Cribl HTTP Source 1221
15.1.9.3. Cribl TCP Source 1229
15.1.9.4. Cribl Stream Source (Deprecated) 1235
15.1.10. System 1241
15.1.10.1. Datagen Source 1241
15.1.10.2. Exec Source 1243
15.1.10.3. File Monitor Source 1248
15.1.10.4. Journal Files Source 1257
15.1.10.5. System Metrics Source 1261
15.1.10.6. System State Source 1269
15.1.11. AppScope Source 1280
15.1.12. CrowdStrike FDR Source 1288
15.1.13. Datadog Agent Source 1295
15.1.14. Elasticsearch API Source 1306
15.1.15. HTTP/S (Bulk API) Source 1317
15.1.16. Raw HTTP/S Source 1328
15.1.17. Metrics Source 1336
15.1.18. Model Driven Telemetry Source 1343
15.1.19. NetFlow Source 1348
15.1.20. OpenTelemetry (OTel) Source 1361
15.1.21. SNMP Trap Source 1370
15.1.22. Syslog Source 1377
15.1.23. TCP JSON Source 1388
15.1.24. TCP (Raw) Source 1395
15.1.25. UDP (Raw) Source 1402
15.1.26. Windows Event Forwarder Source 1408
15.1.26.1. Client Certificate Authentication for Windows Event Forwarder 1424
15.1.26.2. Kerberos Authentication for Windows Event Forwarder 1427
15.1.27. Wiz Source 1432
15.2. Destinations 1440
15.2.1. Managing Destinations 1446
15.2.2. Amazon 1450
15.2.2.1. Amazon CloudWatch Logs Destination 1450
15.2.2.2. Amazon Kinesis Data Streams Destination 1457

15.2.2.3. Amazon S3 Compatible Stores Destination 1465
15.2.2.4. Amazon SQS Destination 1475
15.2.3. Azure 1482
15.2.3.1. Azure Blob Storage Destination 1482
15.2.3.2. Azure Data Explorer Destination 1489
15.2.3.3. Azure Event Hubs Destination 1501
15.2.3.4. Azure Monitor Logs Destination 1510
15.2.3.5. Microsoft Sentinel Destination 1517
15.2.4. Data Lakes 1527
15.2.4.1. Cribl Lake Destination 1527
15.2.4.2. Amazon S3 Destination 1529
15.2.4.3. Amazon Security Lake Destination 1535
15.2.5. Elastic 1542
15.2.5.1. Elasticsearch Destination 1542
15.2.5.2. Elastic Cloud Destination 1551
15.2.6. Google Cloud 1558
15.2.6.1. Google Security Operations (SecOps) Destination 1558
15.2.6.2. Google Cloud Logging Destination 1567
15.2.6.3. Google Cloud Pub/Sub Destination 1574
15.2.6.4. Google Cloud Storage Destination 1580
15.2.7. Kafka 1587
15.2.7.1. Kafka Destination 1587
15.2.7.2. Confluent Cloud Destination 1598
15.2.7.3. Amazon MSK Destination 1609
15.2.8. Metrics 1620
15.2.8.1. Graphite Destination 1620
15.2.8.2. StatsD Destination 1625
15.2.8.3. StatsD Extended Destination 1630
15.2.9. New Relic Ingest 1635
15.2.9.1. New Relic Events Destination 1635
15.2.9.2. New Relic Logs & Metrics Destination 1642
15.2.10. Prometheus 1650
15.2.10.1. Prometheus Destination 1650
15.2.10.2. Grafana Cloud Destination 1657
15.2.10.3. Loki Destination 1666
15.2.11. Splunk 1673
15.2.11.1. Splunk HEC Destination 1673

15.2.11.2. Splunk Single Instance Destination 1682
15.2.11.3. Splunk Load Balanced Destination 1689
15.2.12. Internal 1701
15.2.12.1. Cribl HTTP Destination 1701
15.2.12.2. Cribl TCP Destination 1710
15.2.12.3. Cribl Stream Destination (Deprecated) 1718
15.2.12.4. Default Destination 1723
15.2.12.5. DevNull Destination 1724
15.2.12.6. Output Router Destination 1725
15.2.13. CrowdStrike Falcon LogScale Destination 1728
15.2.14. ClickHouse Destination 1735
15.2.15. CrowdStrike Falcon Next-Gen SIEM Destination 1743
15.2.16. Datadog Destination 1749
15.2.17. Dynatrace HTTP Destination 1757
15.2.18. Dynatrace OTLP Destination 1765
15.2.19. Exabeam Security Operations Platform Destination 1772
15.2.20. Filesystem/NFS Destination 1778
15.2.21. Honeycomb Destination 1784
15.2.22. InfluxDB Destination 1790
15.2.23. MinIO Destination 1797
15.2.24. NetFlow Destination 1806
15.2.25. OpenTelemetry (OTel) Destination 1809
15.2.26. SentinelOne DataSet Destination 1818
15.2.27. ServiceNow Cloud Observability 1826
15.2.28. SignalFx Destination 1835
15.2.29. SNMP Trap Destination 1841
15.2.30. Sumo Logic Destination 1844
15.2.31. Syslog Destination 1852
15.2.32. TCP JSON Destination 1865
15.2.33. Wavefront Destination 1872
15.2.34. Webhook Destination 1878
15.3. Destination Backpressure Triggers 1895
15.4. Persistent Queues 1903
15.4.1. Planning for Persistent Queues 1908
15.4.2. Configuring Persistent Queues 1915
15.5. About Load Balancing 1922
15.6. Configure Host Metadata 1924
15.7. Cribl Edge to Cribl Stream 1926

15.8. Amazon 1930
15.8.1. Integrating with Other Services 1930
15.8.1.1. AWS Cross-Account Data Collection 1930
15.8.1.2. Amazon S3 Better Practices 1936
15.8.1.3. Amazon Security Lake Integration 1961
15.8.1.4. Collecting Logs from Amazon ECS Containers 1970
15.8.2. Azure 1972
15.8.2.1. Preparing the Azure Workspace 1972
15.8.2.2. Azure Event Hubs Integrations 1977
15.8.2.3. Microsoft Sentinel SIEM Integration 1982
15.8.2.3.1. DCR Template with Stream Values 1988
15.8.3. Splunk 2030
15.8.3.1. Splunk Cloud Platform and BYOL Integrations 2030
15.8.3.2. Switch Cribl Stream Destinations from S2S to Splunk HEC 2031
15.8.3.3. Splunk to Elasticsearch 2035
15.8.3.4. Splunk to Exabeam 2041
15.8.3.5. Splunk Stream to Cribl Stream 2049
15.8.3.6. Decryption of Data in Splunk 2053
15.8.3.7. Stream-to-Splunk Encryption 2057
15.8.4. Syslog 2063
15.8.4.1. Syslog Best Practices 2063
15.8.4.2. Palo Alto Syslog to Cribl.Cloud 2077
15.8.5. Configure Upstream Logging Agents 2083
15.8.6. BigPanda/Webhook Integration 2095
15.8.7. Gigamon to Cribl Stream 2099
15.8.8. System Metrics to Grafana 2101
15.8.9. Kafka Authentication with Kerberos 2106
15.8.10. Moogsoft/Webhook Integration 2108
15.8.11. Nightfall Integration 2114
15.8.12. Managing QRadar Licenses 2118
15.8.13. Slack/Webhook Integration 2122
15.8.14. Tanium to Cribl Stream 2124
15.8.15. Zscaler NSS Integration 2131
16. Knowledge Libraries 2138
16.1. Lookups Library 2139
16.2. Event Breakers 2143
16.3. Parsers Library 2157

16.4. Global Variables Library 2159
16.5. Regex Library 2161
16.6. Grok Patterns Library 2164
16.7. Schemas Library 2165
16.8. Parquet Schemas 2168
16.9. Database Connections 2177
16.10. HMAC Functions 2181
16.11. AppScope Configs 2183
17. Reference 2191
17.1. API Docs 2191
17.2. HTTP Response Codes 2200
17.3. Cribl Expression Syntax 2201
17.4. Cribl Expressions 2204
17.4.1. C.Crypto – Data Encryption and Decryption 2205
17.4.2. C.Decode and C.Encode - Encoding and Decoding 2208
17.4.3. C.Lookup – Inline Lookup Methods 2213
17.4.4. C.Mask – Data Masking Methods 2217
17.4.5. C.Net – Network Methods 2224
17.4.6. C.Text – Text Methods 2230
17.4.7. C.Time – Time Methods 2234
17.4.8. Miscellaneous Expression Methods 2240
17.5. CLI Reference 2247
17.6. Environment Variables 2271
17.7. Config Files 2278
17.7.1. cribl.yml 2282
17.7.2. breakers.yml 2288
17.7.3. certificates.yml 2289
17.7.4. groups.yml 2290
17.7.5. inputs.yml 2291
17.7.6. instance.yml 2366
17.7.7. jobs.yml 2367
17.7.8. job-limits.yml 2386
17.7.9. leader.yml 2387
17.7.10. licenses.yml 2389
17.7.11. limits.yml 2390
17.7.12. logger.yml 2392
17.7.13. mappings.yml 2393
17.7.14. messages.yml 2394

17.7.15. outputs.yml 2395
17.7.16. parsers.yml 2456
17.7.17. perms.yml 2457
17.7.18. policies.yml 2458
17.7.19. regexes.yml 2461
17.7.20. roles.yml 2462
17.7.21. samples.yml 2463
17.7.22. schemas.yml 2464
17.7.23. scripts.yml 2465
17.7.24. secrets.yml 2466
17.7.25. service.yml 2467
17.7.26. vars.yml 2468
18. Better Practices / Usage Examples 2469
18.1. Tips and Tricks 2469
18.2. Lookup Applications 2473
18.2.1. Ingest-Time Lookups 2473
18.2.2. Managing Large Lookups 2478
18.2.3. Lookups as Filters for Masks 2482
18.2.4. Lookups and Regex Magic 2485
18.2.5. Updating Lookups in Multiple Packs 2496
18.2.6. Updating Lookups with a REST API 2500
18.3. Sampling Applications 2502
18.3.1. Sampling 2502
18.3.2. Sample Logs 2504
18.3.3. Access Logs: Apache, ELB, CDN, S3, Etc. 2510
18.3.4. Firewall Logs: VPC Flow Logs, Cisco ASA, Etc. 2513
18.4. Transformation Applications 2516
18.4.1. Code Function Examples 2516
18.4.2. Ingest-Time Fields 2527
18.4.3. Masking and Obfuscation 2529

1. Introduction

1.1. About Cribl Stream

All the docs to goat you started with Cribl Stream

- Download all docs as a PDF – 4.9.2 | Download Cribl Stream | Get Cribl.Cloud
- Questions not answered here? We'd love to help you. Meet us in #Cribl Community Slack – sign up here

---

What Is Cribl Stream?

Cribl Stream helps you process machine data – logs, instrumentation data, application data, metrics, etc. – in real time, and deliver them to your analysis platform of choice. It allows you to:

- Add context to your data, by enriching it with information from external data sources.
- Help secure your data, by redacting, obfuscating, or encrypting sensitive fields.
- Optimize your data, per your performance and cost requirements.

Sources, Cribl Stream, Destinations

Cribl Stream ships in a single, no-dependencies package. It provides a refreshing and modern interface for working with and transforming your data. It scales with – and works inline with – your existing infrastructure, and is transparent to your applications.

Who Is Cribl Stream For?

Cribl Stream is built for administrators, managers, and users of operational/DevOps and security intelligence products and services.

How Can I Get Started with Cribl Stream?

You can quickly create a Cribl.Cloud account to get Cribl Stream running on infrastructure that Cribl manages on your behalf. Or you can deploy Cribl Stream software on your own infrastructure, Kubernetes Pods, or containers. For differences between these options, see these topics:

- Why Use Cloud Deployment?
- Cribl.Cloud vs. Self-Hosted

Both options offer a range of free and paid alternatives. With an Enterprise Cloud plan, you have the additional option of a hybrid deployment. Here, Cribl manages the control plane (Leader) for you on Cribl.Cloud, but your data plane (Workers) can run on any mix of Cribl-managed versus self-hosted infrastructure.

1.2. Basic Concepts

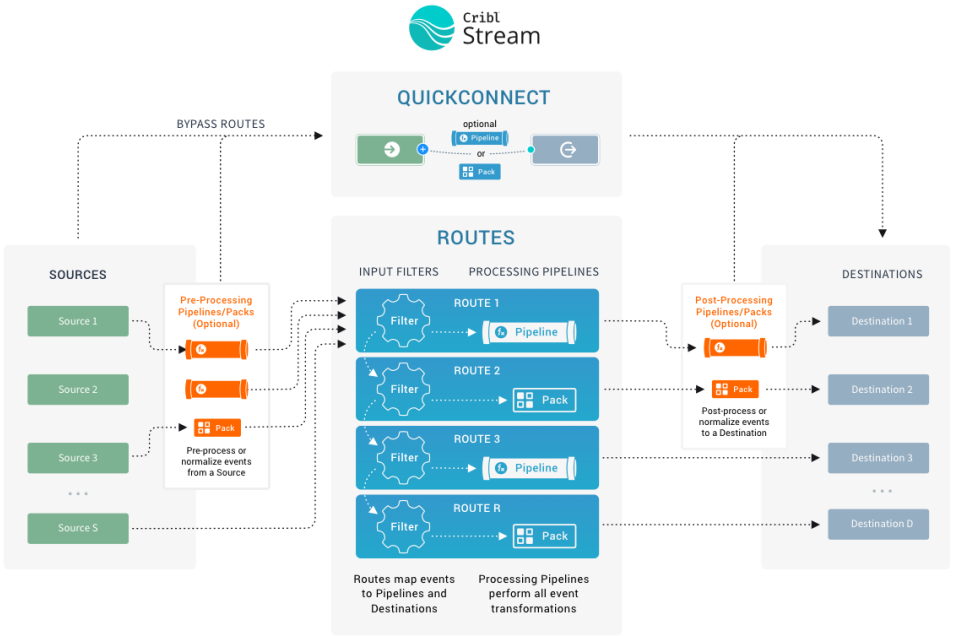
Notable features and concepts to get a fundamental understanding of Cribl Stream

---

As we describe features and concepts, it helps to have a mental model of Cribl Stream as a system that receives events from various sources, processes them, and then sends them to one or more destinations.

Sources, Cribl Stream, Destinations

Let's zoom in on the center of the above diagram, to take a closer look at the processing and transformation options that Cribl Stream provides internally. The basic interface concepts to work with are Sources, which collect data; and Routes, which manage data flowing through Pipelines, which consist of Functions.



Routes, Pipelines, Functions

Sources

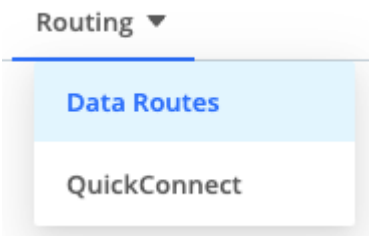
Sources are configurations that enable Cribl Stream to receive data from remote senders (Splunk, TCP, Syslog, etc.), or to collect data from remote file stores or the local machine.

QuickConnect

QuickConnect is a graphical interface for setting up data flow through your Cribl Stream deployment. You can quickly drag and drop connections between Sources and Destinations, optionally including – or excluding – Pipelines or Packs.

The only major constraint is that QuickConnect completely bypasses Routes. So QuickConnect configurations have no Routing table, and no conditional cloning, cascading, or routing of data – every QuickConnect connection is parallel and independent.

Use the **Routing** menu to toggle between the **Data Routes** and **QuickConnect** interfaces. (The **Routing** menu appears at the top of the **Worker Groups** page in a Distributed deployment, and at the top of the Stream Home page in a Single-instance deployment.)



Select Data Routes to use the Routing table, or QuickConnect to bypass Routes

Routes

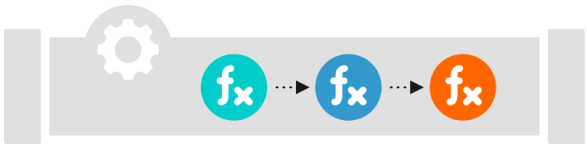
Routes evaluate incoming events against **filter** expressions to find the appropriate Pipeline to send them to. Routes are **evaluated in order**. Each Route can be associated **with only one** Pipeline and one output (configured as a Cribl Stream **Destination**).

By default, each Route is created with its `Final` flag set to `Yes`. With this setting, a Route-Pipeline-Destination set will consume events that match its filter, and that's that.

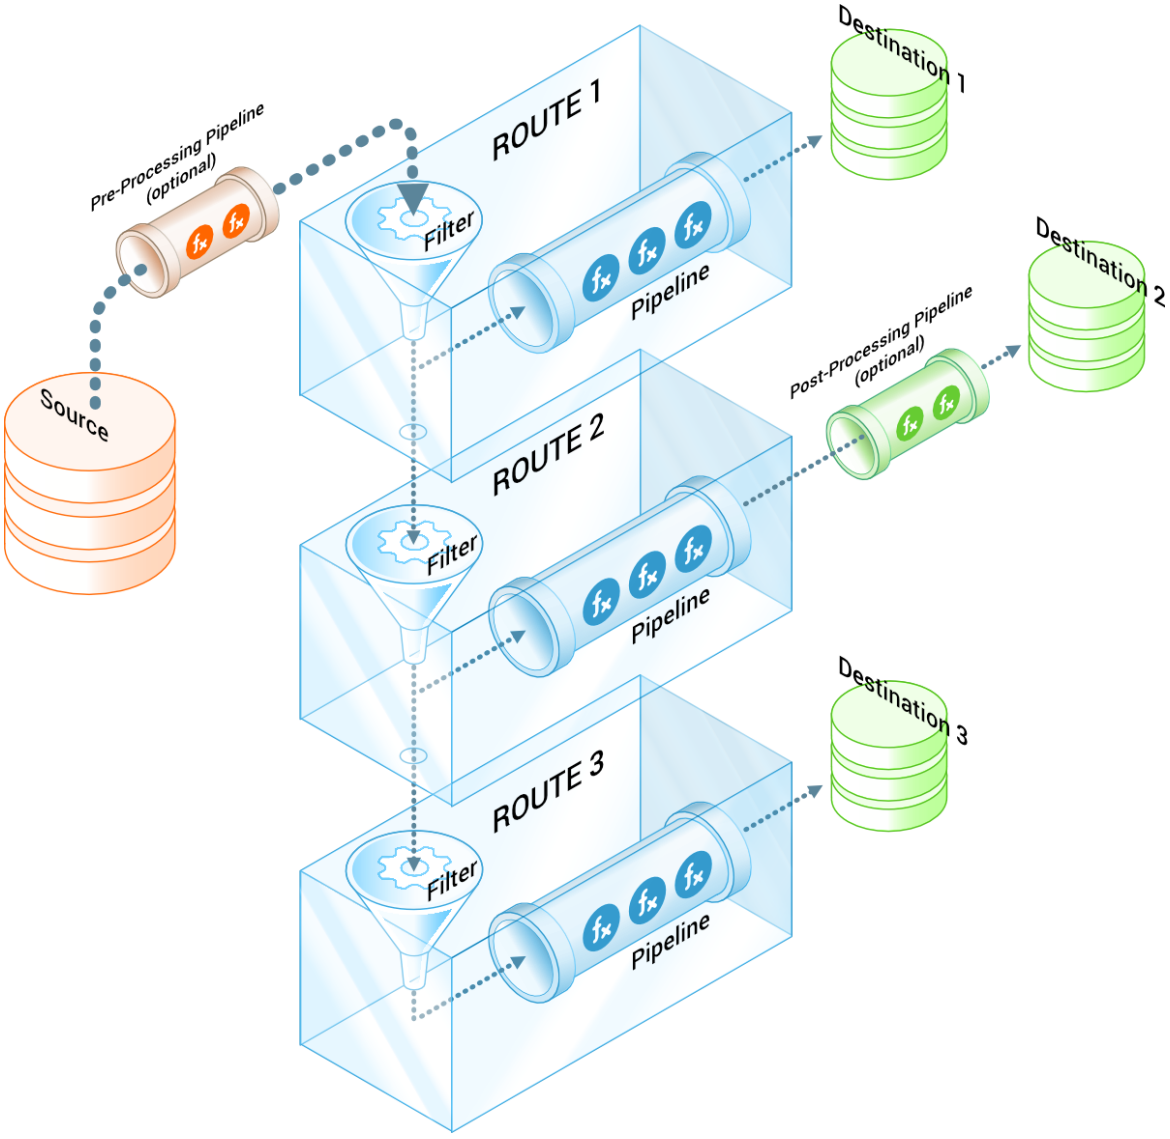
However, if you disable the Route's `Final` flag, one or more event **clones** will be sent down the associated Pipeline, while the original event continues down Cribl Stream's Routing table to be evaluated against other configured Routes. This is very useful in cases where the same set of events needs to be processed in multiple ways, and delivered to different destinations. For more details, see Routes.

Pipelines

A series of Functions is called a Pipeline, and the order in which you specify the Functions determines their execution order. Events are delivered to the beginning of a Pipeline by a Route, and as they're processed by a Function, the events are passed to the next Function down the line.



Pipelines attached to Routes are called **processing Pipelines**. You can optionally attach **pre-processing Pipelines** to individual Cribl Stream Sources, and attach **post-processing Pipelines** to Cribl Stream Destinations. All Pipelines are configured through the same UI – these three designations are determined only by a Pipeline's placement in Cribl Stream's data flow.



Pipelines categorized by position

Events only move forward – toward the end of a Pipeline, and eventually out of the system. For more details, see Pipelines.

Functions

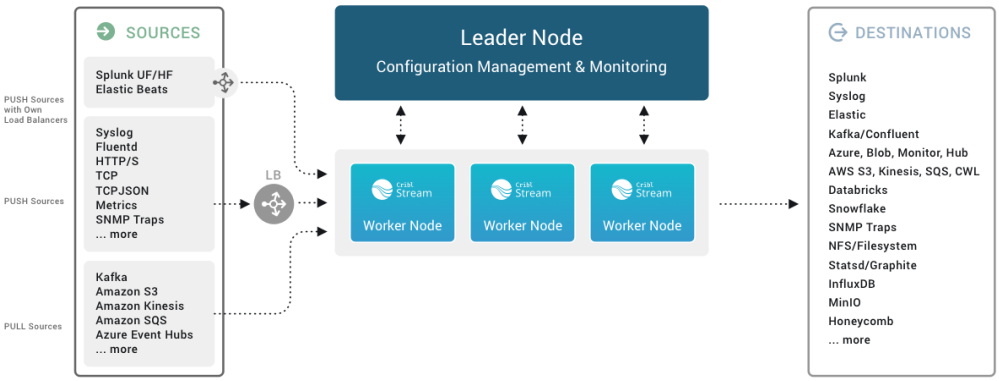
At its core, a **Function** is a piece of code that executes on an event, and that encapsulates the smallest amount of processing that can happen to that event. For instance, a very simple Function can be one that replaces the term `foo` with `bar` on each event. Another one can hash or encrypt `bar`. Yet another function can add a field – say, `dc=jfk-42` – to any event with `source=*us-nyc-application.log`.

Functions stacked in a Pipeline

Functions process each event that passes through them. To help improve performance, Functions can optionally be configured with filters, to limit their processing scope to matching events only. For more details, see Functions.

A Scalable Model

You can scale Cribl Stream up to meet enterprise needs in a distributed deployment. Here, multiple Cribl Stream Workers (instances) share the processing load. But as you can see in the preview schematic below, even complex deployments follow the same basic model outlined above.



Distributed deployment architecture

Shared-Nothing Architecture

All Cribl Stream deployments are based on a shared-nothing architecture pattern. This means that each instance (or Worker Node) and its associated Worker Processes operate autonomously, handling inputs, outputs, and event processing independently.

This architecture ensures scalability and resilience. The system, composed of a Leader and multiple Worker Nodes, will continue to operate even if individual Worker Processes or Worker Nodes fail. It also allows individual Nodes to upgrade without system-wide downtime.

1.3. Cribl.Cloud Vs. Self-Hosted

A Cribl.Cloud deployment differs in several ways from a customer-managed (on-prem) deployment of Cribl Stream software on your own infrastructure. Keep in mind these differences as you choose how to launch Cribl Stream. Also consider these differences as you navigate the product's UI, in-app help (including tooltips), and documentation.

Cloud-Only Features

Certain Cribl products and features are available **only** on Cribl.Cloud:

- Cribl Search, an application for searching, exploring, and analyzing machine data in place and at API endpoints.
- Cribl Lake, a data lake solution for long-term, full-fidelity data storage.
- Workspaces, an option for isolating parallel Cribl Leaders with separate access controls and other configurations.

For details about how all Cribl products interoperate to manage data, see Cribl Reference Architecture, Full-Suite.

Simplified Administration

Cribl.Cloud has been designed with options to accommodate everyone – from first-time evaluators to Enterprise customers who manage a worldwide network of private-cloud, public-cloud, and/or data-center deployments.

Cribl.Cloud's Free offering is designed to help you launch Cribl Stream – and to start processing data – as quickly and easily as possible. Upgrading to a paid Standard or Enterprise plan provides expanded deployment and configuration options.

For a comparison of features in Free, Standard, and Enterprise Cribl.Cloud plans, see Pricing.

Simplified Distributed Architecture

Cribl.Cloud is preconfigured as a Distributed deployment for Cribl Stream or Cribl Edge. A Free or Standard plan allows only a single Worker Group, and some Distributed Settings cannot be configured.

With an Enterprise plan, Cribl always provides at least two Workers, and will scale up further Workers as needed to meet your peak load. With an Enterprise plan, you also have the option to configure additional

hybrid Worker Nodes and Worker Groups.

Git Preconfigured

Without an Enterprise plan, the **Settings** > **Global** > **System** > **Git Settings** section is omitted. However, a local `git` client is preconfigured in your Cribl.Cloud portal. On the top nav, use the **Version Control** button (with a branched symbol) to commit/push changes to `git`. Select **Deploy** to deploy your committed changes. Cribl.Cloud does not support Git remote repos.

Automatic Restarts and Upgrades

Without an Enterprise plan, the **Settings** > **Controls** link are omitted. Cribl handles Leader and Worker Group restarts automatically on your behalf.

Simplified Access Management and Security

In Cribl.Cloud, you can manage access control for your Organization by selecting **Organization** in the sidebar and then selecting **Members & Teams**. The options on this tab will vary depending on your plan.

If you have a Cribl.Cloud Enterprise plan, you can use the Key Management Service (KMS), which maintains the keys Cribl Stream uses to encrypt secrets on Worker Groups and Worker Nodes. Go to **Settings** > **Security** > **KMS** to configure KMS.

If you add an Enterprise Plan, cloud and hybrid Leaders support Local and Google SSO authentication, along with OpenID Connect (OIDC) and SAML federated authentication. Cribl.Cloud does not currently support LDAP.

Permission- and Role-based access control (RBAC) is simplified in Cribl.Cloud. For details, see Member Permissions.

Security Features Comparison: Self-Hosted vs. Cribl.Cloud

The following table outlines the security responsibilities for self-hosted and Cribl.Cloud deployments, highlighting key differences in deployment security, data protection, threat detection, and access control.

Feature	Self-Hosted	Cribl.Cloud
Deployment Security	Customer responsible for securing the deployment environment (network isolation, physical access control, user access management).	Cribl manages the security of the cloud infrastructure.

Feature	Self-Hosted	Cribl.Cloud
Configuration Security	Customer responsible for securing configuration files and tokens.	Cribl manages the security of configuration files and tokens.
Git Configuration Security	Customer responsible for securing the Git repository.	Cribl manages the security of the Git repository.
Data at Rest	Customer responsible for encryption and key management.	Encrypted at rest by using industry standard encryption (e.g., AES-256) for storage services.
Data in Motion	Customer configures encryption (TLS) for data in transit.	Pre-configured TLS for some sources. Can be further configured.
Threat Detection & Response	Customer responsibility. Use Cribl Stream security features (limited) and external tools.	Cribl bolsters its security posture with internal security teams and an external MSSP, ensuring comprehensive protection for its production and corporate environments through threat detection, workload scanning, and vulnerability management.
Patch Management	Customer responsible for applying security patches to Cribl Stream and underlying infrastructure.	Cribl manages patching of Cribl.Cloud (Cribl-managed) infrastructure.
Access Control	Customer configures user roles and permissions (RBAC).	Simplified RBAC with Enterprise plans offering advanced options (SSO, KMS).
Authentication	Customer configures authentication methods.	Local and SAML/OIDC IDP with Enterprise plans (additional options).
Key Management	Customer manages encryption keys.	Enterprise plans offer Key Management Service (KMS) for key storage.
Compliance	Customer responsible for adhering to compliance standards.	SOC 2 Type II compliant and GDPR-compliant (Cribl.Cloud).

Transparent Licensing

The Cribl.Cloud sidebar does not display a **Settings** > **Global** > **Licensing** link. This is because your license is managed by your parent Cribl.Cloud portal, where you can check credits and usage history on the Billing tab.

Other Simplified Settings

These features are available only on customer-managed hybrid Cribl Stream Workers:

- Script Collector
- Staging directory support in File-based Destinations
- Tee Function
- File System Collector
- Filesystem Destination

These features are available only in on-prem deployments:

- **Settings** > **Global** > **Scripts** (if enabled – Cribl.Cloud does not support configuring or running shell scripts).

These features are unavailable on Cribl-managed Stream Workers in Cribl.Cloud:

- System State Source
- AppScope Source's **Filter Settings**

Configuring persistent queues in a Cribl.Cloud deployment requires an Enterprise plan. On customer-managed (hybrid or on-prem) Worker Groups and on all Edge Nodes, you can freely define the **Max queue size**, based on the disk space you provision.

However, on Cribl-managed Worker Groups, each Source or Destination's queue is allocated a maximum of 1 GB disk space per Worker Process. (Given this automatic configuration, Cribl-managed Sources and Destinations expose only limited PQ controls.)

Available Ports and TLS Configurations

To get data into Cribl.Cloud, your Cribl.Cloud portal provides several Sources and ports already enabled for you, plus 11 additional TCP ports (`20000-20010`) that you can use to add and configure more Cribl Stream Sources.

TLS Details

TLS encryption is pre-enabled for you on several Sources, also indicated on the your Workspace's **Data Sources** tab.

Cribl HTTP and Cribl TCP Sources/Destinations

Use the Cribl HTTP Destination and Source, and/or the Cribl TCP Destination and Source, to relay data between Worker Nodes connected to the same Leader.

This traffic does not count against your ingestion quota, so this routing prevents double-billing. (For related details, see Exemptions from License Quotas.)

Simplified Source, Collector, and Destination Configuration

Several commonly used Sources are preconfigured for you within Cribl.Cloud's UI, and are ready to use.

The Exec Source is unavailable on Cribl-managed Workers in Cribl.Cloud, but is available on hybrid Workers.

The Cribl Internal Source's CriblLogs option, when used on Cribl-managed Worker Groups in Cribl.Cloud, contains only logs related to Sources and Destinations.

1.4. Cribl Stream Tour

This is a quick visual overview of configuring primary Cribl Stream components. It covers both the QuickConnect graphical UI and the more flexible Data Routing alternative, where you can conditionally branch the same incoming data to specific processing logic and destinations.

This tour is an ideal way to quickly familiarize yourself with Cribl Stream's UI and its general data-flow options. You can walk through the steps below in a free Cribl.Cloud environment, without installing any software.

While this tour is not a prerequisite to the adjacent Getting Started Guide and Distributed Quick Start tutorials, it will accelerate your later progress through them. The adjacent tutorials focus on on-prem deployments, processing Pipelines configuration, and more-complex routing options.

Accessing Cribl Stream

The quickest way to start your progress through this tour is by signing up for a free Cribl.Cloud account. Cribl will manage all infrastructure for you, and you can upgrade your deployment to a flexible paid plan whenever you want more capacity. Log in and you'll be ready to go.

If you prefer to deploy Cribl Stream on your own infrastructure, see Installing on Linux. Then register your deployed software. Registration will unlock a free license with similar capabilities to a Cribl.Cloud free plan. Customize your password (if desired) and you'll be ready to go.

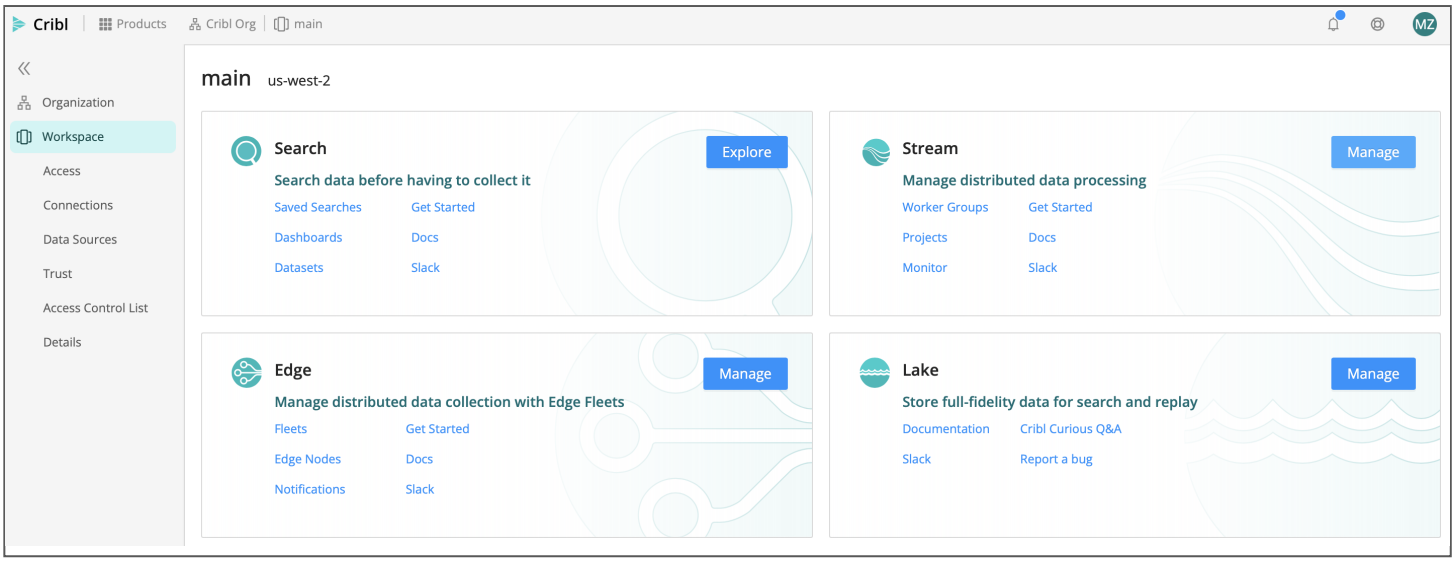
Setting Up the Tour on Cribl.Cloud

These first steps apply only to a Cribl.Cloud Organization. If you've deployed Cribl Stream as a single instance on your own Linux infrastructure, skip ahead to Simple or Complex Routing?.

Examples throughout this tour prioritize a Cribl.Cloud environment, which defaults to one Worker Group with one or two Workers. If you're running a single instance on your own Linux infrastructure, the examples will be equally valid, but you can ignore steps about deploying Groups.

Depending on how and when you take this tour – your environment, your plan or license tier (from free to Enterprise), and the date – some Cribl Stream pages might look slightly different from some screen captures in this tour. Again, the instructions will be equally valid.

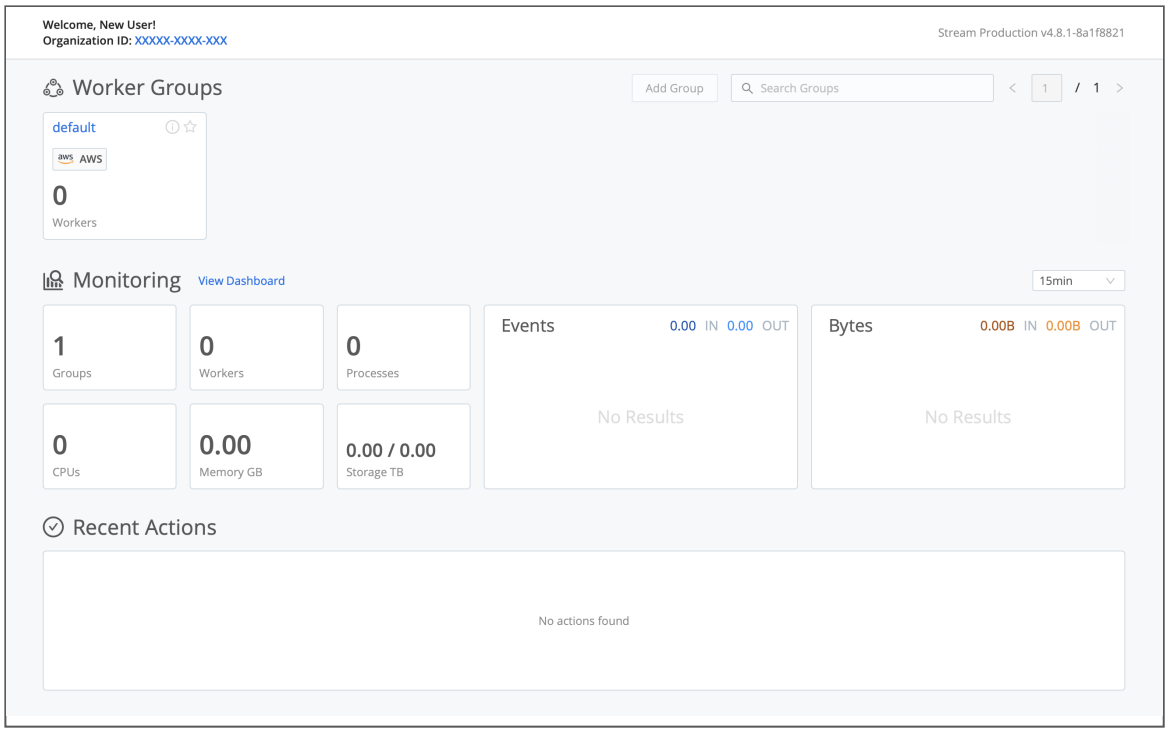
1. From your Cribl.Cloud Organization's home page, select the **Stream** tile's **Manage** button.



Navigating to Cribl Stream

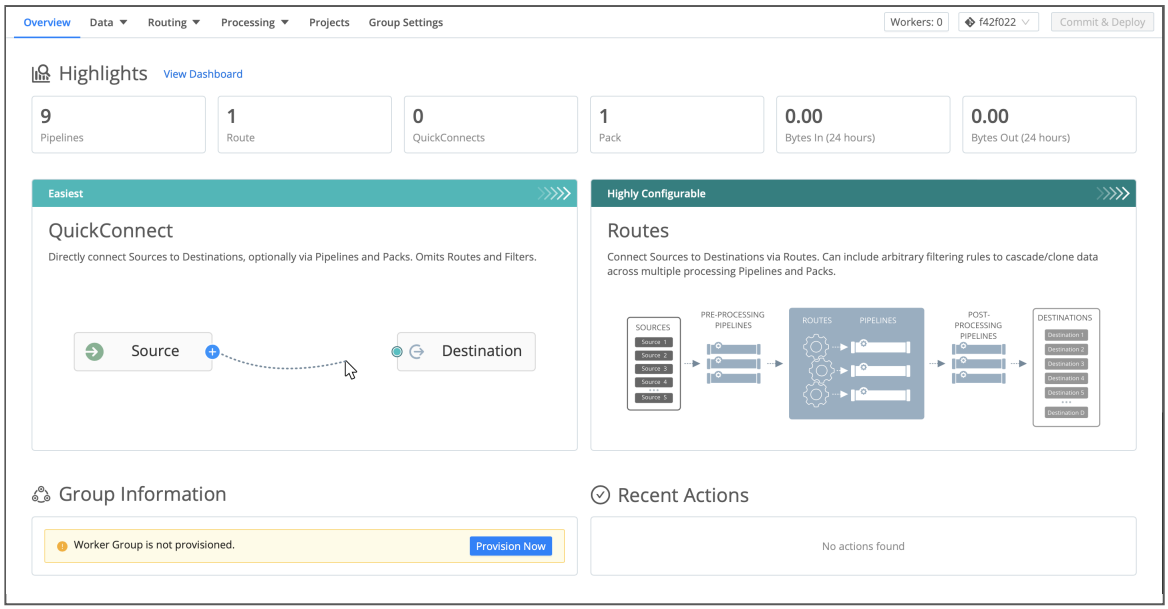
2. On the resulting **Worker Groups** page, select the `default` Group.

   (A Worker Group is a collection of processing instances that share the same configuration. For details, see the Distributed Deployment topic.)



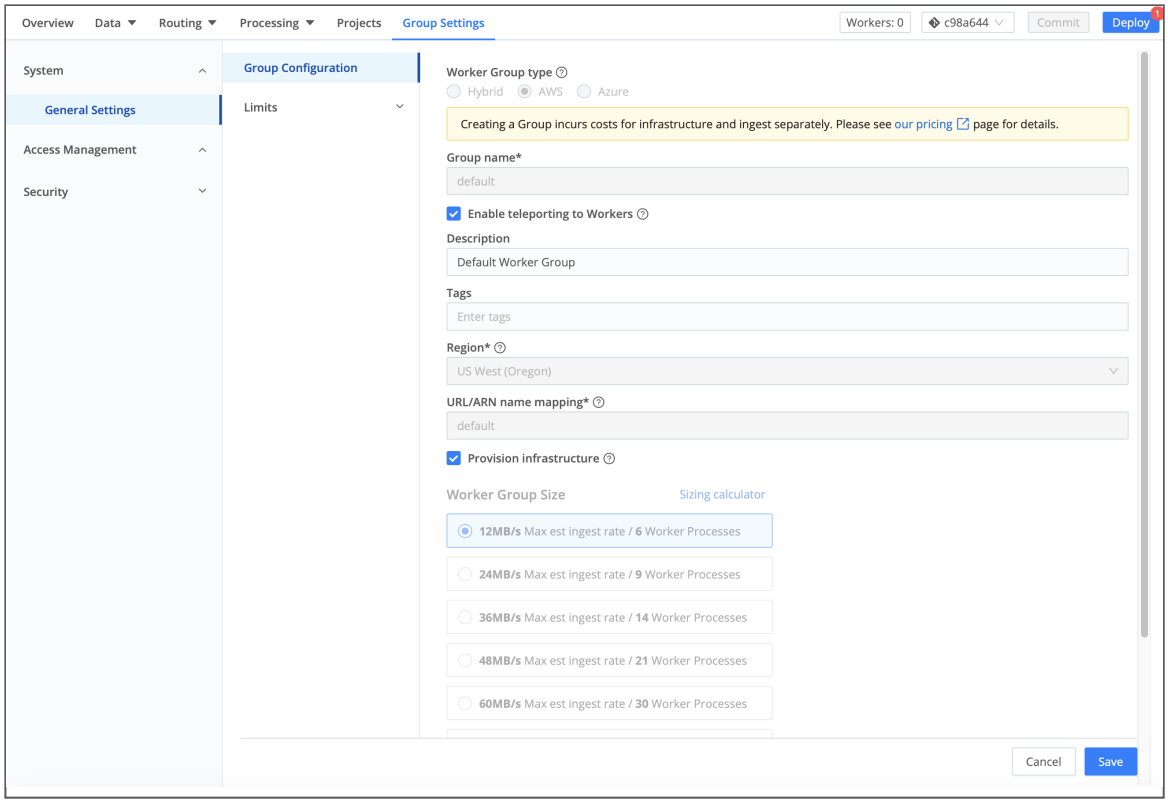
Selecting the `default` Worker Group

3. If you see a **Worker Group is not provisioned** warning, select the **Provision Now** button to enable the data flow we'll configure below.



`default` Group's initial state

4. As shown below, select both the **Enable teleporting to Workers** and the **Provision infrastructure** check boxes. Leave other defaults selected, and select **Save**.



Enabling the `default` Group

When you see a **Settings saved** confirmation banner, you're ready to commit and deploy your newly provisioned Worker Group.

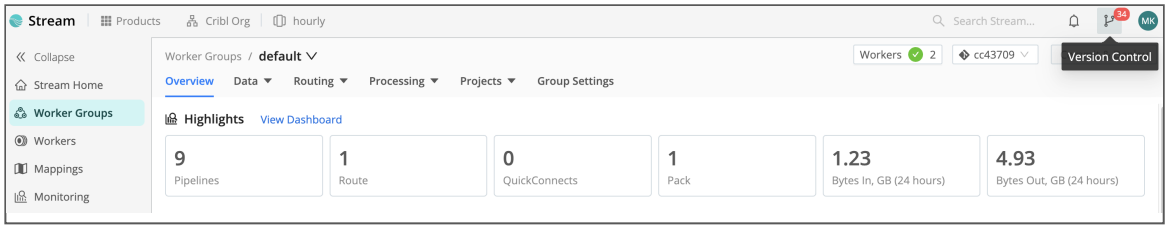
Committing and Deploying Config Changes

After any significant configuration change, you'll be prompted to use Cribl Stream's built-in version control (Git) features to deploy (or redeploy) your Workers and commit your configuration changes. Your first prompt is to deploy your newly provisioned Worker Group:

1. Select the blue **Deploy** button at the upper right (shown above with a red highlight indicator).

   Leave the default commit message intact and click **Deploy**. This will make your newly provisioned Group ready to process data.

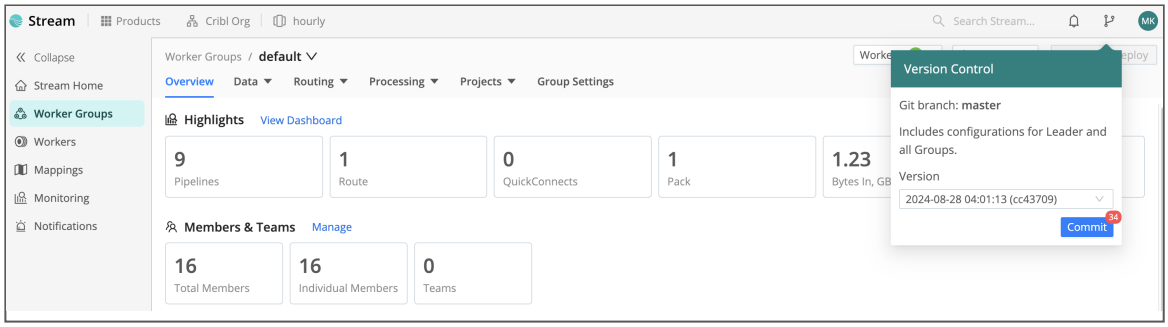
2. Next select the red-highlighted Version Control button at the upper right.



Version Coontrol button

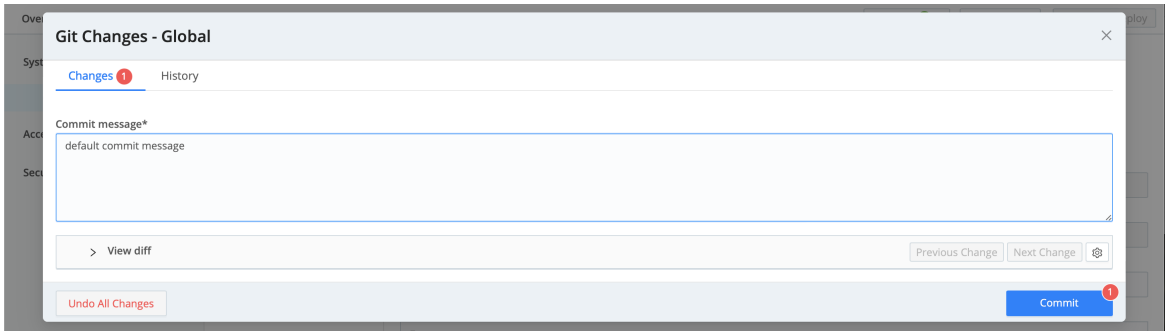
3. In the resulting drop-down, select the **Commit** button.

   (We'll explain all Version Control details later in this topic.)



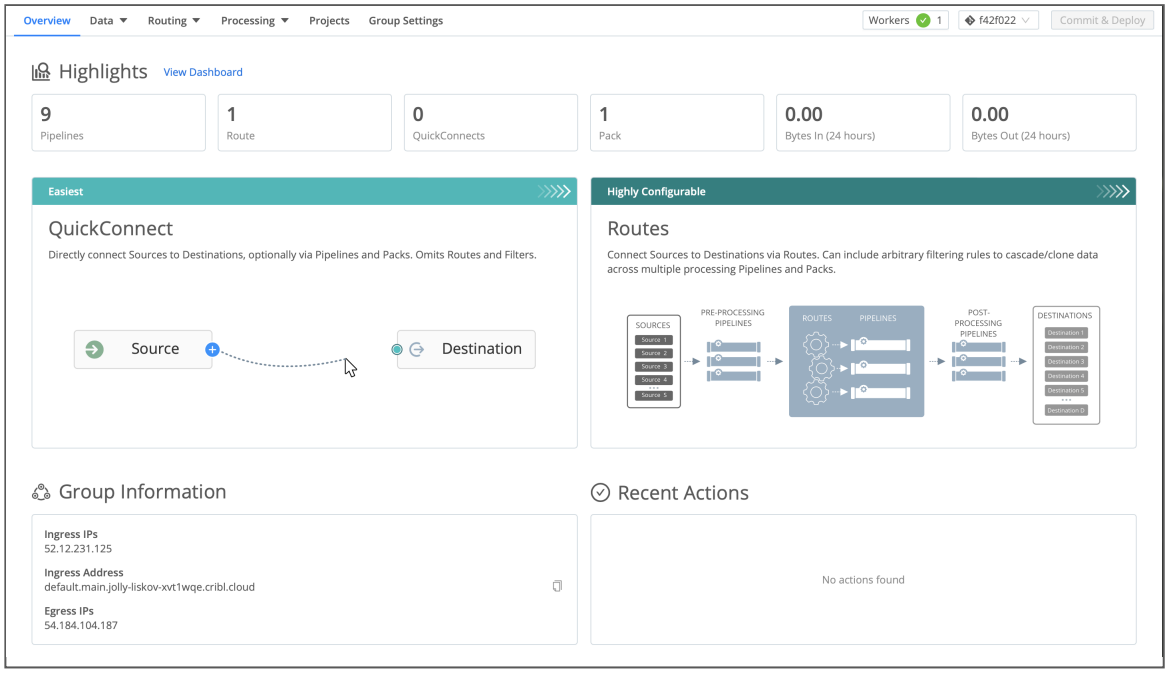
Committing a configuration change

4. In the resulting **Git Changes – Global** modal, accept all defaults, and again select **Commit** to close the modal.



5. If you don't already see a display like that shown below, select **Stream Home** to restore the **Worker Groups** page, then again select the `default` Group. You're now set up for the rest of this tour.

   To begin configuring this Group, you now have a two-up choice of **QuickConnect** or **Routes** tiles. How to choose? See the next section.



`default` Group enabled and ready to flow some data

For More Information

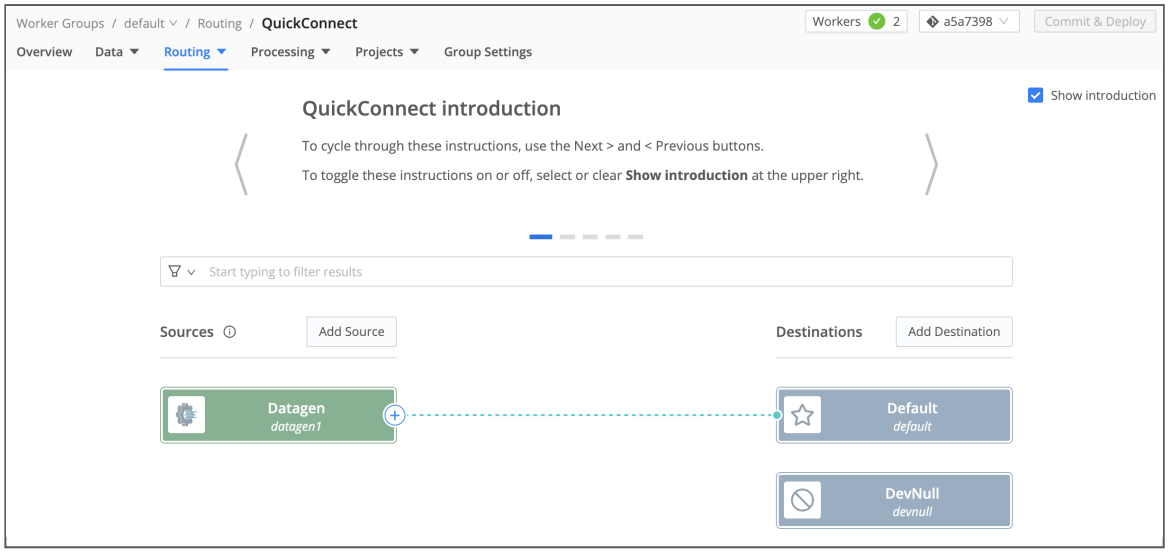
- Cribl.Cloud Launch Guide

Simple or Complex Routing?

Your first choice is how simply or intricately you want to configure data flow from the first data Source you set up. Cribl Stream offers two user interfaces:

- QuickConnect (the left tile shown above) provides a simple visual UI. You drag and drop connections from Sources on the left to Destinations on the right. Each connection can include as much or as little intermediate processing as you like. To remove a connection, just drag it off the Destination (you'll get a confirmation modal). The only practical limitation here is that data flow through every Source -> Destination connection must be parallel and independent.
- Data Routing (the right tile shown above) provides fine-grained control, via a more traditional UI that you configure across separate modals and pages. You build a Routing table with conditional processing. This

can cascade and clone data across multiple processing Routes, according to the arbitrary filtering rules and sequence that you define.



Configuring data flow in QuickConnect

So the trade-off between these two options is ease of use versus flexibility. These two options are separate, but not mutually exclusive: You can set up simultaneous data flows through QuickConnect and Data Routes.

You can also move Sources, and their connections to Destinations, between the two UIs. So one obvious option is to configure your first data flow in QuickConnect, and then move to the Routing UI as your familiarity and needs expand.

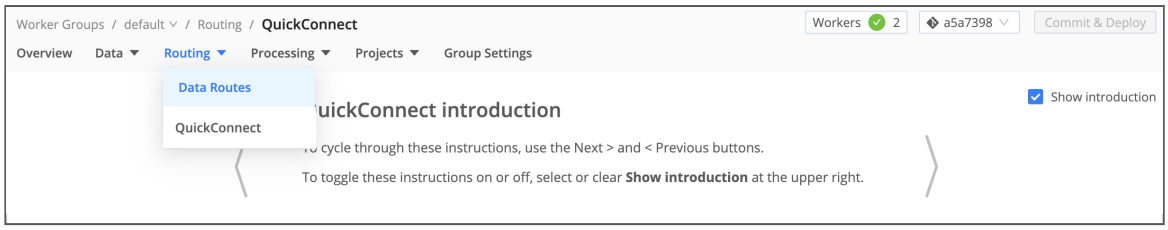
Each configured Source instance can be assigned only to QuickConnect or Routing, not both. To switch it to the opposite environment, you'll need to move it there, or duplicate its configuration there.

Navigate Between User Interfaces

To work in QuickConnect, select the left tile shown above, or select **Routing** > **QuickConnect**.

To work in the Routing UI, select the right tile shown above, or select **Routing** > **Data Routes**.

You can always switch between the two environments from a Worker Group, by using the **Routing** submenu.



Traversing between QuickConnect and Data Routes

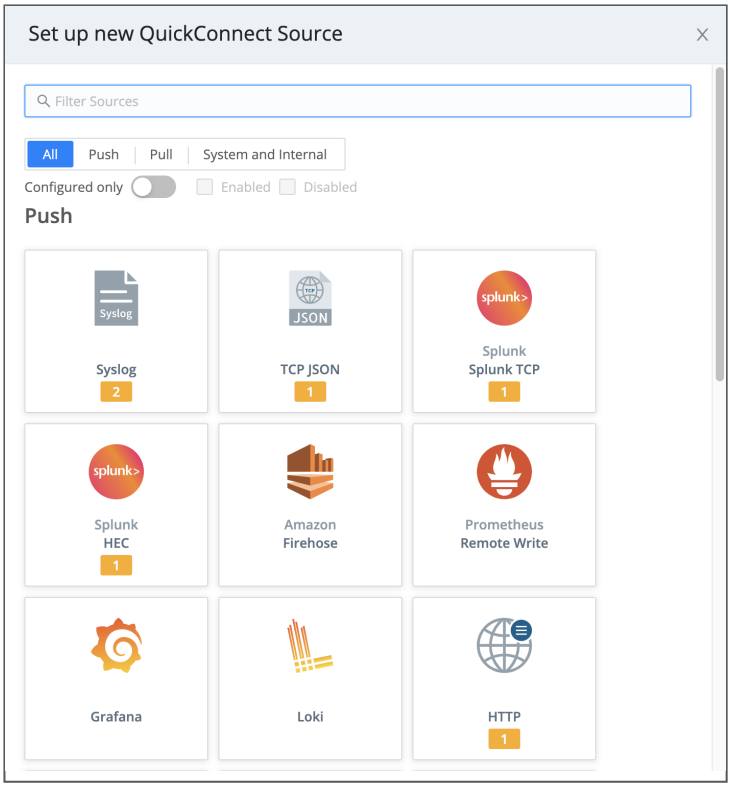
Configure a Source

A Source is a model of an upstream service sending data into the system. In this model, you configure authentication and/or other needed parameters.

You can configure multiple instances of a given Source type, each with different parameters. You can also attach processing that's specific to each instance. Cribl Stream provides the Datagen Source type to generate sample inbound events for development and testing.

Using QuickConnect

In QuickConnect, select the **Add Source** button on the left (Sources) side. In the resulting left drawer, search for and select your desired Source type to begin configuring a new instance of that Source.



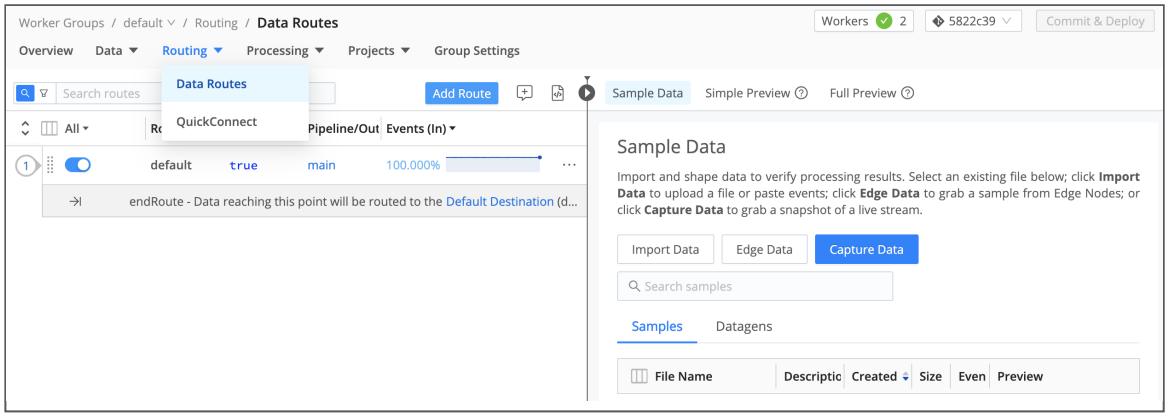
Selecting a Source through the QuickConnect UI

To configure (or reconfigure) a Source that's already present in QuickConnect, hover over its tile and select the **Configure** button.

For multiple Sources of the same type, tiles will be consolidated in a stack until you click the stack to display the hidden tiles.

Using Data Routes

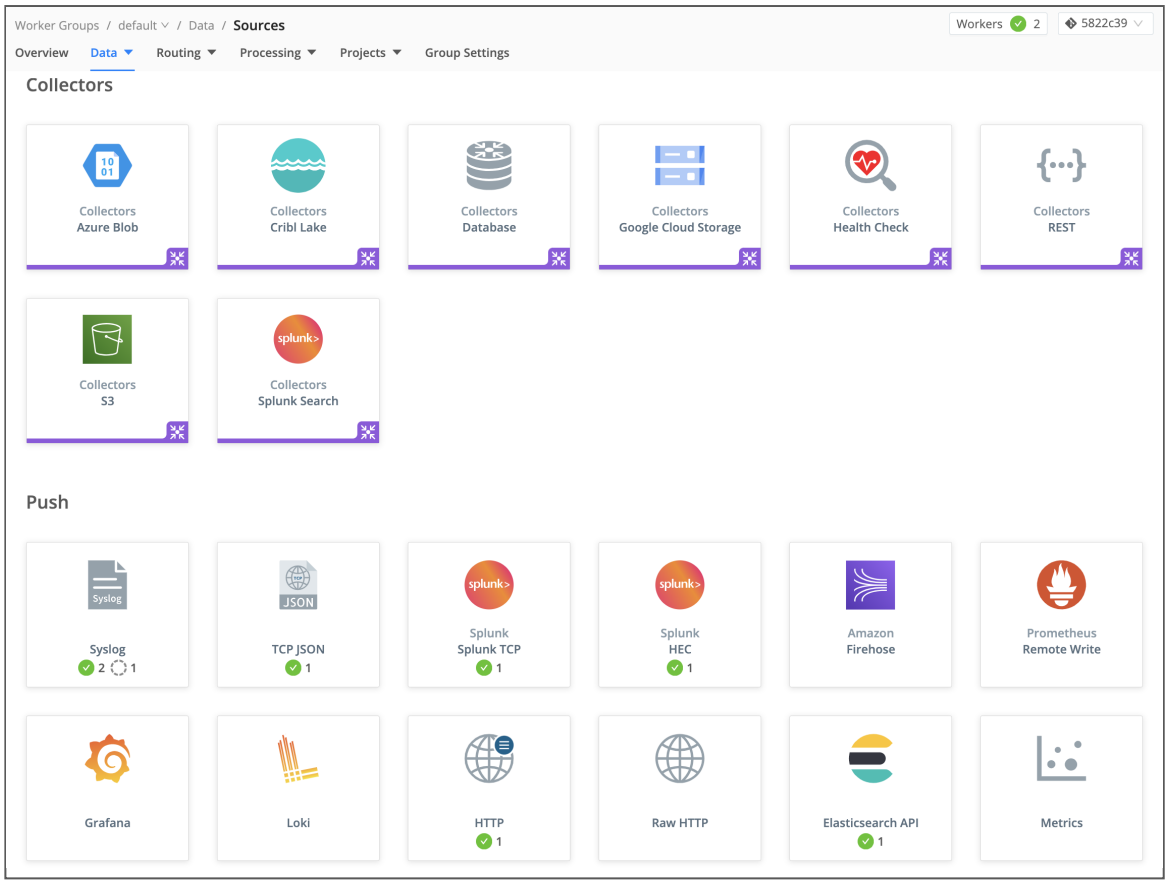
In the Routing UI, first select **Data** > **Sources**.



Selecting a Source through the Routing UI

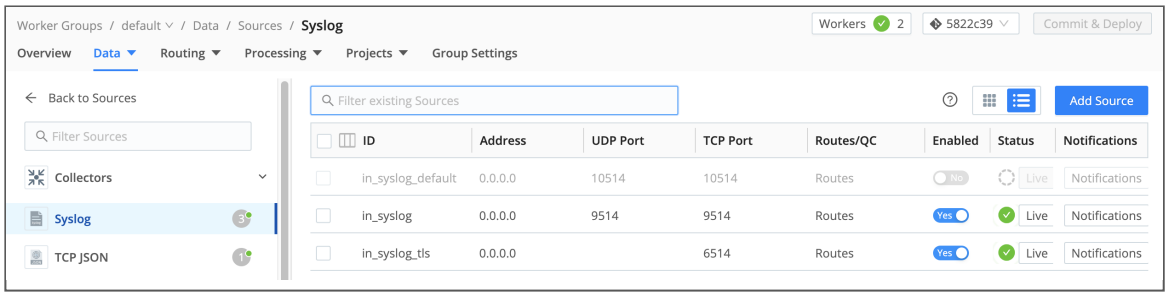
On the resulting **Sources** page, search for your desired Source type, then select its tile to begin configuring a new instance of that Source.

(After you click through to a Source, the same set of peer Sources will be available in the left nav.)



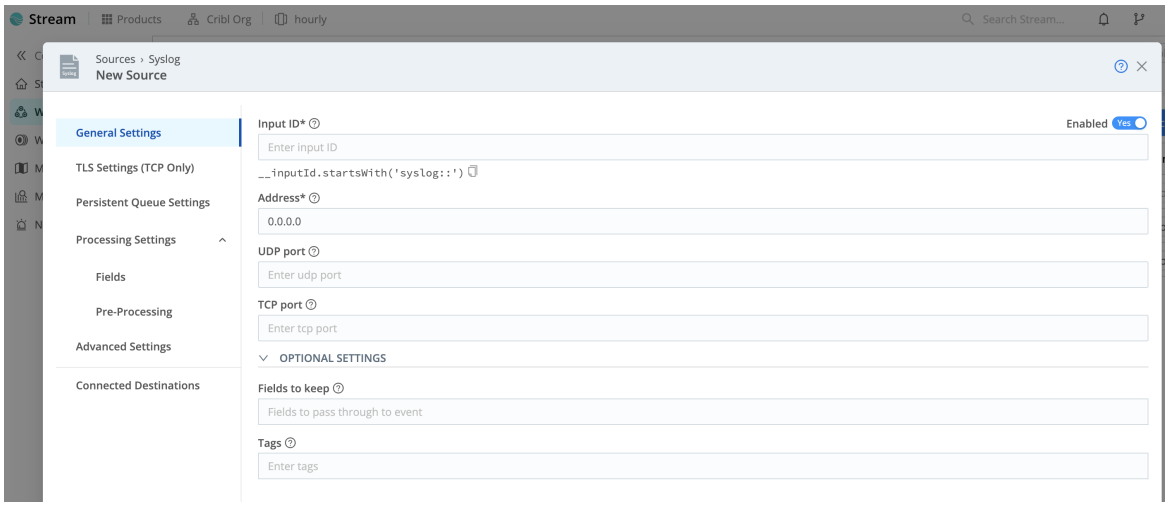
Sources page

Select an existing Source's row here to access its configuration, or select **Add Source** to configure a new instance of that Source.



Syslog Sources UI

You then configure (or reconfigure) the Source in a modal like this:



Syslog config modal

For More Information

- Sources
- Using Datagens
- QuickConnect
- Routes

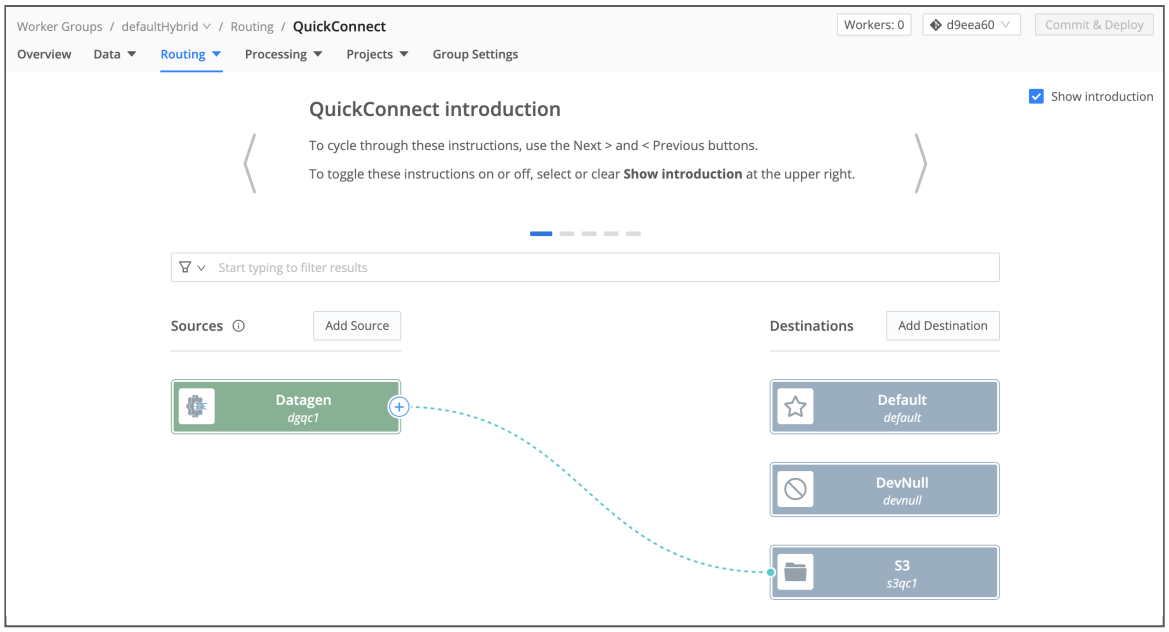
Configure a Destination

A Cribl Stream Destination is a model of a downstream receiver of events, enabling you to configure authentication and/or other needed parameters.

As with Sources, you can configure multiple instances of a given Destination type, each with different parameters. You can attach processing that's specific to each instance.

Using QuickConnect

To connect a configured Source to a Destination tile already present on the right, just drag from the Source and drop the connector onto the Destination. A pop-up will prompt you to configure the connection via a Passthru, Pipeline or Pack (explained below).

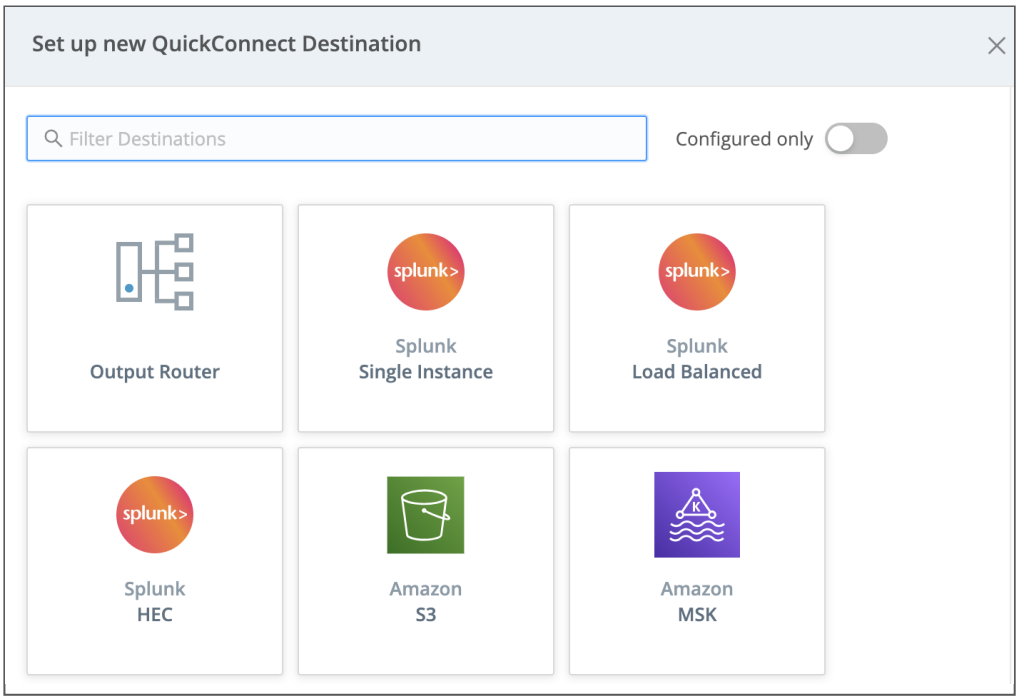


Multiple Destinations added to QuickConnect

To configure (or reconfigure) the Destination, hover over its tile and select the **Configure** button.

For multiple Destinations of the same type, tiles will be consolidated in a stack until you click the stack to display the hidden tiles.

To add a new Destination, select the **Add Destination** button on the right (Destinations) side. In the resulting right drawer, search for and select your desired Destination type to begin configuring a new instance of that Destination.

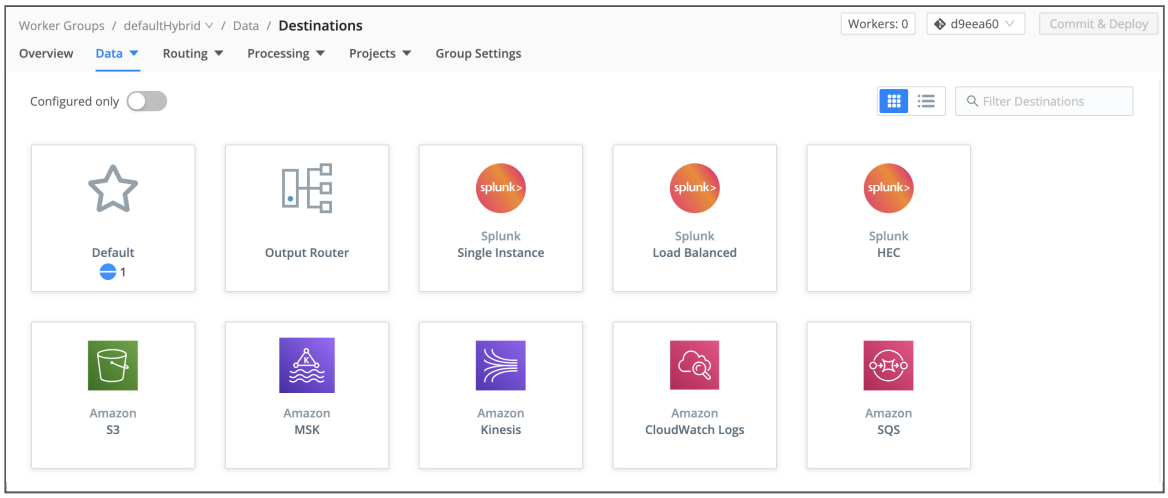


Selecting additional Destinations in QuickConnect

Using Data Routes

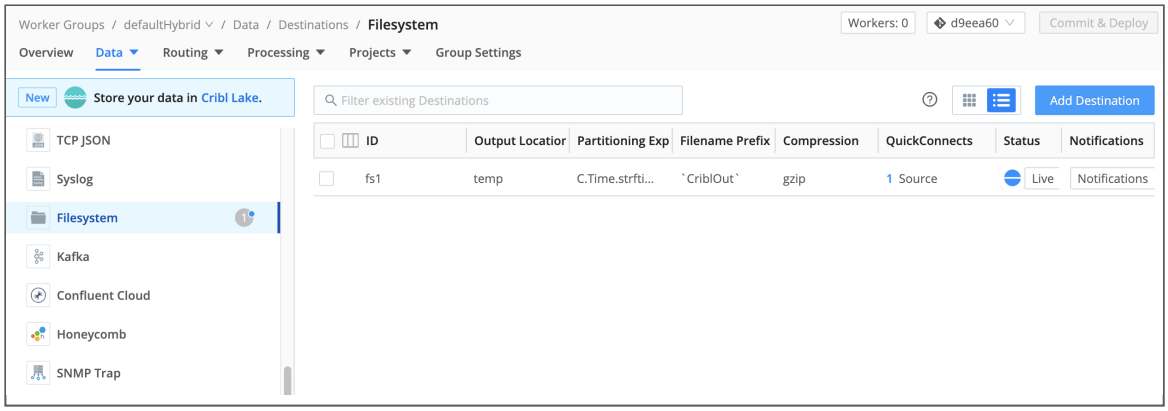
In the Routing UI, first select **Data** > **Destinations**. On the resulting **Destinations** page, search for your desired Destination type, then select its tile to begin configuring it.

(After you click through to a Destination, the same set of peer Destinations will be available in the left nav.)



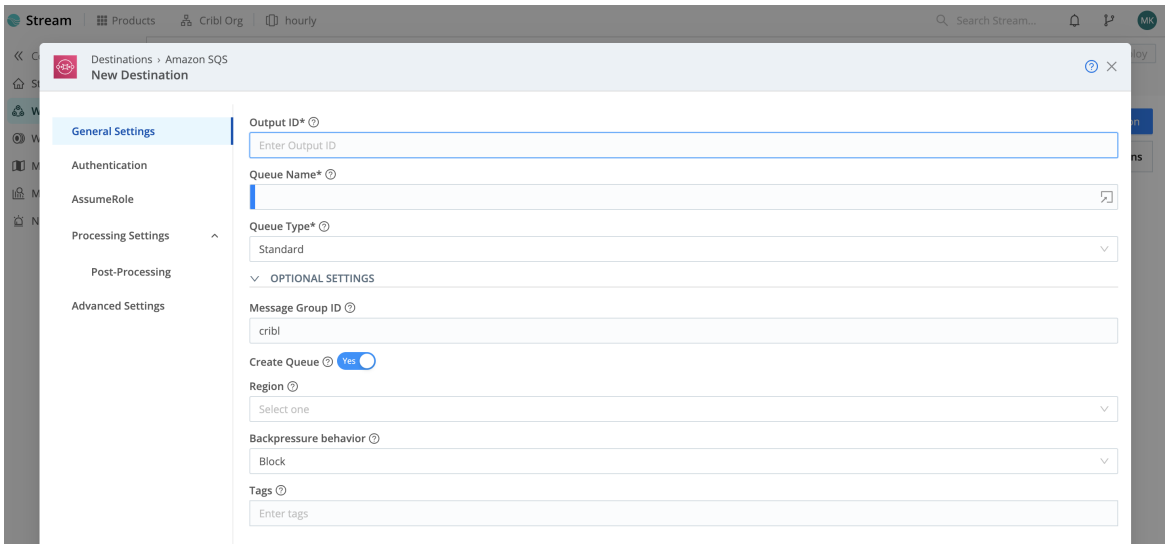
Destinations page

Select an existing Destination's row here to access its configuration, or select **Add Destination** to configure a new instance of that Destination.



Destinations UI

You then configure (or reconfigure) the Destination in a modal like this:



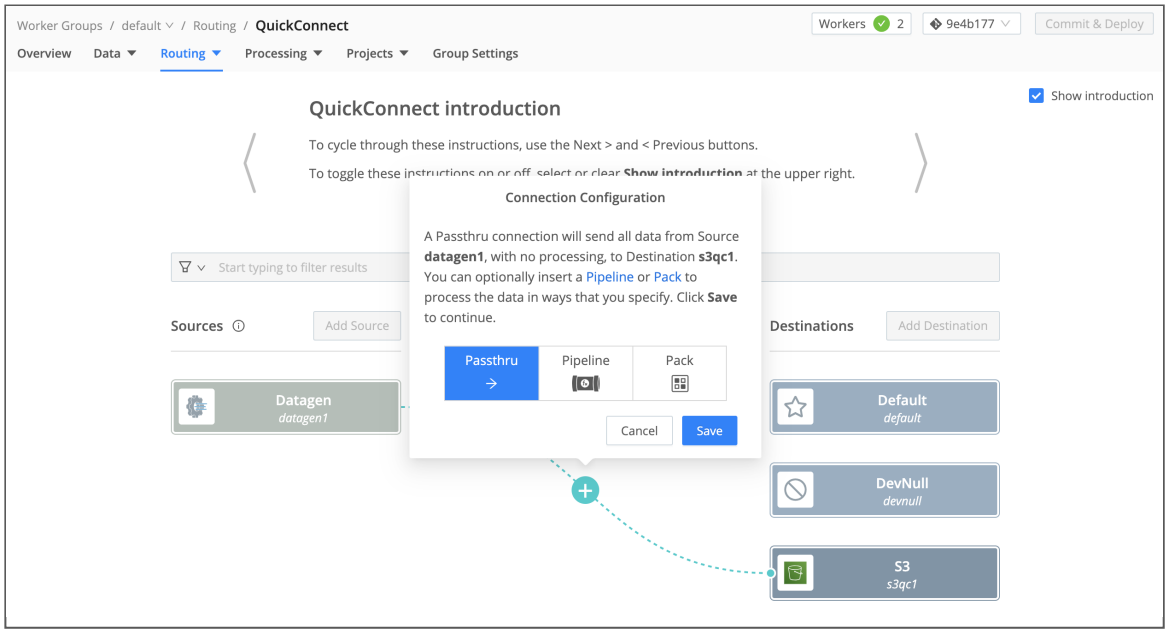
Destination config modal

For More Information

- Destinations

Connect: Passthru, Pipeline, or Pack

In QuickConnect, as soon as you drag and drop a Source -> Destination connection, a pop-up dialog will prompt you to select a connection type: **Passthru**, **Pipeline**, or **Pack**. (In Data Routes, you'll make the same choices elsewhere.)



Selecting a connection type in QuickConnect

What are these options?

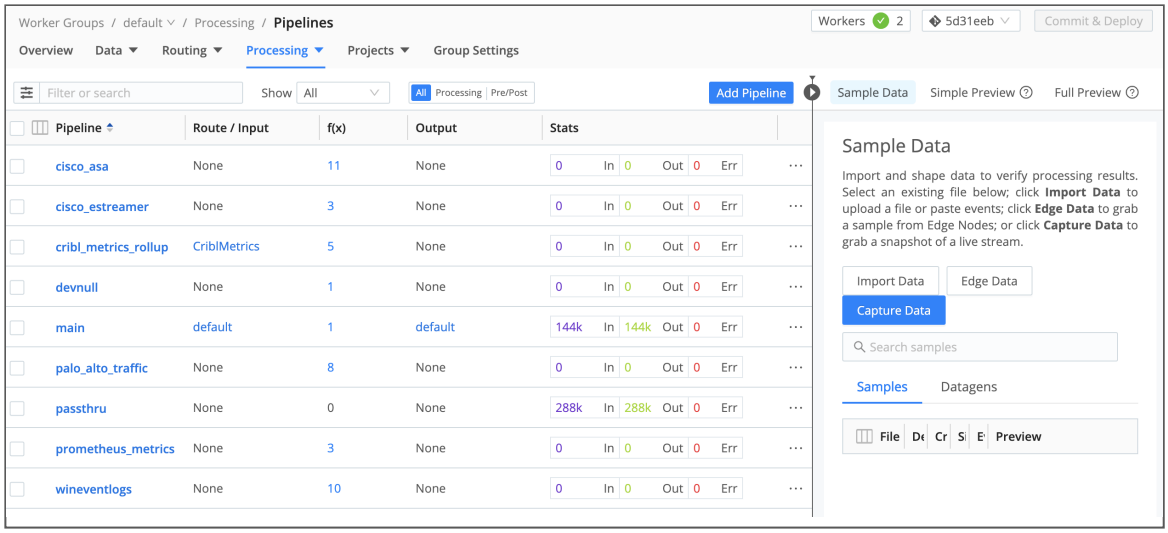
- A **Passthru** establishes a simple direct connection between a Source -> Destination pair.
- A Pipeline hosts a stack of Functions to process your data, in the order you arrange them.
- A Pack is a microcosm of a whole Cribl Stream configuration, designed to share configs between Worker Groups or deployments. A Pack can encapsulate its own Pipelines, Routes, Knowledge libraries, and sample data (but not data Sources or Destinations). A Pack can snap in wherever you can use a Pipeline.

So let's unpack Pipelines, where you'll define most of your event processing.

Pipeline Options

When you first create a new Pipeline, it's empty, making it equivalent to **Passthru**. Cribl Stream provides a set of out-of-the-box Pipelines for specific purposes. As you can see below, one of these is a **passthru** Pipeline. This similarly contains no Functions – making it the Data Routes UI's equivalent of QuickConnect's **Passthru** button.

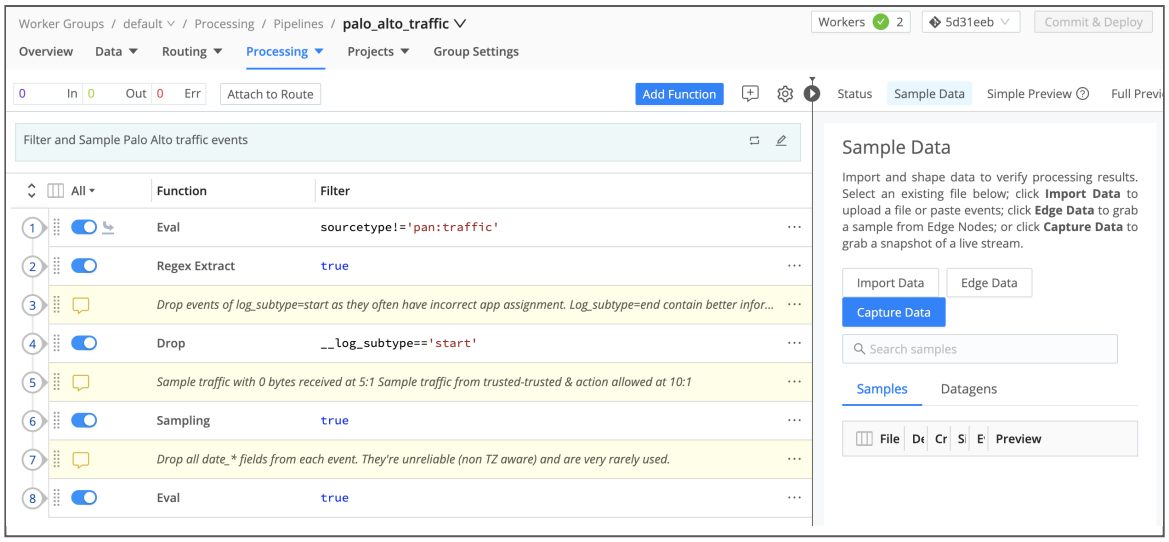
For these reasons, it's easy to start with an empty Pipeline, and then add Functions as you need them.



Pipelines Shipped with Cribl Stream

A Pipeline, as you populate it, is a stack of processing Functions and optional comments. Use the accordions on the left to expand or collapse each Function. Use the check boxes on the left to enable/disable each Function – preserving structure as you develop and debug the processing flow.

Use the right **Sample Data** pane to preview how the Pipeline's current state transforms a set of events. (Controls here enable you to capture live data, save it to sample or Datagen files, and reload those files.)



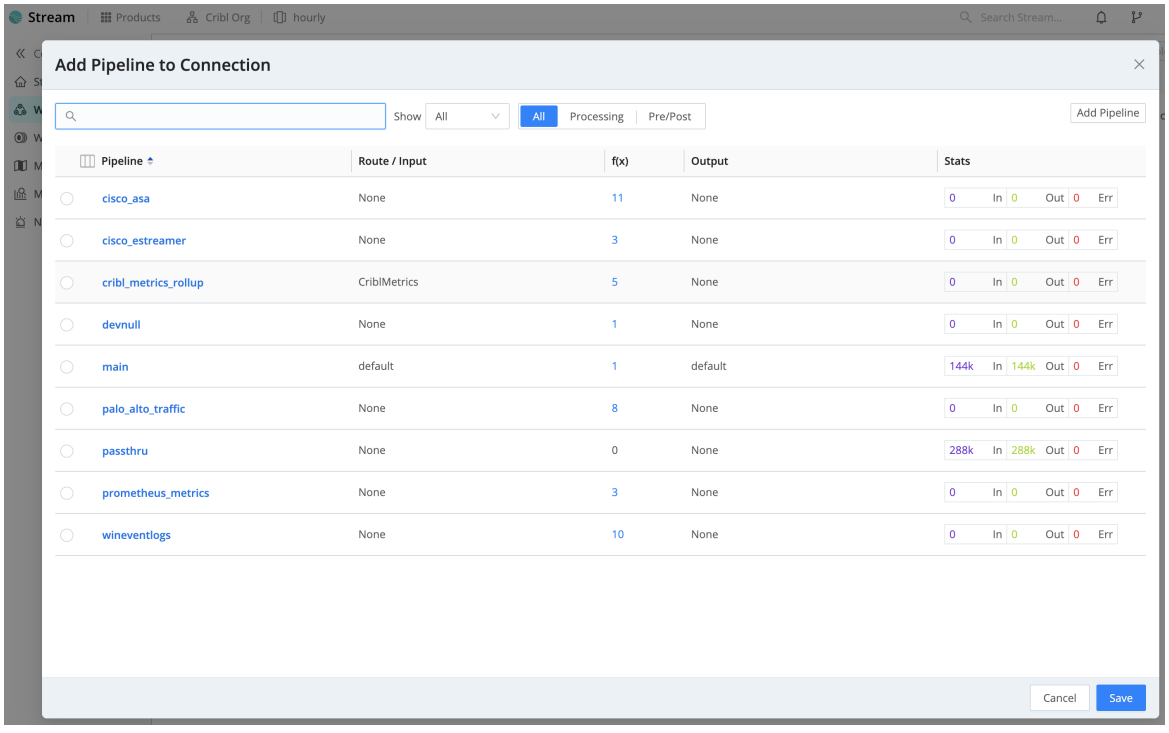
A Pipeline's Functions stack

Although you'll configure most data shaping in processing Pipelines between Sources and Destinations, you can also attach a pre-processing Pipeline to any Source instance, and a post-processing Pipeline to any Destination instance. Use these options when you need to "condition" the specific data type handled by a particular inbound or outbound integration.

Connect via QuickConnect

To select a connection type in QuickConnect, select the appropriate button in the pop-up dialog shown above. To accept the default **Passthru** option, just select **Save**. Your Source and Destination will now be connected.

If you select **Pipeline**, you'll see an **Add Pipeline to Connection** modal. Here, you can select an existing Pipeline, or select **Add Pipeline** to define a new one. Then select **Save** here to establish the connection.



Add Pipeline to Connection modal

Selecting **Pack** opens an **Add Pack to Connection** modal that works exactly the same way.

Whichever option you choose here, your connection between this Source and Destination is now complete.

To get data flowing, jump ahead to commit and deploy your new configuration.

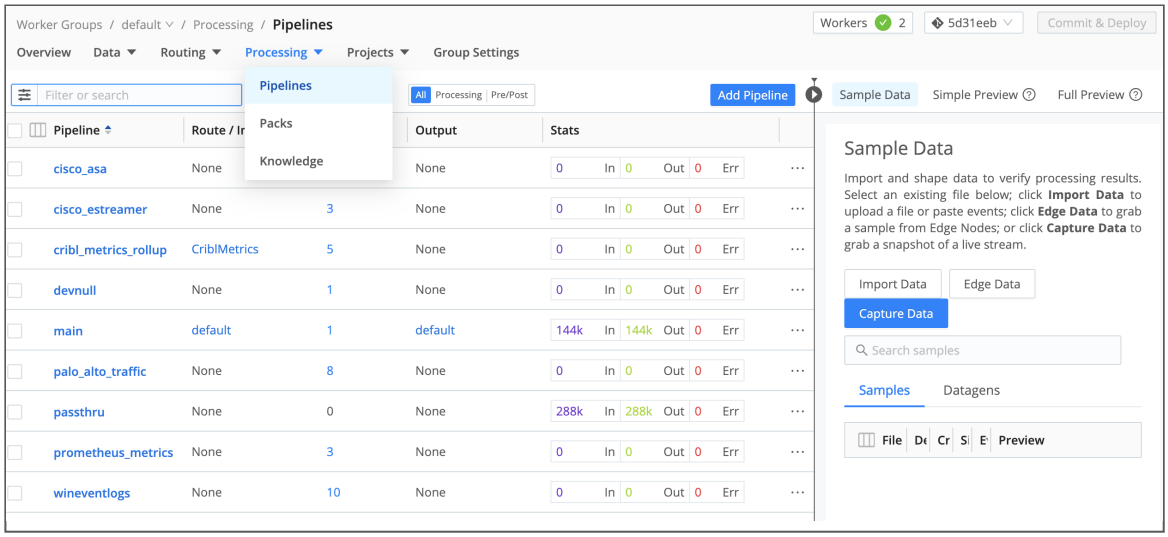
Connect via Data Routes

The Data Routes UI enables you to finely configure multiple, interdependent connections between Sources and Destinations. Events clone and cascade across a Routing table, based on the filtering rules and sequence you define.

In exchange for this flexibility, you sacrifice QuickConnect's one-stop, snap-together UI metaphor. After configuring your Sources and Destinations – which you've already done above – you need to connect them by separately setting up at least one Pipeline and one Route.

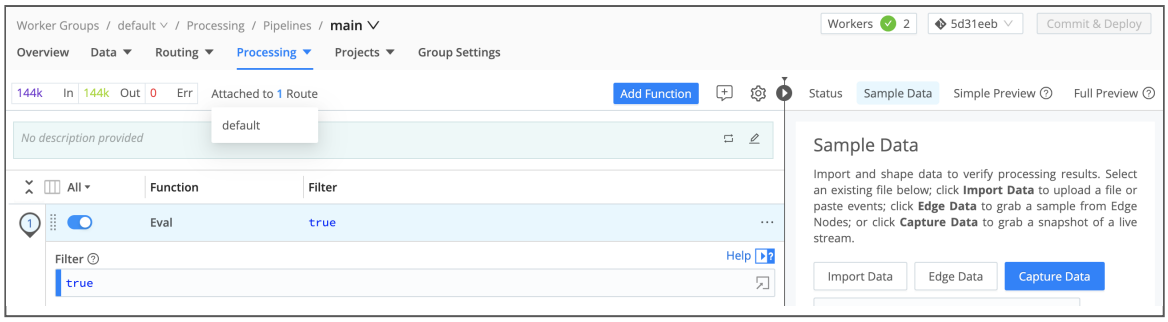
Pipelines Access

From a Worker Group, select **Processing** > **Pipelines**. In addition to the minimal **passthru** Pipeline identified above, other simple building blocks here include **main** (which initially contains only a simple Eval Function) and **devnull** (which contains a single Function that just drops events).



Routing to Pipelines

Out-of-the-box Pipelines are already connected to Routes. When you click into a Pipeline, you can hover to display the connected Route, as shown here. But as our final connection step, let's next look at how to connect up everything (Source, Pipeline, Destination) in a Route.



Checking Pipeline's Route connection

For More Information

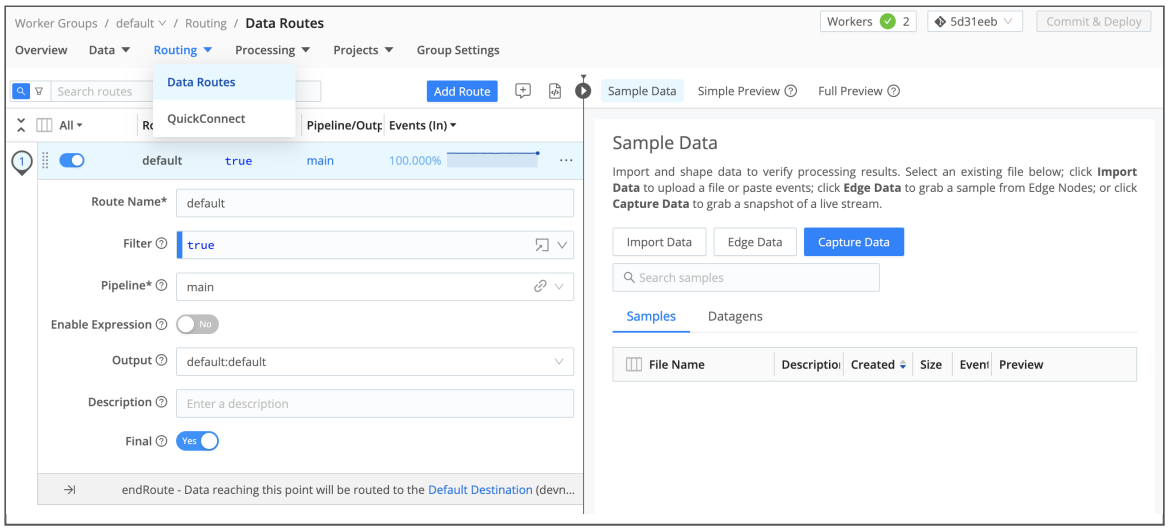
- Refine Data with Functions walks you through configuring Cribl's built-in Pipeline Functions to perform common processing tasks like parsing, masking, adding, deleting, and renaming event fields.

Configure a Route

In the Data Routes UI, a Route is where you complete a data-flow connection. Each Route connects exactly one Pipeline with exactly one Destination.

This combination can consume data from one, multiple, or all the Sources you've configured on the Data Routes side. (QuickConnect Sources are separate, but you can open those Sources' configs to move them to the Data Routes UI.) This is governed by the filtering we'll see below.

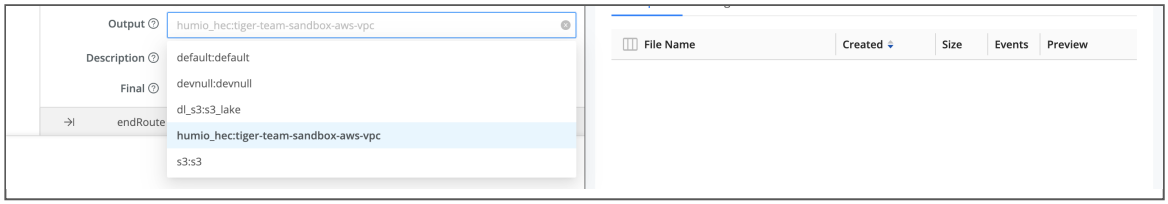
To open the Routing table, from a Worker Group, select **Routing** > **Data Routes**.



Accessing the Routing table

As you can see, Cribl Stream ships with one starter Route named `default`. It's configured as follows:

- The **Filter** expression is set to **true**. This simple, default expression makes data from **all** active Sources available to this Route. (See finer filtering options below.)
- The **Pipeline** drop-down is where you set the 1:1 Pipeline:Route connection. This starter Route's Pipeline defaults to **main**, but you can select any one other configured Pipeline.
- The **Output** drop-down defines the single Destination for this Pipeline:Route connection. If this isn't already set to your chosen Destination, you'll most likely want to select that here. (Note that each option displayed on this list corresponds to the unique, arbitrary **Output ID** set on one **instance** of a Destination type. So some names might initially be unfamiliar.)



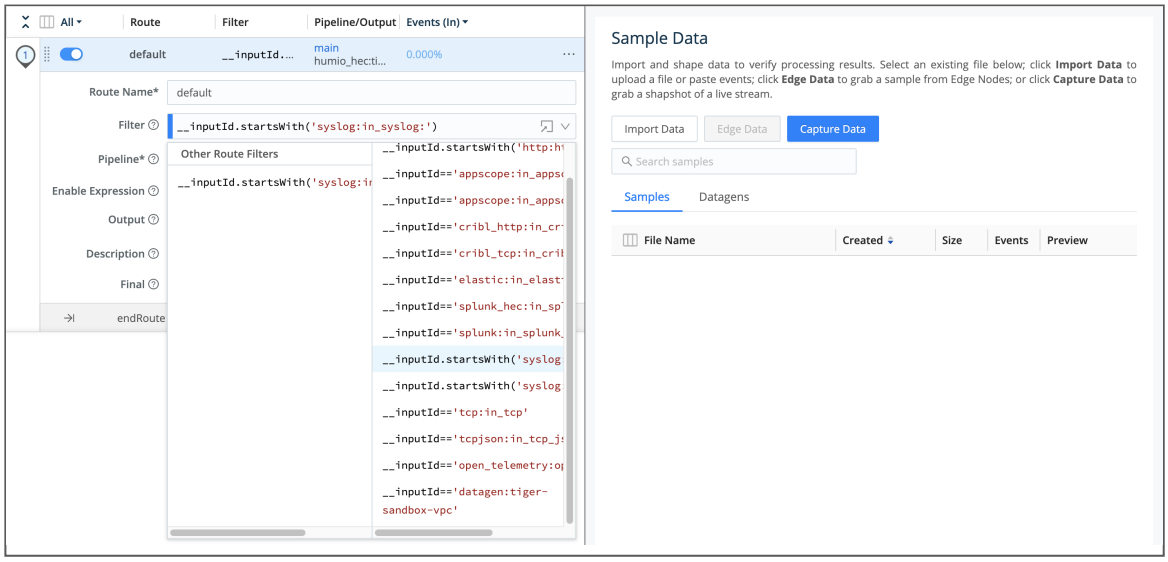
Changing a Route's Destination (Output)

To get data flowing, jump ahead to commit and deploy your new configuration.

Filter a Route's Input Data

When you want a Route to ingest data from only one Source, or a subset of Sources, you expand its **Filter** expression beyond the default **true** catch-all.

Filter is itself a drop-down. Open it to select among typeahead suggestions for several common inbound data types.



Tuning a Route's Filter expression

You can select one of these expressions and then modify it, using the same `__inputId` syntax. In the example expression below, note that the identifier after the `:` is – as with the **Output** options we saw above – the arbitrary name of one Syslog Source instance:

```
__inputId.startsWith('syslog:in_syslog:')
```

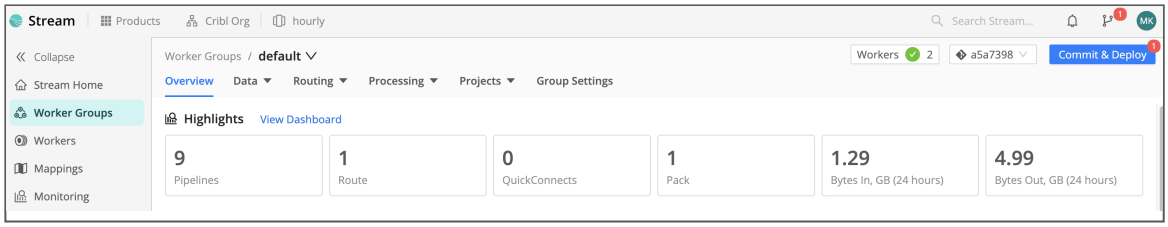
For More Information

- Cribl Expression Syntax > Filters

Commit/Deploy and Monitor

To get data flowing as you expect, you'll always need to use Cribl Stream's built-in version-control (Git) integration to commit your configuration changes and deploy them to your event-processing Worker instances. If you started this tour on Cribl.Cloud, you first used this during initial setup in Committing and Deploying Config Changes above.

After any significant configuration change, you'll be prompted with Group-level **Commit/Deploy** buttons like this at the upper right:



Commit & Deploy prompt

If you're using an on-prem version of Cribl Stream, different version-control settings might display **Commit** and **Deploy** as separate buttons:.

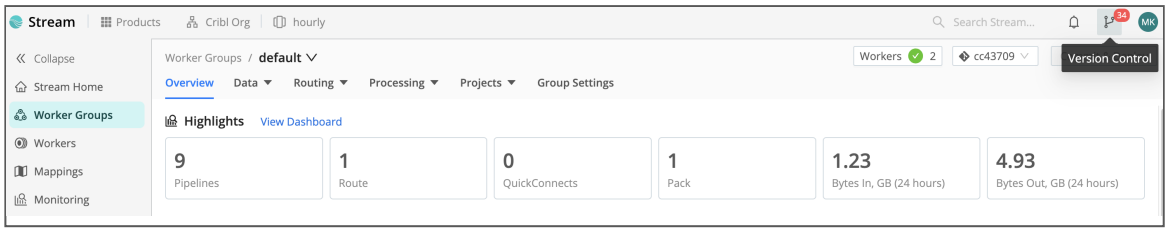
Selecting either flavor of the **Commit** button will display the confirmation modal you saw above. Just be sure to select the appropriate buttons to both commit **and** deploy your changes.

Confirming Data Flow

Data should now start flowing through the Workers. (You can check this by selecting the **Monitoring** link. This takes you to read-only dashboards. If necessary, select **Stream Home** and your Group when you want to return to configuration options.)

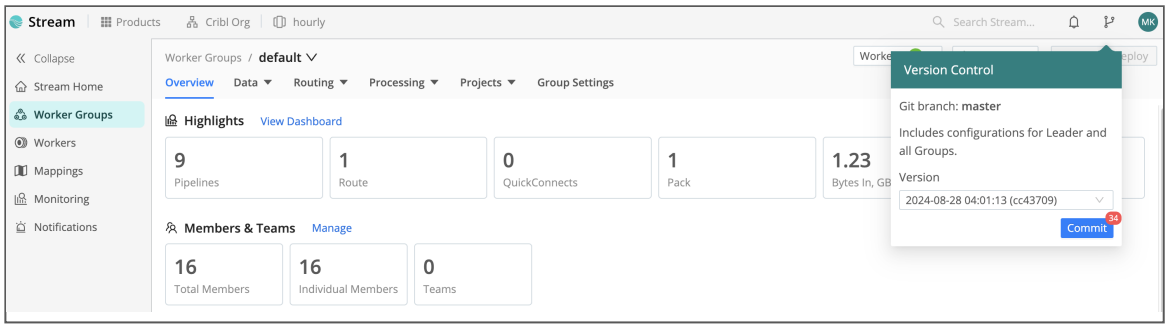
Product-Wide (Leader) Commit

As you saw during initial setup: In return for clearing all the red-dot prompts, your reward will be one more red dot, on the top nav's product-wide Version Control button. This is because Cribl Stream sees the preceding deploy to Workers as a change to record (commit) on the **Leader's** configuration.



Leader commit prompt

This top-level commit isn't necessary to enable data flow, but it backs up and safeguards your overall configuration. Select the button to display one final confirmation prompt:



Confirming a commit on the Leader

Select **Commit** here, confirm the commit and your configuration is complete!

For More Information

- Version Control > Committing Changes
- Version Control > Collapse Actions
- Monitoring

Moving Ahead with Cribl Stream

To quote a fundamental treatise on DevOps and SecOps: you know all the rules by now, and the fire from the ice. To delve deeper into Cribl Stream's data shaping and routing options, follow these links to conceptual overview and reference topics.

1.5. Getting Started Guide

This guide walks you through planning, (optionally) installing, and configuring a basic deployment of Cribl Stream. You'll capture some realistic sample log data, and then use Cribl Stream's built-in Functions to redact, parse, refine, and shrink the data.

By the end of this guide, you'll have assembled all of Cribl Stream's basic building blocks: a Source, Route, Pipeline, several Functions, and a Destination. You can complete this tutorial using Cribl Stream's included sample data, without connections to – or licenses on – any inbound or outbound services.

Assuming a cold start (from first-time setup of a Cribl.Cloud or self-hosted instance), this guide might take about an hour. But you can work through it in chunks, and Cribl Stream will persist your work between sessions.

If you've already launched a Cribl Stream instance (either Cribl.Cloud or self-hosted), skip ahead to Get Data Flowing.

If you'd prefer a similar tutorial based on Cribl Stream's simplified QuickConnect visual UI, start with our Cribl Stream Tour.

Once you've mastered all the techniques in this tutorial, check out our Distributed Quick Start, where you'll see how to apply them to a typical production deployment across multiple hosts.

Cloud or Self-Hosted?

To quote Robert Frost and Robert Plant (of Led Zeppelin), there are two paths that you can go by:

- Do this tutorial with a free Cribl.Cloud instance, hosted by Cribl. Follow the registration instructions in the section just below. This skips you past all the requirements and installation sections below – you'll have nothing to install or host. Because Cribl.Cloud always runs in Distributed deployment, this will require a few extra clicks (all clearly labeled) later in the tutorial's body. But it will give you immediate experience with Cribl Stream's typical production mode.
- Do this tutorial by downloading and installing Cribl Stream software on your own hardware or virtual machine. Follow the Requirements and Download and Install instructions below. You'll need to provide your own infrastructure. But if you're planning to use self-hosted/on-prem Cribl Stream in production, this will walk you through its realistic setup.

To fully experience a real-world, self-hosted production setup, you can switch your Cribl Stream installation to Distributed deployment. And then chase this tutorial with our

> Distributed Quick Start, which fully exercises Distributed deployment's multiple Workers and Worker Groups.

For a detailed comparison, see Cribl.Cloud vs. Self-Hosted.

Quick Start with a Cloud Instance

As indicated just above, you can skip installing Cribl Stream software – and skip this tutorial's next several sections – by registering a free Cribl.Cloud instance. Cribl will quickly spin up a fully functioning copy of Cribl Stream for you, and manage it on your behalf. To use this fastest option:

1. In the Cribl.Cloud Launch Guide, follow the four steps listed in Registering a Cribl.Cloud Portal.
2. In the same Cribl.Cloud Launch Guide, jump ahead to follow the four steps listed in Managing Cribl.Cloud.
3. That's it! Come right back to this tutorial, and skip ahead to Get Data Flowing.

> Really, skip all the other sections of the linked Cloud Guide, and all this tutorial's sections between here and Get Data Flowing. We told you this was a quick start!

Requirements for Self-Hosted Cribl Stream

The minimum requirements for running this tutorial are the same as for a Cribl Stream production Single-instance deployment.

OS

- Linux kernel >= 3.10 and glibc >= 2.17.

Example distributions: Ubuntu 16.04, Debian 9, RHEL 7, CentOS Linux 8, CentOS Stream 9, SUSE Linux Enterprise Server 12, Amazon Linux 2.

Tested so far on Ubuntu (14.04, 16.04, 18.04, and 20.04), CentOS Stream 9, and Amazon Linux 2.

System

- 1 GHz (or faster), 64-bit CPU.
- 4+ physical cores, 8 GB+ RAM – all beyond your basic OS/VM requirements.
- 5 GB free disk space (more if persistent queuing is enabled).

We assume that 1 physical core is equivalent to 2 virtual/hyperthreaded CPUs (vCPUs) on Intel/Xeon or AMD processors; and to 1 (higher-throughput) vCPU on Graviton2/ARM64 processors.

Browser

- Chrome, Firefox, Safari, and Microsoft Edge: the five most-recent versions.

Network Ports

By default, Cribl Stream listens on the following ports:

Component	Default Port
UI default	`9000`
HTTP Inbound, default	`10080`
User options	+ Other data ports as required.

You can override these defaults as needed.

Plan for Production

For higher processing volumes, users typically enable Cribl Stream's Distributed Deployment option. While beyond the scope of this tutorial, that option has a few additional requirements, which we list here for planning purposes:

- Port `4200` must be available on the Leader Node for Workers' communications.
- Git (1.8.3.1 or higher) must be installed on the Leader Node, to manage configuration changes.

See Sizing and Scaling for further details about configuring Cribl Stream to handle large data streams.

Download and Install Cribl Stream

To avoid permissions errors, you should both install and run (next section) Cribl Stream as the same Linux user. For details on creating a new user (addressing both systemd and initd distro's), see Enabling Start on Boot.

Download the latest version of Cribl Stream at https://cribl.io/download/.

Un-tar the `.tgz` file in a directory of your choice (such as `/opt/`). Here's general syntax, then a specific example:

```
tar xvzf cribl-<version>-<build>-<arch>.tgz
tar xvzf cribl-3.5.0-fa5eb040-linux-x64.tgz
```

You'll now have Cribl Stream installed in a `cribl` subdirectory, by default: `/opt/cribl/`. We'll refer to this `cribl` subdirectory throughout this documentation as `$CRIBL_HOME`.

Run Cribl Stream

In your terminal, switch to the `$CRIBL_HOME/bin` directory (e.g,: `/opt/cribl/bin`). Here, you can start, stop, and verify the Cribl Stream server using these basic `./cribl` CLI commands:

- **Start**: `./cribl start`
- **Stop**: `./cribl stop`
- **Get status**: `./cribl status`

For other available commands, see CLI Reference.

Next, in your browser, open `http://<hostname>:9000` (example: `http://localhost:9000`) and log in with default credentials (`admin`, `admin`).

Register your copy of Cribl Stream when prompted.

After registering, you'll be prompted to change the default password.

That's it!

Get Data Flowing

With Cribl Stream now running – either in Cribl.Cloud or in your self-hosted copy – you're ready to configure a working Cribl Stream deployment. You'll set up a Source, Destination, Pipeline, and Route, and will assemble several built-in Functions to refine sample log data.

Add a Source

Each Cribl Stream Source is a configuration model of a data input. Options include Splunk, Elasticsearch API, Elastic Beats, Kinesis, Kafka, syslog, HTTP, TCP JSON, and others.

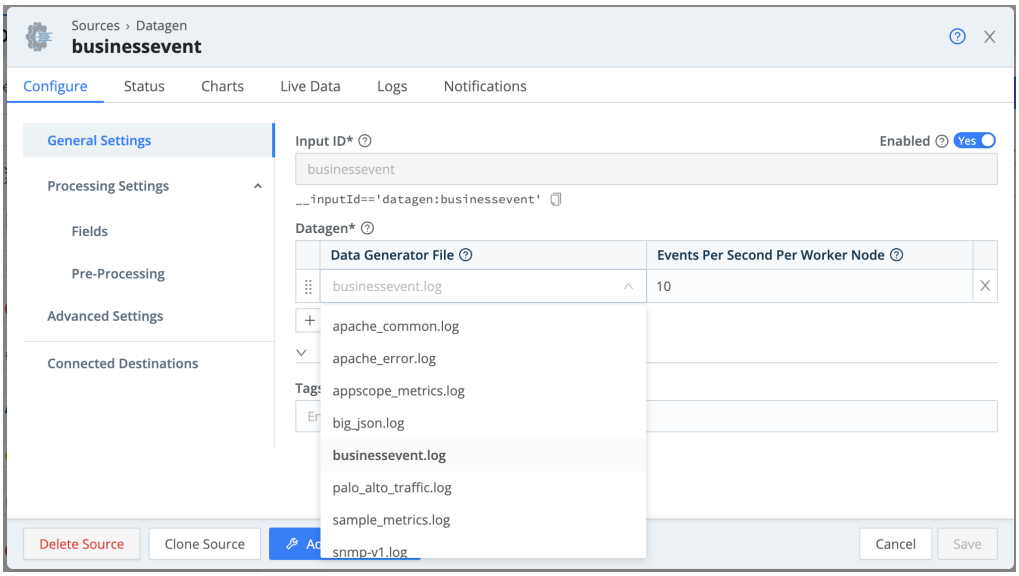
A Source provides a graphical interface for configuring and managing Cribl software's integration with the upstream sender. You specify endpoints, access/authorization credentials, protocols, and a wide range of options for load management and processing. You can create and maintain multiple Sources for the same type of sender, each with its own configuration details.

For this tutorial, you will enable a Cribl Stream built-in datagen (data generator) that generates a stream of realistic sample log data:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. If you're working with a new instance of Stream, you will only see one Worker Group named `default`. Select that Worker Group or another Worker Group.
2. On the **Worker Groups** submenu, select **Data** > **Sources**.
3. From the **Data Sources** page's tiles or left menu, select **Datagen**. (You can use the search box to jump to the **Datagen** tile.)
4. Select **Add Source** to open the **New Source** modal.
5. In the **Input ID** field, name this Source `businessevent`.
6. In the **Data Generator File** drop-down, select `businessevent.log`. This generates log events for a business scenario. We'll look at their structure shortly, in Capture and Filter Sample Data.
7. Select **Save**.

If you're on Cribl.Cloud or any other Distributed deployment, select **Commit & Deploy** at Cribl Stream's upper right before proceeding. Then, in the resulting dialog box, select **Commit & Deploy** to confirm. You'll see a **Commit successful** message.

The `Yes` toggle in the **Enabled** column indicates that your Datagen Source has started generating sample data.



Add a Destination

Each Cribl Stream Destination is a configuration model of a data output. Options include Elasticsearch, Splunk, Kafka, Kinesis, InfluxDB, Snowflake, Databricks, TCP JSON, and others.

A Destination provides a graphical interface for configuring and managing Cribl software's integration with the downstream receiver. You specify endpoints, access/authorization credentials, protocols, and options for load management and processing. You can create and maintain multiple Destinations for the same type of receiver, each with its own configuration details.

For this tutorial, we'll use Cribl Stream's built-in **DevNull** Destination. This simply discards events – not very exciting! But it simulates a real output, so it provides a configuration-free quick start for testing Cribl Stream setups. It's ideal for our purposes.

To verify that **DevNull** is enabled, let's walk through setting up a Destination, then setting it up as Cribl Stream's default output:

On Cribl.Cloud or any other Distributed deployment, first select **Worker Groups** in the sidebar and select a Worker Group such as `default`.

1. On the **Worker Groups** submenu, select **Data** > **Destinations**.
2. From the list of Destinations, select **DevNull**.
   (You can use the search box to jump to the **DevNull** tile.)
3. On the **devnull** row, look for the **Live** indicator under **Status**. This confirms that the **DevNull** Destination is ready to accept events.
4. From the list of Destinations, select the **Default** Destination at the top.
5. Verify that **devnull** (the Destination we just examined) appears in the **Default Output ID** column.

If you're on Cribl.Cloud or any other Distributed deployment, select **Commit & Deploy** at Cribl Stream's upper right (if available) before proceeding. Then, in the dialog box, select **Commit & Deploy** to confirm. You'll see a **Commit successful** message.

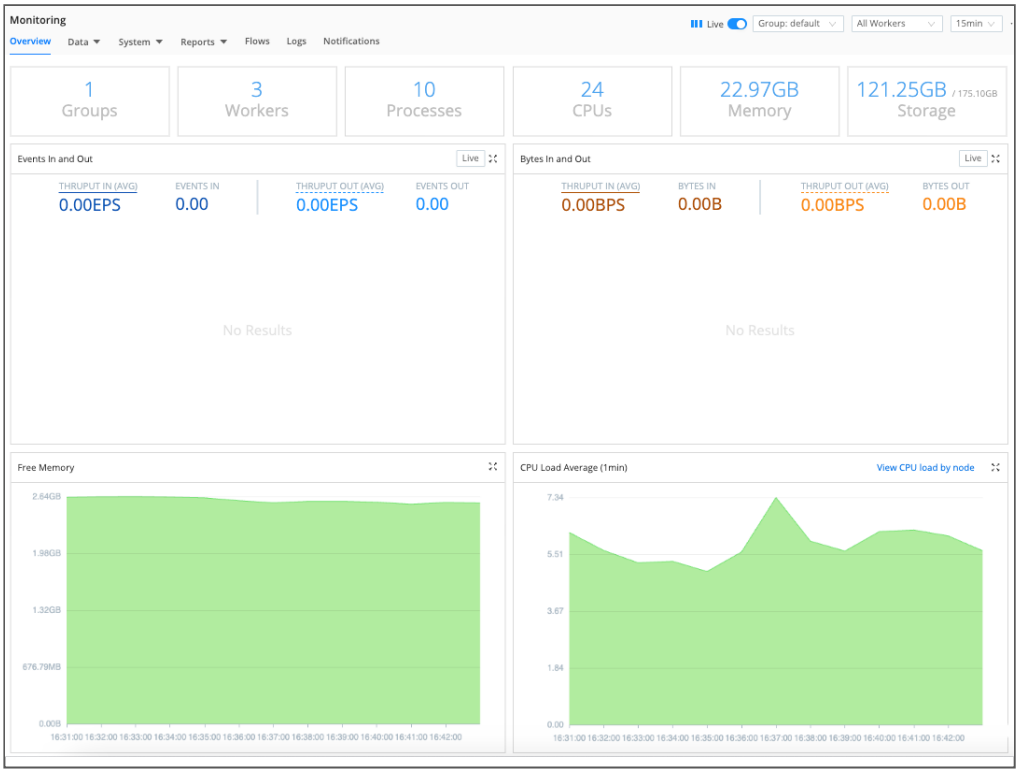
We've now set up data flow on both sides. Is data flowing? Let's check.

Monitor Data Throughput

Cribl Stream Monitoring features provide real-time and historical insights into the status and health of the application and its components. You can monitor performance and resource utilization over configurable time ranges, to tune performance and allocate infrastructure.

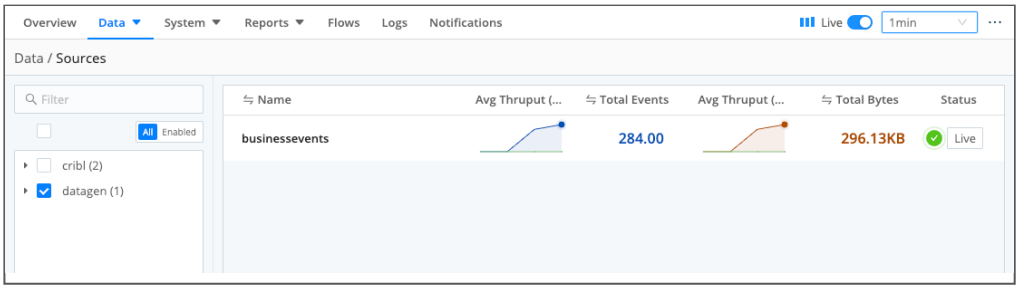
You can configure alerts triggered by a wide range of conditions, and can send the resulting Notifications to common receivers, specific email addresses, or custom webhooks.

In the sidebar, select **Monitoring**. This opens a summary dashboard, where you should see a steady flow of data in and out of Cribl Stream. The left graph shows events in/out. The right graph shows bytes in/out.



Monitoring dashboard

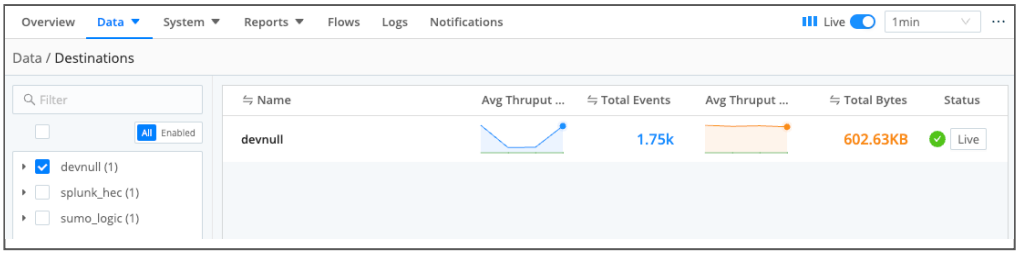
You can use the upper **Monitoring** submenu to open detailed displays of Cribl Stream components, collection jobs and tasks, and Cribl Stream's own internal logs. Select **Data** > **Sources** on the submenu to switch to this view:



Monitoring Sources

This is a compact display of each Source's inbound events and bytes as a sparkline. You can select each Source's Expand button (highlighted at right) to zoom up detailed graphs.

Select **Data** > **Destinations** on the submenu. This displays a similar sparklines view, where you can confirm data flow out to the **devnull** Destination:



Monitoring Destinations

With confidence that we've got data flowing, let's send it through a Cribl Stream Pipeline, where we can add Functions to refine the raw data.

Create a Pipeline

A Pipeline is a stack of Cribl Stream Functions, which are at the heart of the application's data management. You can insert Functions to accomplish a wide range of processing tasks: event breaking, parsing, unrolling and flattening, serialization, aggregation, sampling, field addition/removal, data masking and transformation, regex and Grok extraction, and lookups and enrichment.

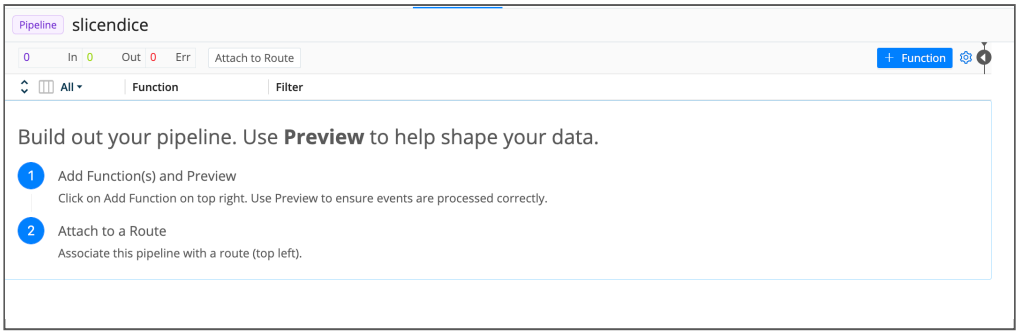
Configuring Pipelines is therefore central to refining your data. Each Pipeline provides a central Cribl Stream workspace – so let's get one going.

1. On Cribl.Cloud or any other Distributed deployment, first select a Worker Group. Then, on the **Worker Groups** submenu, select **Processing** > **Pipelines**.
   You now have a two-pane view, with a **Pipelines** list on the left and **Sample Data** controls on the right. (We'll capture some sample data momentarily.)
2. In the **Pipelines** pane, select **Add Pipeline**, then select **Add Pipeline**.
3. In the new Pipeline's **ID** field, enter a unique identifier. (For this tutorial, you might use `slicendice`.)
4. Optionally, enter a **Description** of this Pipeline's purpose.
5. Select **Save**.

Now scroll through the right **Preview** pane. Depending on your data sample, you should now see multiple events struck out and faded – indicating that Cribl Stream will drop them before forwarding the data.

If you're on Cribl.Cloud or any other Distributed deployment, select **Commit & Deploy** at Cribl Stream's upper right before proceeding. Then, in the dialog box, select **Commit & Deploy** to confirm. You'll see a **Commit successful** message.

Your empty Pipeline now prompts you to preview data, add Functions, and attach a Route. So let's capture some data to preview.



Pipeline prompt to add Functions

Capture and Filter Sample Data

As you test and refine your Pipeline's data processing, it's ideal to avoid touching production data, and to avoid paying ingress or egress charges. Cribl Stream provides a set of Data Preview features to help you avoid these pitfalls. The right **Sample Data** pane provides multiple tools for:

- Grabbing data from multiple places (inbound streams, copy/paste, and uploaded files).
- Saving and reloading sample data files.
- Previewing and testing data transformations as you build them.

Since we've already got live (simulated) data flowing in from the datagen Source we built, let's grab some of that data.

Capture New Data

1. In the right pane, select **Capture Data**.
2. Select **Capture**, then accept the drop-down's defaults – select **Start**.
3. When the modal finishes populating with events, select **Save as Sample File**.
4. In the **SAMPLE FILE SETTINGS** fly-out, change the generated **File Name** to a name you'll recognize, like `be_raw.log`.
5. Select **Save**. This saves to the **File Name** you entered above, and closes the modal. You're now previewing the captured events in the right pane. (Note that this pane's **Simple Preview** tab now has focus.)
6. Select the **Show more** link to expand one or more events.

By skimming the key-value pairs within the data's `_raw` fields, you'll notice the scenario underlying this preview data (provided by the `businessevents.log` datagen): these are business logs from a mobile-phone provider.

To set up our next step, find at least one `marketState` K=V pair. Having captured and examined this raw data, let's use this K=V pair to crack open Cribl Stream's most basic data-transformation tool, Filtering.

Filter Data and Manage Sample Files

1. Select the right pane's **Sample Data** tab.
2. Again select **Capture New**.
3. In the **Capture Sample Data** modal, replace the **Filter Expression** field's default `true` value with this simple regex: `_raw.match(/marketState=TX/)`
   We're going to Texas! If you type this in, rather than pasting it, notice how Cribl Stream provides typeahead assist to complete a well-formed JavaScript expression.
   You can also select the Expand button at the **Filter Expression** field's right edge to open a modal to validate your expression. The adjacent drop-down enables you to restore previously used expressions.

Expand button and history drop-down

4. Select **Capture**, then **Start**.
   Using the **Capture** drop-down's default limits of 10 seconds and 10 events, you'll notice that with this filter applied, it takes much longer for Cribl Stream to capture 10 matching events.
5. Select **Cancel** to discard this filtered data and close the modal.
6. On the right pane's **Sample Data** tab, select **Simple** beside `be_raw.log`.

This restores our preview of our original, unfiltered capture. We're ready to transform this sample data in more interesting ways, by building out our Pipeline's Functions.

Refine Data with Functions

Functions are pieces of JavaScript code that Cribl Stream invokes on each event that passes through them. By default, this means all events – each Function has a **Filter** field whose value defaults to `true`. As we just saw with data capture, you can replace this value with an expression that scopes the Function down to particular matching events.

In this Pipeline, we'll use some of Cribl Stream's core Functions to:

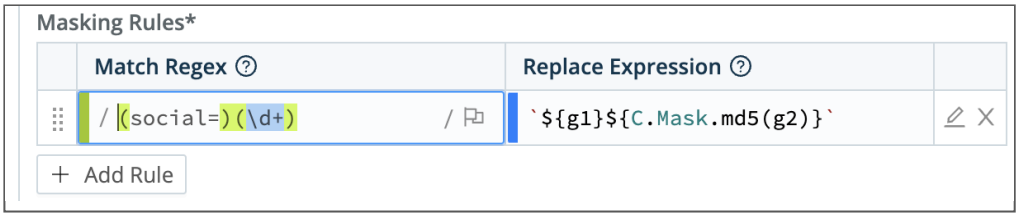
- Redact (mask) sensitive data
- Extract (parse) the `_raw` field's key-value pairs as separate fields.
- Add a new field.

- Delete the original `_raw` field, now that we've extracted its contents.
- Rename a field for better legibility.

Mask: Redact Sensitive Data

In the right **Preview** pane, notice each that event includes a **social** key, whose value is a (fictitious) raw Social Security number. Before this data goes any further through our Pipeline, let's use Cribl Stream's `Mask` Function to swap in an md5 hash of each SSN.

1. In the left **Pipelines** pane, select **Add Function**.
2. Search for `Mask`, then select it.
3. In the new Function's **Masking Rules**, select the into **Match Regex** field.
   Now we want to build the **Match Regex/Replace Expression** row shown just below.
4. Enter or paste this regex, which simply looks for the string `social=`, followed by any digits: `(social=)(\d+)`
5. In **Replace Expression**, paste the following hash function. The backticks are literal: `` `${g1}${C.Mask.md5(g2)}` ``
6. Note that **Apply to Fields** defaults to `_raw`. This is what we want to target, so we'll accept this default.
7. Select **Save**.

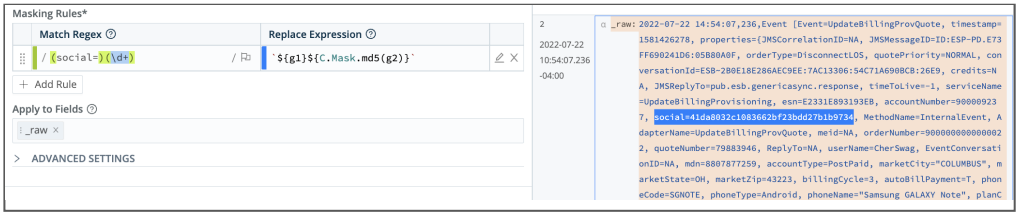


Entering a Masking Rule to hash Social Security numbers

You'll immediately notice some obvious changes:

- The **Preview** pane has switched from its **IN** to its **OUT** tab, to show you the outbound effect of the Pipeline you just saved.
- Each event's `_raw` field has changed color, to indicate that it's undergone some redactions.

Now locate at least one event's **Show more** link, and select to expand it. You can verify that the `social` values have now been hashed.

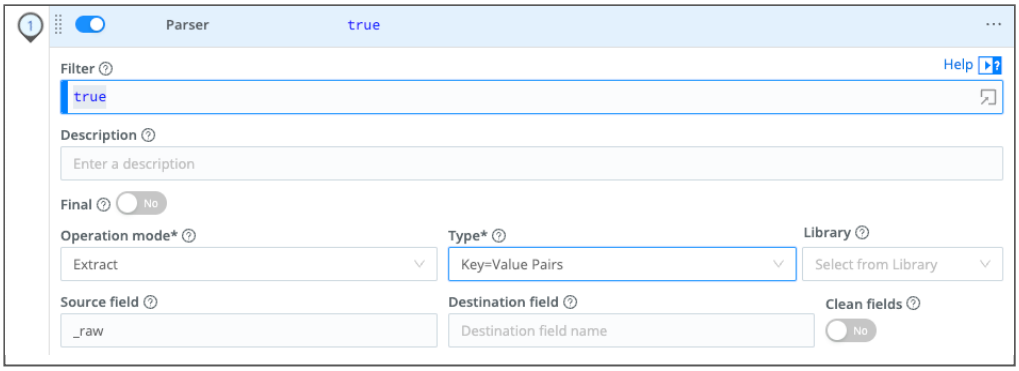


Mask Function and hashed result

Parser: Extract Events

Having redacted sensitive data, we'll next use a Parser function to lift up all the `_raw` field's key-value pairs as fields:

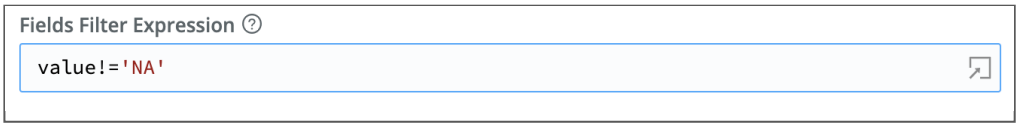
1. In the left **Pipelines** pane, select **Add Function**.
2. Search for `Parser`, then select it.
3. Leave the **Operation Mode** set to its `Extract` default.
4. Set the **Type** to `Key=Value Pairs`.
5. Leave the **Source Field** set to its `_raw` default.
6. Select **Save**.



Parser configured to extract K=V pairs from `_raw`

You should see the **Preview** pane instantly light up with a lot more fields, parsed from `_raw`. You now have rich structured data, but not all of this data is particularly interesting: Note how many fields have `NA` ("Not Applicable") values. We can enhance the **Parser** Function to ignore fields with `NA` values.

1. In the Function's **Fields Filter Expression** field (near the bottom), enter this negation expression: `value!='NA'`.
   Note the single-quoted value. If you type (rather than paste) this expression, watch how typeahead matches the first quote you type.
2. Select **Save**, and watch the **Preview** pane.



Filtering the Parser Function to ignore fields with 'NA' values

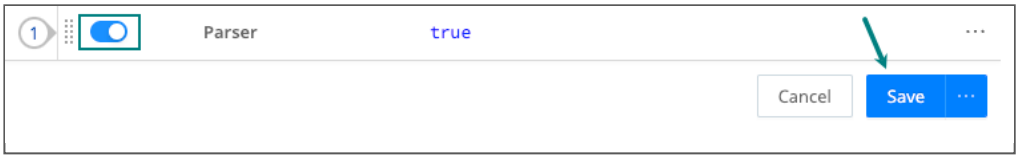
Several fields should disappear – such as `credits`, `EventConversationID`, and `ReplyTo`. The remaining fields should display meaningful values. Congratulations! Your log data is already starting to look better-organized and less bloated.

Missed It?

If you didn't see the fields change, toggle the Parser Function `Off`, select **Save** below, and watch the **Preview** pane change. Using these toggles, you can preserve structure as you test and troubleshoot each Function's effect.

Note that each Function also has a **Final** toggle, defaulting to `Off`. Enabling **Final** anywhere in the Functions stack will prevent data from flowing to any Functions lower in the UI.

Be sure to toggle the Function back `On`, and select **Save** again, before you proceed!



Toggling a Function off and on

Next, let's add an extra field, and conditionally infer its value from existing values. We'll also remove the `_raw` field, now that it's redundant. To add and remove fields, the **Eval** Function is our pal.

Eval: Add and Remove Fields

Let's assume we want to enrich our data by identifying the manufacturer of a certain popular phone handset. We can infer this from the existing `phoneType` field that we've lifted up for each event.

Add Field (Enrich)

1. In the left **Pipelines** pane, select **Add Function**.
2. Search for `Eval`, then select it.
3. Select **Add Field** to open the **Evaluate Fields** table.
   Here you add new fields to events, defining each field as a key-value pair. If we needed more key-value pairs, we could select `+ Add Field` for more rows.
4. In the table's first row, select into the **Name** field and enter: `phoneCompany`.
5. In the adjacent **Value Expression** field, enter this JS ternary expression that tests `phoneType`'s value: `phoneType.startsWith('iPhone') ? 'Apple' : 'Other'` (Note the `?` and `:` operators, and the single-quoted values.)

6. Select **Save**. Examine some events in the **Preview** pane, and each should now contain a `phoneCompany` field that matches its `phoneType`.

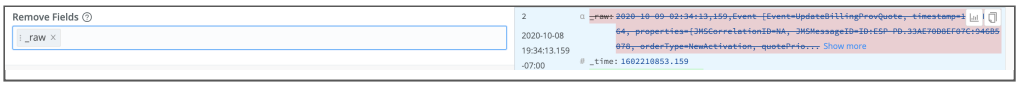
Adding a field to enrich data

Remove Field (Shrink Data)

Now that we've parsed out all of the `_raw` field's data – it can go. Deleting a (large) redundant field will give us cleaner events, and reduced load on downstream resources.

1. Still in the **Eval** Function, select into **Remove Fields**.
2. Type: `_raw` and press **Tab** or **Enter**.
3. Select **Save**.

The **Preview** pane's diff view should now show each event's `_raw` field stripped out.



Removing a field to streamline data

Our log data has now been cleansed, structured, enriched, and slimmed-down. Let's next look at how to make it more legible, by giving fields simpler names.

Rename: Refine Field Names

1. In the left **Pipelines** pane, select `Add Function`.
   This rhythm should now be familiar to you.
2. Search for `Rename`, then select it.
3. Select **Add fields** to open the **Rename fields** table.
4. Select into the new Function's **Rename fields** table.

This has the same structure you saw above in Eval: Each row defines a key-value pair.

5. In **Current name**, enter the longhaired existing field name: `conversationId`.
6. In **New name**, enter the simplified field name: `ID`.
7. Watch any event's `conversationId` field in the **Preview** pane as you select **Save** at left. This field should change to `ID` in all events.

Drop: Remove Unneeded Events

We've already refined our data substantially. To further slim it down, a Pipeline can entirely remove events that aren't of interest for a particular downstream service.

As the "Pipeline" name implies, your Cribl Stream installation can have multiple Pipelines, each configured to send out a data stream tailored to a particular Destination. This helps you get the right data in the right places most efficiently.

Here, let's drop all events for customers who use prepaid monthly phone service (that is, **not** postpaid):

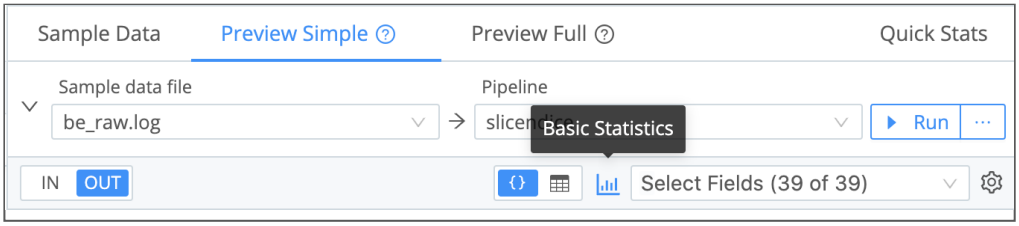
1. In the left **Pipelines** pane, select **Add Function**.
2. Search for `Drop`, then select it.
3. Select into the new Function's **Filter** field.
4. Replace the default `true` value with this JS negation expression: `accountType!='PostPaid'`
5. Select **Save**.

Now scroll through the right **Preview** pane. Depending on your data sample, you should now see multiple events struck out and faded – indicating that Cribl Stream will drop them before forwarding the data.

A Second Look at Our Data

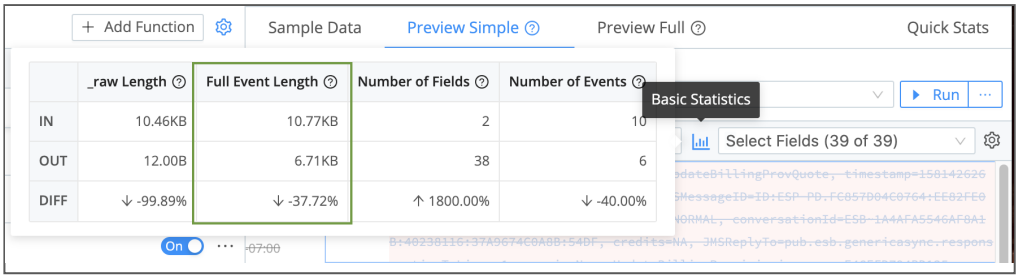
Torture the data enough, and it will confess. By what factor have our transformations refined our data's volume? Let's check.

In the right **Preview** pane, select the **Basic Statistics** button:



Displaying Basic Statistics

Even without the removal of the `_raw` field (back in Eval) and the dropped events, you should see a substantial % reduction in the **Full Event Length**.



Data reduction quantified

Woo hoo! Before we wrap up our configuration: If you're curious about individual Functions' independent contribution to the data reduction shown here, you can test it now. Use the toggle `Off` > **Save** > **Basic Statistics** sequence to check various changes.

Add and Attach a Route

We've now built a complete, functional Pipeline. But so far, we've tested its effects only on the static data sample we captured earlier. To get dynamic data flowing through a Pipeline, we need to filter that data in, by defining a Cribl Stream Route.

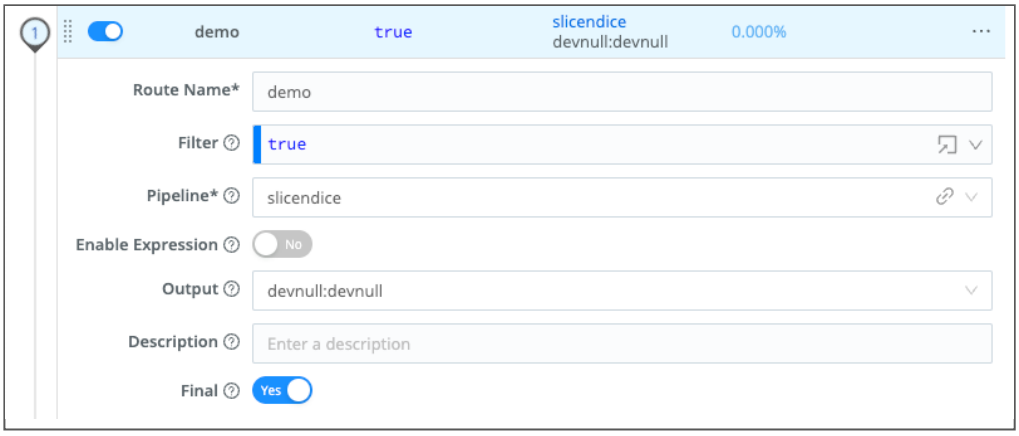
Routes provide a way to connect processing Pipelines to Destinations that send your transformed data out to specific downstream receivers. You can maintain Pipelines and Routes separately, but each Route attaches one Pipeline to one Destnation.

1. At the **Pipelines** page's top left, select **Attach to Route**.
   This displays the **Routes** page. It's structured very similarly to the **Pipelines** page, so the rhythm here should feel familiar.
2. Select `Add Route`.
3. Enter a unique, meaningful **Route Name**, like `demo`.
4. Leave the **Filter** field set to its `true` default, allowing it to deliver all events.
   Because a Route delivers events to a Pipeline, it offers a first stage of filtering. In production, you'd typically configure each Route to filter events by appropriate `source`, `sourcetype`, `index`, `host`, `_time`, or other characteristics. The **Filter** field accepts JavaScript expressions, including AND (`&&`) and OR (`||`) operators.
5. Set the **Pipeline** drop-down to our configured `slicendice` Pipeline.
6. Leave the **Enable Expression** field set to its `No` default. Toggling this field to `Yes` changes the **Output** field to an **Output Expression** field where you can enter a JavaScript expression for your **Destination**

name.

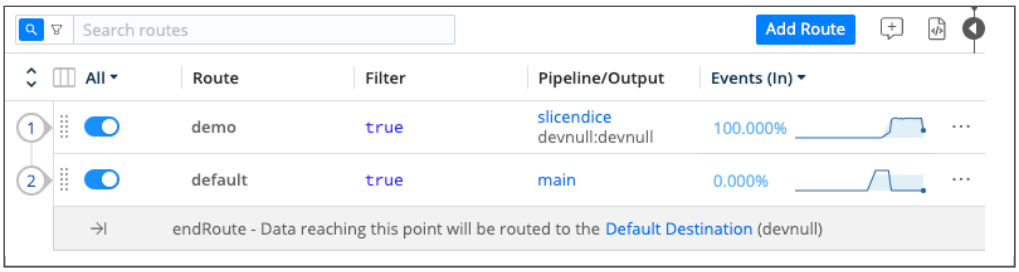
7. Set the **Output** drop-down to either `devnull` or `default`.
   This doesn't matter, because we've set `default` as a pointer to `devnull`. In production, you'd set this carefully.
8. You can leave the **Description** empty, and leave **Final** set to `Yes`.
9. Grab the new Route by its left handle, and drag it above the `default` Route, so that our new Route will process events first. You should see something like the screenshot below.
10. Select **Save** to save the new Route to the Routing table.

If you're on Cribl.Cloud or any other Distributed deployment, select **Commit & Deploy** at Cribl Stream's upper right before proceeding. Then, in the dialog box, select **Commit & Deploy** to confirm. You'll see a **Commit successful** message.



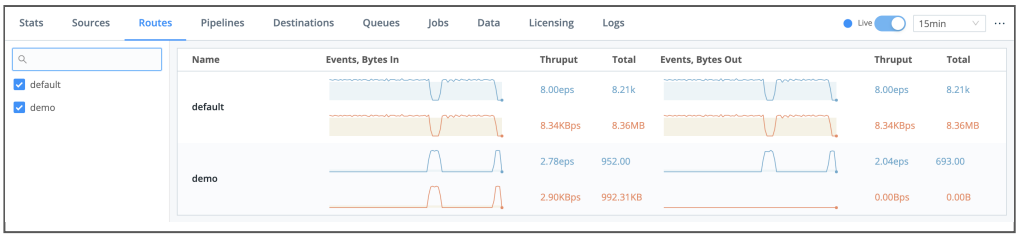
Configuring and adding a Route

The sparklines should immediately confirm that data is flowing through your new Route:



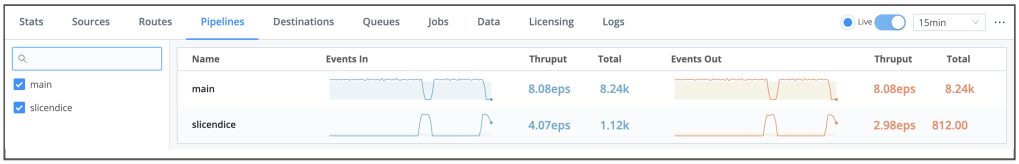
Live Routes

To confirm data flow through the whole system we've built, select **Monitoring** in the Stream sidebar. Then, select **Data** > **Routes** and examine `demo`.



Monitoring data flow through Routes

Also select **Monitoring** in the Stream sidebar. Then, select **Data** > **Pipelines** and examine `slicendice`.



Monitoring data flow through Pipelines

What Have We Done?

Look at you! Give yourself a pat on the back! In this short, scenic tour – with no hit to your cloud-services charges – you've built a simple but complete Cribl Stream system, exercising all of its basic components:

- Downloaded, installed, and run Cribl Stream.
- Configured a Source to hook up an input.
- Configured a Destination to feed an output.
- Monitored data throughput, and checked it twice.
- Built a Pipeline.
- Configured Cribl Stream Functions to redact, parse, enrich, trim, rename, and drop event data.
- Added and attached a Route to get data flowing through our Pipeline.

Next Steps

Interested in guided walk-throughs of more-advanced Cribl Stream features? We suggest that you next check out these further resources.

- Cribl Stream Sandboxes: Work through general and specific scenarios in a free, hosted environment, with terminal access and real data inputs and outputs.
- Distributed Quick Start: Building on this tutorial that you've just completed, launch and configure a Cribl Stream Distributed deployment. You'll work with a small but realistic model of a fully scaleable production deployment.
- Use Cases documentation: Bring your own services to build solutions to specific challenges.

- Cribl Concept: Pipelines – Video showing how to build and use Pipelines at multiple Cribl Stream stages.
- Cribl Concept: Routing – Video about using Routes to send different data through different paths.

Cleaning Up

Oh yeah, you've still got the Cribl Stream server running, with its `businessevent.log` datagen still firing events. If you'd like to shut these down for now, in reverse order:

1. On the **Worker Groups** submenu, go to **Data** > **Sources** > **Datagen**.
2. In the **Enabled** column, disable the `businessevent` datagen.
3. In your terminal's `$CRIBL_HOME/bin` directory, shut down the server with: `./cribl stop`

That's it! Enjoy using Cribl Stream.

1.6. Distributed Quick Start

This tutorial builds on our Cribl Stream Tour and Getting Started Guide by walking you through a Distributed deployment – Cribl Stream's typical deployment type for production.

For concepts and deeper details underlying the techniques presented here, see Distributed Deployment.

Requirements

To exercise these distributed features, you'll need the following prerequisites.

Licenses and Instances

This tutorial is tiered to accommodate different Cribl Stream license types:

- With a Cribl Stream Free, One, or Standard license, you'll install three Cribl Stream instances on one or multiple physical or virtual machines – one Leader Node, and two Worker Nodes.
- To do the **optional** section on adding and managing multiple Worker Groups, you'll need an Enterprise or Sales Trial license/plan.

Basic Setup

Basic building blocks are identical to the Getting Started Guide. Please refer to the following sections of that tutorial for details, as needed:

- (System) Requirements
- Download and Install Cribl Stream
- Run Cribl Stream

To set up the multiple instances you'll need, choose among the options below in Three Instances, Pick Any Medium. But first, let's lay out the division of labor in a single Worker Group.

Distributed Deployment (Identical Workers)

A Distributed deployment enables Cribl Stream to scale out to handle higher data volumes, load-balancing with failover, and parallel data processing based on conditional mapping and routing.

A single Leader Node manages multiple Worker Nodes. The Leader distributes and updates configuration on the Workers, handles version control, and monitors the Workers' health and activity metrics. The Workers do

all the data processing.

Here, we'll show how this works by configuring a Leader and two Workers. This configuration is compact, and can be demonstrated without an Enterprise (or other paid) license/plan. But you can extrapolate the same technique to setting up enterprise-scale deployments of hundreds of Workers, to handle petabytes of data.

Cribl Stream Free, One, and Standard licenses support only a single Worker Group (named `default`), so in this example, all Workers share identical configuration. With an Enterprise license/plan, you can organize Workers into multiple Groups, with varying configurations to handle scenarios like on-premises versus cloud tech stacks, or data centers in different geographic locations. For details, see Worker Groups – What Are They and Why You Should Care.

Three Instances, Pick Any Medium

You'll need to deploy three Cribl Stream instances – with SSH access – on one or more physical machines, virtual machines, or containers. If you haven't already provisioned this infrastructure, you have several alternatives, listed in the following subsections:

- Docker Containers
- Curl
- Amazon Lightsail
- AWS/EC2 (CloudFormation Optional)
- Kubernetes/Helm

Pick whichever approach will make it easiest for you to get the infrastructure launched – based on familiarity, preference, or availability.

We Don't Need No Stinkin' Permissions Errors!

Cribl's Docker containers come with Cribl Stream preinstalled. If you select any other option, be sure to both install and run Cribl Stream as the same Linux user. (For details on creating a new user – addressing both systemd and initd distro's – see Enabling Start on Boot.)

Docker Containers

You can use the Docker Compose (`docker-compose.yml`) file below to easily stand up a Cribl Stream Distributed deployment of a Leader and multiple Workers on one machine.

Before you use the Docker Compose file

1. Open the `docker-compose.yml` file in a text editor.
2. Replace both instances of `INSERT_TOKEN` with a unique, secure token value.
3. Save the updated `docker-compose.yml` file.

docker-compose.yml

```
version: '3.8'
services:
  master:
    image: cribl/cribl:latest
    environment:
      - CRIBL_DIST_MODE=master
      - CRIBL_DIST_MASTER_URL=tcp://INSERT_TOKEN@0.0.0.0:4200
      - CRIBL_VOLUME_DIR=/opt/cribl/config-volume
    ports:
      - "19000:9000"
    volumes:
      - "~/cribl-config:/opt/cribl/config-volume"
  workers:
    image: cribl/cribl:latest
    depends_on:
      - master
    environment:
      - CRIBL_DIST_MODE=worker
      - CRIBL_DIST_MASTER_URL=tcp://INSERT_TOKEN@master:4200
    ports:
      - 9000
```

When you run the `docker compose` command, the `~/cribl-config` local directory is created automatically for use as a persistent configuration store for Cribl Stream.

If you prefer to use ephemeral storage, you can delete line 8 (the `CRIBL_VOLUME_DIR` definition) and lines 11–12 (the `volumes` configuration) before running the `docker compose` command. But this will make it hard to stop and restart the same infrastructure, if you want to do the tutorial in chunks.

To deploy a Leader Node, plus (for example) two Workers already configured and wired up to the Leader, use this command:

```
docker compose up -d --scale workers=2
```

To deploy a different number of Workers, just change the `workers=2` value. By default, the above command pulls the freshest stable image (tagged `cribl/cribl:latest`) from Cribl's Docker Hub. It defaults to the following URLs and ports:

- Leader URL: `http://localhost:19000`
- Worker URLs: `http://localhost:<automatically-assigned-host-ports>`

If you're running the container itself on a virtual machine, replace `localhost` with the VM's IP address. The automatic assignment of available host-OS ports to the Workers prevents port collisions. **Within** the Docker container, these ports will forward over TCP to port 9000. To see the ports assigned on the OS, enter:

```
docker ps
```

You should see results like these:

```
CONTAINER ID   IMAGE                COMMAND                  CREATED          STATUS
a3de9ea8f46f   cribl/cribl:latest   "/sbin/entrypoint.sh…"   12 seconds ago   Up 10 s
40aa687baefc   cribl/cribl:latest   "/sbin/entrypoint.sh…"   12 seconds ago   Up 10 s
df362a65f7d1   cribl/cribl:latest   "/sbin/entrypoint.sh…"   13 seconds ago   Up 11 s
```

The **PORTS** column shows the host-OS ports on the left, forwarding to the container-internal ports on the right. You can use the `docker_workers_N` ports if you want to log directly into Workers. In the above example:

- Worker1 URL: `http://localhost:63411`
- Worker2 URL: `http://localhost:63410`

If your Leader is crashing with two Workers, make sure you are allocating enough memory to Docker.

Once your three instances are running, proceed to Configure Leader Instance.

Curl

Use our Download page's `curl` command to directly install Cribl Stream onto your chosen infrastructure.

For x64 processors, use: `curl -Lso - $(curl https://cdn.cribl.io/dl/latest-x64) | tar zxv`

For ARM64 processors: `curl -Lso - $(curl https://cdn.cribl.io/dl/latest-arm64) | tar zxv`

Once you've configured the first Cribl Stream instance as a Leader, you can bootstrap Workers from the Leader. Or you can create Workers (with tags) from the Leader, using a `curl` command of this form:

`curl 'http://<leader-ip-or-hostname>:9000/init/install-worker.sh?token=<token>&tag=<tag1>&tag=<tag2>'`

For example: `curl 'http://localhost:9000/init/install-worker.sh?token=<token>&tag=dev&tag=test''`

Once your three instances are running, proceed to Configure Leader Instance.

Amazon Lightsail

Amazon Lightsail provides a quick, simple way to deploy Cribl Stream to AWS instances. Amazon's Get Started with Linux/Unix-based Instances in Amazon Lightsail tutorial walks you through setting up your instances and connecting via SSH.

- The free (first month) tier is all you need for this tutorial.
- As the "platform," Cribl recommends selecting **Amazon Linux 2 (default CentOS)**.
- Lightsail doesn't support IAM roles assigned to instances, or advanced load balancing, but it's adequate for this tutorial, which is not a production deployment.

Once your three instances are running, proceed to Configure Leader Instance.

AWS/EC2 (CloudFormation Optional)

You can deploy Cribl Stream's AWS EC2 instances using Cribl's CloudFormation template, see our AWS/EC2 Quick Start Guide on GitHub. Follow the **Cribl Stream Distributed** instructions. (You'll be responsible for the costs of your AWS infrastructure.)

If you prefer to deploy your own EC2 instances, the free tier is fine for this tutorial. Cribl recommends selecting **Amazon Linux 2 (default CentOS)** AMIs. Relevant instructions are linked below.

1. See any of these AWS Docs for EC2 deployment:
    - Tutorial: Getting Started with Amazon EC2 Linux Instances
    - Launching an Instance Using the Old Launch Instance Wizard
    - How Can I Create and Connect to an Amazon Linux EC2 Instance?
2. See these AWS instructions for SSH access:
    - Connect to Your Linux Instance Using an SSH Client

Once your three instances are running, proceed to Configure Leader Instance.

Kubernetes/Helm

Use Cribl's Helm charts to deploy Kubernetes pods, then proceed to the next section:

- Kubernetes Leader Deployment
- Kubernetes Worker Deployment

Configure Leader Instance

Once you've set up your Leader and Worker instances via your chosen approach above, you're ready to configure these instances and their communication.

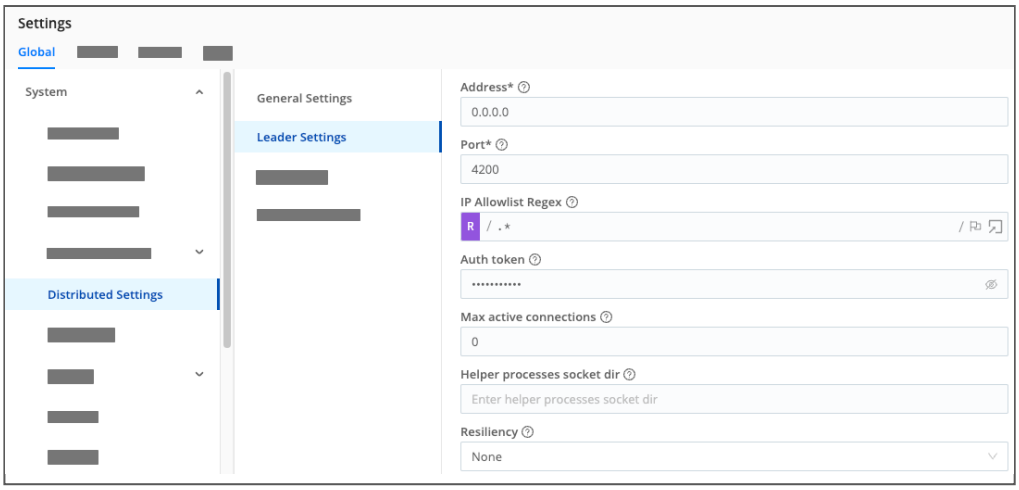
If you used an installation option like Docker Containers above, it has already preconfigured all three instances for you. This section and the next Configure Workers section will show you how to verify, and/or modify, these preset configurations.

If you want to jump ahead, your next required configuration step is Add a Source, further down.

Configure the first instance in Leader mode, and open port 4200.

1. Log into the Leader. Depending on the deployment method you chose, this will be at `http://<localhost-or-IP-address>:9000` or `http://<localhost-or-IP-address>:19000`. Use the default `admin/admin` credentials.
2. Complete the registration form.
3. In the sidebar, select **Settings**, then **Global**.
4. Select **Distributed Settings**, then **General Settings**.
5. In **Mode**, choose `Leader`.
6. Select **Leader Settings**, and make sure the **Port** is set to `4200`.
   (This port must be open for Workers to communicate with the Leader.)
7. Select **Save** to restart the Cribl server in Leader mode.

Keep the Leader's tab open, so that we can verify connectivity with the Workers after configuring them (in the next section).



Distributed > Leader Settings

8. Optional but recommended: In the sidebar, select **Worker Groups**. Then enable **UI Access** for your Group(s). This way, you will be able to click through from the Leader's **Workers** page to view and manage each Worker's UI, distinguished by a purple border. (This option handles authentication for you, so you don't need to manage or enter the Workers' credentials.)

Configure Workers

Next, configure the two other instances as Workers that report to the Leader to receive processing instructions. We'll configure one instance through the UI, and (optionally) bootstrap the other from the Leader.

Configure Worker via UI

1. Log into the first Worker instance. Depending on the deployment method you chose, this will be at `http://<localhost-or-IP-address>:9000` or at: `http://<localhost-or-IP-address>:<automatically-assigned-host-port>`. Use the default `admin/admin` credentials.
2. Complete the registration form, if displayed.
3. In the sidebar, select **Settings**, then **Global**.
4. Select **Distributed Settings**, then **General Settings**.
5. In **Mode**, choose `Stream: Managed Worker (managed by Leader)`.
6. Leave other settings on this tab unchanged, including **Default Group**: `default`. (This is the literal name of the single Worker Group available with free licenses.)
7. Select **Leader Settings**, and make sure the **Address** matches the domain of the Leader you previously configured.
8. Still in **Leader Settings**, display the **Auth token** value. Optionally, you can change this from the default.
9. Leave other settings unchanged, and select **Save** to restart this instance as a managed Worker.

Bootstrap Worker from Leader

You can (if you choose) configure the second Worker instance using exactly the same procedure you used just above. But here, we'll offer you a simplified version of Cribl Stream's Bootstrapping Workers from Leader procedure for downloading the config from the Leader to the second Worker:

First, switch to the terminal/console of the instance you've reserved for this second Worker.

Next, if you didn't change the default **Auth token** value when you previously configured the Leader, run this command as root user:

```
curl http://<leader-hostname-or-IP>:9000/init/install-worker.sh | sh -
```

If you cannot run as root, insert `sudo` as you pipe to the shell:

```
curl http://<leader-hostname-or-IP>:9000/init/install-worker.sh | sudo sh -
```

To instead pipe to a bash shell:

```
curl http://<leader-hostname-or-IP>:9000/init/install-worker.sh | [sudo] bash -
```

If you substituted a custom **Auth token** value on the Leader, enter:

```
curl http://<leader-hostname-or-IP>:9000/init/install-worker.sh?token=<your-custom-t
```

Or, for bash:

```
curl http://<leader-hostname-or-IP>:9000/init/install-worker.sh?token=<your-custom-t
```

The bootstrap script will install Cribl Stream into `/opt/cribl` on the target instance.

Verify Workers' Communication with the Leader

With both Workers configured, next make sure they're visible to the Leader.

1. Return to the Leader instance you previously configured.

2. In the sidebar, select **Workers**.
3. You should now see both Workers, mapped to the `default` **Group**.

If one or both Workers are missing, repeat the preceding Configure Worker via UI and/or Bootstrap Worker from Leader procedures until the Workers show up.

Otherwise, if both Workers are present, we can now configure a few more resources to get data flowing through this distributed setup.

If you're interested in details about the communication among Cribl Stream instances, see How Do Workers and Leader Work Together.

Once you've configured a Worker to point to the Leader Node, the Leader will assign the Worker a new, random admin password. This secures each Worker from unintended access. If you need to reconfigure the Worker later, you can either:

- Enable the Leader's **UI access** option, as recommended above; or
- Reset the password on the Worker Group – see Set Worker Passwords.

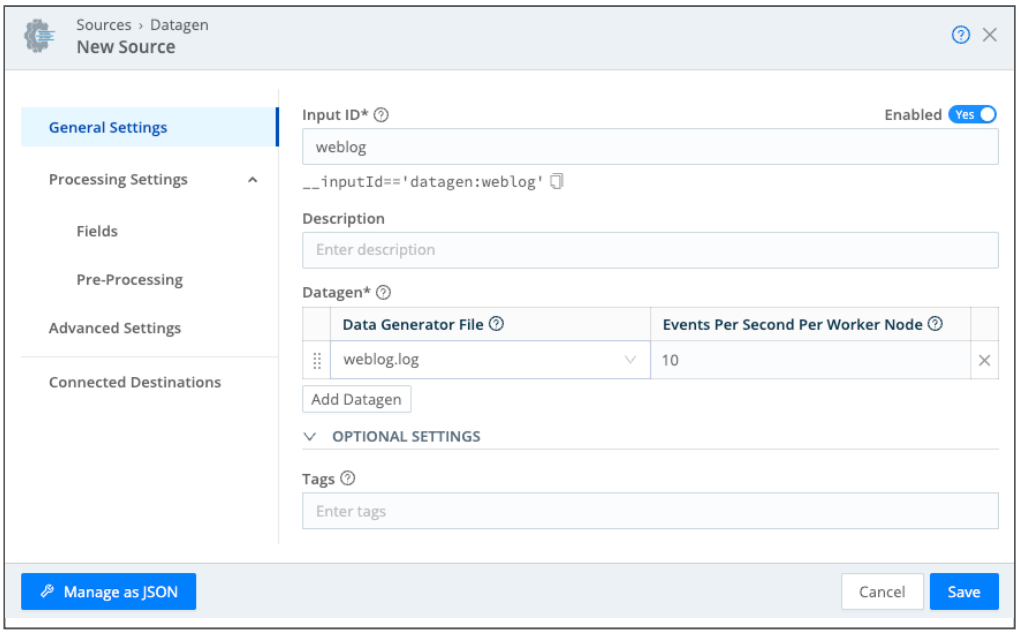
Add a Source

To minimize dependencies, this section walks you through enabling a Cribl Stream built-in Datagen Source to get some (fake) events flowing into your Workers. (This is the same approach used in our single-instance Getting Started Guide tutorial, but using a different datagen.)

If you prefer to configure Cribl Stream to receive events from a real data input that you've already set up, see our Sources topic for a link to the appropriate instructions.

1. In the Leader's sidebar, select **Worker Groups**.
2. Select the Group name.
   (Working with a free license, we're implicitly configuring this Source on the `default` Group.)
3. On the **Worker Groups** submenu, select **Data**, then **Sources**.
4. Select the **Datagen** tile. (You can use the search box.)
5. Select **Add Source** to open a **New Source** modal.
6. In the **Input ID** field, name this Source `weblog` (or any unique name).
7. In the **Data Generator File** drop-down, select `weblog.log`.
   This generates simulated log events for a website.
8. Keep the **Events per Second per Worker Node** at the default `10` EPS for now.

9. Select **Save**.
   In the **Enabled** column, the toggle set to `Yes` indicates that your Datagen Source has started generating sample data.
10. Select **Commit** at the upper right, enter a commit message, and select **Commit & Deploy**.
    This uses Cribl Stream's `git` integration to record the `default` Group's new configuration and deploy it to your Workers.



Source (Datagen) configuration

If you'd like to verify that the Datagen is sending events, wait about a minute for them to start accumulating. Then, on the **Datagen** Sources page, select **Live** in the **Status** column for your configured Source. On the resulting **Live Data** tab, you should see events arrive within the default 10-second capture.

Add a Destination

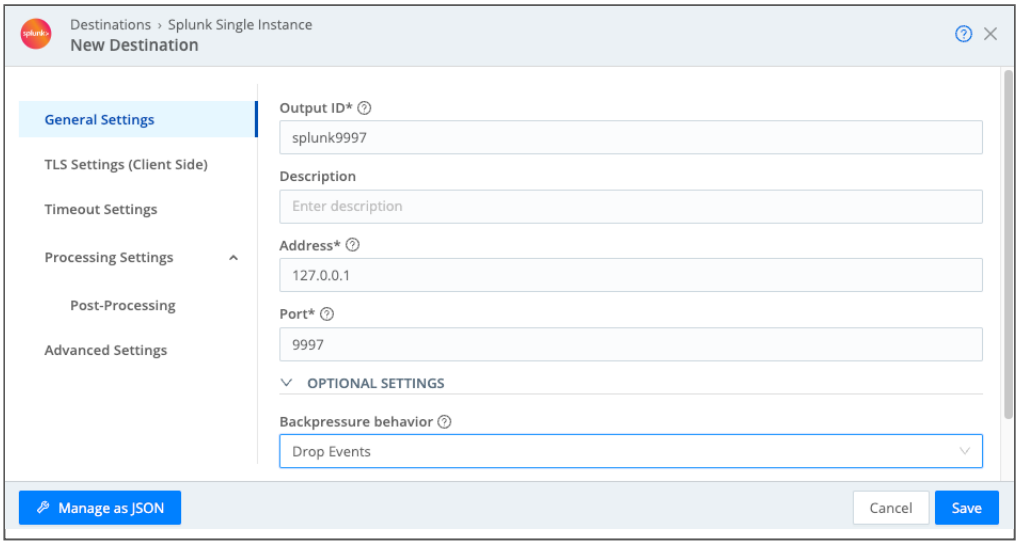
On the output side, choose any of these options:

- To configure a realistic output, but with no real dependencies and no license requirement, follow the Simulated Splunk Destination instructions just below.
- For a simpler option, jump to the Internal Destination instructions further down.
- To send data to a real receiver that you've already set up, see our Destinations topic for a link to the appropriate instructions.

Simulated Splunk Destination

Here, you'll go through the steps of configuring a typical Splunk Destination, but you'll use netcat to spoof the receiver on port 9997.

1. In the Cribl Stream Leader's UI, configure a Splunk Single Instance Destination, following these instructions. For this simulated output:
    - Set the **Address** to `127.0.0.1` (that is, localhost).
    - Do not precede this IP address with any `http://` or `https://`
    - Leave the **Port** at the default `9997`.
    - Set the **Backpressure behavior** to `Drop Events`.



A glorious spoofed Splunk Destination config

2. In the **Version Control** menu at the upper right, select **Commit**, enter a commit message, and confirm the commit.
3. Select **Deploy** to deploy this new configuration to your Workers.
4. In the first Worker instance's terminal/console, shell in, then enter `cd /opt/cribl/bin` to access Cribl Stream's CLI.
5. Enter `nc -h` to check whether netcat is installed on this Linux instance.

If the command fails, follow your Linux distro's steps for installing netcat. (For example, for Ubuntu instructions, see Docker Notes below.)

6. Enter `./cribl nc -l -p 9997` to have netcat listen on port 9997, but simply discard data.

Docker Notes

If you're using a container like Docker, before shelling in at step 4 above, you'll need to first open a shell inside that container: `docker exec -it <CONTAINER ID> /bin/bash`

In the above Docker Containers deployment example, you'd want to open the shell on the `docker_workers_1` container, whose `<CONTAINER ID>` was `a3de9ea8f46f`.

Cribl's Docker containers currently run Ubuntu 20.04.6. You can install netcat with this sequence of commands:

```
apt update
apt install netcat
```

The data you'll now see displayed in the terminal will be gibberish, because of Splunk's proprietary data format.

If data isn't flowing, you might need to restart Workers. You can do this through Cribl Stream's UI. With Docker containers, use `docker compose down`, followed by `docker compose up`.

You can streamline future Commit and Deploy steps by entering a **Default commit message**, and by collapsing actions to a combined **Commit and Deploy** button. Both options are available at **Settings** > **Global** > **System** > **Git Settings** > **General**.

Internal Destination

As an alternative to the Splunk instructions above, you can configure Cribl Stream's built-in DevNull Destination to capture events and discard them. (This is the same Destination used in our single-instance Getting Started Guide tutorial.)

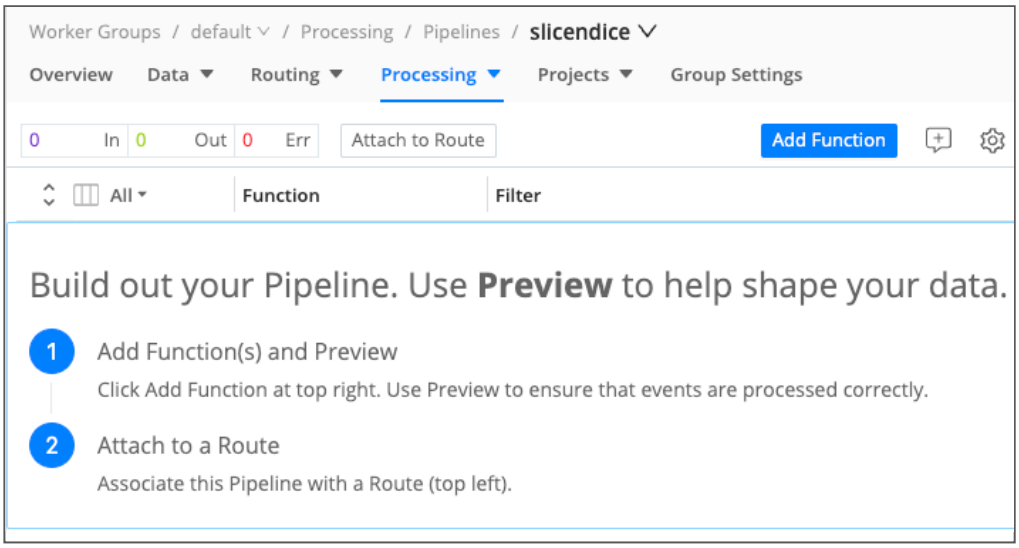
1. In the sidebar, select **Worker Groups**.
2. Select the Group name.
   (Working with a free license, we're implicitly configuring this Source on the `default` Group.)
3. On the **Worker Groups** submenu, select **Data**, then **Destinations**.
4. Select the **DevNull** tile. (You can use the search box.)
5. On the resulting **devnull** row, look for the **Live** indicator under **Status**. This confirms that the **DevNull** Destination is ready to accept events.
6. In the Destinations list on the left, select the **Default** Destination at the top.
7. Verify that **Default Output ID** points to the **devnull** Destination we just examined.
8. Select **Commit** at the upper right, enter a commit message, and select **Commit & Deploy**.

Add a Pipeline

To complete this Distributed deployment with realistic infrastructure, let's set up a Pipeline and Route.

If you've already done the Getting Started Guide, you've already created a `slicendice` Pipeline. In the following steps, skip ahead to adding an Eval Function.

1. From the **Worker Group** submenu, select **Processing**, then **Pipelines**.
2. Select **Add Pipeline**, then **Add Pipeline** again.
3. In the new Pipeline's **ID** field, enter a unique identifier (for example, `slicendice`).
4. Optionally, enter a **Description** of this Pipeline's purpose.
5. Select **Save**.

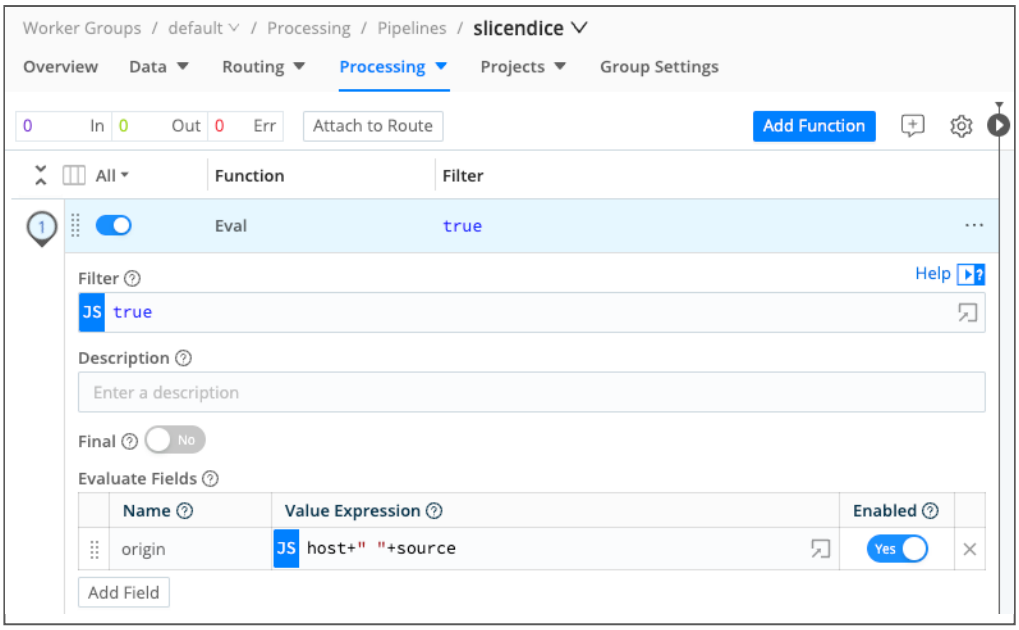


Pipeline saved

Add an Eval Function

Now add an Eval Function to the Pipeline:

1. At the top of the **Pipelines** page, select **Add Function**.
2. Search for the `Eval` Function, and select it.
3. In the new Function's **Evaluate Fields** section, select **Add Field**.
4. In the **Name** column, name the field `origin`.
5. In the **Value Expression** column, enter: `host+" "+source`
   This new `origin` field will concatenate the host and source fields from incoming events.



Adding Eval Function to Pipeline

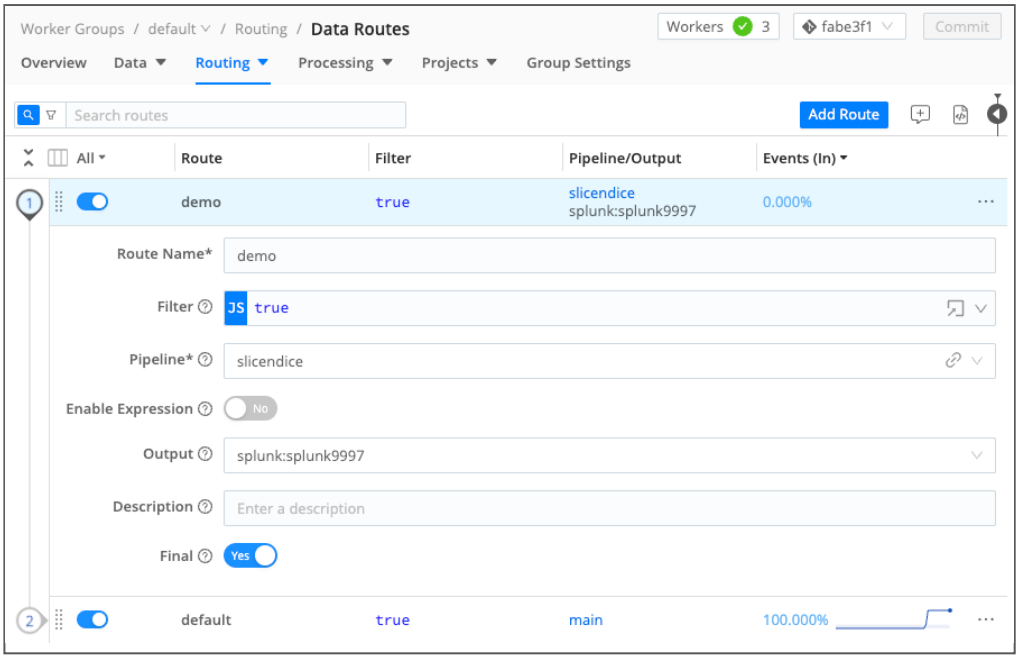
6. Select **Save** to store the Function's configuration.
7. **Commit** and **Deploy** the new Pipeline configuration.
8. Optionally, open the right pane and select **Capture Data** to verify throughput.

Add a Route

If you've already done the Getting Started Guide, you've already created a `demo` Route, attached to the `slicendice` Pipeline. In the following steps, just modify the Route to send data to the new Destination you configured above.

1. At the top of the **Pipelines** page, select **Attach to Route**.
2. Select **Add Route**.
3. Enter a unique **Route Name**, like `demo`.
4. Leave the **Filter** field set to its `true` default, allowing it to deliver all events.
5. Set the **Pipeline** drop-down to our configured `slicendice` Pipeline.
6. Set the **Output** drop-down to the Destination you configured above. If you boldly chose the Simulated Splunk Destination, this will be named something like `splunk:splunk9997`.
7. You can leave the **Description** empty, and leave **Final** set to `Yes`.
8. Grab the new Route by its left handle, and drag it to the top of the Routing table, so that our new Route will process events first. You should see something like the screenshot below.
9. Select **Save** to save the new Route configuration.
10. **Commit** and **Deploy** your changes.

11. Still assuming you configured a simulated Splunk output, look at the terminal where you're running netcat. You should now see events arriving.

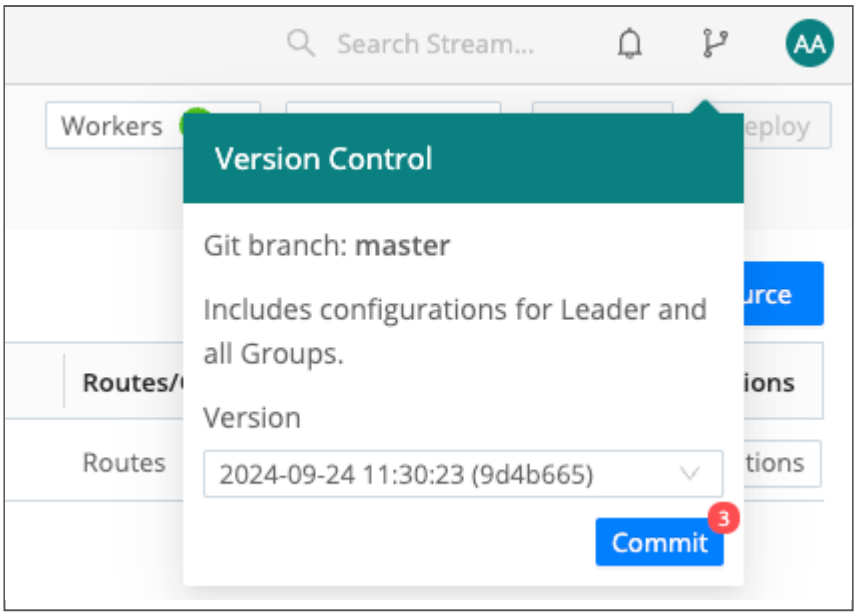


Route attached to Pipeline and Destination

Managing Workers (Scaling)

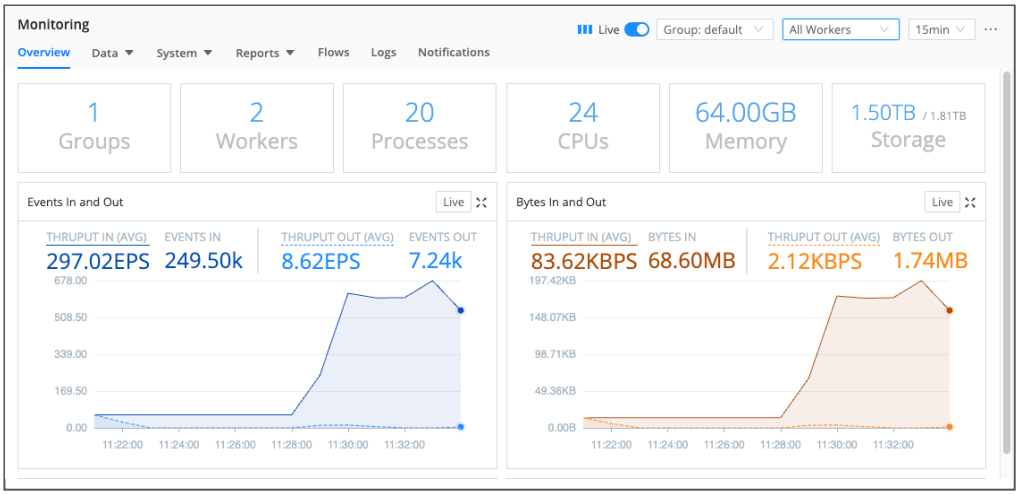
With all our infrastructure in place, let's look at how a Cribl Stream Distributed deployment scales up to balance the incoming event load among multiple Workers.

1. In the Leader's sidebar, select **Worker Groups**.
2. Select the Group name.
   (Working with a free license, we're implicitly configuring this Source on the `default` Group.)
3. On the **Worker Groups** submenu, select **Data**, then **Sources**.
4. Find the **Datagen** Source you configured earlier and select it.
5. Change the **Events per Second per Worker Node** from the default `10` EPS to a high number, like `200` EPS.
6. Select **Save**, then **Commit** and **Deploy** this higher event load.
7. From the **Version Control** menu at the top tight, select **Commit** to commit the Leader's newest config version. In the resulting modal, select **Commit** again to confirm.
   This uses Cribl Stream's `git` integration to save a global configuration point for your whole deployment, which you can roll back to.



Committing Leader's config

8. In the sidebar, select **Monitoring**.
9. Watch as the following changes unspool over the next few minutes:
    - The **CPU Load Average (1 min)** will spike as the higher event volume floods the system.
    - The **Workers** indicator at th top will drop to `0` as the Workers restart with the new configuration you've deployed to them, and then rebound to `2`.
    - If you use the **All Workers** drop-down at upper right to toggle between your two individual Workers, you should see that Cribl Stream is balancing roughly equal event loads among them.



10. To confirm that both Workers are `alive`: In the sidebar, select **Workers**.
11. To wrap up, repeat this procedure's first six steps to set the Datagen's rate back down to `10` EPS, and then save, commit, and deploy all changes.

What Have We Done?

This completes your setup of a basic Distributed deployment, using a free license, and configuring a single Worker Group of two identically configured Worker Processes. (You can extrapolate these same techniques you've just mastered to spin up virtually any number of Workers in the same way.)

To see how you can set up multiple Worker Groups – with separate configurations optimized for separate data flows – continue to the next section, noting its licensing prerequisites.

If you're deferring or skipping that option, jump ahead to Cleaning Up.

Add and Manage Multiple Worker Groups (Optional)

To add and manage more than one Worker Group – everything in this optional section – you'll need an Enterprise or Sales Trial license for your on-prem Cribl Stream deployment, or an Enterprise (or equivalent) plan for your Cribl.Cloud Organization. For details on adding multiple Worker Groups on Cribl.Cloud, see Cribl.Cloud Worker Groups.

See Licensing for how to acquire and install one of the above license types. Install the license on your Leader instance, and then commit this as a Leader config change (top nav's **Global Config** dialog), before you proceed.

Here, we'll build on the infrastructure we've created so far to:

- Configure Mapping Rules.
- Verify how Cribl Stream balances large data volumes among Worker Processes.
- Add a second Worker Group, data Source, and Destination.
- Add a second Pipeline and attach it to its own Route.
- Reconfigure Mapping Rules to send each Source's data through a separate Group.

To keep this Quick Start tutorial focused on techniques, rather than on configuring lots of infrastructure, we'll assign just one Worker to each Worker Group – one of the two Workers we launched above. But in production, you'll be able to apply the same principles to setting up any number of Worker Groups, with any number of Workers.

Multiple-Group Setup

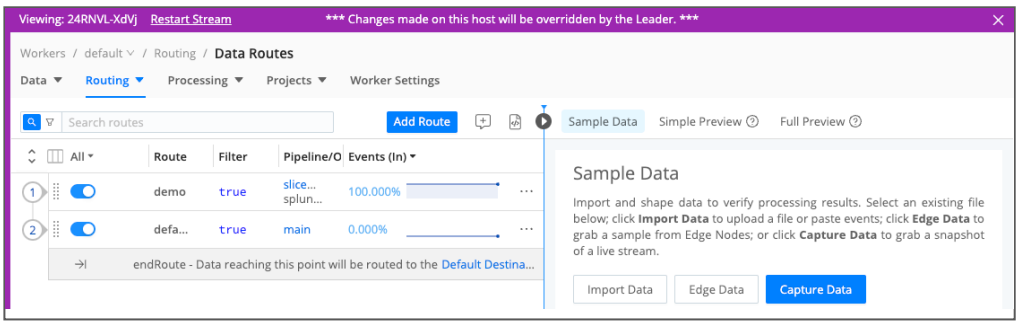
With an Enterprise or Sales Trial license/plan, Cribl Stream's UI adds some extra features.

The **Worker Groups** page now supports multiple Groups. (For now, you still see only the single `default` Group – but we'll change that a few sections down.)

On Cribl.Cloud, the **Worker Groups** page adds extra columns. You'll see each Group's Worker type (customer-managed / hybrid versus Cribl-managed / Cribl.Cloud) and, for Cloud Groups, the infrastructure provider (AWS or Azure), anticipated ingress rate and Provisioned status. For details, see Cribl.Cloud Worker Groups.

Note that if you've enabled Worker UI access, you can click directly through to each of your Workers. This feature will come in handy just below. To try it out:

1. Either select **Workers** in the top right of the **Worker Groups** page, or select **Workers** in the sidebar.
2. Select the desired Worker's link in the **GUID** column.
3. A purple header indicates that you're viewing a Worker's UI.
4. To return to the Leader, select any option in the sidebar.



Leader's remote view of Worker's UI

Check/Restart Workers

For the remaining steps, we want to make sure both our Workers (configured earlier) are up. Cribl Stream's top header should indicate `2 WORKERS`. You can verify that they're `alive` by selecting **Workers** in the sidebar, as shown earlier. If so, proceed to Map Groups by Config.

If either or both Workers are down, restart them:

1. Make sure you've enabled Worker UI access. (It's time!)
2. Click through to a dormant Worker's UI.
3. When you see that Worker's UI (purple header), select **Restart Stream**.
4. Confirm your choice, and wait for a confirmation message to appear for a few seconds.
5. Return to the Leader's UI.
6. If the other Worker is down, repeat the above steps to restart it as well.

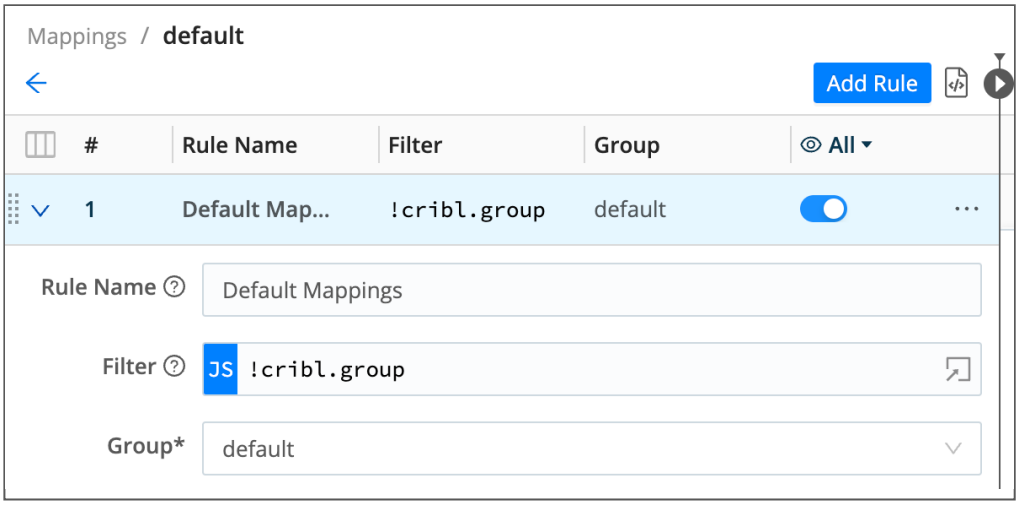
Map Groups by Config

With both Workers confirmed up, let's look at how Cribl Stream has automatically mapped all these existing workers to the `default` Group.

1. In the sidebar, select **Mappings**.
2. You now see a default Mapping Ruleset, also literally named `default`. Select it.

A Cribl Stream Leader can have multiple Mapping Rulesets configured, but only one can be active at a time.

3. This `default` Ruleset contains one initial Rule, literally named `Default Mappings`. Expand its accordion as shown below.
   (The `default` Ruleset and Rule naming are separate from the `default` Group's naming. All of these out-of-the-box starting configurations have been named...literally.)



Default Mapping Rule

Below the **Rule Name**, a Mapping Rule has two functional fields:

- **Filter**: `!cribl.group` – this value expression specifies "Not already assigned to a Worker Group."
- **Group**: `default` – this value specifies "Assign to the `default` Group."

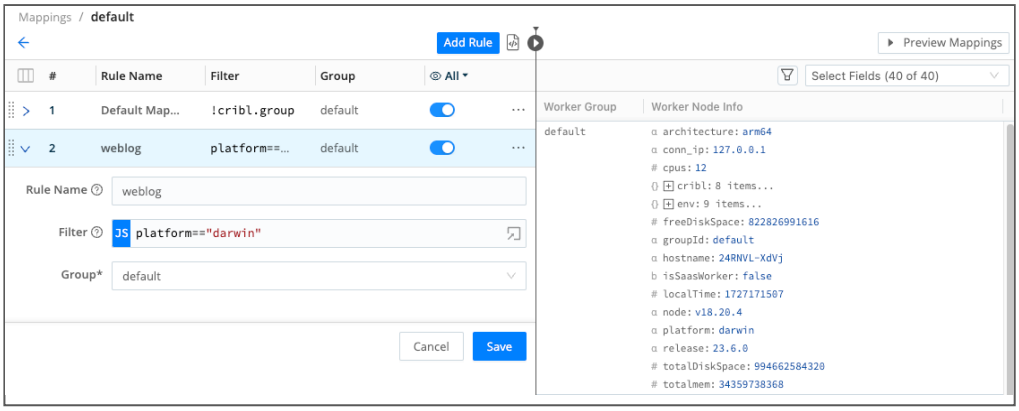
So this is a catch-all rule. By following it, the Leader has assigned all (both) registered Workers to the `default` Group.

Let's make a more-specific rule, mapping a specific Worker (by hostname) to this Group, which receives events from our `weblog` Datagen Source.

Add Mapping Rules

1. Select **Add Rule**. Then configure the new Rule as shown below:
   - **Rule Name**: `weblog` – for simplicity.

- **Filter**: `platform=="<this-worker's-platform>"` – get this value from the right Preview pane. Look for the `platform` field's value. In the example shown below, we got `"darwin"`.
- **Group**: `default` – this is the only option available.



A specific Mapping Rule by Filter condition

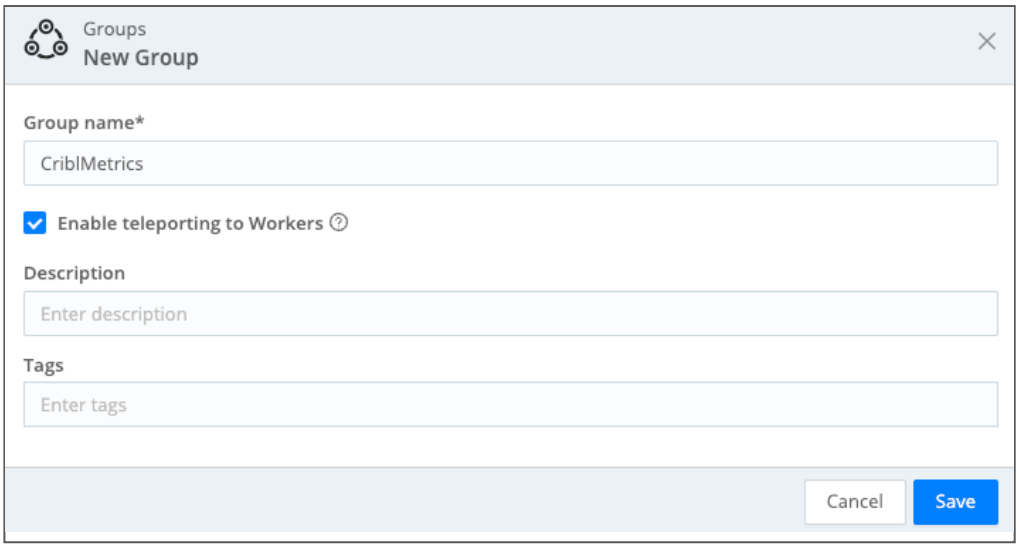
2. Select **Save** to add this Rule.
3. Confirm the warning that changes will take effect immediately.
4. From the **Version Control** menu, select **Commit** to commit the Leader's new config.

For more Mapping Rules/Rulesets details and examples, see Distributed Deployment.

Next, we'll add a second Worker Group; add a second Source (relaying Cribl Stream's internal metrics); and then add another Mapping Rule, to map our second Worker to the new Group.

Add Another Worker Group

1. In the Leaders' sidebar, select **Worker Groups**.
2. Select **Add Group**.
3. Name the new Group `CriblMetrics` to match its purpose.
4. Select **Enable teleporting to Workers**.



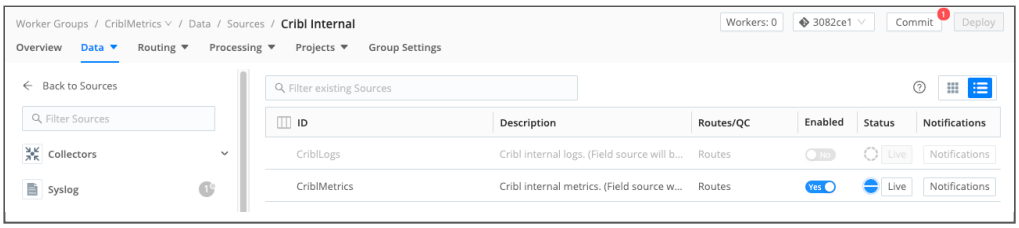
Creating a new Group

5. Save the Group.
6. Select **Deploy** on the new Group's row, and confirm your choice. The new Group should deploy immediately.
7. From the **Version Control** menu, select **Commit** to commit the new config on the Leader.

Add Another Source

On the new Group, we'll now enable a **Cribl Internal: Metrics** Source, representing a second data type.

1. In the sidebar, select **Worker Groups** , and then select the new `CriblMetrics` Group.
2. On the **Worker Groups** submenu, select **Data**, then **Sources**.
3. Select the **Cribl Internal** tile.
4. Enable the `CriblMetrics` Source and confirm.



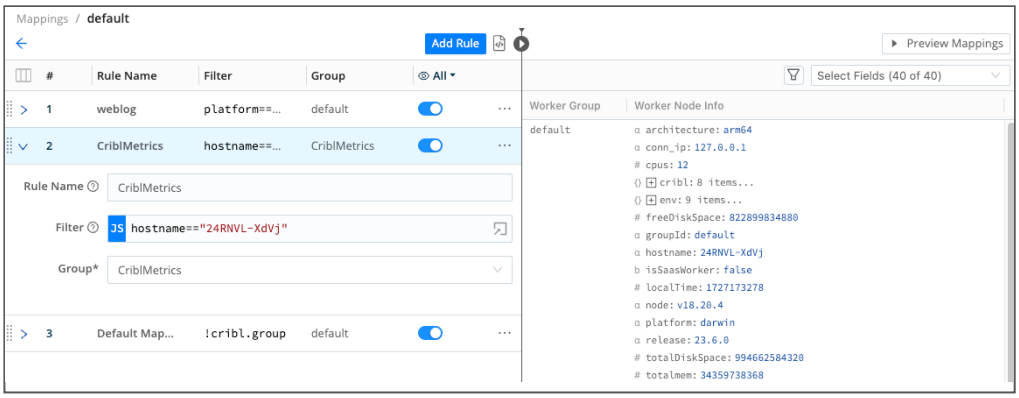
CriblMetrics Source enabled

5. Select **Commit** to commit the new config on the Leader and Group.
6. From the **Version Control** menu, select **Commit** to deploy this new configuration to your Workers.

Map Workers to Groups

Now let's map this new group to the CriblMetrics Source's incoming events:

1. In the sidebar, select **Mappings**.
2. Select the `default` Mapping Ruleset to open it.
3. Select **Add Rule**. Then configure the new Rule as shown below:
    - **Rule Name**: `CriblMetrics` – for simplicity.
    - **Filter**: `hostname=="<this-worker's-hostname>"` – get this value from the right Preview pane. In the second Worker down, look for the `hostname` field's value. In the example shown below, we got `"2ca68fec7de0"`.
    - **Group**: `CriblMetrics` – this is the Group we want to map.
4. Move the `Default Mappings` rule to the bottom of the Ruleset, reflecting its catch-all function.
5. Select **Save** to store the new configuration.
6. Confirm the warning that changes will take effect immediately.

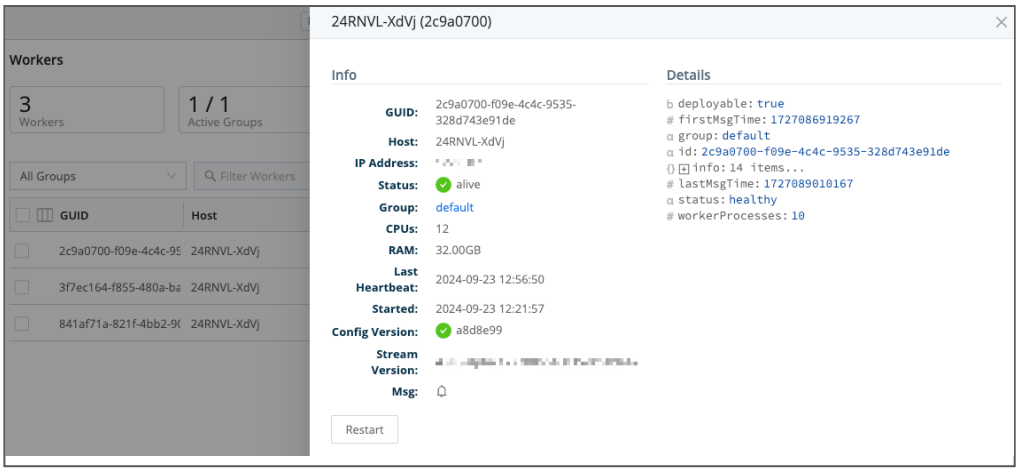


Adding a Rule to map the CriblMetrics Worker to its own Group

7. From the **Version Control** menu, select **Commit** to commit the Leader's new config.

We now have two data Sources and two Worker Groups – one each for (Web) logs versus (Cribl Internal) metrics – along with two Mapping Rules to map data accordingly. To confirm the Workers' assignment to the two Groups, select **Workers** in the sidebar.

To confirm further details about the Workers, in the sidebar, select **Workers**, and on the resulting **Workers** page, click anywhere on the Worker Node's row to reveal more details:



Worker Node Details

Configure Metrics Output

With incoming metrics now mapped to our second Worker Group, we next need to configure this Group's output. Here, we'll rely on a metrics-oriented Pipeline and a Destination that ship with Cribl Stream, and create a new Route to connect everything up.

Examine the Metrics Pipeline

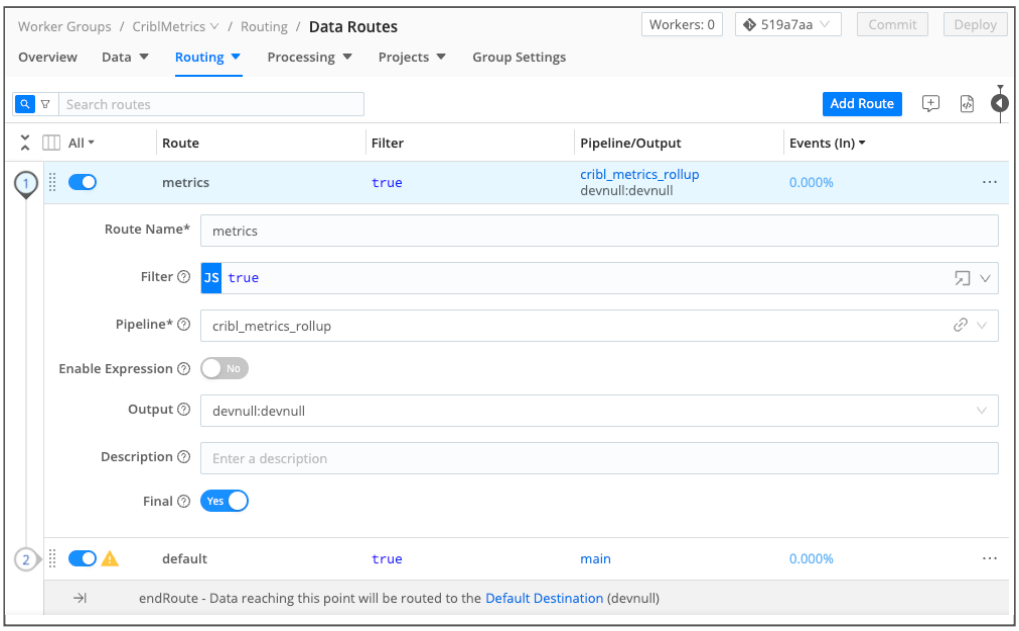
1. In the sidebar, select **Worker Groups** , and then select the `CriblMetrics` Group.
2. On the **Worker Groups** submenu, select **Processing**, then **Pipelines**.
3. Find the `cribl_metrics_rollup` Pipeline, and click it to expand it.
4. Expand this Pipeline's Functions (including Comments) to see its configuration. It's preconfigured with a Rollup Metrics Function to aggregate metrics to a 30-second time window. Next is an Eval Function that filters for Cribl (Cribl Stream) internal metrics and tags them on outgoing events with a new field.

Add Another Route

We'll connect this existing Pipeline to a new Route:

1. At the top of the `cribl_metrics_rollup` Pipeline page, select **Attach to Route**.
2. Select **Add Route**.
3. Enter a unique **Route Name**, like `metrics`.
4. Leave the **Filter** field set to its `true` default, allowing it to deliver all events.
5. Make sure the **Pipeline** drop-down is set to `cribl_metrics_rollup`.
6. As the **Output** (Destination), select our old friend `devnull:devnull`.
   This is Cribl Stream's preconfigured Destination that simulates a downstream service while simply dropping events.

7. You can leave the **Description** empty, and leave **Final** set to `Yes`.
8. Grab the new Route by its handle, and drag it to the top of the Routing table, so that our new Route will process events first. You should see something like the screenshot below.
9. Select **Save** to save the new Route configuration.
10. **Commit** and **Deploy** your changes.



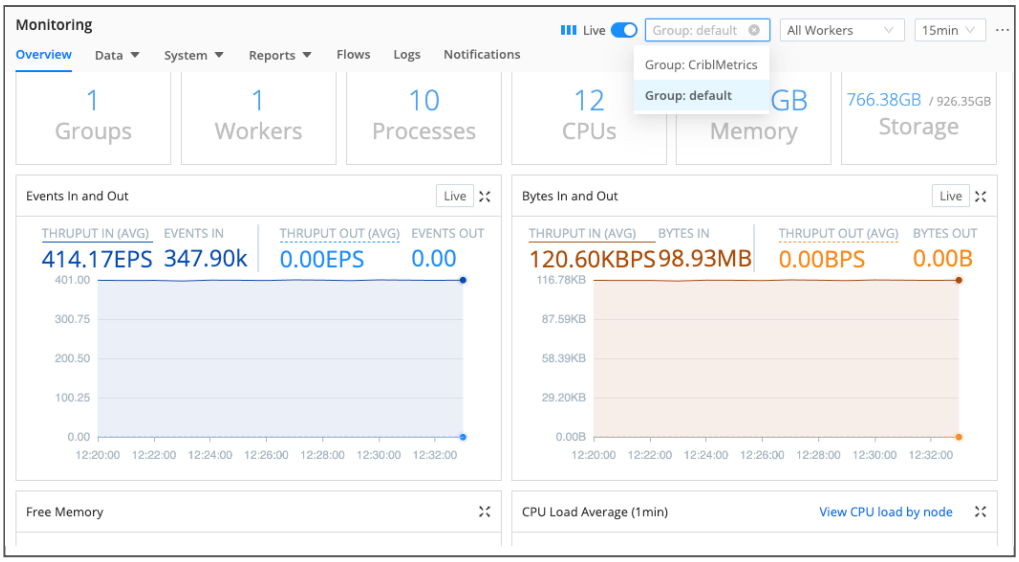
Cribl metrics Route, Pipeline, and Destination wired up

Verify the Multi-Group Deployment

From the sparkline on the Route you just configured, you can already see that metrics data is flowing all the way "out" of Cribl Stream – simulated here by the DevNull Destination.

To verify the whole configuration you've created, in the sidebar, select **Monitoring**. On the **Monitoring** page, use the **All Groups** drop-down (upper right) to toggle between the two Worker Groups to see the division of labor:

- Group `default` (the out-of-the-box Group we configured first) handles the `weblog.log` data.
- Group `CriblMetrics` handles the metrics data.

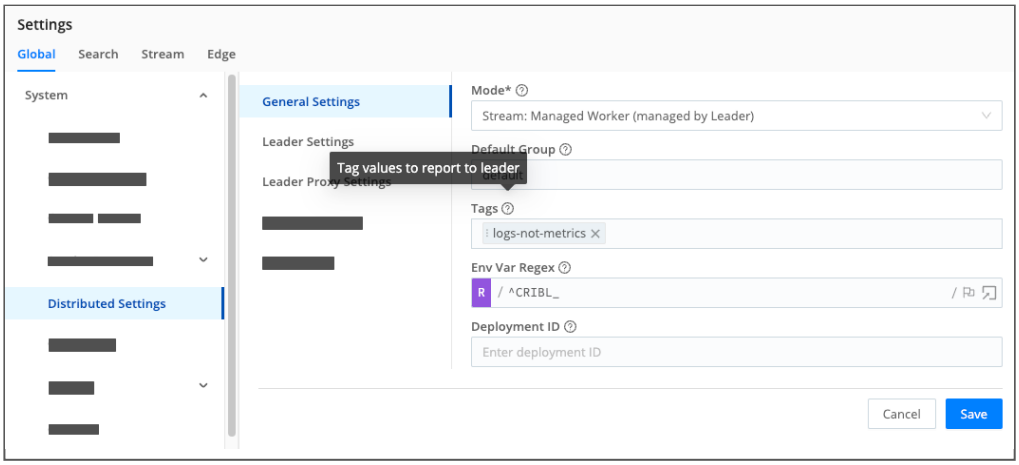


Monitoring individual Worker Groups' throughput

All the Distributed Things – Review

Before a final section where you can tear down your infrastructure, here's a recap of the simple (but expandable) distributed model we've created, with some ideas for expanding it:

- A Distributed deployment enables Cribl Stream to scale out to higher data volumes. This load-balancing occurs even with a single Worker Group, in which all Workers share the same configuration.
- By adding multiple Worker Groups, you can partition Worker Nodes (and their data flows) by different configurations. In this demonstration, we simply mapped Workers to Groups by the Workers' `hostname`. But you can map by a range of arbitrary criteria to meet your production needs.
- For example: Different Groups can be managed by different teams. You can filter on DNS rules to send relevant data to the relevant team's Group.
- Different Groups can also maintain configurations for different regions' data privacy or data retention requirements.
- You can also Map workers arbitrarily using Tags and other options.



More About Worker Groups, Nodes, and Processes – Definitions

Cribl Stream refers to "Workers" at several levels. Now that you've been initiated into building distributed deployments, here's a guide to the fine points of distinguishing these levels:

- A **Worker Group** holds one or multiple **Worker Nodes**.
- Each Worker Node functions like an independent Cribl Stream Single-instance deployment. Worker Nodes don't coordinate directly with each other – they're coordinated only through communication to/from the Leader Node.
- Each Worker Node contains a configured number of **Worker Processes**. Unlike the above grouping abstractions, this is the level that actually processes data. To load-balance among Worker Processes, Cribl Stream's API Process round-robins incoming connections to them.

When deploying on AWS/EKS, Worker Groups should not span Availability Zones. If you have EBS persistent volumes, and a node fails, its replacement won't be able to access the peer volume across AZs.

Clean Up

If and when you choose to shut down the infrastructure you've configured for this demonstration:

- Navigate to Cribl Stream's `default` Group > **Data** > **Sources** > **Datagen**, and disable the toggle beside `weblog.log`.
- If you configured a second Worker Group: Navigate to Cribl Stream's `CriblMetrics` Worker Group > **Data** > **Sources** > **Cribl Internal**, and disable the toggle beside **CriblMetrics**.
- If you have `netcat` running on a Worker's terminal/console, `^C` it.
- There's no need (or way) to switch off the **DevNull** Destination – it just is.
- If desired, **Commit** and **Deploy** these changes.
- If you're running the Cribl Stream server(s) on cloud instances that will (ultimately) incur charges, you're now free to shut down those cloud resources.

Next Steps

Interested in guided walk-throughs of more-advanced Cribl Stream features? We suggest that you next check out these further resources.

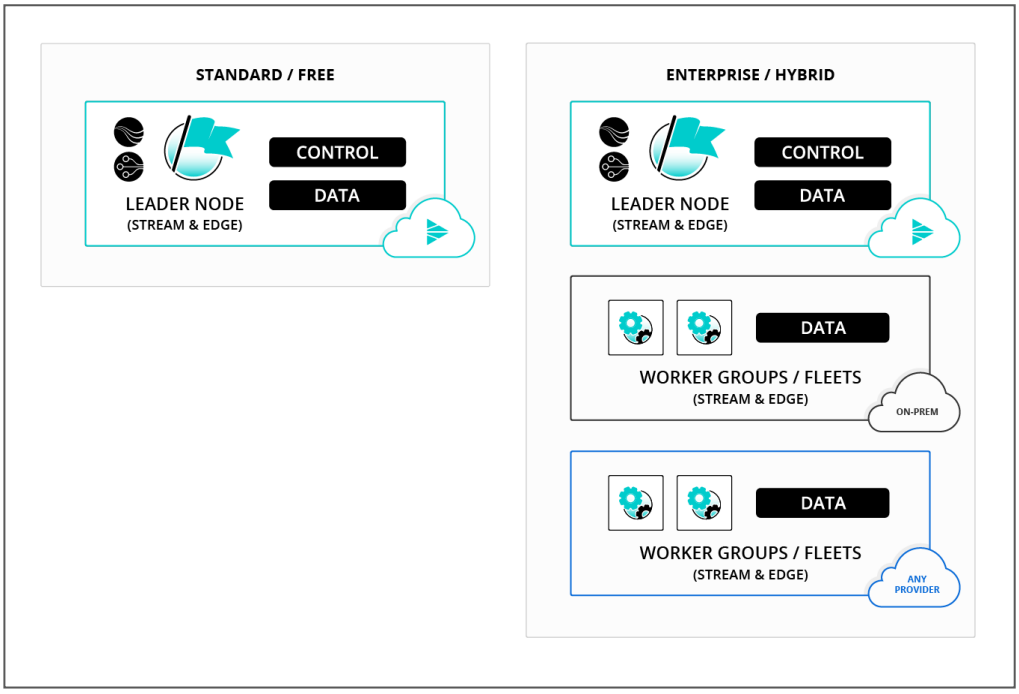
- Distributed Deployment: All the details behind the deployment approach you just mastered in this tutorial.
- Cribl Stream Sandboxes: Work through general and specific scenarios in a free, hosted environment, with terminal access and real data inputs and outputs.
- Use Cases documentation: Bring your own services to build solutions to specific challenges.
- Cribl Concept: Pipelines – Video showing how to build and use Pipelines at multiple Cribl Stream stages.
- Cribl Concept: Routing – Video about using Routes to send different data through different paths.

2. Cribl.Cloud

If you select a Cribl.Cloud deployment, Cribl assumes responsibility for hosting and managing your Cribl Stream infrastructure.

Cribl.Cloud comes in both free and paid versions. By upgrading to a Cribl.Cloud Enterprise plan, you can implement a **hybrid deployment** of any complexity.

In hybrid deployments, the Leader resides in Cribl.Cloud, and manages Stream Workers and Edge Nodes regardless of their location. Your data processing configuration can consist of any combination of Workers and Edge Nodes: Cribl-managed, in private cloud instances that you manage, or in your data centers.



Standard/free versus Enterprise/hybrid deployment

For an overview of additional features available on Enterprise plans, see Pricing.

Why Use Cloud Deployment?

Cribl.Cloud is designed to simplify deployment, and to provide certain advantages over using your own infrastructure, in exchange for some current restrictions (because Cribl will manage some configuration on your behalf). Cribl.Cloud offers these advantages, among others:

- Full Cribl Stream power with no responsibility to install or manage software for the Leader Node. Cribl.Cloud is fully hosted and managed by Cribl, so you can launch a configured instance within minutes.
- Access to Cribl Search to search, explore, and analyze machine data in place.

- Access to Cribl Lake, a data lake solution for long-term, full-fidelity data storage.
- Access to Workspaces, where you can isolate parallel Cribl Leaders with separate access controls and other configurations.
- Automated delivery of upgrades and new features.
- Leaders and Cribl-managed Worker Nodes encrypt data at rest (including configuration and sample files) at the disk level.
- Free, up to 1 TB/day of data throughput (data ingress + egress) for all new accounts.
- Quick expansion of your Cribl.Cloud deployment beyond the free tier's limits by purchasing credits toward metered billing. Pay only for what you use.

For a more-detailed comparison of Cribl.Cloud versus customer-managed ("on-prem") deployments of Cribl Stream software on your own infrastructure, see Cribl.Cloud vs. Self-Hosted.

If you're new to Cribl Stream, please see our Basic Concepts page and Getting Started Guide for orientation. Cribl.Cloud always runs in Distributed mode – for details about this, see Simplified Distributed Architecture.

Cloud Pricing

Beyond the free tier, an optional paid Cribl.Cloud account – whether Standard or Enterprise – offers direct support, plus expanded daily data throughput according to your needs. From your Cribl.Cloud Organization, select **Go Enterprise** to submit an inquiry about upgrading your free account, and Cribl will respond.

You'll pay only for what you use – the data you send to Cribl Stream, and the data sent to external destinations. However, data sent to your AWS S3 storage is always free. For details, see Pricing.

2.1. Initial Cribl.Cloud Setup

Your first step to using Cribl.Cloud is to sign up on the Cribl.Cloud portal (see Registering a Cribl.Cloud Portal below), to create your Cribl.Cloud Organization.

Your Organization will display a dedicated portal, which has a network and access boundary that isolates your Cribl resources from all other users. (For details, see Cribl.Cloud Data Isolation.)

The portal will initially be on a **free** Cribl.Cloud plan. Certain throughput and administration limits apply to a free account. When you need more capacity and/or options, it's easy to upgrade to a paid or Enterprise plan – just select **Go Enterprise** in your Cribl.Cloud portal.

The Cribl.Cloud Suite is listed on AWS Marketplace. When you're ready for a paid plan, you can use your Enterprise Discount Program (EDP) credits here to run Cribl products, billed through your AWS account – with no need for a separate procurement process.

Registering a Cribl.Cloud Portal

Ready to take the plunge? Here's how to register and manage a Cribl.Cloud instance.

First, if you haven't already signed up on Cribl.Cloud:

1. Start at: https://cribl.cloud/signup/
2. Register with your work email address.
3. Follow the on-screen instructions to provide your name and additional (optional) personal information, agree to the Subscription Services Agreement, and then use the welcome email you receive from Cribl to verify your account.
4. On the organizations page, select **Add Organization**.
5. In the **New Organization** modal, enter an **Organization Name** (a friendly alias for the randomly generated ID that Cribl will assign to your Organization), and then select an AWS **Region** to host your Cribl.Cloud Leader. Cribl currently supports the following Regions:
    - `US West (Oregon)`
    - `US East (Virginia)`
    - `US East (Ohio)`
    - `Europe (Frankfurt)`
    - `Europe (London)`
    - `Asia Pacific (Sydney)`

- `Canada (Central)`

Note that each user can register only one active Organization on the free tier. For details, see notes on Member Permissions.

6. Complete the quick survey to let us know how you plan to use Cribl. The goals you select and the Sources and Destinations you choose will be used to offer you personalized guidance as soon as you open your Workspace.

Troubleshooting Resources

Cribl University's Troubleshooting Criblet on How to Log Into Cribl.Cloud walks you through the whole registration and login flow. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Troubleshooting Criblets and Advanced Troubleshooting short courses.

2.2. Managing Cribl.Cloud

The Cribl.Cloud portal is the place where you get an overview of and manage your organization, configure network settings, and control user access and billing information.

Switch Organizations

When you own or are a Member of multiple Cribl.Cloud Organizations, you can switch between the Organizations:

1. In the top bar, hover over the name of your Organization.
2. In the drop-down, select the Organization you want to switch to.

Alternatively, in the drop-down you can select **Manage Organizations**. You will move to an Organization landing page, displayed to an Organization's Owners and Admins, where you can view details of all your Organizations, switch to any of them, add a new one or delete one, if you have proper permissions.

Configure Organization Details

To customize your Organization information, in the sidebar, select **Organization**.

You can modify the following information:

Field name	Description
Organization Name	A "friendly" name for your Organization. Upon signing in, Members will see this alias above the Organization ID on the Select Organization page.
Description	Add further details about your Organization.
Opt in to beta features	If displayed, this check box enables access to new options that Cribl has not yet made generally available. As with all beta features, expect some instability in exchange for advancing to the cutting edge of your Cribl.Cloud.

Select **Save** to immediately apply your changes.

You can check additional information about your Organization, including the AWS region it is located in, the software version, and license, by selecting **Organization Details** at the bottom of the sidebar.

Ingress Ports

Your Cribl.Cloud Organization's preconfigured and user-configurable ports for inbound data are set at the Workspace level. For details, see Cribl.Cloud Ports.

Get Support

In the top bar, select the **Support** icon to access a set of links with additional resources about Cribl Stream, including:

- Sandboxes (free, interactive tutorials on fully hosted integrations)
- Cribl University
- Concept/demo videos

2.3. Cribl.Cloud Billing

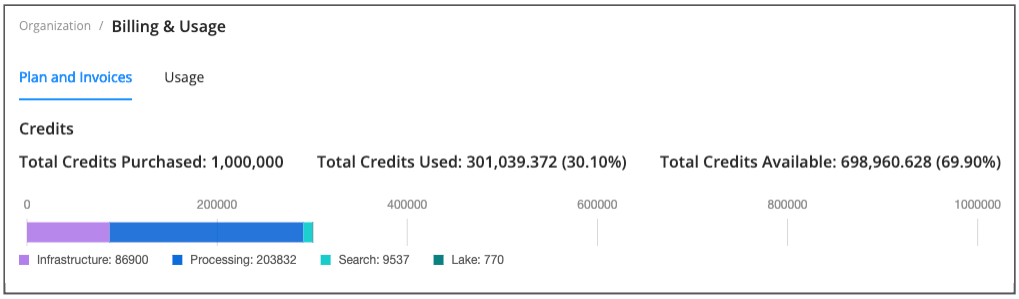
In the Cribl.Cloud portal, you can check the plan of your Cribl.Cloud Organization, track data usage, and preview and download invoices.

Check Cribl.Cloud Plan and Credits

To check the plan that your Organization is running:

1. In the sidebar, select **Organization**, then **Billing & Usage**.
2. On the **Billing & Usage** submenu, select **Plan and Invoices**.

Here you can see a bar of purchased, used, and available **Credits** on your account. Color-coding breaks down usage by infrastructure versus processing (data throughput).



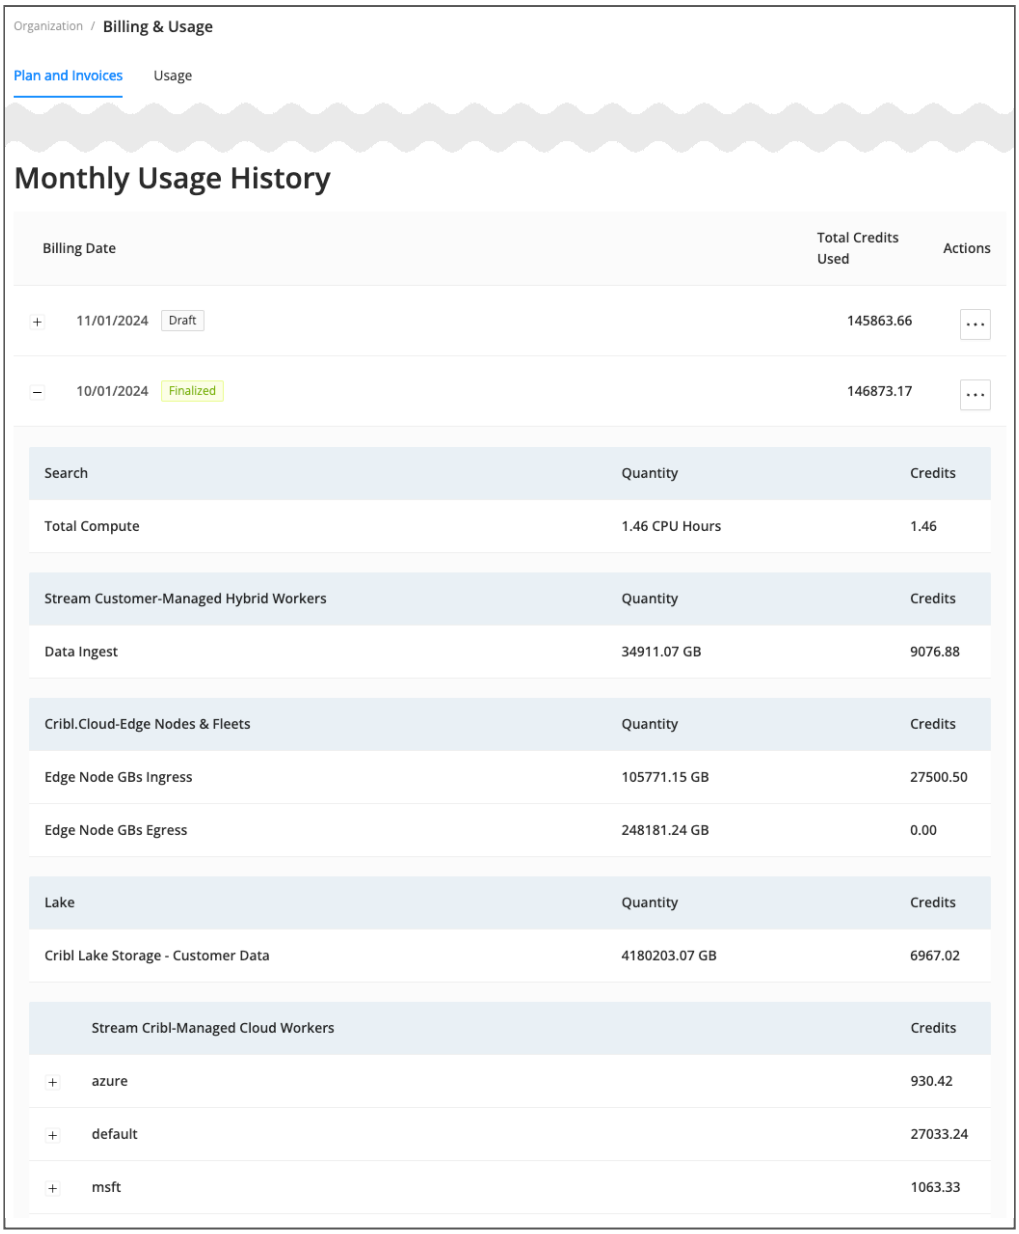
Credit usage bar

Under **Plan**, you can see the details if your Cribl.Cloud plan, including its period and start date.

Check Data History

Monthly Usage History offer details about your credits usage in the current and prior months. Here, you can break out usage on the following:

- Cribl Search
- Cribl Lake
- Hybrid Workers (ingest billing only)
- Groups of Cribl-managed Workers in Cribl.Cloud (with ingest versus infrastructure breakouts per Group)
- Connected Environments GB in (on-prem Leaders passing usage data to Cribl.Cloud). See the article on Connecting On-Premises Leaders to Cribl.Cloud Billing for more information.



Plan and Invoices

Credits carry over across billing periods, as long as you renew your Cribl.Cloud plan.

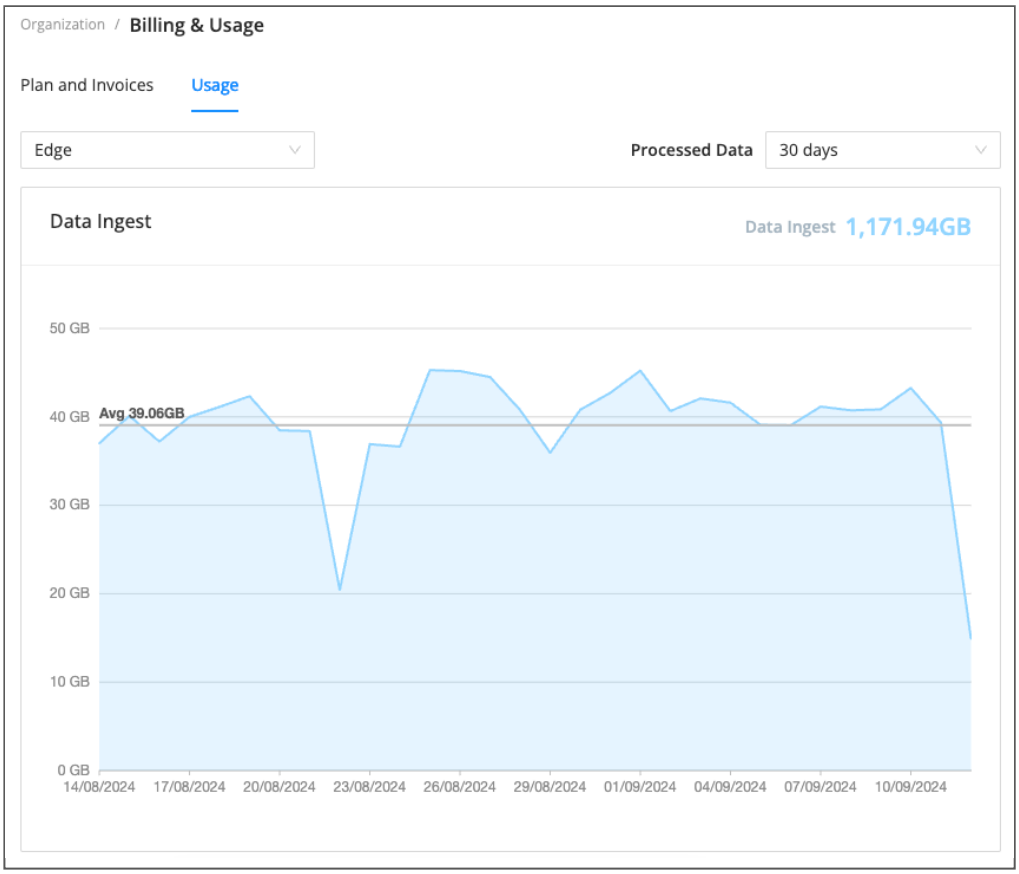
To check detailed information about data usage:

1. In the sidebar, select **Organization**, then **Billing & Usage**.
2. On the **Billing & Usage** submenu, select **Usage**.

Select a product to view its graphs (including any Connected Deployments), and adjust the duration of time for which data was processed over a selectable trailing period of 7 days to 1 year. For more information on Connected Deployments, see Connecting On-Premises Leaders to Cribl.Cloud Billing.

Stream	Search	Lake	Edge
The **Stream** graph shows credits usage for **Data in**, **Data out**, and **Infrastructure**. Using the **Processed Data** drop-down, you can filter the aggregate display down to individual Cribl-managed Groups in Cribl.Cloud, or to all customer-managed (hybrid) Groups.	The **Search** graph shows billed **Search Compute** in CPU hours and **Total Compute Costs**.	The **Lake** graph shows **Total Usage** and **Data Usage**.	The **Edge** graph shows **Data Ingest** and **Data Egress**.

- The trend line shows daily averages, and you can hover over data points to pop out details.
- At the right side of each graph is a total for the selected period.



Billing > Usage tab

Download Invoices

You can download your monthly Cribl.Cloud invoices as CSV or JSON files. Then, use them in external tools to help with budget planning and analytics or store them for historical purposes.

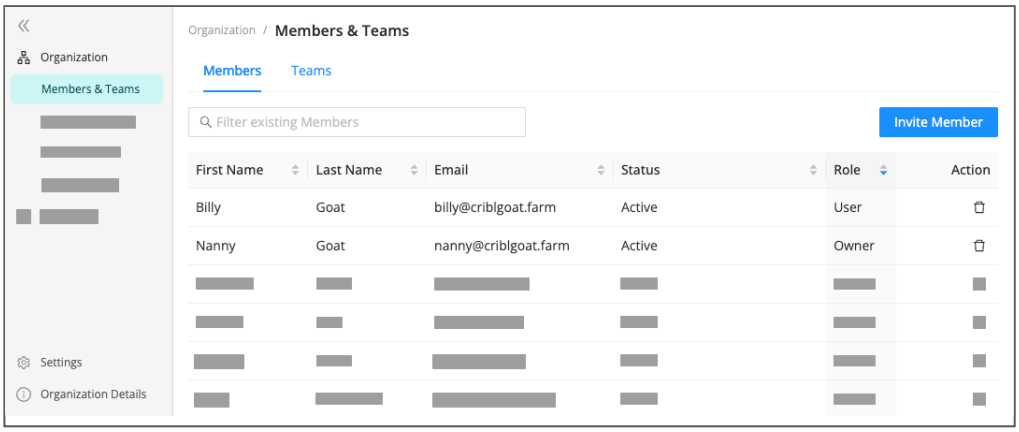
You can only download finalized invoices, not draft ones.

To download an invoice:

1. In the sidebar, select **Organization**, then **Billing & Usage**.
2. On the **Billing & Usage** submenu, select **Plan and Invoices**.
3. Under **Monthly Usage History**, hover over ••• in the **Actions** column of the invoice you want to download.
4. Select **Download CSV** or **Download JSON**.

2.4. Managing Cribl.Cloud Members

From the **Organization** > **Members & Teams** page, an Organization's Owner can invite new users to join the Organization, assign Permissions to new and existing Members, remove pending invites, and remove existing Members.



Members & Teams page: Managing Invites and Members

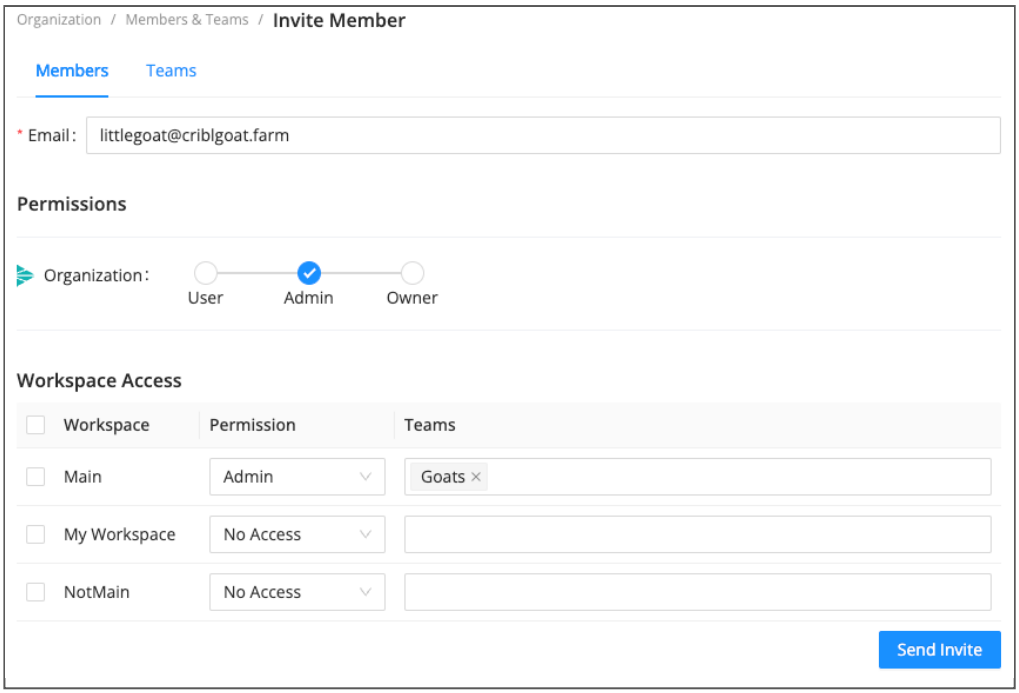
Inviting Members

To invite a new Member:

1. On the top bar, select **Products**, and then select **Cribl**.
2. In the sidebar, select **Organization**, and then select **Members & Teams**.
3. On the **Members & Teams** submenu, select **Members**.
4. Select **Invite Member** to open the page shown below.
5. Enter the **Email** of the new user you want to invite.
6. Under **Permissions**, assign appropriate role on your Organization.
7. If you selected the **User** role, under **Workspace Access**, define access to specific Workspaces.

Assigning the **User** role requires certain plan/license tiers. For details, see Pricing.

8. If you selected the **Member** Permission for any Workspace, additionally select product-level permissions for that Workspace.
9. Select **Send Invite** to send the invitation.



Invite Member modal

Responding to Invites

An invited Member receives an email with an **Accept Invitation** link to either sign into their existing Cribl.Cloud account, or else sign up to create an account and its credentials.

After signing in, they'll have access to your Organization and Cribl Stream instance at the Permission level you've specified.

Organization Member Permissions

You assign Permissions per individual user when you invite them to your Organization, or after they join it. Cribl.Cloud does not currently support globally predefining or assigning group Permissions, as with on-prem Cribl Stream.

For Permissions that you can assign at the lower product, Worker Group, and resource levels (all of those only with certain plan/license tiers, see our Members and Permissions topic, which also covers on-prem counterparts to the Cribl.Cloud Organization-level Permissions listed here.

Permission	User	Admin	Owner
Log into the system			
Update own Member profile			

Permission	User	Admin	Owner
View Stream Worker groups you have access to			
`Admin` Access to all Products			
View and execute Leader commits			
View and modify Global Settings			
Manage ACLs (Access Control lists)			
View and update SSO settings			
View Data Sources and Trust Policies			
Manage API Credentials			
View and manage Cribl Suite Global Settings			
View and manage (provision, update, and delete) Stream Worker Groups			
View the Organization's Billing dashboards			
Download invoices			
View Organization Details			
Update Organization Details			
Delete an Organization			
View Organization Members			
Manage (invite, update, delete) Organization Members			

Each user can have Owner Permissions for multiple organizations, and each organization can have multiple users as Owners. However, each user – as defined by their email address – can register only one active Organization, and only if they are not already the Owner of a different Organization.

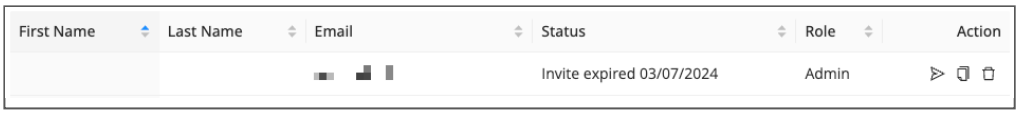
Cribl.Cloud has retired the access-management model of Local Users and Roles/Policies that Cribl applications used prior to v.4.2. Create and configure only **Members** on Cribl applications – references elsewhere in Cribl docs to Local Users do not apply to Cribl.Cloud.

Managing Invites

While an invite is pending, the **Members & Teams** page offers you these options in the **Action** column to deal with commonly encountered issues:

- **Resend Invite**: If your invited Member didn't receive your invitation email, you can click this button to resend it.
- **Copy Invite Link**: If emails aren't getting through at all, click this button to copy and share a URL that will take the invitee directly to the signup page. This target page encapsulates the same identity, Organization, and Permission you specified in the original email invite.
- **Revoke Invite**: This is for scenarios where you need to revoke a pending invite. (You sent someone a duplicate invite, your invitee is spending too much time in space to be a productive collaborator, etc.) After clicking this button, you'll see a confirmation dialog.

After seven days, if an invite has been neither accepted nor revoked, it expires.



Managing Invites

Removing Members

To remove a Member from your Organization:

1. In the sidebar, select **Organization**, and then select **Members & Teams**.
2. Select **Members**, and next to the Member you want to remove, select **Remove Member** from the **Action** column.

Users will retain access to any other Cribl.Cloud Organizations they own or are Members of.

Removing SSO Members

If your Organization is using SSO integration, the IDP (identity provider) admin manages Members in the IDP system. When you remove such a Member from the IDP, they will still be left in the Members list in the UI.

After removing the Member from the IDP, you also need to manually delete them from the Members list in the Cribl.Cloud Portal to completely remove them from the UI.

2.5. Managing Cribl.Cloud Worker Groups

Using Cribl.Cloud's in-app controls, you provision Cribl-managed Worker Nodes in Cribl.Cloud to match the throughput capacity you need. With certain plan/license tiers, you have the option to add and configure multiple Cribl-managed and/or customer-managed (hybrid) Groups.

Cloud Worker Group Providers

Cribl-managed Worker Groups in Cribl.Cloud can be based in one of two providers: AWS or Azure.

Select the provider based on, for example, where your primary Sources and Destinations are located. This will help you reduce transit costs and reduce latency.

The supported regions are:

AWS Region name	AWS Region	Azure Region Name	Azure Region
Australia East	`ap-southeast-2`	Australia East	`australiaeast`
Canada Central	`ca-central-1`	Canada Central	`canadacentral`
Germany West Central	`eu-central-1`	Germany West Central	`germanywestcentral`
UK South	`eu-west-2`	UK South	`uksouth`
US East (N. Virginia)	`us-east-1`	East US	`eastus`
US East (Ohio)	`us-east-2`	East US 2	`eastus2`
US West (Oregon)	`us-west-2`	West US 2	`westus2`

Create a Cloud Worker Group

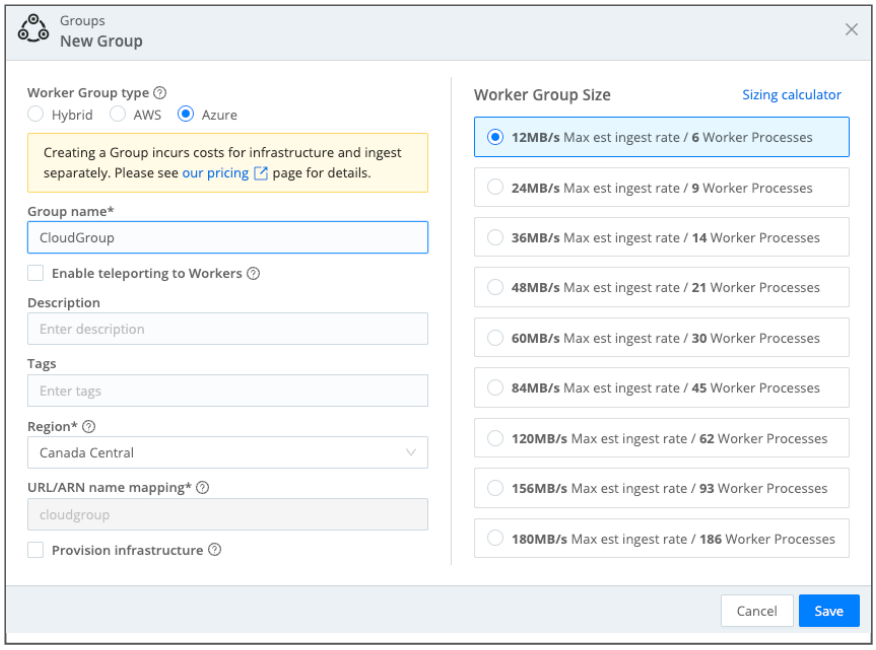
All Cribl.Cloud Organizations start out with one Worker Group. To create additional Cloud Worker Groups (with certain plan/license tiers):

1. On the top bar, select **Products**, and then select **Stream**.
2. Select **Add Group**.
3. In the **New Group** modal, in **Worker Group Type**, select your preferred provider: `AWS` or `Azure`.

You can create up to 10 Cloud Worker Groups per Workspace. If you need to increase this limit, contact Cribl Support.

4. Select the Azure or AWS **Region** where you want to locate the Worker Group.
5. Enter a **Group name**.
6. Select **Enable teleporting to Workers** if you want to enable authenticated access to the Worker Node's UI from the Leader.
7. Select **Provision infrastructure** if you want Cribl.Cloud to automatically create Worker Nodes.
8. The **URL/ARN name mapping** is an auto-generated, unique identifier for your Cloud Worker Groups. It follows stricter naming rules than the Group name.
9. Optionally, enter a **Description**.
10. You can also add **Tags** to help organize Worker Groups into logical categories. Then, you can search by tags on the **View all Groups** interface.
11. Use the **Sizing calculator** to determine the recommended **Worker Group Size**. For details, see Using the Sizing Calculator.
12. Select the **Worker Group Size** based on the recommendation. This setting controls the number of Worker Nodes that will be provisioned, assuming a 1:2 ingest:egress ratio.
13. Confirm with **Save**.

For general guidance about capacity required for your deployment, see our Planning and Sizing topics.



Adding and sizing a new Cloud Group

Use the Sizing Calculator

The Sizing calculator is an in-built feature within Cribl Stream Cloud that aids users in determining the appropriate size for their Worker Groups, either during creation or resizing processes. This tool helps you make informed decisions based on your specific data volume and processing needs.

When creating a new Worker Group, the **Sizing calculator** section is within the Worker Group configuration modal. When resizing an existing Worker Group, navigate to the **Group Settings** > **Group Configuration** section for the desired Worker Group.

To generate the recommended sizing:

1. Use the slider to enter the anticipated **Daily inbound data volume** in `TB`.
2. Use the slider to enter the anticipated **Daily outbound data volume** in `TB`.
3. Select your **Processing load** based on data transformation complexity. **Low** for simple tasks like Masking or Renaming, **Medium** for functions like Rollups or Aggregations, and reserve **High** for resource-intensive operations like Regex extraction or custom code.
4. Select **Recommend Sizing**. The tool will highlight a recommended **Worker Group Size** tier. You can choose a different tier from the available options if your needs differ slightly from the recommendation.

Provision and Manage Infrastructure

If you select **Provision Infrastructure**, the infrastructure will be provisioned about 30 minutes later. You will receive an in-portal notification confirming the change.

You can change Worker Group configuration later, including modifying the **Worker Group Size**, which may change the number of provisioned Worker Nodes.

Control Costs

Cribl will draw down your Cribl.Cloud credits to cover the base cost of maintaining the infrastructure, as well as your normal cost for ingested data.

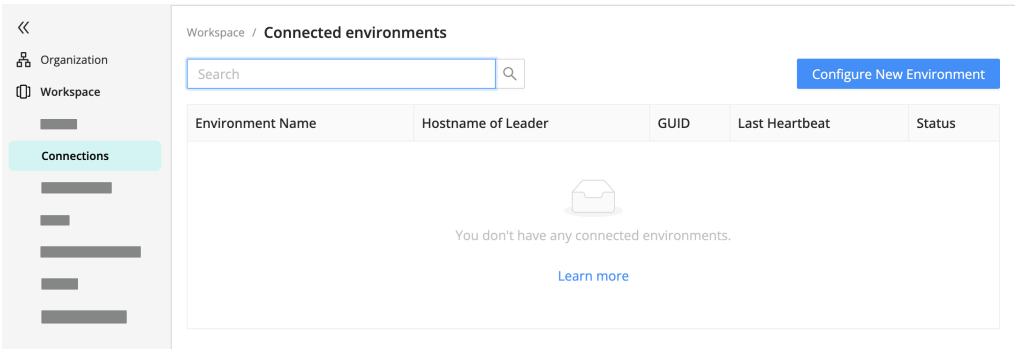
You can minimize the costs by clearing **Provision infrastructure**. You can do so either when creating the Worker Group, or at any later time when you are ingesting no data. With this setting, the Worker Group will go dormant, and your base infrastructure cost for this Worker Group will be `0`. In this state, the Worker Group will contain no Worker Nodes and will ingest no data.

When you deprovision a Worker Group, Stream retains the configuration so you can reprovision it if

needed. However, any persistent queue data on the Worker Nodes will be permanently deleted.

2.6. Connect On-Premises Leaders To Cribl.Cloud Billing

If you have an on-prem Cribl Stream environment and a Cribl.Cloud account on certain plan/license tiers, you can use the **Connected Environments** option to establish a connection between the on-prem Leader and the Cribl.Cloud Leader. Then, use the **Connections** page in your Cribl.Cloud account to manage credit consumption for all of your on-prem environments from one Cribl.Cloud interface. This feature is called Universal Subscription.



The Connected Environments UI

This replaces the on-prem license, and gives you the flexibility to maintain your on-premises deployments without managing multiple licenses and tracking spend across environments.

▶ Cribl Stream Environment Components

Connecting your on-prem Leader to Cribl.Cloud allows you to:

- Monitor credit consumption for each of your on-prem Cribl Stream environments from one user interface.
- Create a connection between the Cribl Stream on-prem Leader and the Cribl.Cloud Leader, which receives billing and usage metrics from the on-prem Leader.

Limitations of the Universal Subscription Feature

Connecting environments has some usage limitations:

- The Universal Subscription feature is available on Cribl.Cloud with certain plan/license tiers. For details, see Pricing.
- Single-instance deployments of Cribl Stream aren't eligible for a Universal Subscription.
- Your Distributed deployment's on-prem Leader must be running Cribl Stream 4.7.x or newer.

Before You Begin Connecting On-Prem Leaders

There are a few tasks you must complete before you can start connecting your on-prem Leader to Cribl.Cloud:

Create a Cribl.Cloud Account

To use Connected Environments, you must have a Cribl.Cloud account on a certain plan/license tier. See our documentation on Initial Cribl.Cloud Setup.

Decide How You Want to Connect to the Leader

There are three ways to enable a Cribl.Cloud to on-prem Leader connection:

- From the Cribl.Cloud account in **Connections**, **Connected Environments**.
- From the on-prem Leader in **Distributed Settings**, **Cloud Connection**.
- Using the command line or environment variable, from either the Cribl.Cloud Leader or on-prem Leader.

The setup instructions in this article will cover each of the connection options.

Purchase Cribl.Cloud Enterprise Plan with Credits

Universal Subscription gives you the option to manage an existing on-premises license with Cribl.Cloud credits.

To do this, contact your sales team, who will help you convert your license to credits.

Add Connected Environments in Cribl.Cloud

To connect existing on-prem Cribl Stream Distributed deployments to Cribl.Cloud, select an on-prem Leader that is running Cribl Stream 4.7.x or newer, then use the following steps.

If you have multiple environments, such as staging and production enviroments when using GitOps, you must connect each environment individually.

1. On the top bar, select **Products**, and then select **Cribl**.
2. In the sidebar, select **Workspace**, and then select **Connections**.
3. Select **Configure New Environment** and fill out the following fields:

Field	Description	Example
Environment name	A name for your environment. This name will display on the **Connected Environments page**. You can search for and filter environments by name.	Goat Farm East Production
Workspace hostname/ID	Hostname of your Cribl.Cloud Workspace. This field is read-only.	`example.goat-farm-prod.cribl.cloud`
Workspace port number	Port number that the Workspace Leader uses to communicate with the on-premises Leader.	`4200`
Workspace token	The auth token of the Cribl.Cloud Leader. This field is read-only and is automatically populated.	`a12bcDEFgHiJKLmnOpQRstuvw3x4z56`

Script type	The format of the script to connect to the on-prem Leader:
	◦ Environment variable
	◦ CLI
		Environment variable:
		`CRIBL_DEPLOYMENT="Goat Farm West Product`
		`CRIBL_CLOUD_WORKSPACE_URL="tls://a12bcDE`
		CLI:
		`./cribl cloud-workspace`
		`-d "Goat Farm West Production"`
		`-H example.goat-farm-prod.cribl.cloud`
		`-p 4200`
		`-u a12bcDEFgHiJKLmnOpQRstuvw3x4z56`

4. If you're using the CLI option, follow these steps, in order:
    - Click **Copy Script**.
    - Open a command-line window, in the environment whose Leader you want to connect to Cribl.Cloud.
    - `cd` into the `$CRIBL_HOME/bin` subdirectory.
    - Paste the script results onto the command line, and run the script.

5. If you're using the environment variable, copy its output, and set it when (or before) you run `cribl start`. How you set this variable depends on your deployment.

   For example, if your Cribl Stream deployment is running in a container, set the environment variable in the container via run call or configuration.

   If you're running your own server, you can set environment variables for the `cribl` user, or you can declare the variable along with the `start` command. For details, see our CLI Reference.

Enable the On-Prem Leader Connection to Cribl.Cloud

You can connect a Cribl Stream Leader to an existing Enterprise Cribl.Cloud Organization.

1. In the sidebar, select **Settings**.
2. Navigate to **Global**, then select **Distributed Settings**.
3. Select **Cloud Connection**.
4. Toggle **Join Cribl.Cloud Workspace** to `Yes`.
5. Fill in the required fields:

Field	Description
Connection URL	The **Cribl.Cloud URL** to connect to this Leader. In your Cribl.Cloud Organization, locate this field value on the sidebar's **Workspace** > **Access** tab.
Connection port	The port for the Cribl.Cloud Leader. Default is `4200`.
Connection auth token	The authentication token for the Cribl.Cloud Leader.

6. Select **Save**.
7. In the Cribl Subscription Services Agreement modal, select **Agree** to accept the agreement.
8. In the confirmation modal, select **Yes** to save changes and restart.

Once you connect an on-prem Leader to a Cribl.Cloud Organization, the license type changes to a Cribl.Cloud billing account and the **Licensing** page will not be accessible. To return to using an on-prem license, toggle **Join Cribl.Cloud Workspace** to `No`, select **Save**, and select **Yes** in the confirmation modal to save changes and restart.

Explore Credit Consumption for Connected Environments

Now that you have a successful connection to your Cribl.Cloud Organization, you can view the incoming usage data and credit consumption for your on-prem and Cloud deployments of Cribl Stream. You must be an Organization Owner to view this data.

For more information on Cribl.Cloud billing, go to the Cloud Billing and Usage page.

View Usage Data

1. In the sidebar, select **Organization**, then **Billing & Usage**.
2. On the **Billing & Usage** submenu, select **Usage**.
3. Select the product drop-down to choose a **Connected Deployment** of Cribl Stream.

On this page, you can view GB in and GB out for the connected environment.

View Credit Consumption

1. In the sidebar, select **Organization**, then **Billing & Usage**.
2. On the **Billing & Usage** submenu, select **Plan and Invoices**.
3. In **Monthly Usage History**, expand the **Billing Date** and scroll to the **Connected Environments** table.

Here, you will see each on-prem environment that is connected to this Cribl.Cloud Organization, and the credits each environment is consuming.

2.7. Enterprise Cloud

With a Cribl.Cloud Enterprise plan, you have the same options and flexibility that an Enterprise license provides for an on-prem Distributed deployment – and more:

- Configuring and managing multiple Worker Groups and Fleets.
- Notifications within Cribl apps, to PagerDuty, and/or to other services via webhook.
- Fine-grained, role-based control of Member Permissions on your Cribl.Cloud Organization and on individual product resources.
- Single sign-on/SSO authentication from external identity providers.
- The hybrid deployment option, described just below.

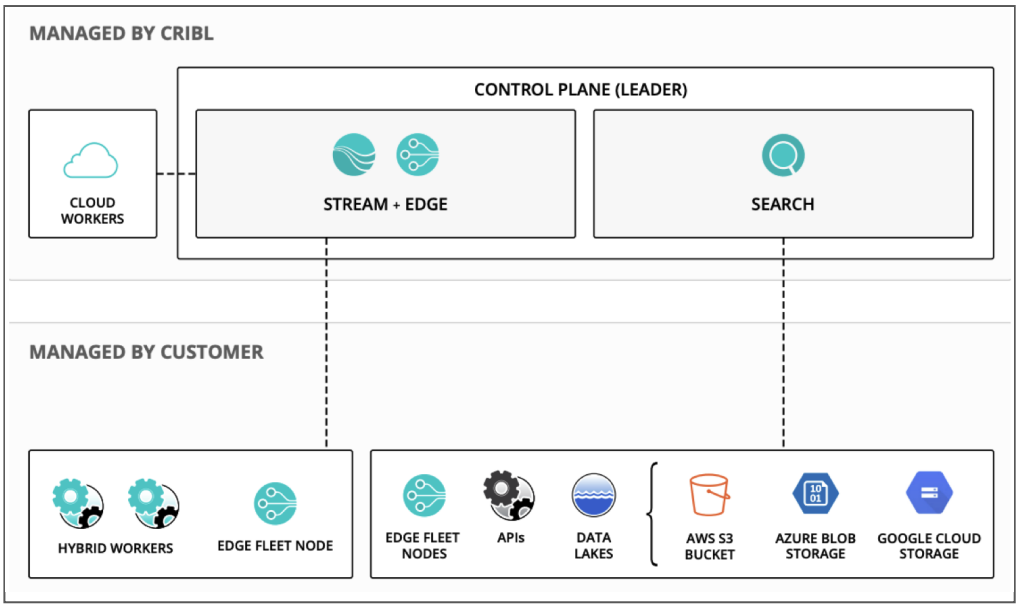
With an Enterprise Plan, the Leader resides in Cribl.Cloud, and controls a flexible mix of Cribl-managed and/or customer-managed Worker Groups. Cribl manages the Leader's high availability on your behalf.

For other Enterprise features – and for comparisons between Cribl.Cloud plans and on-prem licenses – see Cribl's Pricing page.

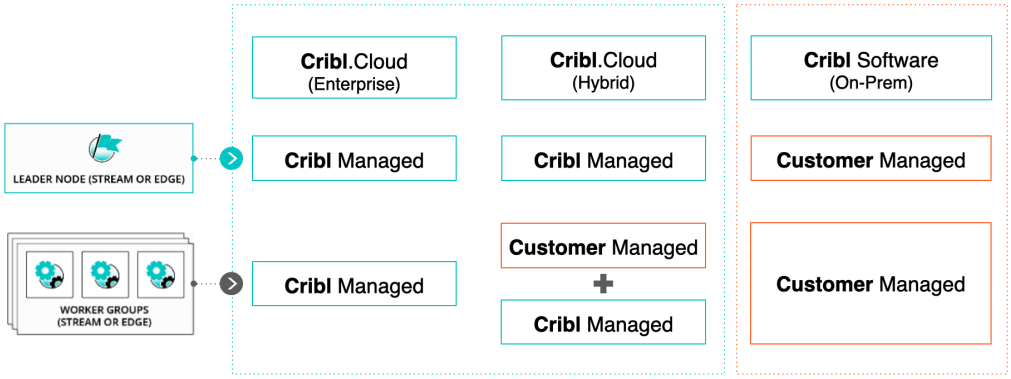
Hybrid Deployment

The diagrams below show the comparative flexibility of a hybrid Cribl.Cloud deployment. The Leader (control plane) resides in Cribl.Cloud, while the Workers that process the data can be in any combination of the following environments:

- In Cribl.Cloud, managed by Cribl.
- In public or private cloud instances that you manage.
- On-premises in your data centers.



Enterprise hybrid deployment, with control plane and Cribl-managed Workers in Cribl.Cloud



Enterprise hybrid deployment, with only control plane in Cribl.Cloud

As the footprint of your operations grows or changes, this flexibility makes it easy to reconfigure Cribl Stream in tandem. You can rapidly expand Cribl Stream observability into new cloud regions – and replace monitored hardware data centers with cloud instances – all while maintaining one centralized point of control.

You can also add Workers or Edge Nodes, and reassign them to different Worker Groups, by easily auto-generating Stream or Edge command-line scripts within Cribl Stream's UI.

Hybrid Requirements

A hybrid deployment imposes these configuration requirements:

- Hybrid Workers (meaning, Workers that you deploy on-prem, or in cloud instances that you yourself manage) must be assigned to a different Worker Group than the Cribl-managed `default` Group – which can contain its own Worker Nodes.

- All Worker Nodes' hosts must allow outbound communication to the Cribl.Cloud Leader's port 4200 at `https://main-<Organization-name>.cribl.cloud:4200`, to enable configuration and workload management by the Leader.
- On all Worker Nodes' hosts, firewalls must allow outbound communication on port 443 to the Leader and to `https://cdn.cribl.io`. This port is also used to bootstrap hybrid Workers from the Leader.
- All Worker Nodes require connectivity to `https://cdn.cribl.io/telemetry/`. For details on testing this connectivity, on the metadata transmitted to Cribl, and on how we use that data, see Telemetry Data.
- If this traffic must go through a proxy, see System Proxy Configuration for configuration details.
- To verify your Leader's Region and public URL, open the Access Details modal.

Note that you are responsible for data encryption and other security measures on Worker Node instances that you manage.

Adding (Bootstrapping) Workers

To add Workers to your hybrid Cribl.Cloud deployment, Cribl recommends that you use the script outlined in Bootstrap Workers from Leader. Hosts for the new Workers must open the same ports (4200 and 443) listed in Hybrid Requirements.

You have three options for generating the script, outlined in these subsections of the Bootstrap topic linked above:

- Auto-generate it from the Leader's UI.
- Make a `GET` API request to the Leader.
- curl the same API request.

In Cribl Edge, you access all these bootstrap options via the Manage Edge Nodes page's **Add/Update Edge Node** control.

Hybrid Cribl HTTP/TCP Configuration

If you use the Cribl HTTP Destination and Source pair, or the Cribl TCP Destination and Source pair, to relay data between Worker Nodes connected to the same Leader, configuring hybrid Workers demands particular care.

The Worker Nodes that host each pair's Destination and Source must specify exactly the same Leader Address. Otherwise, token verification will fail – breaking the connection, and preventing data flow. In hybrid Cribl.Cloud deployments, the Leader's Address format is `main-<your-Org-ID>.cribl.cloud`. When configuring a hybrid Worker, use that format in the **Address** field.

To configure hybrid Workers:

1. Log directly into their UI, then select **Settings** > **Global** > **Distributed Settings**. Make sure the **Mode** is set to **Stream: Managed Worker (managed by Leader)** or **Edge: Managed Edge (managed by Leader)** (which might require a restart).
2. Then select **Leader Settings**, and ensure a consistent entry in the **Address** field.

3. Deploying Cribl Stream Software

3.1. Planning And Sizing

3.1.1. Deployment Planning

There are at least **three** key factors that will determine the type of Cribl Stream deployment in your environment:

- Amount of Incoming Data: This is defined as the amount of data planned to be ingested per unit of time. E.g., how many MB/s or GB/day?
- Amount of Data Processing: This is defined as the amount of processing that will happen on incoming data. E.g., are there a lot of transformations, regex extractions, parsing functions, field obfuscations, etc.?
- Routing and/or Cloning: Is most data going to a single destination, or is it being cloned and routed to multiple places? This is important because destination-specific serialization tends to be relatively expensive.

These factors are covered in detail in Sizing and Scaling, and in our Architectural Considerations introduction to reference architectures.

Type of Deployment

- Use Cribl.Cloud to quickly launch a Cribl-managed deployment of the combined Cribl applications suite (Stream, Edge, and Search). With this option, Cribl assumes responsibility for provisioning and managing all infrastructure, on your behalf.
- Use Single-Instance/Basic Deployment when incoming data volume is low, and/or amount of processing is light.
- Use Distributed Deployment to accommodate increased load. (See Sizing and Scaling for detailed guidance. See Bootstrap Workers from Leader to streamline Workers' deployment via scripting.)

OS and System Requirements

Leader and Worker Nodes should have sufficient CPU, RAM, network, and storage capacity to handle your **specific** workload. It's very important to test this before deploying to production. For details, see OS and System Requirements.

Cluster Installation/Configuration Checklist

This section compiles basic checkpoints for successfully launching a distributed cluster.

1. Provision Hardware

- 1 Leader Node (see specs/requirements in OS and System Requirements above).
- 4 Worker Nodes (see specs/requirements in OS and System Requirements above).
- Acquire an evaluation (Sales Trial) License from the Cribl Sales Team.

2. Configure Leader Node

- Install `git` if not present (for example, `yum install git`).
- Open the necessary ports.
- Download, Install, and Launch Cribl.
- Enable Start at Boot.
- Configure as a Leader.
- Confirm Worker Processes Settings at `-2` (via **Settings** > **Global** > **System** > **Manage Processes**).
- Install License.

3. Configure Worker Nodes

- Enable GUI Access. Administrators will need to connect to the TCP:9000 port on each Node.
- Download, Install, and Launch Cribl.
- Enable Start at Boot.
- Configure as a Worker. (Give each Worker the (arbitrary) tag `POV`.)
- Confirm Worker Processes Settings at `-2` (via **Settings** > **Global** > **System** > **Manage Processes**).
- Install License.

4. Map Workers to Groups

- On the Leader Node, create a Worker Group.
  - Name the Worker Group (arbitrarily) `POV`.
- On the Leader Node, confirm that workers are connecting.
  - In the sidebar, select **Workers**.
- Map Workers to `dev` Worker Groups.
  - Use the Filter: `cribl.tags.includes('POV')`.

5. Other

If you will be using Cribl Stream's GeoIP enrichment feature, install the MaxMind database onto the Cribl Stream Leader and all Worker Nodes.

3.1.2. Sizing And Scaling

A Cribl Stream installation can be scaled **up** within a single instance and/or scaled **out** across multiple instances. Scaling allows for:

- Increased data volumes of any size.
- Increased processing complexity.
- Increased deployment availability.
- Increased number of destinations.

We offer specific examples below, and introduce reference architectures in Architectural Considerations.

Scale Up

A Cribl Stream deployment can be configured to scale up and utilize as many resources on hosts as required. You control this differently on Cribl-managed versus customer-managed Worker Groups.

To optimize Cribl-managed Worker Nodes in Cribl.Cloud, navigate to the desired Worker Group's **Group Settings** > **Group Configuration** section. Then adjust the Sizing Calculator to determine the appropriate size for your Worker Group.

With an on-prem Single-instance deployment, you govern resource allocation in **Settings** > **System** > **Service Processes** > **Processes** section.

With an on-prem Distributed deployment or hybrid group, you allocate resources per Worker Group. From Stream Home, navigate to **Worker Groups** > `group-name` > **Group Settings** > **Worker Processes**.

In any of the above on-prem scenarios, these controls are available:

- **Process count**: Indicates the number of Worker Processes to spawn. Positive numbers specify an absolute number of Workers. Negative numbers specify a number of Workers relative to the number of CPUs in the system. like this: {`<number of CPUs available>` minus `<this setting>`}. The default is `-2`.
  Cribl Stream will correct for an excessive + or - offset, or a `0` entry, or an empty field. Here, it will guarantee at least the **Minimum process count** set below, but no more than the host's number of CPUs available.
- **Minimum process count**: Indicates the minimum number of Worker Processes to spawn. Overrides the **Process count**'s lowest result. A `0` entry is interpreted as "default," which here yields `2` Processes.
- **Memory (MB)**: Amount of heap memory available to each Worker Process, in MB. Defaults to `2048`. (See Estimating Memory Requirements below.) Heap memory is allocated dynamically from the OS as it is requested by the Process up to the amount dictated by this setting. If a Process needs more than the

amount of heap memory allocated, it will encounter an `Out of memory` error, which is logged to `$CRIBL_HOME/log/cribl_stderr.log`. This error indicates either a memory leak or that the memory requirements are too low for the workload being performed by the Process. Cribl support can help you troubleshoot this situation.

For changes in any of the above controls to take effect, you must select **Save** and then restart the Cribl Stream server via **Settings** > **Global** > **System** > **Controls** > **Restart**. In a distributed deployment, also deploy your changes to the Groups.

For example, assuming a Cribl Stream system running on Intel or AMD processors with 6 physical cores hyperthreaded (12 vCPUs):

- If **Process count** is set to `4`, then the system will spawn exactly 4 processes.
- If **Process count** is set to `-2`, then the system will spawn 10 processes (12-2).

Allocate a Maximum Number of Worker Processes

To provision a container with a set number of Worker Processes, use the `CRIBL_MAX_WORKERS` environment variable.

Worker processes handle data ingestion and processing tasks. Improper configuration can lead to:

- **Unstable container deployments**: Incorrect Worker Process settings might cause your containers to malfunction or become unstable.
- **Outages**: Unforeseen resource consumption due to excessive number of Worker Processes can lead to Cribl crashing and service outages.

A couple notes about the `CRIBL_MAX_WORKERS` environment variable:

- The value you designate represents the **maximum** number of Worker Processes for the container. If there are fewer actual CPUs than designated in the variable, the container will provision with the number of Worker Processes that match the actual number of CPUs.
- Several different factors determine the final number of Worker Processes. Cribl uses the lowest number of all of these:
    - The Cribl license Worker Process limit
    - The number of actual Worker Processes (with **Process count** factored in)
    - The Worker count configured in `cribl.yml`
    - `CRIBL_MAX_WORKERS` (if configured)

  For example:
    - License limit: 7

- Number of actual Worker Processes (OS based): 4, calculated as number of actual Worker Processes (`6`) and **Process count** (`-2`)
- Worker Processes in `cribl.yml`: 5
- `CRIBL_MAX_WORKERS`: 3

There are three final assigned Worker Processes, because 3 is the lowest number of all the values above.

Example configurations

Docker

```
docker run -e CRIBL_MAX_WORKERS=2
```

Helm

```
helm install --set env.CRIBL_MAX_WORKERS=2
```

The `values.yml` file

```
env:
  CRIBL_MAX_WORKERS: 2
```

By default, Cribl sets the Worker Process count to `-2` (`Worker Processes (CPU cores) = total CPU cores - 2`). If you don't configure `CRIBL_MAX_WORKERS` and directly launch a container, it inherits the default behavior. This can lead to inefficient resource usage, particularly on machines with many CPU cores.

Scale Out

When data volume, processing needs, or other requirements exceed what a single instance can sustain, a Cribl Stream deployment can span multiple Nodes. This is known as a distributed deployment. Here, you can centrally configure and manage Nodes' operation using one administrator instance, called the Leader.

It's important to understand that Worker Processes operate in parallel, i.e., independently of each other. This means that:

1. Data coming in on a single connection will be handled by a single Worker Process. **To get the full benefits of multiple Worker Processes, data should come in over multiple connections.**
   For example, it's better to have five connections to TCP 514, each bringing in 200GB/day, than one at 1 TB/day.

2. Each Worker Process will maintain and manage its own outputs. For example, if an instance with two Worker Processes is configured with a Splunk output, then the Splunk destination will see two inbound connections.
   For further details, see Shared-Nothing Architecture.

Capacity and Performance Considerations

As with most data processing applications, Cribl Stream's expected resource utilization will be proportional to the type of processing that is occurring. For instance, a Function that adds a static field on an event will likely perform faster than one that applies a regex to find and replace a string. Currently:

- A Worker Process will utilize up to 1 physical core (encompassing either 1 or 2 vCPUs, depending on the processor type.
- Processing performance is proportional to CPU clock speed.
- All processing happens in-memory.
- Processing does not require significant disk allocation.

Throughout these guidelines, we assume that **1 physical core** is equivalent to:

- 2 virtual/hyperthreaded CPUs (vCPUs) on Intel/Xeon or AMD processors.
- 1 vCPU on Graviton2/ARM64 processors.

Overall guideline: Allocate 1 physical core for each 400GB/day of IN+OUT throughput.

Examples

Estimating Number of Cores

In estimating core requirements – per processor type, it's important to distinguish among vCPUs versus physical cores.

Intel/Xeon/AMD Processors with Hyperthreading Enabled

To estimate the number of cores needed: Sum your expected input and output volume, then divide by 400GB per day per physical core.

- Example 1: 100GB IN -> 100GB out to each of 3 destinations = 400GB total = 1 physical core (or 2 vCPUs).
- Example 2: 3TB IN -> 1TB out = 4TB total = 10 physical cores (or 20 VCPUs).

- Example 3: 4 TB IN -> full 4TB to Destination A, plus 2 TB to Destination B = 10TB total = 25 physical cores (or 50 vCPUs).

Graviton2/ARM64 Processors

Here, 1 physical core = 1 vCPU, but overall throughput is ~20% higher than a corresponding Intel or AMD vCPU. So, to estimate the number of cores needed: Sum your expected input and output volume, then divide by 480GB per day per vCPU.

- Example 1: 100GB IN -> 100GB OUT to each of 3 destinations = 400GB total = 1 physical core.
- Example 2: 3TB IN -> 1TB OUT = 4TB total = 8 physical cores.
- Example 3: 4 TB IN -> full 4TB OUT to Destination A, plus 2 TB OUT to Destination B = 10TB total = 21 physical cores.

Remember to also account for an additional core per Worker Node for OS/system overhead.

Estimating Number of Nodes

When sizing the number of Stream Worker Nodes, there are two other factors to consider:

- Number of Nodes sized for peak workloads;
- Number of Nodes offline.

This will allow you to create a robust Cribl Stream environment that can handle peak workloads even during rolling restarts and maintenance downtime.

General guidance includes:

- On each Node, Cribl recommends at least 4 ARM vCPUs, or at least 8 x86 vCPUs (i.e., 4 cores with hyperthreading). Below this theshold, the OS overhead from reserved threads claims an excessive percentage of your capacity.
- On each Node, Cribl recommends no more than 48 ARM vCPUs, or 48 x86 vCPUs (i.e., 24 cores with hyperthreading). This allocation handles disk I/O requirements when persistent queueing engages.
- Plan to successfully handle peak workloads even when 20% of your Worker Nodes are down. This allows for OS patching, and for conducting rolling Stream upgrades and restarts.
- For customers in the 5–20 TB range, size for 4-8 Worker Nodes per Worker Group.

Sizing Example for a Deployment

Step 1: Calculate the total inbound + outbound volume for a given deployment.

In this example, your deployment has 6TB/day streaming into Worker Nodes for a given site, and this data is being routed to both cheap mass storage (S3) and to your system of analysis – 10 TB/day going out.

Stream Workers must have enough CPUs to handle a total of 16 TB per day IN+OUT.

Step 2: From the available server configurations, size the correct number of Nodes for your environment.

You are considering an AWS Compute-optimized Graviton EC2 instance, with either 16-vCPU or 8-vCPU options. We'll walk you through how to calculate based on each option.

Using Graviton 16-vCPU instances

- Each Node would have 15 vCPUs available to Cribl Stream, each at 480 GB per day per vCPU.
- 15 vCPUs per Node at 480 GB per day per CPU = 7200 GB/day per Node.
- 7200 GB/day divided by 1024 GB/TB = 7 TB/day.
- To handle the workload of 16 TB/day, you need 3 Nodes. Make sure you always round up.
- 20% of 3 Nodes ≈ 1 Node. Make sure you always round up. To provide for redundancy during patching, maintenance, or restarts, you need one additional server.

With 4x 16-vCPU Nodes, you have 28 TB/day capacity, and can support 21 TB/day with one Node down.

Using Graviton 8-vCPU instances

- Each Node would have 7 vCPUs available to Stream, each at 480 GB per day per vCPU.
- 7 vCPUs per Node at 480 GB per day per CPU = 3360 GB/day per Node.
- 3360 GB/day divided by 1024 GB/TB = 3.3 TB/day.
- To handle the workload of 16 TB/day, you need 5 Nodes. Make sure you always round up.
- 20% of 5 Nodes = 1 Node. To provide for redundancy during patching, maintenance, or restarts, you need one additional server.

With 6x8-vCPU Nodes, you have 19.8 TB/day capacity, and can support 16.5 TB/day with one Node down.

If you are optimizing for price, AWS pricing is linear based on the total number of cores. So six 8-vCPU systems are roughly 75% the cost of four 16-vCPU systems.

If you are optimizing for potential future expansion, the 4x16-vCPU systems would offer ideal additional capacity.

Estimating Memory Requirements

The general guideline for memory allocation is to start with the default 2048 MB (2 GB) per Worker Process, and then add more memory as you find that you're hitting limits.

Memory use is consumed per component, per Worker Process, as follows:

1. Lookups are loaded into memory.
   (Large lookups require extra memory allocation – see Memory Sizing for Large Lookups.)
2. Memory is allocated to in-memory buffers to hold data to be delivered to downstream services.
3. Stateful Functions (Aggregations and Suppress) consume memory proportional to the rate of data throughput.
4. The Aggregations Function's memory consumption further increases with the number of **Group by**'s.
5. The Suppress Function's memory use further increases with the cardinality of events matching the **Key expression**. A higher rate of distinct event values will consume more memory.

Recommended AWS, Azure, and GCP Instance Types

You could meet the requirement above with multiples of the following instances:

AWS – Intel processors, Compute Optimized Instances. For other options, see here.

Minimum	Recommended
c5d.2xlarge (4 physical cores, 8vCPUs) c5.2xlarge (4 physical cores, 8vCPUs)	c5d.4xlarge or higher (8 physical cores, 16vCPUs) c5.4xlarge or higher (8 physical cores, 16vCPUs)

AWS – Graviton2/ARM64 processors, Compute Optimized Instances. For other options, see here.

Minimum	Recommended
c6g.2xlarge (8 physical cores, 8vCPUs) c6gd.2xlarge (8 physical cores, 8vCPUs)	c6g.4xlarge or higher (16 physical cores, 16vCPUs) c6gd.4xlarge or higher (16 physical cores, 16vCPUs)

Azure – Compute Optimized Instances

Minimum	Recommended
Standard_F8s_v2 (4 physical cores, 8vCPUs)	Standard_F16s_v2 or higher (8 physical cores, 16vCPUs)

GCP – Compute Optimized Instances

Minimum	Recommended
c2-standard-8 (4 physical cores, 8vCPUs) n2-standard-8 (4 physical cores, 8vCPUs)	c2-standard-16 or higher (8 physical cores, 16vCPUs) n2-standard-16 or higher (8 physical cores, 16vCPUs)

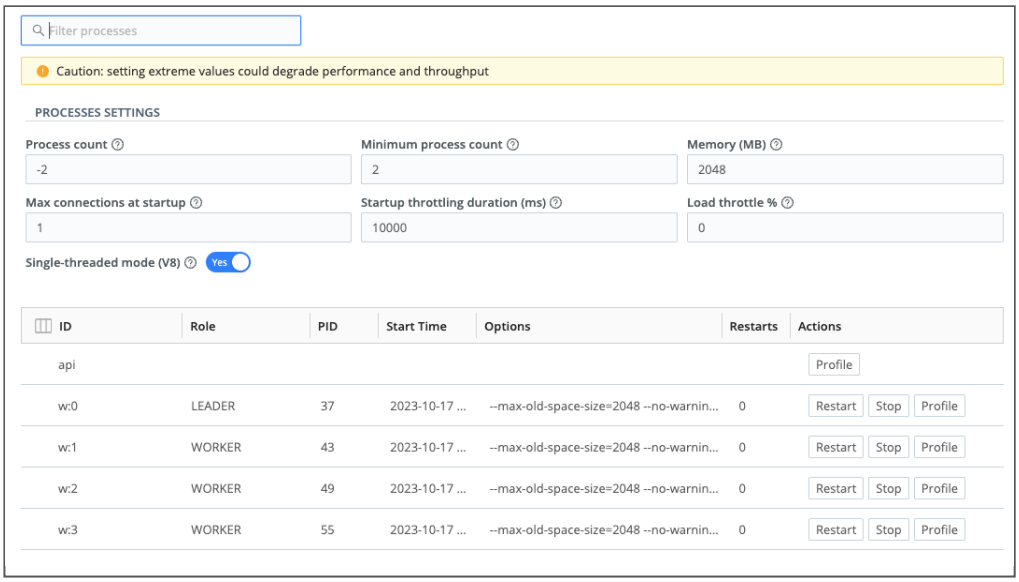
In all cases, reserve at least 5GB disk storage per instance, and more if persistent queuing is enabled.

Measuring CPU or API Load

You can profile CPU and API usage on individual Worker Processes.

Single-Instance Deployment

Go to **Settings** > **System** > **Service Processes** > **Processes**, and select **Profile** on the desired row.

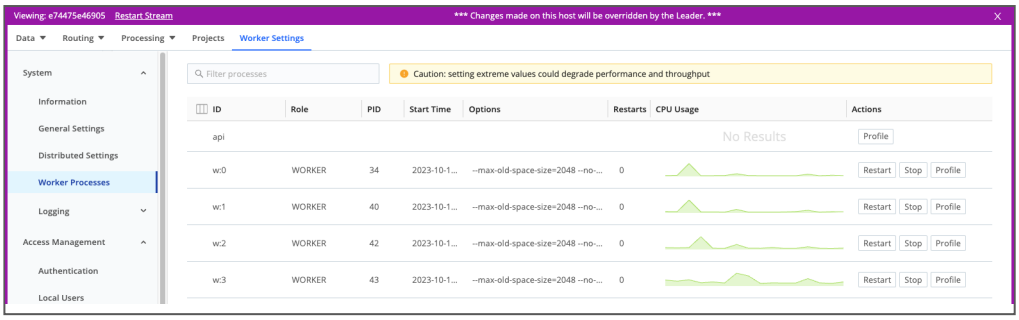


Worker CPU profiling (single-instance)

Distributed Deployment

This requires a few more steps:

1. Enable Worker UI Access if you haven't already.
2. In the sidebar, select **Workers**.
3. Select the **GUID** link of the Worker Node you want to profile.
4. Select **Worker Settings** from that Worker Node's submenu.
5. Select **System** > **Worker Processes**, and then select **Profile** on the desired Worker Process. To profile the API usage, click **Profile** on the **api** row.



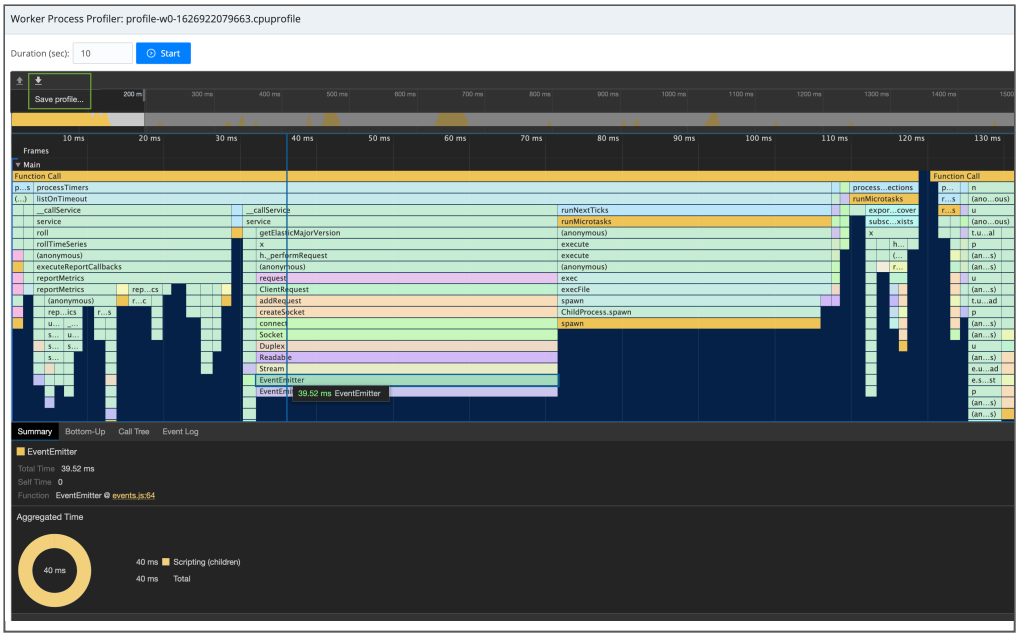
Worker CPU profiling (distributed)

Generating a CPU or API Profile

In either a single-instance or distributed deployment, you will now see a **Worker Process Profiler** modal.

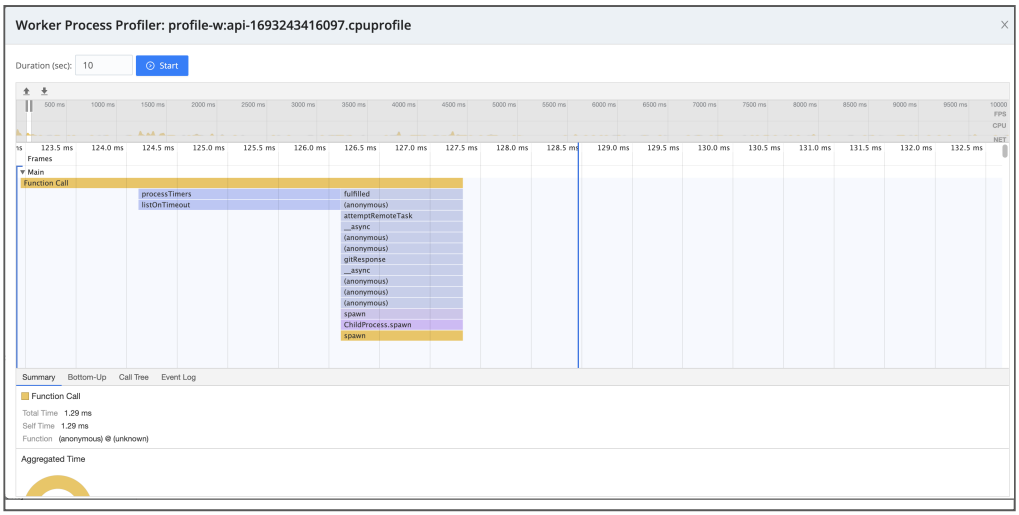
The default **Duration (sec)** of `10` seconds is typically enough to profile continuous issues, but you might need to adjust this – up to several minutes – to profile intermittent issues. (Longer durations can dramatically increase the lag before Cribl Stream formats and displays the profile data.)

Click **Start** to begin profiling. After the duration you've chosen (watch the progress bar), plus a lag to generate the display, you'll see a profile something like this:



Worker CPU profile

Profiling the API process can be a helpful troubleshooting tool if the Leader is slow.



API profile

Below the graph, tabs enable you to select among **Summary**, **Bottom-Up**, **Call Tree**, and **Event Log** table views.

To save the profile to a JSON file, click the **Save profile** ( ) button we've highlighted at the modal's upper left.

Whether you've saved or not, when you close the modal, you'll be prompted to confirm discarding the in-memory profile data.

See also: Diagnosing Issues > Including CPU Profiles.

3.1.3. Architectural Considerations

This guide introduces Cribl Stream reference architectures by outlining some considerations to keep in mind when architecting your deployment. It covers different potential architectures, with each approach's advantages, limitations, and alternatives.

Architecting a deployment is always about finding the balance between cost versus risk. Once you're familiar with the contents of this guide, you'll be able to consciously make decisions about where your deployment should sit on that spectrum.

See our reference architectures for different use cases. You can replay several Webinar presentations of this material on Cribl's YouTube channel.

"It Depends"

This guide is not intended to replace Sizing and Scaling, but rather to complement it by outlining the consequences of various architectural decisions. (As needed, please either read Sizing and Scaling first, or refer to it to look up concepts.)

General Sizing Considerations

Some basic sizing variables are your processors, expected data throughput, and requirements for memory, disk space, connections volume, and the Stream Leader's own needs.

Processors

Your primary consideration in sizing processors is your data throughput capacity, which depends on the number of Worker Processes.

Overall guideline: Allocate 1 physical core for each 400GB/day of IN+OUT throughput.

This can vary based on processor speeds or types. (For example, Graviton ARM processors' throughput is 20% higher than x86-64 processors' reference 400GB/day.) But in this guide's calculations, we'll assume 400GB/day IN+OUT per processor, and dig into what that really means. Please adjust your own calculations as needed.

Throughput

Where we reference total throughput capacity below: Because Cribl Stream can send events to multiple Destinations and filter out unneeded events, IN won't always be the same as OUT. For example, 400GB IN+OUT could mean 200GB IN + 200GB OUT, but it could also mean 300GB IN + 100GB OUT, or any combination of IN+OUT that adds up to 400GB/day.

Memory

Memory requirements also play into architecture considerations. Depending on what type of processing you'll be doing, those requirements might vary. You might know your memory requirements in advance. Or you might monitor memory usage and increase it as your processing complexity increases. The default of 2GB per Worker Process is a good starting point.

Disk Space

The base recommendation, 5GB of free disk space, applies to the volume where Cribl Stream is installed. Beyond that, if you choose to use Persistent Queues, you will need to calculate additional disk space – based on the velocity of your data, and your desired duration before reaching a full queue. Normally, you must define the maximum disk space a queue can use, per Worker Process, for each Source or Destination. However, if you use a separate volume for Persistent Queues, you can remove those limits, and allow the queues to take up the whole volume if needed.

Object-store Destinations use a staging directory to write out files before sending them out. If you're using one of these Destinations, please review our Amazon S3 Better Practices for sizing and architecture considerations.

In both cases, using fast disks is important, to prevent the disks from becoming bottlenecks.

Number of Connections

Beyond throughput and pipeline complexity, some resources get used for setting up and breaking down TCP connections. In the field, Cribl often sees one CPU core support 400 connections (or 200 for vCPUs), but that depends on EPS (events per second) and other demands on the system resources.

If your calculations show more than 250 connections per CPU core, you should look closer at EPS and processing complexity. In our testing, once you hit the higher end of the EPS spectrum, 150 connections per core at 100 EPS still leave almost 25% capacity in reserve for spikes.

When it comes to outgoing connections, you should also consider memory utilization if you have a lot of TCP receivers. This is because each Worker Process makes a separate connection and consumes 2-4MB of RAM. Some Destinations let you adjust the maximum number of connections.

Leader Node

All the above discussion concerns Worker Nodes, because they are the ones responsible for processing the data. The Leader Node's requirements should not need to expand beyond these initial recommendations, unless the Leader needs to manage Edge Fleets, in which case reference Cribl's Edge docs.

Finding the Balance Between Risk and Cost

Beyond your basic requirements, you should of course plan contingency capacity to support resource demands that exceed ideal circumstances.

Plan for Failure

Given the wrong circumstances, failure will happen. Your job, when architecting a deployment, is to examine the various failure scenarios and decide what level of resources you are willing to allocate to prevent failure. This is analogous to deciding how many nines of reliability you're willing to pay for.

Throughput Variability

The 400GB/day IN+OUT guidance mentioned above assumes that your data flow is relatively flat. This means you're expecting that every second, each Worker Process is handling about ~4.74MB of data IN+OUT. However, in reality, the load varies based on time of day or other system activities.

For example, you might experience higher load during business hours. Or you might have an hourly upstream process that causes spikes of activity. Also, depending on the nature of your organization, you might have certain days, or planned events, when you expect users' increased load on your systems. Then there are unplanned events, such as outages or DDoS attacks, that might lead to decreased capacity or increased demands.

Another factor to consider, if you're using Persistent Queues, is that flushing those queues will increase the total throughput demand – including on the downstream systems that need to be able to handle the burst. Unfortunately, there are too many variables to have a generic recommendation here, but a starting point of ~10% headroom is a good idea. As we discuss in the conclusion, you'll need to test these assumptions.

Now that we're digging deeper into throughput, you should start thinking about where to set a threshold, beyond which you know your system is likely to fail. If you have data flowing into a system of analysis that can let you look at your current ingestion rate, this can be a good start.

You want to look at the busiest times, and drill down far enough to see what your historical maximum per-second throughput has been. Past performance is not guarantee of future results, but it will at least give you an idea of what to expect.

If you have new Sources, or if you don't have a good way of estimating current throughput, you'll have to make some assumptions about future behavior. In the end, take whatever you come up with for expected MB/sec

throughput, add whatever safety margin you feel is appropriate, and multiply back out by 84 (24*60*60/1024) to get GB/day throughput.

Exceeding Capacity

As you are deciding how much safety margin to plan into your environment, it also helps to think through what happens when you exceed capacity. Depending on the types of Sources you have, an overloaded deployment might have different failure modes. This ranges from the possibility of immediate data loss in the case of UDP, to simple delays in the case of Pull Sources. Some Push Sources, such as Cribl Edge or Splunk Universal Forwarders, have the capacity to pause or buffer the data flow for some duration.

Single-Instance Deployment

The simplest type of deployment is single-instance. Let's look at the case of a 4 core (8 vCPUs), 16GB RAM, single-instance deployment:

Resource	Total	Used by WPs	Used by system/API
Cores (vCPUs)	4 (8)	3 (6)	1 (2)
RAM	16GB	12GB	4GB

With the default assumption of 400GB/day IN+OUT, and sending to a single Destination, the above configuration can process an average of 1200GB/day.

Let's make a few more assumptions:

- Peak usage during the day is 2x average.
- Persistent Queues for 4 hours of data.
- We want to withstand a 2x burst over typical usage from the Source.
- Our Source is syslog UDP*, so going over capacity means lost data.

(* We're assuming that the load is distributed evenly among all Worker Processes. Further down, we'll talk about why we're making that assumption, and the dangers of "pinning" Worker Processes.)

We're working backwards for this one, but it's a good exercise. Taking the 1200GB/day capacity, dividing it by 2 for peak load, and then dividing by 2 again for burst tolerance, we come up with 300GB/day adjusted capacity. So with this deployment, we can safely say we can handle a 300GB/day stream of syslog UDP data.

Because we want the ability to keep 4 hours of data in a Persistent Queue, we want to use the peak-load number for that. Our upfront assumption is that peak load is 2x normal load, which is 600GB/day, or

25GB/hour. 100GB of disk space should be sufficient, unless we expect the 2x bursts to last a significant duration. If we want to withstand a 1-hour burst during peak times, 125GB of disk space would be needed.

Where Single-Instance Fails

The obvious practical limitation here is that all data is flowing through a single system. This means that if you bring your single-instance deployment down for patching, or experience an unexpected outage, you'll be losing data. This might be acceptable for test purposes, but in production, there are very few scenarios in which you **won't** lose data with a single-instance deployment:

- All your Sources are Pull Sources.
- Your Push Sources can pause the data flow when Stream Workers are not available.

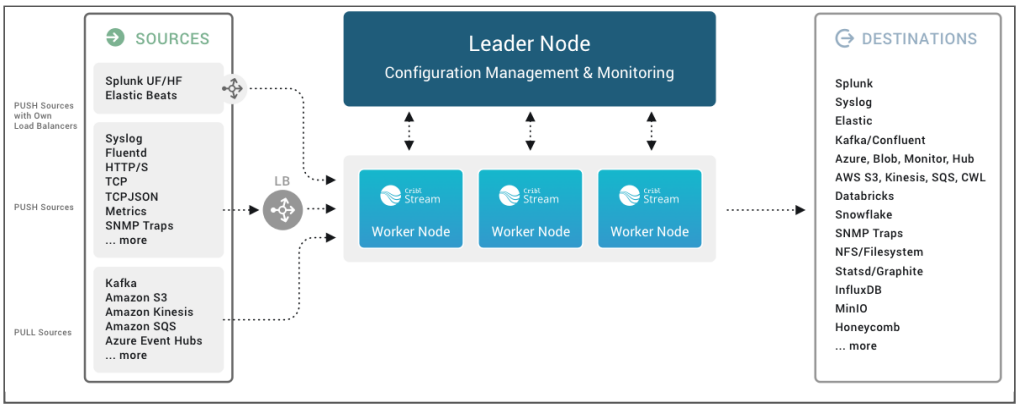
A distributed deployment, with multiple Worker Nodes, is a more robust solution that doesn't have these limitations. So next, let's look at a simple distributed example.

Distributed Deployment

The simplest distributed deployment involves a Leader Node and one or more Worker Nodes. A single Worker Node suffers from the same limitations as the single-instance deployment, so in this section we'll look at scenarios with multiple Worker Nodes.

You might be sizing a Worker Group when working with either a Cribl.Cloud Leader or an on-prem Leader. For an on-prem Leader, use our recommended system requirements.

The main thing to consider with multiple Workers is that you'll need a load balancer for all Push Sources that don't natively support balancing across multiple Worker Nodes. You can see this added load balancer called out (as **LB**) in our Distributed Deployment Architecture diagram:



Distributed deployment architecture

How Many Worker Nodes?

The next consideration is, how many Worker Nodes do you need? Having multiple Worker Nodes allows you to continue processing data while one Node is down for maintenance – so your sizing is determined by the remaining Worker Nodes. Here, you have a matrix of adjusting scaling vertically vs. horizontally, so let's look at the math:

Effectively, 2 Worker Nodes means you lose 50% capacity when one is down. With 3 Nodes, you lose 33%. With 6 Nodes, you lose 17%. You will lose 2 vCPUs in overhead on each Node, but at larger scales, the benefits outweigh the costs.

Let's look at an example using the naive 400GB/day per core capacity (i.e., 200GB/day per vCPU or Worker Process). We'll pick approximately comparable desired throughput of 5.6-6TB/day, and see how the math works out.

2 Worker Nodes

32 vCPUs x2 Nodes = 64 vCPUs (- 2 vCPUs/Node for overhead) = 60 WPs

1 Node downs during patching: 30 WPs*0.2=6 TB capacity

6 TB/64 vCPUs = 0.09 TB/vCPU

3 Worker Nodes

16 vCPUs x3 Nodes = 48 vCPUs (-2 vCPUs/Node for overhead) = 42 WPs

1 Node downs during patching: 28 WPs*0.2=5.6 TB capacity

5.6 TB/48 vCPUs = 0.12 TB/vCPU

6 Worker Nodes

8 vCPUs x6 = 48 vCPUs (-2 vCPUs/Node for overhead) = 36 WPs

1 Node downs during patching: 30 WPs*0.2 TB/WP = 6 TB capacity

6TB/40 vCPUs = 0.15 TB/vCPU

As we can see, once your required throughput is high enough to make the 2 vCPU/Node tax negligible, a larger number of Worker Nodes is advantageous. You can do the math for your specific use case – remembering to adjust for expected peak usage and desired spike tolerance.

That said, having **3 Worker Nodes is usually the recommended minimum**, since this provides resilience against unplanned outages even when one Worker is down for planned maintenance.

Where a Single Worker Group Can Fail

Even provisioning an "adequate" number of Worker Nodes, in a single Worker Group, might not be fully resilient if you encounter connection pinning, data bursts, or other unexpected resource demands.

Pinning

In Single-Instance Deployment above, we included the caveat of "assuming that the load is distributed evenly among all Worker Processes." In reality, you need to validate this assumption. In some situations, you'll need to take additional measures to assure that it's true, or work around cases when it is not.

Pinning is a situation where a single TCP or UDP Source is sending a large amount of data over a single connection, causing that connection to be "pinned" to a single Worker Process. If the throughput is high enough, and the load balancer is unable to break up that connection, the affected Worker Processes might be overloaded and unable to keep up.

In a Distributed Deployment, to mitigate pinning, the Syslog Source provides a TCP Load Balancing option, as do the TCP JSON and Cribl TCP Sources.

On TCP Sources and deployments where these options are unavailable, you can minimize pinning by having the sender establish separate connections. If that's not possible, try isolating a Worker Group that receives this input from all other processing responsibilities – this will maximize the throughput that this Group can handle.

Burst Loads Affecting Push Sources

Most of the time, your Push Sources will generate a reasonably predictable, consistent load. Using the sizing considerations outlined above, you should be able to come up with a Worker Group sized appropriately for your desired risk-versus-cost balance.

However, this balance can be upset when you have a surge of data that makes your system temporarily busier than you accounted for. The greatest impact would be felt by Push Sources that have no way to handle backpressure, such as UDP Sources.

A prime example of data burst is an ad-hoc run of a large Collection job. With multiple Worker Groups, you can separate Push versus Pull Sources, and can even use an Auto Scaling group group for large Collection jobs if desired.

Unexpected Resource Hogs

Our throughput estimates are based on certain assumptions about the average level of complexity of operations performed on the data. As you're creating your Pipelines, at some point you might decide that you require additional resources to meet your data-processing needs. Certain combinations of Function, logic, and throughput will consume extra resources.

When expanded resource demands happen in a predictable, controlled manner, all is well. However, we've seen cases where an inefficient regular expression, or a memory-hungry custom Collection script, will cause a whole Worker Group to get overloaded. This leads to crashes, or to performance poor enough to cause data loss. Pipeline profiling helps with some of this. But using separate Worker Groups is an option to provide additional isolation.

Multiple Worker Groups

At the beginning of Distributed Deployment, we considered the limitations of a single Worker Group, and examined some strictly sizing-related reasons for multiple Worker Groups. Here, let's consider some other reasons you might decide to take advantage of multiple Worker Groups.

In some cases, it makes sense to create separate Worker Groups, each close to their data. In other cases, multiple Groups might be necessary for your architecture based on other needs. Here are a few examples, which might not be directly applicable to your scenario, but which should help you realize when multiple Groups might benefit your deployment:

- Keeping Workers close to their data to optimize syslog over UDP.
- Controlling egress costs, by reducing and compressing data before it leaves your cloud provider's region.
- Separating Push Sources versus Pull/Collector Sources.
- Geographical restrictions on data location, such as GDPR.
- Reducing or increasing the number of Workers connecting with a Source or a Destination.
- Centralize certain processing that is dependent on external systems, such as Redis lookups.
- Reducing the frequency of Stream config deployments, in cases where a deployment might disrupt data flow – such as triggering rebalancing among Kafka-based Sources.

Conclusion

As you can see by now, our "it depends" subtitle applies. But we hope that reading this guide has familiarized you with key aspects of what "it" depends on. There is no single "best practice" for sizing, because your own best architecture will depend on considering all options, including your risk-versus-cost balance, to define your own solution.

Equipped with the contents of this guide, you should be able to make better decisions about the potential risks and mitigations appropriate for your environment. After initial deployment, you can monitor utilization trends in the different resources we covered. As your needs evolve, so can your architecture. You'll make assumptions, and when the potential for failure is beyond your tolerance, you can adjust accordingly.

Some final considerations: Is it worth stress-testing your environment, or a downscaled version of it? What's the likelihood of everything going wrong at the same time – your throughput volume spiking to the highest

acceptable level, while your Destinations are unavailable and your Persistent Queues are filling up? It depends.

To firm up your own architecture, consult Cribl support, Community Slack, or the Cribl Solutions Engineering or Professional Services experts dedicated to your deployment.

3.1.4. Ports

Cribl Stream requires certain ports to be open, and additional ports are needed if you intend to use specific integrations or options to work.

Leader

In a Distributed deployment, the following ports must be open on the Leader Node. Ensure that the Leader is reachable on those ports from **all** Workers.

Default Port	Protocol	Purpose	Direction
`9000`	HTTP/S	Cribl Stream UI.	In
`9000`	HTTP/S	Bootstrapping Worker Nodes from Leader (on-premises).	In
`443`	HTTP/S	Bootstrapping Worker Nodes from Leader (Cribl.Cloud).	In
`4200`	TCP	Heartbeat/Metrics/Leader requests/notifications to clients (for example: live captures, teleporting, status updates, config bundle notifications, and so on).	In
`4200`	HTTP/S	Software upgrade (via path, not CDN).	In

If you want to use proxy for communication between Leader and Worker Nodes, use SOCKS proxy instead of HTTP/S. You need to use SOCKS proxy, because HTTP/S proxies typically don't support raw TCP sockets that Leader-Worker communication uses.

Workers

The following ports are used by Worker Nodes.

Default Port	Protocol	Purpose	Direction
`9000`	TCP	Cribl Stream UI.	In
`4200`	HTTP/S	Config bundle downloads.	Out

Default Port	Protocol	Purpose	Direction
`4200`	TCP	Heartbeat/Metrics/Leader requests/notifications to clients (for example: live captures, teleporting, status updates, config bundle notifications, and so on).	Out
`443`	TCP	(In Cribl.Cloud hybrid deployments) Communication with the Leader and with `https://cdn.cribl.io`.	Out

Other Ports

This section lists port allocations for specific transport protocols and other special purposes.

Common Ports

Default Port	Protocol	Purpose	Direction
53	UDP	DNS lookups.	Out
389	TCP	LDAP Auth (non-TLS).	Out
443	TCP	OIDC Auth (TLS).	Out
636	TCP	LDAP Auth (TLS).	Out

Integrations and Apps

Integrations with specific services via Sources and Destinations or apps may require opening dedicated ports on Worker Nodes.

The defaults are listed below, but when configuring each Source or Destination you can choose another port.

Default Port	Protocol	Purpose	Direction
162	UDP	SNMP Trap collection (non-TLS). The preconfigured SNMP Trap Source listens on port `9162`.	In
162	UDP	SNMP Trap Destination (non-TLS).	Out
443	HTTP/S	Collection from and output to multiple HTTPS-based Sources and Destinations.	In/Out

Default Port	Protocol	Purpose	Direction
4317	TCP	Collection from OpenTelemetry.	In
5986	HTTP/S	Windows Event Forwarder Source.	In
8081	TCP	Kafka Schema Registry.	Out
8088	TCP	Splunk HEC input and output.	In/Out
8089	TCP	Splunk Search.	In
8125	TCP/UDP	Output to StatsD, StatsD Extended, and Graphite (non-TLS).	Out
9090	TCP	Collection/discovery from Prometheus Scraper.	Out
9092	TCP	Collection from Confluent Cloud or Kafka, used when no port is provided.	Out
9092	TCP	Output to Confluent Cloud or Kafka, used when no port is provided.	Out
9093	TCP	Output to Azure Event Hubs.	Out
9997	TCP	Splunk TCP Source.	Out
10000		Splunk to Cribl Stream data port (Cribl App for Splunk).	In/Out
10070	TCP	TCP JSON data.	In
10080	TCP	Collection from HTTP JSON Sources.	In
10200	HTTP/S	Cribl HTTP Destination.	In
10300	TCP	Cribl TCP Destination.	In
10420		| `criblstream` Splunk search command to Cribl Stream (Cribl App for Splunk).	In/Out

Cribl.Cloud Ports

Cribl.Cloud provides a set of ports linked to Sources enabled by default for your Workspace. To view them:

1. From your Cribl.Cloud Organization's top bar, select **Products**.
2. Then from the sidebar, select **Cribl** > **Workspace**, and then **Data Sources**.

Additionally, Cribl.Cloud makes the `20000 – 20010` port range available for configuring other Sources.

Available Ports	Protocol	Purpose	Direction
`20000 – 20010`	TCP	Additional Sources in Cribl.Cloud.	In

No other ports can be opened for Cribl-managed Worker Groups in Cribl.Cloud.

Overriding Default Ports

You can override the Cribl Stream UI port (`9000`), as well as other settings, in the `$CRIBL_HOME/local/cribl/cribl.yml` configuration file.

The defaults are stored in `$CRIBL_HOME/default/cribl/cribl.yml`.

3.2. On-Prem Deployment

3.2.1. Deployment Types

Deployment guide to get you started with self-hosted Cribl Stream

---

There are at least **two** key factors that will determine the type of Cribl Stream deployment in your environment:

- Amount of Incoming Data: This is defined as the amount of data planned to be ingested per unit of time. E.g. How many MB/s or GB/day?
- Amount of Data Processing: This is defined as the amount of processing that will happen on incoming data. E.g., is most data passing through and just being routed? Or are there a lot of transformations, regex extractions, field encryptions? Is there a need for heavy re-serialization?

Single-Instance Deployment

When volume is low and/or amount of processing is light, you can get started with a single instance deployment.

Distributed Deployment

To accommodate increased load, we recommend scaling up and perhaps out with multiple instances.

Splunk App Deployment

If you have an existing Splunk Heavy Forwarder infrastructure that you want to use, you can deploy Cribl App for Splunk. See the note below before you plan.

Cribl App for Splunk Deprecation Notice

Please see details here.

Kubernetes/Helm Deployment

You can deploy Cribl Stream Leader Nodes (or single instances) and Worker Nodes via Cribl's Helm charts.

Docker Deployment

You can deploy Cribl Stream instances using images from Cribl's public Docker Hub.

3.2.2. OS And System Requirements

For a successful Cribl Stream deployment, verify that your system meets the minimum hardware and software specifications outlined below.

Leader Node Requirements

Given the Leader's critical role in coordinating Worker instances, we recommend deploying it on a stable and highly available infrastructure.

All the quantities listed below are **minimum** requirements.

Specification	Requirements
OS	• Linux kernel >= 3.10 and glibc >= 2.17, OpenSSL >= 3.0. • Example distributions: Ubuntu 16.04, Debian 9, RHEL 8, CentOS Linux 8, CentOS Stream 9, SUSE Linux Enterprise Server 12, Amazon Linux 2. • Tested so far on Ubuntu (14.04, 16.04, 18.04, and 20.04), CentOS Stream 9, and Amazon Linux 2. • As of October 16, 2024, Cribl has deprecated support for the CentOS Linux 7 distro, which reached its end of life on June 30, 2024.
System	• 1 GHz (or faster), 64-bit CPU. • 4+ physical cores*, 8 GB+ RAM – all beyond your basic OS/VM requirements. • 5 GB free disk space. * We assume that 1 physical core is equivalent to 2 virtual/hyperthreaded CPUs (vCPUs).
Git	`git` must be available on the Leader Node. See details below.
Browser Support	The five most-recent versions of Chrome, Firefox, Safari, and Microsoft Edge.

Worker Node and Single-Instance Requirements

This section outlines the requirements for deploying Worker Nodes and Single-instance deployments. For a deeper understanding of these concepts, see Worker Nodes and Single-instance deployments.

Requirements

The Worker Node requirements are identical to Single-instance deployments. All quantities listed below are minimum requirements.

Specification	Requirements
OS	• Linux kernel >= 3.10 and glibc >= 2.17, OpenSSL >= 3.0. • Example distributions: Ubuntu 16.04, Debian 9, RHEL 8, CentOS Linux 8, CentOS Stream 9, SUSE Linux Enterprise Server 12, Amazon Linux 2. • Tested so far on Ubuntu (14.04, 16.04, 18.04, and 20.04), CentOS Stream 9, and Amazon Linux 2. • As of October 16, 2024, Cribl has deprecated support for the CentOS Linux 7 distro, which reached its end of life on June 30, 2024.
System	• 1 GHz (or faster), 64-bit CPU. • 4+ physical cores*, 8 GB+ RAM – all beyond your basic OS/VM requirements. • 5 GB free disk space. * We assume that 1 physical core is equivalent to 2 virtual/hyperthreaded CPUs (vCPUs).
Git	`git` must be available on the Leader Node. See details below.
SELinux Support	`enforcing` mode is supported, but not required.

Requirements Considerations

Keep the following considerations in mind:

Cloud VM Recommendations

To fulfill the requirements using cloud-based virtual machines, see Recommended AWS, Azure, and GCP Instance Types.

Core Equivalency

We consider 1 physical core to be equivalent to:

- 2 virtual/hyperthreaded CPUs (vCPUs) on Intel/Xeon or AMD processors
- 1 (higher-throughput) vCPU on Graviton2/ARM64 processors

Memory Requirements

- Each Worker Process can consume memory up to its maximum heap size, plus Node.js overhead, and additional memory that scales with configuration (e.g., Destination type and number).
- Ensure your total host memory allocation covers the memory usage of all Worker Processes and OS requirements.
- Continuously monitor Node memory usage, especially after configuration changes.
- For additional details, see Estimating Number of Cores.

Capacity Planning

See Sizing and Scaling for capacity planning details.

Set Capabilities for Cribl Stream

If Cribl Stream needs to listen on low ports 1–1024, it will need privileged access. You can set Linux capabilities that grant Cribl Stream sufficient rights to perform specific privileged tasks, based on kernel privilege. To run Cribl Stream as non-root user, consider setting the following capabilities:

Set Linux Capabilities	Permissions
`CAP_NET_BIND_SERVICE`	Allows Cribl Stream to push Sources that bind to TCP/UDP port numbers below `1024`.
`CAP_DAC_READ_SEARCH`	Allows the `cribl` user to access the File Monitor Source's Manual mode feature. This capability bypasses the default Linux permissions for files and directories.
`CAP_SYS_PTRACE`	Allows the `cribl` user to scan open files for running processes, and to access the File Monitor Source's Auto-mode feature.

For details about setting these capabilities, see Persisting Overrides.

Set the `CRIBL_HOME` Environment Variable

The `CRIBL_HOME` env is available in the Cribl Stream application, but not on your terminal. If you want to use `$CRIBL_HOME`, you can:

- Assign it once, using the `export` command: `export CRIBL_HOME=/opt/cribl`
- Set it as a default, by adding it to your to your terminal profile file.

Version Control with `git`

Cribl Stream requires `git` (version 1.8.3.1 or higher) to be available locally on the host where the Leader Node will run. **Configuration changes must be committed to git before they're deployed.**

If you don't have `git` installed, see Git Documentation for details on how to get started.

The Leader Node uses `git` to:

- Manage configuration versions across Worker Groups.
- Provide users with an audit trail of all configuration changes.
- Allow users to display diffs between current and previous config versions.

Port Requirements

- Configure firewalls on Leader and Worker hosts to allow outbound HTTPS connections to `https://cdn.cribl.io` on port 443 during installation.
- Refer to the list of required ports for Distributed deployments to function, and verify that they are continously open.
- If your network requires a proxy, configure your system proxy settings as described in System Proxy Configuration. Be sure to exclude cluster communication from the proxy to avoid performance issues.
- Cribl prioritizes S3 downloads for Worker Nodes, with automatic fallback and firewall allowlisting tips for optimal performance. See, Optimized Bundle Delivery from S3 for details.

FIPS Mode Requirements

Federal Information Processing Standards (FIPS) is a set of US government standards and guidelines for information security. You can deploy Cribl Stream in **FIPS mode**. This mainly restricts the cryptographic algorithms used within Cribl Stream, and also enforces stricter password requirements.

To learn about system and password requirements, as well as instructions for running Cribl Stream in FIPS mode, refer to the FIPS Mode document.

3.2.3. Single-Instance/Basic Deployment

Getting started with Cribl Stream on a single instance

For small-volume or light processing environments – or for test or evaluation use cases – a single instance of Cribl Stream might be sufficient to serve all inputs, event processing, and outputs. This page outlines how to implement a single-instance deployment.

Architecture

Install on Linux

For system requirements, see Worker Node and Single-Instance Deployment Requirements. To launch Cribl Stream in compliance with secure Federal Information Processing Standards (FIPS), see FIPS Mode.

- Install the package on your instance of choice. Download it here.
- Ensure that required ports are available (see Network Ports).
- Un-tar in a directory of choice, e.g., in the `/opt/` directory: `tar xvzf cribl-<version>-<build>-<arch>.tgz`

Install Cribl Stream and Cribl Edge on the Same Host

You can run an Edge Node with a Leader that is managing Cribl Stream, or an Edge Node and a Worker Node on the same host. For details, see Installing Cribl Edge and Cribl Stream on the Same Host.

Next, refer to the Run Cribl Stream topic for details on managing Cribl Stream.

3.2.4. Run Cribl Stream

Run Cribl Stream: Start, Stop, and Reload the Service

Cribl Stream Commands

To run Cribl Stream in FIPS mode, **do not** use the commands below right away; instead, first consult the FIPS Mode topic.

Go to the `$CRIBL_HOME/bin` directory, where the package was extracted (for example: `/opt/cribl/bin`). Here, you can use `./cribl` to:

- **Start**: `./cribl start`
- **Stop**: `./cribl stop`
- **Reload**: `./cribl reload`
- **Restart**: `./cribl restart`
- **Get status**: `./cribl status`
- **Switch a distributed deployment to single-instance mode**: `./cribl mode-single` (uses the default address:port `0.0.0.0:9000`)

Executing the `restart` or `stop` command cancels any currently running collection jobs. For other available commands, see CLI Reference.

Next, go to `http://<hostname>:9000` and log in with default credentials (`admin:admin`). You can now start configuring Cribl Stream with Sources and Destinations, or start creating Routes and Pipelines.

In the case of an API port conflict, the process will retry binding for 10 minutes before exiting.

Shutdown and Restart Sequence

Different types of configuration changes produce different behaviors in the Worker, as illustrated in the table below.

Configuration change example	How Cribl Streamresponds
Change from one Route to another	Reloads the contents of memory
Add a new Source or Destination	Restarts the Worker Process
Make a change in system settings that requires restarting the API Process	Restarts the API Process and Worker processes

The Leader initiates the configuration change by sending requests to each Worker to trigger deployment. If the change is in the third category from the table above, it will restart the Worker.

Beginning in Cribl Stream v.4.7, when a Worker receives an explicit shutdown command, it follows this sequence:

1. The API Process begins waiting for the Worker Processes to exit.
2. Each Worker Process shuts down its input Sources.
3. Each time one of its input streams ends, a given Worker Process receives a signal event from the Cribl Sream event processor directing it to flush out any stateful Pipeline Functions (such as Aggregations, Sampling, Dynamic Sampling, and Suppress).
4. The Worker Process waits to allow data to "drain" – that is, to finish flowing through the streams processing engine. This waiting period, called the **Drain timeout**, defaults to 10 seconds; see Shutdown settings. When it ends, any data not flushed out – for example, because of an error on downstream receivers – will be lost. If this happens, the `shutdown.lost_events` metric reports the number of events lost.
5. When all the Worker Processes have finished flushing and exited, the API Process reports metrics to the Leader.
6. The API Process exits, and the Worker has now shut down.

When the Leader sends a signal that causes Workers to restart, they all restart at the same time. This can result in a time interval during which no Workers are available to accept connections from upstream senders. If you encounter this problem, you can try configuring a shorter drain timeout, enabling Workers to finish restarting more quickly. This workaround, however, increases the risk of losing outbound data by allowing Worker Processes less time to flush it.

Shutdown/Restart with PQ

Enabling Persistent Queues on Destinations that support it brings both an advantage and a risk:

- The advantage is that enabling PQ generally helps ensure data delivery to your downstream systems.
- The risk is that you might see duplicate events when a Worker Process restarts.

This can happen because PQ only marks events as safe to discard once they have been handed off to the host OS to send out. So, if the Worker Process exits **before** all events have flushed, the final handful of events will not have been marked as committed and removed. Upon restart, Cribl Stream will still see them, and will resend them.

Enabling Start on Boot

Cribl Stream ships with a CLI utility that can update your system's configuration to start Cribl Stream at system boot time. The basic format to invoke this utility is:

```
[sudo] $CRIBL_HOME/bin/cribl boot-start [enable|disable] [options] [args]
```

You will need to run this command as root, or with `sudo`. For options and arguments, see the CLI Reference.

Most Linux distributions now use `systemd` to start processes at boot, while older distributions might still use `initd`. If you are not sure which service should be configured at startup, check with your Linux administrator. Then follow the corresponding procedure below.

Using systemd

To **enable** Cribl Stream to start at boot time with **systemd**, you need to run the `boot-start` command. Make sure you first create any user you want to specify to run Cribl Stream. For example, to run Cribl Stream on boot as existing user `cribl`, you'd use:

```
sudo $CRIBL_HOME/bin/cribl boot-start enable -m systemd -u cribl
```

This will install a unit file (as shown below) named `cribl.service`, and will start Cribl Stream at boot time as user `cribl`. A `-configDir` option can be used to specify where to install the unit file. If not specified, this location defaults to `/etc/systemd/system/`.

If necessary, change ownership for the Cribl Stream installation:

```
[sudo] chown -R cribl $CRIBL_HOME
```

Next, use the `enable` command to ensure that the service starts on system boot:

```
[sudo] systemctl enable cribl
```

To **disable** starting at boot time, run the following command:

```
sudo $CRIBL_HOME/bin/cribl boot-start disable
```

Other available `systemctl` commands are:

```
systemctl [start|stop|restart|status] cribl
```

Note the file's default `65536` hard limit on maximum open file descriptors (known as a `ulimit`). The minimum recommended value is `65536`. Linux tracks this per user account. You can view the current soft `ulimit` for max open file descriptors with `$ ulimit -n` while logged in as the same user running the `cribl` binary.

Installed systemd File

```
[Unit]
Description=Systemd service file for Cribl Stream.
After=network.target

[Service]
Type=forking
User=cribl
Restart=always
RestartSec=5
LimitNOFILE=65536
PIDFile=/install/path/to/cribl/pid/cribl.pid
ExecStart=/install/path/to/cribl/bin/cribl start
ExecStop=/install/path/to/cribl/bin/cribl stop
ExecReload=/install/path/to/cribl/bin/cribl reload
TimeoutSec=60

[Install]
WantedBy=multi-user.target
```

Persisting Overrides on systemd

By default, disabling and re-enabling boot start will regenerate the `cribl.service` file. To persist any overrides – such as proxy or privileged port usage – use this command:

```
systemctl edit cribl
```

This opens a text editor that prompts you to enter overrides, then saves them to a persistent file at:

```
/etc/systemd/system/cribl.service.d/override.conf
```

Do NOT Run Cribl Stream as Root!

If Cribl Stream needs to listen on low ports 1–1024, it will need privileged access. You can enable this on systemd by adding this configuration key to your `override.conf` file:

```
[Service]
AmbientCapabilities=CAP_NET_BIND_SERVICE
```

If you want to add extra capabilities, such as reading certain resources (such as, `/var/log/*`), add `CAP_DAC_READ_SEARCH` and `CAP_SYS_PTRACE` in a space-separated format as follows:

```
[Service]
AmbientCapabilities=CAP_NET_BIND_SERVICE CAP_DAC_READ_SEARCH CAP_SYS_PTRACE
```

Using initd

To **enable** Cribl Stream to start at boot time with **initd**, you need to run the `boot-start` command. If the user that you want to run Cribl Streams does not exist, create it prior to executing. For example, running Cribl Stream as user `cribl` on boot:

```
sudo $CRIBL_HOME/bin/cribl boot-start enable -m initd -u cribl
```

This will install an `init.d` script in `/etc/init.d/cribl.init.d`, and will start Cribl Stream at boot time as user `cribl`. A `-configDir` option can be used to specify where to install the script. If not specified, this location defaults to `/etc/init.d`.

If necessary, change ownership for the Cribl Stream installation:

```
[sudo] chown -R cribl $CRIBL_HOME
```

To **disable** starting at boot time, run the following command:

```
sudo $CRIBL_HOME/bin/cribl boot-start disable
```

To control Cribl Stream, you can use the following initd commands:

```
service cribl [start|stop|restart|status]
```

Persisting Overrides on initd

Notes on preserving required permissions across restarts and upgrades:

Do NOT Run Cribl Stream as Root!

If Cribl Stream is required to listen on ports 1–1024, it will need privileged access. On a Linux system with POSIX capabilities, you can achieve this by adding the `CAP_NET_BIND_SERVICE` capability. For example: `# setcap cap_net_bind_service=+ep $CRIBL_HOME/bin/cribl`

On some OS versions (such as CentOS), you must add an `-i` switch to the `setcap` command. For example: `# setcap -i cap_net_bind_service=+ep $CRIBL_HOME/bin/cribl`

Important: Upgrading Cribl Stream will remove the `CAP_NET_BIND_SERVICE` capability from the `cribl` executable, so you'll need to re-run the appropriate `setcap` command again after each upgrade.

Upon starting the Cribl Stream server, a `bind EACCES 0.0.0.0:<port>` error in the API or Worker logs (depending on the service) might indicate that `setcap` did not successfully execute.

System Proxy Configuration

For details on configuring Cribl Stream to send and receive data through proxy servers, see our System Proxy Configuration topic.

Scaling Up

A single-instance installation can be configured to scale up and utilize as many resources on the host as required. See Sizing and Scaling for details.

Anti-Virus Exceptions

If you are running anti-virus software on a Cribl Stream instance's host OS, here are general guidelines for minimizing accidental blockage of Cribl Stream's normal operation.

Your overall goals are to prevent the anti-virus software from locking any files while Cribl Stream needs to write to them, and from triggering any changes that Cribl Stream would detect as needing to be committed.

First, if Persistent Queues are enabled on any Destinations, exclude any directories that these Destinations write to. This is especially relevant if you're writing queues to any custom locations outside of `$CRIBL_HOME`.

Next, for any non-streaming Destinations that you've configured, exclude their staging paths.

Next, exclude these subdirectories of `$CRIBL_HOME`:

- `state/`
- `log/`
- `.git/` (usually only exists on Leader Nodes)
- `groups/` (on Leader Nodes)
- `local/` (on Workers or Leader)

Finally, avoid scanning any processes. Except for the queueing/staging directories already listed above, Cribl Stream runs everything in memory, so scanning process memory will slow down Cribl Stream's processing and reduce throughput.

Collecting Host Metadata

Cribl Stream can add a `__metadata` property to every event produced from every enabled Source. See Configure Host Metadata for more information.

3.2.5. Configure Cribl Stream For Non-Root User

We strongly recommended to never run Cribl Stream as the root user. Privileged access might be necessary, however, if Cribl Stream needs to read certain resources (such as `/var/log/*`), or to listen on low ports 0–1023. Here are two methods to grant this access while maintaining a non-root user:

- **Using Systemd capabilities**: Set Linux capabilities that grant Cribl Stream sufficient rights to perform specific privileged tasks. For details, see Set Capabilities for Cribl Stream below.
- **Using setcap (Linux with POSIX capabilities)**: This method directly modifies the executable file to grant it specific privileges. For details, see Persisting Overrides on initd.

Set Capabilities for Cribl Stream

Capabilities are permissions that grant privileged processes sufficient rights to accomplish a specific task, based on a kernel privilege. To run Cribl Stream as non-root user, consider setting the following capabilities:

Capability	Permissions
`CAP_NET_BIND_SERVICE`	Allows Cribl Stream to push Sources that bind to TCP/UDP port numbers below `1024`.
`CAP_DAC_READ_SEARCH`	Allows the `cribl` user to access the File Monitor Source's Manual mode feature. This capability bypasses the default Linux permissions for files and directories.
`CAP_SYS_PTRACE`	Allows the `cribl` user to access the File Monitor Source's Auto-mode feature.

For details about setting these capabilities, see Persisting Overrides.

OS-Specific Options

On some OS versions (such as CentOS), you must add an `-i` switch to the `setcap` command. For example: `# setcap -i cap_net_bind_service=+ep $CRIBL_HOME/bin/cribl`

Upgrading Cribl Stream will remove the `CAP_NET_BIND_SERVICE` capability from the `cribl` executable, so you'll need to re-run the appropriate `setcap` command after each upgrade.

Changing Ownership of Cribl Stream After Startup

To change the ownership of Cribl Stream from root to a non-root user after the application has already been started, you must modify the ownership of both the primary installation directory (`$CRIBL_HOME`) and any Cribl Stream-related directories in the `/tmp` directory. If you changed the default `/tmp` directory location using the **System** > **General Settings** > **Sockets** > **Directory** setting, then adjust the location accordingly. Use the `chown` command to change the owner of these directories to the desired non-root user. To complete the process, restart the Cribl Stream application instance to ensure the changes take effect.

3.2.6. Distributed Deployment

Cribl Stream Distributed deployment is a multi-instance deployment that is fit for large data volumes and increased processing.

In a Distributed deployment, a single Leader Node manages all Worker Nodes and is responsible for tracking and monitoring their activity metrics, keeping configurations in sync, and handling version control.

The following topics explain more high-level concepts related to Distributed deployment:

- To facilitate authoring and management of configuration settings for a particular set of Worker Nodes as a group, see Worker Groups.
- To plan for unexpected outages in Distributed deployments, see Leader High Availability/Failover.

For detailed deployment requirements, see OS and System Requirements, and for details on managing Cribl Stream, see Run Cribl Stream.

Concepts

Review the following basic concepts as a first step toward understanding how a Distributed deployment works.

Single instance: A single Cribl Stream instance, running as a standalone (not distributed) installation on one server.

Leader Node: A Cribl Stream instance that runs in **Leader** mode. You use the Leader Node to centrally monitor and author configurations for the Worker Nodes in a Distributed deployment.

Worker Node: A Cribl Stream instance that runs as a **managed Worker**. The Leader Node fully manages the configuration of each Worker Node. (By default, the Worker Nodes poll the Leader for configuration changes every 10 seconds.)

Worker Group: A collection of Worker Nodes that share the same configuration. You map Workers to a Worker Group using a Mapping Ruleset.

- Use multiple Worker Groups to make your configuration reflect organizational or geographic constraints. For example, you might have a US Worker Group, an APAC Worker Group, and an EMEA Worker Group, each with their own distinct certifications and settings.

Worker Process: A Linux process within a Single Instance, or within Worker Nodes, that handles data inputs, processing, and output. The process count is constrained by the number of physical or virtual CPUs available; for details, see Sizing and Scaling.

Mapping Ruleset: An ordered list of filters used to map Workers Nodes into Worker Groups.

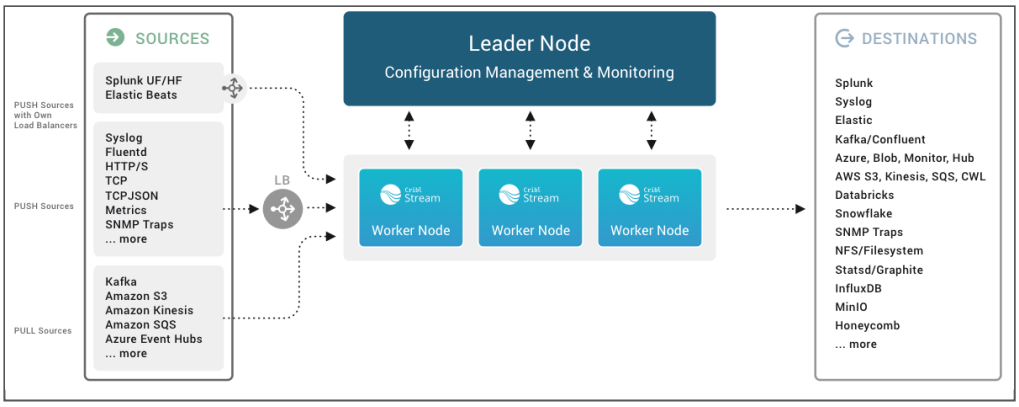
Options and Constraints

You can manually change the local configuration on a Worker Node, but changes won't persist on the filesystem. To permanently modify the configuration of a Worker Node, save and commit it, and then deploy it from the Leader Node. See Deploy Stream Configurations.

With certain license tiers, you can configure Permissions-based or Role-based access control at the Worker Group level. Non-administrator users can access Workers only within the Worker Groups on which they're authorized.

Architecture

Here's a visual overview of a distributed Cribl Stream deployment.



Distributed deployment architecture

The division of labor among components of the Leader Node and Worker Nodes in a Distributed deployment is as follows:

Leader Node

- API Process: Handles all the API interactions.
- Config Helpers: One process per Worker Group. Helps with maintaining configurations, previews, etc.

Worker Nodes

- API Process: Handles communication with the Leader Node (that is, with its API Process) and handles other API requests.
- Worker Processes: Handle all the data processing.

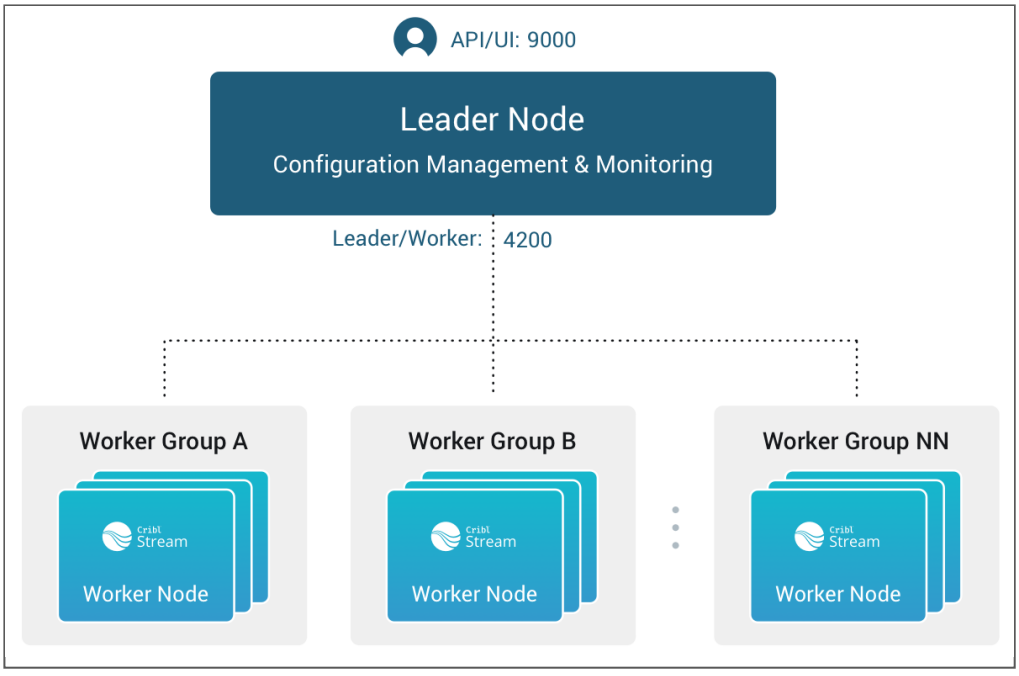
For comparison, the division of labor on a Single-instance deployment is simpler, because the Leader Node and Worker Nodes are essentially condensed into one stack:

- API Process: Handles all the API interactions.
- Worker Processes: Handle all data processing.
    - One Worker Process in a Cribl Stream deployment has a dual role: it processes data like other Worker Processes and assists the Leader Node in managing configurations. The API Process functions similarly to a Leader Node's API Process, handling API requests and responses. Other Worker Processes operate as standard Worker Nodes, primarily focused on data processing.

How Worker Nodes and the Leader Node Work Together

The Leader Node has two primary roles:

- It serves as a central location for the operational metrics of Worker Nodes. The Leader Node contains a monitoring console that includes dashboards that cover almost every operational aspect of the deployment.
- It authors, validates, deploys, and synchronizes configurations across Worker Groups.



Leader Node/Worker Nodes relationship

Network Port Requirements (Defaults)

The following are the default network port requirements.

- UI access to Leader Node: TCP 9000.
- Worker Node to Leader Node: TCP 4200. Used for Heartbeat/Metrics/Leader requests/notifications to clients (for example: live captures, teleporting, status updates, config bundle notifications, and so on).
- Worker Node to Leader Node: HTTPS 4200. Used for config bundle downloads.

Communication

Worker Nodes periodically (every 10 seconds) send a heartbeat to the Leader Node. This heartbeat includes information about the Worker Nodes and a set of current system metrics. The heartbeat payload includes facts – such as hostname, IP address, GUID, tags, environment variables, current software/configuration version, etc. – that the Leader Node tracks with the connection. If a Worker Node fails to successfully send two consecutive heartbeats, it is removed from the Workers page until the next time Leader Node receives a heartbeat message from it.

When a Worker Node checks in with the Leader Node:

1. The Worker Node sends heartbeat to Leader Node.
2. The Leader Node uses the Worker Node's configuration, tags (if any), and Mapping Rules to map it to a Worker Group.
3. The Worker Node gets its Worker Group's updated configuration bundle, if necessary.

In-Flight Data Safeguarding

If a Worker Node goes down, it loses any data that it's actively processing. With streaming senders (Push Sources), Cribl Stream normally handles that data only in-memory. So, to minimize the chance of data loss, configure persistent queues on Sources and/or Destinations that support it.

Leader/Worker Dependency

If the Leader Node goes down, Worker Groups can continue autonomously receiving and processing incoming data from most Sources. They can also continue executing Collection tasks already in process.

However, if the Leader Node fails, future scheduled Collection jobs will also fail. So will data collection on the Amazon Kinesis Data Streams, Prometheus Scraper, and all Office 365 Sources, which function as Collectors.

Workers GUID on Host Image or VM

When you install and first run the software, Cribl Stream generates a GUID that it stores in a `.dat` file located in `CRIBL_HOME/local/cribl/auth`, e.g.:

```
$ cat /opt/cribl/local/cribl/auth/676f6174733432.dat
{"it":1647910738,"phf":0,"guid":"e0e48340-f961-4f50-956a-5153224b34e3","lics":["licer
```

When deploying Cribl Stream as part of a host image or a virtual machine, be sure to remove this file, so that you don't end up with duplicate GUIDs. Cribl Stream will regenerate the file on the next run.

Commit and Deploy Controls

Distributed mode includes Worker Group-specific **Commit** and **Deploy** controls. These controls function differently from the global **Commit** button.

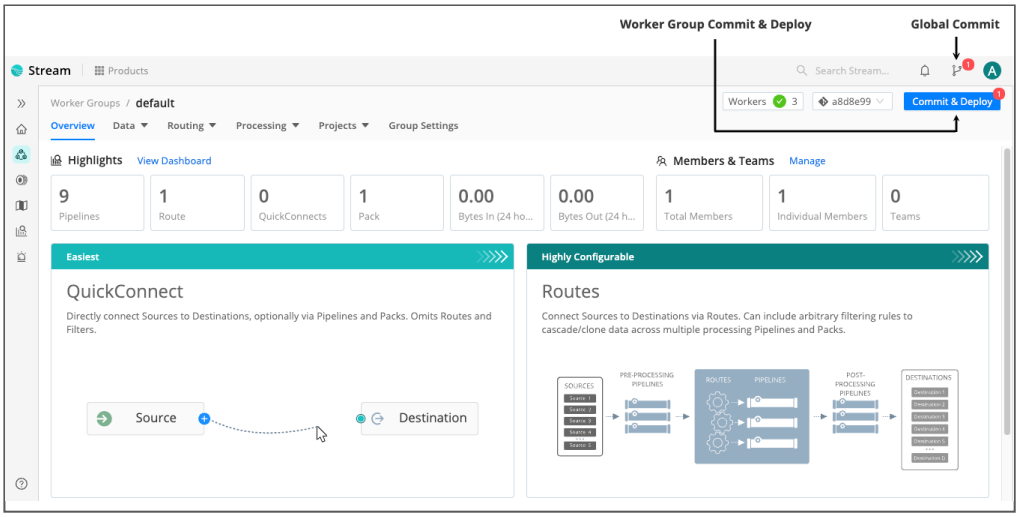
The global **Commit** button:

- Commits configurations for *all* Worker Groups and for the Leader Node.
- Does not deploy configurations.

The Worker Group **Commit** and **Deploy** buttons:

- Commit and deploy configurations for the currently selected Worker Group only.

These controls will appear slightly differently depending on whether you have changes committed but not yet deployed, and on whether you've enabled the Collapse actions setting.



Commit and Deploy controls in the user interface

For details, see Version Control.

Manage Workers and Worker Groups

To manage your Cribl Stream deployment's resources, use the Worker and Worker Group management features.

Manage Worker Groups

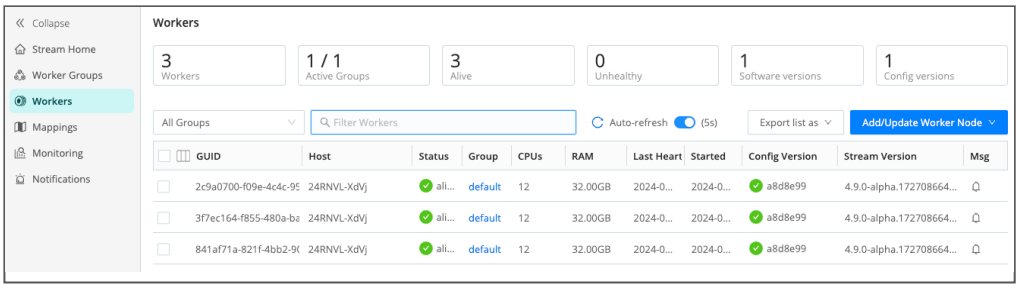
To manage Worker Groups, in the sidebar, select **Worker Groups**.

This opens the **Worker Groups** landing page, where you can view summary of information for each Worker Group and select it to view its Worker Nodes.

Manage Workers

To manage Worker Nodes, in the sidebar, select **Workers**.

The **Workers** tab provides status information for each Worker Node in the selected Worker Group. An **Auto-refresh** toggle (on by default) ensures that the **Config Version** automatically refreshes when you commit or deploy. (This option is available in Cribl Stream 4.4 and newer and appears only in Worker Groups that contain fewer than 100 Worker Nodes.)



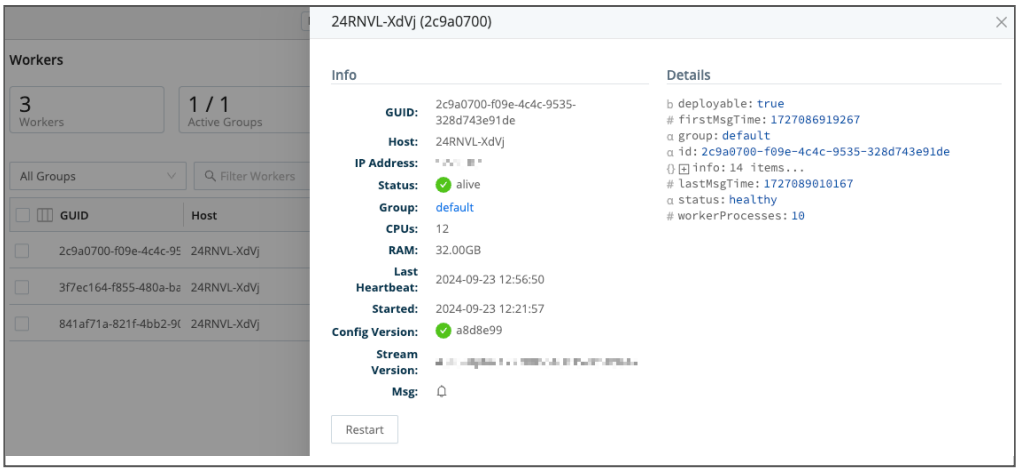
Worker Nodes status/controls

If you see unexpected results here, keep in mind that:

- Worker Nodes that miss 5 heartbeats, or whose connections have closed for more than 30 seconds, will be removed from the list.
- For a newly created Worker Group, the **Config Version** column can show an indefinitely spinning progress spinner. This happens because the Worker Nodes are polling for a config bundle that has not yet been deployed. To resolve this, select **Deploy** to force a deploy.

To export the list of Worker Nodes, select the **Export list as** drop-down. Select `JSON` or `CSV` as the export file format. If a list has any filters applied, the exported list will also be filtered. To export an entire list, remove any applied filters.

To reveal more details about a Worker Node, click anywhere on its row.



Worker Node details

Manage Mappings

The **Mappings** page displays status and controls for the active Mapping Ruleset.

To manage your mapping rulesets, select **Mappings** in the sidebar.

Select a Mapping Ruleset ID to manage and preview its rules.

Auto-Scale Workers and Load-Balance Incoming Data

If data flows in via load balancers, make sure to register all instances. Each Cribl Stream Node exposes a health endpoint that your load balancer can check to make a data/connection routing decision.

Health Check Endpoint	Healthy Response
`curl http://<host>:<port>/api/v1/health`	`{"status":"healthy"}`

3.2.6.1. Set Up Leader And Worker Nodes

In a Distributed deployment, each Cribl Stream instance runs in a defined mode: either as a Leader Node, governing the whole deployment, or as a Worker Node managed by the Leader.

You can select the mode in which any instance operates, using:

- Environment Variables
- UI Settings
- UI Access to Workers (Teleporting)
- Add Tags to Workers in Teleport View
- CLI
- `instance.yml`

Internally, the mode for a Leader Node is called `master`, which corresponds to an earlier, outdated name for the mode. That is why you will see `master` in commands, configuration keys and environment variable names.

Set Mode with Environment Variables

You can configure the mode for Leader and Worker Nodes via environment variables.

`CRIBL_DIST_MASTER_URL` defines the Leader Node URL for the deployment. If `CRIBL_DIST_MASTER_URL` is set, the mode for the instance defaults to `worker`. Set `CRIBL_DIST_MASTER_URL` in the following way:

```
export CRIBL_DIST_MASTER_URL=tcp://${CRIBL_DIST_TOKEN:-criblmaster}@masterHostname:4
```

Alternatively (or if `CRIBL_DIST_MASTER_URL` is not set), you can define the mode for the current instance by using the `CRIBL_DIST_MODE` variable, like this:

```
export CRIBL_DIST_MODE=master
```

Environment variables take priority over other ways of setting up Leader and Worker Nodes. If any `CRIBL_DIST_*` variable is defined in the system, you won't be able to configure Distributed mode settings via UI.

Set Mode with UI Settings

You can configure the mode for each instance in a Distributed deployment via UI.

1. In the sidebar, select **Settings**, then **Global**.
2. Select **Distributed Settings**, then **General Settings**.
3. In **Mode**, choose the mode you want the instance to run as:
    - **Leader**.
    - **Stream: Managed Worker (managed by Leader)**.
4. Select **Leader Settings**, and configure the required Leader settings:
    - **Address** and **Port** for Leader Node.
    - **Address** (for example: `cribleader.mycompany.com`) for Worker.

    If you need to customize the Leader's port (from its default `4200`), you can do so via the CLI's `mode-worker` command.
5. Optionally, customize the remaining settings.

If you configure Leader High Availability/Failover, further **Distributed Settings** changes will be locked for each Leader Node. You can still update distributed settings by modifying configuration files, as outlined on the page linked above.

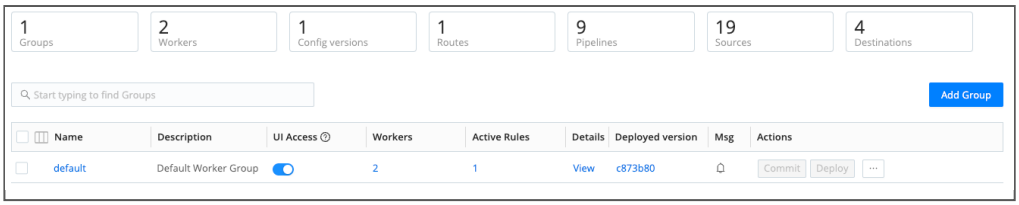
Enable UI Access to Workers (Teleporting)

Remote UI access to Workers (also known as teleporting) enables you to click through from the Leader's **Workers** page to an authenticated view of each Worker's UI.

Any changes that you make on a Worker Node via remote access (with the exception of adding tags) will not be propagated to the Leader Node.

To enable (remote) UI access to Workers from the Leader Node:

1. In the sidebar, select **Worker Groups**.
2. In the row of the Worker Group you want to enable teleporting for, enable **UI Access**.

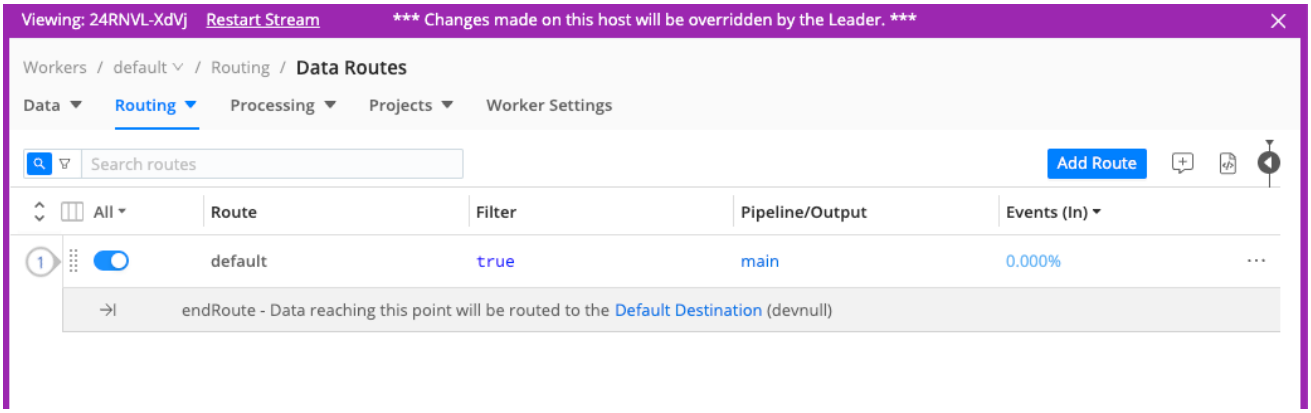


Worker UI access setting

On Cribl.Cloud, the **Worker Groups** page adds extra columns. You'll see each Group's Worker type (customer-managed / hybrid versus Cribl-managed / Cribl.Cloud) and, for Cloud Groups, the anticipated ingress rate and Provisioned status. For details, see Managing Cribl.Cloud Worker Groups.

To access a Worker Node via teleporting:

1. In the sidebar, select **Workers**.
2. Select the link for any Worker Node you want to inspect.
   A purple border that appears around the UI indicates that you are viewing the Worker Node remotely. Select **Restart Stream** on the border to restart the Worker, or select the **X** close button to return to the **Workers** page.



Authenticated view of a Worker

An alternative way of allowing UI access to Workers is enabling the `workerRemoteAccess` configuration key in `groups.yml`.

Add Tags to Workers in Teleport View

You can add tags to a Worker Node you've accessed by teleporting. Tags help the Leader Node map a Worker Node to a Worker Group. Note that changing the tags on a Worker can cause the Leader to map the Worker into a new Group.

1. Teleport into a Worker Node.
2. On the **Workers** submenu, select **Worker Settings**, then **Distributed Settings**.

3. Enter tags for this Worker Node and select **Save**.

In Cribl.Cloud, you can only add tags to *hybrid* Worker Nodes. You must accept the confirmation modal, as changing the tags on a Worker can affect the Worker Group that the Leader maps it into.

Set Mode with CLI

You can configure the mode for an instance in a Distributed Deployment by using commands: `mode-master` and `mode-worker`.

For example, to configure a Worker Node, use command of this form:

```
./cribl mode-worker -H <master-hostname-or-IP> -p <port> [options] [args]
```

`-H` and `-p` are required parameters. For other options, see the CLI Reference. Here is an example command:

```
./cribl mode-worker -H 192.0.2.1 -p 4200 -u myAuthToken
```

Cribl Stream will need to restart after this command is issued.

Set Mode in `instance.yml`

You can configure each instance to be either Leader or Worker in `$CRIBL_HOME/local/_system/instance.yml`, under the `distributed` section, by setting the `mode` value:

Leader Worker

$CRIBL_HOME/local/_system/instance.yml

```
distributed:
  mode: master
  master:
    host: <IP or 0.0.0.0>
    port: 4200
    tls:
      disabled: true
    ipWhitelistRegex: /.&ast;/
    authToken: <auth token>
    enabledWorkerRemoteAccess: false
    compression: none
    connectionTimeout: 5000
    writeTimeout: 10000
```

Leader/Worker Mode and Auth Tokens

When you configure an instance to work as the Leader, switching from a Single-instance to a Distributed mode, Cribl Stream generates a random auth token.

See How to Secure the Auth Token for the Leader Node for information on changing your auth token and allowed characters.

Troubleshooting Resources

Cribl University offers a Troubleshooting Criblet on Attaching Workers to Leaders. (To follow the direct course link, first log into your Cribl University account - it's free!)

3.2.6.2. Manage Worker Groups

Worker Groups are collections of Worker Nodes that share the same configuration. They facilitate authoring and management of configuration settings.

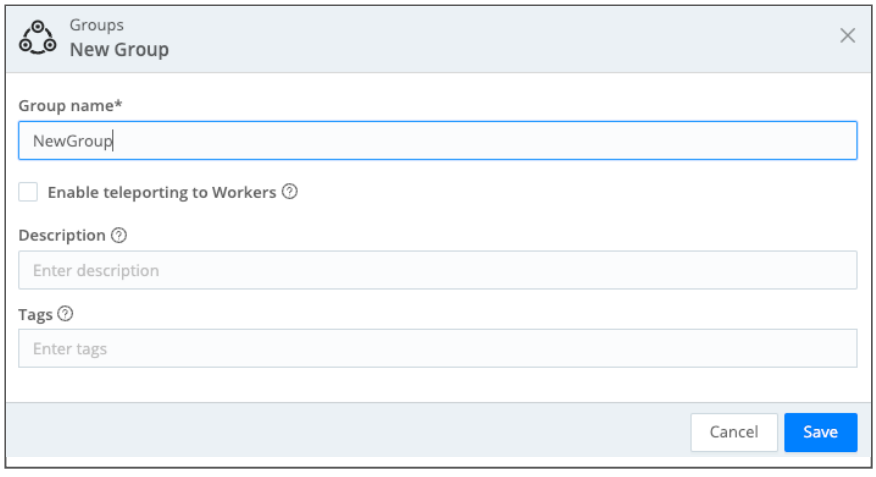
You configure data flow, including Routes, Pipelines, Sources, Destinations, per Worker Group. Each Worker Group also has separate version control.

A Cribl.Cloud deployment with a certain plan tier also allows you to create Cribl-managed Worker Groups in Cribl.Cloud. See Managing Cribl.Cloud Worker Groups for more details.

Create a Worker Group

To create a new Worker Group:

1. In the sidebar, select **Worker Groups**.
2. Select **Add Group**.
3. If you are on Cribl.Cloud and see the **Worker Group type** field, select **Hybrid**.
4. Enter a unique **Group name**.
5. Optionally, you can **Enable teleporting to Workers** to allow UI access for individual Worker Nodes.
6. Optionally, type in a **Description** and select **Tags**.



Creating a New Group

Configuring multiple Worker Groups, or configuring more than 10 Worker Processes, requires a Cribl Stream on-prem deployment with a certain license tier.

To explicitly set passwords for Worker Groups, see User Authentication.

Clone a Worker Group

Cloning a Worker Group copies everything configured on the original Group: Sources, Pipelines, Packs, Routes, and Destinations.

To clone a Worker Group:

1. In the sidebar, select **Worker Groups**.
2. In the **Actions** column, select ••• (Options).
3. Select **Clone**.
4. Configure the cloned group by choosing its name, and optionally description and tags.

Recover a Worker Group

If you delete a Worker Group, you can no longer access its **Version Control** menu. As a result, you also lose the option to directly recover the Worker Group.

You can, however, still recover a deleted Worker Group, using one of the following two methods:

- Create a new Worker Group with the same name.
- Revert commit via command line.

Create a New Worker Group with the Same Name

When you create a new Worker Group with the same name as a deleted one, it will restore that group with all of its configuration.

1. In the sidebar, select **Worker Groups**, then select **Add Group**.
2. Set **Group name** to be exactly the same as the deleted group. Fill in the remaining information and **Save**.
3. If you previously committed the deletion of the original Worker Group, open the **Version Control** menu.
4. Select a previous version of the deleted Worker Group and confirm with **Done**.

Revert Commit via Command Line

You can restore a deleted Worker Group by reverting the deletion commit in version control via command line.

1. Stop the Cribl server.
2. Using command line, look at the version control history for the Leader Node and identify the commit which deleted the Worker Group.
3. Revert to the last commit before the Group was deleted.
4. Restart the Cribl server.

3.2.6.3. Map Workers To Worker Groups

Mapping Rulesets define how Worker Nodes are distributed among Worker Groups. A Ruleset consists of a list of rules that evaluate Filter expressions on the information that Worker Nodes send to the Leader Node.

Only one Mapping Ruleset can be active at any one time.

The ruleset behavior is similar to Routes, where the order matters, and the **Filter** section supports full JavaScript expressions. The ruleset matching strategy is first-match, and one Worker Node can belong to only one Worker Group.

Configuring Mapping Rulesets is possible only when you have started Cribl Stream in Leader mode.

If you define no Mapping Rulesets of your own, the built-in `default` Mapping Ruleset with a `default` rule matching all (`true`) assigns all Worker Nodes to the `default` Worker Group, unless the Worker Node itself specifies differently.

Worker Mapping Priority

Worker Nodes can be assigned to Worker Groups in two ways: via Mapping Rulesets, and by including the group in the Worker's payload. When both are defined, the assignment follows this priority:

1. Group matched by a filter in a Mapping Ruleset.
2. Group defined in the Worker Node.
3. The `default` group.

Create a Mapping Ruleset

To create a Mapping Ruleset:

1. In the sidebar, select **Mappings**.
2. Select **Add Ruleset**
3. Provide a unique **ID** for the new Ruleset and confirm with **Save**.
4. Select the new Ruleset in the table to enter a rule editing screen.

Add Mapping Rules

Each Mapping Ruleset can have one or more rules.

1. Select **Add Rule** to start adding rules. While you build and refine rules, the Preview in the right pane will show which currently reporting and tracked Worker Nodes map to which Worker Groups.
2. For each rule, formulate a **Filter** expression that maps Worker Nodes.
3. In **Group**, identify the Worker Group to which the Worker Node should be assigned.
4. **Save**, and add more rules, if needed.

Activate Mapping Ruleset

A ruleset must be activated before it can be used by the Leader Node.

To activate it, go to **Mappings** and select **Activate** on the required ruleset.

Activating a ruleset deactivates any other existing rulesets.

Mapping Rule Example

This example assumes that you want to define a rule for all hosts that satisfy the following set of conditions:

- IP address starts with `10.10.42` AND Worker Node has more than 6 CPUs, OR:
- `CRIBL_HOME` environment variable contains `w0`.

The rule should assign the Worker Node to `Group420`.

Field	Value
Rule Name	`myFirstRule`
Filter	`(conn_ip.startsWith('10.10.42.') && cpus > 6) || env.CRIBL_HOME.match('w0')`
Group	`Group420`

3.2.6.4. Manage Config Bundles

Cribl Stream uses config bundles, compressed archives containing configuration files and data essential for Worker operation.

Config Bundles

Both Leader and Worker Nodes automatically manage config bundles in the following ways.

Leader Node Bundles

The Leader Node actively manages bundles, performing the following tasks:

- **Cleanup on startup**: Upon startup, the Leader Node clears all bundles.
- **Running state**: The Leader Node maintains a maximum of five bundles per Worker Group while running.
- **Automatic cleanup**: Creating a new bundle triggers the deletion of older ones.

Worker Node Bundles

The Worker Node pulls bundles from the Leader Node and manages them as follows:

- **Cache**: Worker Nodes cache the latest five bundles and their backups.
- **Recent file retention**: Worker Nodes retain any files created within the last ten minutes.
- **Reconfigure cleanup**: Reconfigured events initiate bundle cleanup.

Store Bundles Remotely

Optionally, reduce Leader load by storing bundles in an Amazon S3 bucket. This offloads distribution, allowing Worker Nodes and Edge Nodes to pull bundles directly from S3.

Configure S3 Storage

You can configure bundling in S3 through the following ways:

- **UI**: While configuring **Leader Settings** on a Leader Node, specify an S3 bucket (format: `s3://${bucket}`) for remote bundle storage in the **S3 Bundle Bucket URL** field.
- **YAML**: Define the S3 bucket URL in the `master.configBundles.remoteUrl` property of your `instance.yml` configuration file.
- **Environment variable**: Set the `CRIBL_DIST_LEADER_BUNDLE_URL` environment variable.

Optimized Bundle Delivery

Cribl Stream prioritizes efficient bundle downloads for Worker Nodes. Here's how:

- **Direct S3 downloads (preferred)**: When possible, Cribl prioritizes direct downloads from Amazon S3 for optimal performance.
- **Private network fallback**: Worker Nodes on private networks attempt to retrieve bundles from a Content Delivery Network (CDN). If blocked, they automatically fall back to downloading from the Leader Node.
- **Optional S3 firewall allowlist**: Consider adding `*.s3.amazonaws.com` to your firewall or proxy allowlist (due to non-static S3 addresses) for Worker Nodes with internet access. This ensures smooth downloads and avoids potential disruptions.

3.2.6.5. Deploy Stream Configurations

Cribl Stream configurations are deployed after the bundle containing them is saved and committed. *Deploying* here means **propagating updated configurations to Worker Nodes.**

The typical workflow for deploying Cribl Stream configurations is the following:

1. Configure.
2. Save.
3. Commit (and optionally push).
4. Deploy.

You deploy new configurations at the Worker Group level: Locate the desired Worker Group and select **Deploy**. Worker Nodes that belong to the group will start **pulling** updated configurations on their next check-in with the Leader Node.

Can't Log In to the Worker Node as Admin User?

When a Worker Node pulls its first configuration, the admin password will be randomized, unless specifically changed. This means that users won't be able to log in on the Worker Node with default credentials. For details, see Set Worker/Edge Node Passwords.

Configuration and Lookup File Locations

Node Type	Configuration Location	Lookup File Location
Leader Node	`$CRIBL_HOME/groups/<groupName>/local/cribl/`	`$CRIBL_HOME/groups/<groupName>/`
Worker Node	`$CRIBL_HOME/local/cribl/` (after pulling configurations)	`$CRIBL_HOME/data/lookups` (after pu configurations)

When deployed via the Leader Node, lookup files are distributed to Worker Nodes as part of a configuration deployment.

If you want your lookup files to be part of the Cribl Stream configuration version control process, we recommended deploying using the Leader Node. Alternatively, you can update your lookup file on the individual Worker Nodes, which can be useful for larger lookup files (greater than 10 MB, for example), for lookup files maintained using some other mechanism, or for lookup files that are updated frequently.

For other options, see Managing Large Lookups.

Some configuration changes will require restarts, while many others require only reloads. See Configurations and Restart for details.

Restarts and reloads of each Worker Process are handled automatically by the Worker Node. Note that individual Worker Nodes might temporarily disappear from the Leader's **Workers** tab while restarting.

Worker Process Rolling Restart

During a restart, to minimize ingestion disruption and increase availability of network ports, Worker Processes on a Worker Node are restarted in a rolling fashion. **20% of running processes – with a minimum of one process – are restarted at a time.** A Worker Process must come up and report as **started** before the next one is restarted. This rolling restart continues until all processes have restarted. If a Worker Process fails to restart, configurations will be rolled back.

3.2.6.6. Persistent Socket Connections

Distributed deployments use Unix domain sockets for inter-process communication (IPC) between a Leader Node's distributed processes and services. Multiple Unix domain sockets must exist (created by their respective process) on a Leader's disk. One of these domain socket files ensures that the metrics services operate correctly. On the host where the Leader Node is running, the default location for Unix domain socket files is the operating system temporary directory – for example, `/tmp`.

Many Linux distributions maintain a system cleaner service (such as systemd-tmpfiles) that removes files from the temporary directory periodically, such as every 10 days. If Cribl's sockets are removed, certain product pages (such as Monitoring) break.

You can protect the sockets by either blocking the cleaner or moving the Cribl socket files.

Block the Cleaner

You can stop the host operating system from cleaning socket files out of `/tmp/cribl-*` subdirectories. Using Amazon Linux 2 instances as an example:

1. Add a new `tmp.conf` file to `/etc/tmpfiles.d` with the line: `X /tmp/cribl-*`
2. Restart the system cleaner and reload its configuration using this command: `systemctl restart systemd-tmpfiles-clean.service`
3. Restart the Cribl server via the UI or command line.

Move the Sockets

Alternatively, you can move the Cribl socket files to a different, protected directory. This directory must be relatively close to the root, and the Cribl admin must have permissions to write to it. For example, you could specify: `/var/tmp`.

Specify the directory in **Settings** at **Global** > **System** > **Distributed Settings** > **Leader Settings** > **Helper processes socket dir**.

3.2.7. Splunk App Deployment

Getting started with Cribl App for Splunk

Deploying Cribl App for Splunk

In an on-prem Splunk environment, you can install and configure Cribl Stream as a Splunk app (Cribl App for Splunk), on a Search Head. You **cannot** use Cribl App for Splunk in a Cribl Stream distributed deployment as a Leader, or as a managed Worker. You **cannot** install the app on Splunk Cloud or on a Splunk Heavy Forwarder. (See Single-Instance/Basic Deployment and Distributed Deployment for alternatives.)

Running on a Search Head (SH)

When running on an SH, Cribl Stream is set to **mode-searchhead**, the default mode for the app. It listens for **localhost traffic** generated by a custom command: `criblstream`. The command is used to forward search results to the Cribl Stream instance's TCP JSON input on port `10420`, but it's also capable of sending to any other Cribl Stream instance listening for TCP JSON.

Once received, data can be processed and forwarded to any of the supported Destinations. In addition, several out-of-the box saved searches are ready to run and send their results to Cribl with a single click.

Installing the Cribl App for Splunk on an SH

- Select an instance on which to install.
- Ensure that ports `10000`, `10420`, and `9000` are available. See the Requirements section for more info.
- Get the bits here, and install as a regular Splunk app.
- Restart the Splunk instance.
- Go to `https://<instance>/en-US/app/cribl` or `https://<instance>:9000`, and log in with Splunk **admin** role credentials.

Typical Use Cases for Search Head Mode

- Working with search results in a Cribl Stream pipeline.
- Sending search results to any Destination supported by Cribl Stream.

Commands and Examples

Below are some examples of how to use the `criblstream`, `criblencrypt`, and `cribldecrypt` commands available in this app.

The `cribldecrypt` command can decrypt events originating from multiple Stream Worker Groups or Edge Fleets **only** if you use the same key material on all Worker Groups and Fleets encrypting data.

Forward Search Results to a Cribl Stream Instance

The basic command for sending events to a Cribl Pipeline is `criblstream`, for example:

criblstream command

```
index="my_index" | criblstream dest=host:port
```

Search for a Value

Suppose that you want to search events for a particular value. Because events are encrypted, one approach would be to decrypt all events and then search the unencrypted events for your target value. But decrypting large numbers of events takes a long time, and is extremely inefficient.

Here's a better approach, taking advantage of the fact that the encrypted form of a value is always the same:

1. Encrypt the target value.
2. Search the events (which are still encrypted) for the encrypted form of the target value.
3. If you find events that contain the (encrypted) target value, decrypt them if desired.

You can combine all three steps in a single command:

Search the index for the encrypted target value and decrypt matching events

```
index="encrypted" \
[ | makeresults | eval encrypted_field="target_value" \
| criblencrypt field=encrypted_field keyclass= 0 \
| fields encrypted_field ] | cribldecrypt
```

The `criblencrypt` command requires a `field`, and either a `keyclass` (as shown above) or a `keyid`. For details, see Encryption.

Internal Fields

The Cribl App for Splunk adds the following internal fields to events:

- `_CRIBL_QUEUE`
- `_CRIBL_TCP_ROUTING`

The app forwards these fields to Splunk, because the `transforms.conf` file that ships with the app relies on them.

Beginning with version 4.0, only the Cribl App for Splunk adds these fields. Cribl Stream and Cribl Edge do not. (Earlier versions of Cribl Stream did add these fields, but neither Stream itself nor Splunk receivers have processed them in recent versions.)

3.2.8. Bootstrap Workers From Leader

Boot fully provisioned Workers

Cribl Stream Workers can completely provision themselves, directly from the Leader, upon initial boot. This means that a group of any number of Workers can launch and be fully functional within the cluster, in seconds.

How Does It Work?

A Cribl Stream Leader Node provides a bootstrap API endpoint, at `/init/install-worker.sh`, which returns a shell script. You can run this shell script on any supported machine (see Restrictions below), without Cribl Stream installed. This fully provisions the machine as a Worker Node.

Although you can specify the download URL when you execute the initial curl command, the Cribl Stream package is not downloaded until you generate the script via the API, and then execute it.

For additional information on using environment variables to set the hostname, see Setting the Hostname.

Requirements

All Worker Nodes' hosts must enable ongoing outbound communication to the Leader's port 4200, to enable the Leader to manage the Workers. While the bootstrap script runs, firewalls on each Worker's host must also allow outbound communication on the following ports:

- Port 443 to `https://cdn.cribl.io`.
- Port 443 to a Cribl.Cloud Leader.
- Port 9000 to an on-premises Leader.

If any of this traffic must go through a proxy, see System Proxy Configuration for configuration details.
To anticipate and resolve edge cases not mentioned here, see Restrictions below.

Troubleshoot Root Access or SSL Errors

The script will install Cribl Stream into `/opt/cribl`, and will make system-level changes. For systems like Ubuntu, which don't allow direct root access, you'll need to use the `sudo` prefix when executing the script.

The script will create a user named `cribl` to install, own, and run Cribl Stream/Edge.

If you encounter errors of this form:
`ssl certificate problem: self signed certificate in certificate chain`
...add the `-k` flag to disable certificate validation.

UI Access

Cribl Stream admins can use the UI to concatenate and copy/paste the bootstrap script, automating several steps below. You can use an adjacent option to grab a script that updates a Worker's Group assignment.

To use these options, you must have the `admin` Role on a Distributed deployment's Leader Node, with a certain license tier. You must also create the Worker Groups before using the following instructions to add or reassign Workers to them.

Add New Worker Node

1. In the Cribl Stream sidebar, select **Workers**.
2. On the **Workers** page, select **Add/Update Worker Node**.
3. Select **Linux** > **Add** from the menu.
4. In the **Add Linux Worker** modal, the **Install package location** defaults to `Cribl CDN`. If desired, change this to `Download URL`. (For details about this option, see Add Download URL.)
5. As needed, correct the target **Group**, **User**, and **User Group**, as well as the **Leader hostname/IP** (URI).
6. Copy the resulting script to your clipboard and select **Done** to close the modal.
7. Paste the script onto your Worker Node's command line and execute it.
    - As needed (see the note above), prepend `sudo` to the generated **Script** field's contents, and/or append the `-k` flag.

Update Existing Worker Node

You can also auto-generate a script that will update an existing Worker's Group assignment, and/or assign the Worker to a different Leader:

1. In the Cribl Stream sidebar, select **Workers**.
2. On the **Workers** page, select **Add/Update Worker Node**.
3. Select **Linux** > **Update** from the menu.
4. In the **Update Configuration on Linux Workers** modal, select the new target **Group** for this Worker Node.

5. As needed, correct or change the **Leader hostname/IP** and/or **Leader port number**.
6. The **Script type** drop-down defaults to the `Environment variable` option for generating the script's command. If you're not relying on environment variables, change this to `CLI`.
7. Copy the resulting script to your clipboard and select **Done** to close the modal.
8. Paste the script onto your Worker Node's command line and execute it.
    - As needed (see the note above), prepend `sudo` to the generated **Script** field's contents, and/or append the `-k` flag.

API Spec

Request Format

```
GET http://<leader hostname or IP>:9000/init/install-worker.sh
```

Query Strings

String	Required?	Description
`token`	optional	Leader Node's shared secret (`authToken`). By default, this is set to a random string. You can find this secret in the Leader Node's **Distributed Settings** section. Before v4.5.0, the default token was `criblmaster`. This token is still in use in instances upgraded from an earlier version.
`group`	optional	Name of the cluster's Worker Group. If not specified, falls back to `default`.
`download_url`	optional	Provide the complete URL to a Cribl Stream installation binary. This is especially useful if the Worker Nodes don't have access to the Internet to download from cribl.io.
`tag`	optional	When used in conjunction with Mapping Rules, enables you to specify the Worker Group you want the bootstrapped Worker to join. Multiple tags should be in the form `&tag=tag1&tag=tag2`.
`user`	optional	The user to run Cribl Stream. Defatuls to `cribl`.
`user_group`	optional	The user group that owns all files. Defaults to `cribl`.
`install_dir`	optional	The file path to install Cribl Stream. Defaults to `/opt/cribl`.

Example HTTP Request

```
GET http://<leader hostname or IP>:9000/init/install-worker.sh?token=79364d6e-dead-b
```

As of version 3.0, Cribl Stream's former "master" application components are renamed "leader." While some legacy terminology remains within CLI commands/options, configuration keys/values, and environment variables, this document will reflect that.

Example Response

```
#!/bin/sh

### START CRIBL LEADER TEMPLATE SETTINGS ###

  ${CRIBL_INSTALL_DIR}/bin/cribl start
fi
```

curl Option

An easy way of wrapping HTTP methods is to use the `curl` command. Here is an example, which uses a `GET` operation by default, with the same URL used in the above HTTP example:

```
curl http://<leader hostname or IP>:9000/init/install-worker.sh?token=79364d6e-dead-l
```

Check Requirements above to avoid/resolve port or ownership issues.

Chain Script Execution

The `GET` and `curl` procedures above will only output the contents of the script that needs executing – the script will still need to be manually executed.

However, you can automate that part, too, using a command like the one shown below. This passes the script's contents to the `bash` shell to immediately execute.

```
curl http://<leader hostname or IP>:9000/init/install-worker.sh?token=79364d6e-dead-l
```

As noted above, on Ubuntu and similar systems, you might need to insert `sudo` before the `bash`. If you don't have a bash shell available, you can pipe the command to `| sh -` instead.

Add Download URL

By default, the script gets configured to download the Cribl Stream package from the public Cribl repository. If you want to specify a different download location in the script, you'll use the `download_url` parameter.

To successfully execute the `curl` command while also specifying the download URL, you must enclose the URL in double quotes. The reason for this is that the `&` character that joins multiple HTTP parameters is interpreted by the shell as the operator to run commands in the background. Double-quoting the URL, as shown in this example, prevents this.

```
curl "http://<leader hostname or IP>:9000/init/install-worker.sh?token=79364d6e-dead
```

curl Offline Option

To bootstrap Workers in an internet-disconnected (airgapped) environment, you can separate downloading the installation package from Cribl's repository versus running the `curl` command. Here's an example:

1. Download the installation package from Cribl's download page.

2. Rename the resulting file from `cribl-x.x.x-xxxxxxxx-linux-x64.tgz` to `cribl.tar.gz`.
3. Bootstrap the Worker from the file's current directory, by running a command of this form:

```
curl "https://<mycriblleader.mydomain.ext>:9000/init/install-worker.sh?group=default&
```

Tag to Assign Workers to Worker Groups

Cribl Stream uses Mapping Rulesets to map Workers to Worker Groups. When you create a Worker from a bootstrap script, you can take advantage of Mapping Rulesets to specify which Worker Group you want the newly-created Worker to join. This is done by adding tags to the download URL, in the form `&tag=tag1&tag=tag2`.

Basic Example

Suppose you have a Worker Group, `Group420`, that you want bootstrapped Workers to join.

In the active Mapping Ruleset for `Group420`, create a new rule that maps any Worker with the tag `awseast1` to the `Group420` Worker Group. You can do this with a filter:

```
cribl.tags.include('awseast1')
```

Then, in the bootstrap script, add a download URL with a tag that matches the filter you just created. For example:

```
curl "http://<logstream_leader>:9000/init/install-worker.sh?tag=awseast1&token=<token
```

When you use the script to bootstrap a new Worker, the Worker will be assigned to `Group420`.

Advanced Example

Suppose you have four Worker Groups distributed between two regions and two platforms:

	AWS	Azure
Region 1	`Group01`	`Group02`
Region 2	`Group03`	`Group04`

Using two tags (one for region and one for platform) you can represent all four possible combinations, and thus all four Worker Groups:

- `tag=aws&tag=region1` maps to `Group01`.
- `tag=azure&tag=region1` maps to `Group02`.
- `tag=aws&tag=region2` maps to `Group03`.
- `tag=azure&tag=region2` maps to `Group04`.

For each Worker Group, you'll create a Mapping Rule with a filter for the appropriate tag combination to match. For example, this filter would match `Group04`:

```
cribl.tags.includes('azure') && cribl.tags.includes('region2')
```

Then you can use the tag combination in the download URL of a bootstrap script. For example, the tags in this download URL map to `Group04`:

```
http://<logstream_leader>:9000/init/install-worker.sh?tag=azure&tag=region2&token=<t
```

Any Worker created by the script with the above download URL will be assigned to `Group04`.

Status Codes

Status Code	Reason
200 – OK	All is well. You should have received the script as a response, even with an invalid token.
403 – Forbidden	The node is not configured as a Leader.

Restrictions

Keep the following in mind when using bootstrap scripts:

- Each Worker must normally have access to the internet in order to download the Cribl Stream installation binary from cribl.io. Where this isn't feasible, you can use the `download_url` switch to point to a binary in a restricted location.
- TLS is not enabled by default. If enabled and configured, access to this feature will be over `https` instead of `http`.
- Red Hat, Ubuntu, CentOS, and Amazon Linux are the only supported Worker platforms.

User Data

For public-cloud customers, an easy way to use bootstrap scripts is in an instance's user data. First, be sure to set the Leader Node to `mode = 'leader'`. Then use the following script (changing the command as needed. based on the information above). Upon launch, the Worker Node will reach out to the Leader, download the script, download the Cribl Stream package from the specified location, and then install and configure Cribl Stream:

```
#!/bin/bash
curl http://<leader-node-ip/host-address>:9000/init/install-worker.sh?token=<auth-tol
```

3.2.9. Leader High Availability/Failover

To handle unexpected outages in on-prem Distributed deployments, Cribl Stream supports configuring standby Leaders for failover. In this High Availability (HA) scenario, if the primary Leader goes down, Collectors and Collector-based Sources can continue ingesting data without interruption.

For license tiers that support configuring backup Leaders, see Cribl Pricing.

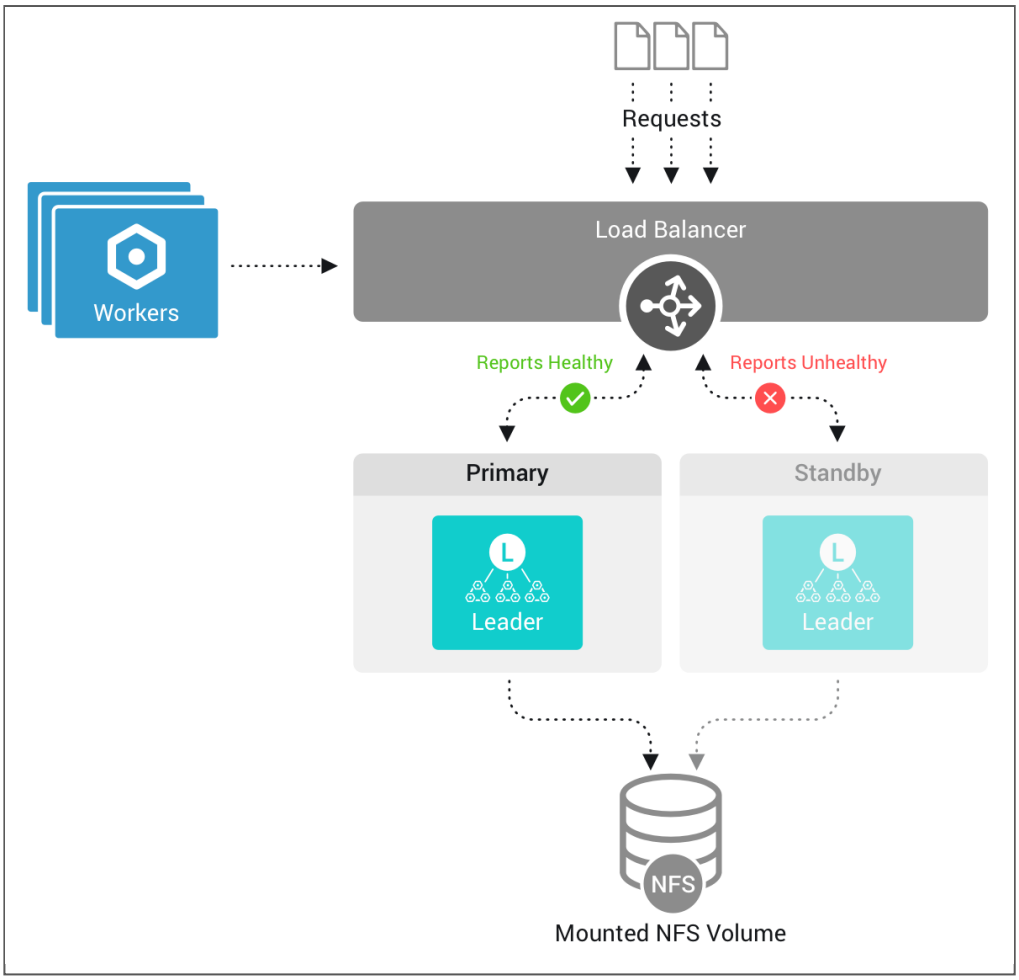
How It Works

There is only ever one active Leader Node at one time. A standby Leader will become active only in the event of failover. In the configuration for all Leaders, you must specify the same **failover volume** – a shared Network File System (NFS) volume.

If the primary Leader Node goes down:

- Cribl Stream will recover by switching to a standby Leader.
- The new Leader will have the same configs, state, and metrics as the previous Leader Node.
- The Worker Nodes connect to the new Leader.

Prior to Cribl Stream 4.7, it was possible for the primary and standby Leaders to be configured differently, potentially causing issues, especially around authentication and authorization.



Leader High Availability/Failover Design

Required Configuration

Before adding a standby Leader, ensure that you have the configuration outlined in this section.

Auth Tokens

All Leaders must have matching auth tokens. If you configure a custom **Auth token**, make sure that all Leaders have that same token.

- In Cribl Stream, check and match these values at each Leader's **Settings** > **Global** > **Distributed Settings** > **Leader Settings** > **Auth token**.
- Or, from the filesystem, check and match all Leaders' instance.yml > `master` section > `authToken` values.

See How to Secure the Auth Token for the Leader Node for information on changing your auth token and allowed characters.

NFS

- On all Leader Nodes, use the latest version of the NFS client. **NFSv4 is required.**
- Ensure that the NFS volume has at least 100 GB available disk space.
- Ensure that the NFS volume's IOPS (Input/Output Operations per Second) is ≥ 200. (Lower IOPS values can cause excessive latency.)
- Ensure that ping/latency between the Leader Nodes and NFS is < 50 ms.

You can validate the NFS latency using a tool like `ioping`. Navigate to the NFS mount, and enter the following command:

```
ioping .
```

For details on this particular option, see the ioping docs.

NFS Mount Options

The Leader Node will access large numbers of files whenever you use the UI or deploy configurations to Cribl Stream Worker Nodes. When this happens, NFS's default behavior is to synchronize access time updates for those files, often across multiple availability zones and/or regions. To avoid the problematic latency that this can introduce, Cribl recommends that you add one of the following NFS mount options:

1. `relatime`: Update the access time only if it is more than 24 hours ago, or if the file is being created or modified. This allows you to track general file usage without introducing significant latency in Cribl Stream. To do the same for folders, add the `reldiratime` option.
2. `noatime`: Never update the access time. (Cribl Stream does not need access times to be updated to operate correctly.) This is the most performant option – but you will be unable to see which files are being accessed. To do the same for folders, add the `nodiratime` option.

Load Balancers

- Configure all Leaders behind a load balancer.
- Expose ports `9000` and `4200` via the load balancer.
- Load balancers must support health checks over HTTP/HTTPS via the `/api/v1/health` endpoint.

Load balancers that support such health checks include:

- Amazon Web Services (AWS) Network Load Balancer (NLB). Suitable for TCP, UDP, and TLS traffic.
- AWS Application Load Balancer (ALB). Application-aware, suitable for HTTP/HTTPS traffic.
- HAProxy.
- NGINX Plus.

AWS Network Load Balancers

If you need to access the same target through a Network Load Balancer, use an IP-based target group and deactivate client IP preservation. For details, see:

- Why can an instance in a target group not reach itself via NLB?
- Why can't a target behind my Network Load Balancer connect to its own Network Load Balancer?

Recommended Configuration

Use the latest NFS client across all Leaders. If you are on AWS, we recommend the following:

- Use Amazon's Elastic File System (AWS EFS) for your NFS storage.
- Ensure that the user running Cribl Stream has read/write access to the mount point.
- Configure the EFS **Throughput mode** to `Enhanced` > `Elastic`.
- For details on NFS mount options, see Recommended NFS mount options.

For best performance, place your Leader Nodes in the same geographic region as the NFS storage. If the Leader and NFS are distant from each other, you might run into the following issues:

- Latency in UI and/or API access.
- Missing metrics between Leader restarts.
- Slower performance on data Collectors.

Set the primary Leader's **Resiliency** drop-down to `Failover`.

Configure Additional Leader Nodes

You can configure additional Leader Nodes in the following ways. These configuration options are similar to configuring the primary Leader Node:

- Using the UI
- Updating the YAML config file
- Using the Command Line
- Using Environment Variables

Remember, the `$CRIBL_VOLUME_DIR` environment variable overrides `$CRIBL_HOME`.

How Cribl Stream Manages Leader Settings

When you first configure a Leader for failover, Cribl Stream will create a new `leader.yml` file in the local `$CRIBL_HOME/local/cribl` directory and will upload it to the failover volume. Configuration stored in the `leader.yml` file on the failover volume will take precedence over what is stored in the local `instance.yml` file.

The `leader.yml` file replicates most of the content of the local `instance.yml`, but leaves out the failover configuration.

While running in failover mode, when you change **Settings** > **Distributed Settings** via the UI, Cribl Stream applies those changes to `leader.yml` in the failover directory.

Use the UI

1. In **Settings** > **Global** > **Distributed Settings** > **General Settings**, select **Mode**: `Leader`.
2. Next, on the **Leader Settings** left tab, select **Resiliency**: `Failover`. This exposes several additional fields.
3. In the **Failover volume** field, enter the NFS directory to support Leader failover. This directory must be outside of `$CRIBL_HOME`. One valid solution is to use `CRIBL_DIST_MASTER_FAILOVER_VOLUME=<shared_dir>`. See Using Environment Variables for more information.
4. Optionally, adjust the **Lease refresh period** from its default `5s`. This setting determines how often the primary Leader tries to refresh its hold on the Lease file.
5. Optionally, adjust the **Missed refresh limit** from its default `3`. This setting determines how many Lease refresh periods elapse before standby Nodes attempt to promote themselves to primary.
6. Select **Save** to restart.

In Cribl Stream 4.0.3 and later, when you save the **Resiliency**: `Failover` setting, further **Distributed Settings** changes via the UI will be locked on both the primary and backup Leader. (This prevents errors in bootstrapping Workers due to incomplete token synchronization between the two leaders.) However, you can still update each Leader's distributed settings by modifying its configuration files, as covered in the very next section.

Use the YAML Config File

In `$CRIBL_HOME/local/_system/instance.yml`, under the `distributed` section:

1. Set `resiliency` to `failover`.
2. Specify a volume for the NFS disk to automatically add to the Leader Failover cluster.

$CRIBL_HOME/local/_system/instance.yml

```
distributed:
  mode: master
  master:
    host: <IP or 0.0.0.0>
    port: 4200
    resiliency: failover
    failover:
      volume: /path/to/nfs
```

Note that `instance.yml` configs are local, not on the shared NFS volume.

Use the Command Line

You can configure another Leader Node using a CLI command of this form:

```
./cribl mode-master -r failover -v /tmp/shared
```

For all options, see the CLI Reference.

Use Environment Variables

You can configure additional Leader Nodes via the following environment variables:

- `CRIBL_DIST_MASTER_RESILIENCY=failover`: Sets the Leader's `Resiliency` to `Failover` mode.
- `CRIBL_DIST_MASTER_FAILOVER_VOLUME=<shared_dir>`: Sets the location of the NFS directory to support Leader failover – for example, `/mnt/cribl`.
- `CRIBL_DIST_MASTER_FAILOVER_MISSED_HB_LIMIT`: Determines how many Lease refresh periods elapse before standby Nodes attempt to promote themselves to primary. Cribl recommends setting this to `3`.
- `CRIBL_DIST_MASTER_FAILOVER_PERIOD`: Determines how often the primary Leader refreshes its hold on the Lease file. Cribl recommends setting this to `5s`.

For further variables, see Environment Variables.

Monitor the Leader Nodes

To view the status of your Leader Nodes, select **Monitoring** > **System** > **Leaders**.

Monitoring Leader Nodes

Upgrade

When upgrading:

1. Stop all Leaders.
2. Upgrade the primary Leader for your Stream or Edge deployment.
3. Upgrade standby Leaders.
4. Start each Leader again, one by one.
5. Upgrade each Worker Node, respectively.

Disable a Standby Leader

Cribl recommends that you maintain a standby Leader to ensure continuity in your on-premises distributed environment. Should you decide to disable it, contact support to assist you.

3.2.10. Converting A Single Instance To Distributed Deployment

If you've configured a Cribl Stream Single-instance deployment and now want to promote it to Distributed, here are a couple of approaches to doing so, while retaining the configuration you've already created.

Simple Copy

We'll start with the simplest scenario, in which you plan to set up distributed mode with a single Worker Group. By default, this group will literally be named `default`. (We'll also explain how to extend this scenario.)

1. If you haven't already installed `git` (required for the Leader), do so as outlined here.
2. Stop the Cribl Stream server (`./cribl stop`).
3. Your single instance's configs are under Cribl Stream's `local/` subdirectory. So, copy `$CRIBL_HOME/local/cribl/*` to `$CRIBL_HOME/groups/default/local/cribl/`. This stages your configs for the `default` Worker Group.
4. Restart Cribl Stream, selecting **Distributed Mode**: `Leader`.
5. At this point, the Leader should have inherited your previous single-instance settings. Commit and deploy these settings to the `default` group, which should resume the same data processing that your single instance was executing.
6. If you want to replicate the same configs to additional Worker Groups, add those groups now on the **Worker Groups** page. Then repeat the preceding four steps, targeting the new subdirectories that have been created on the filesystem for the new groups.

Creating multiple Worker Groups requires certain license tiers. For details, see Pricing.

rsync

This alternative approach uses `rsync` to replicate your single-instance configs.

1. Use this command to rsync your single-instance configuration to each of your distributed Groups (replacing the `<group-name>` placeholder here):

```
rsync -a $cribl/local/cribl newmaster:$cribl/groups/<group-name>/local/
```

2. Restart Cribl Stream, selecting **Distributed Mode**: `Leader`.

3. Commit and deploy the new configuration.

3.3. Orchestrated Deployment

3.3.1. Kubernetes/Helm Deployment

Boot fully provisioned Leader and Worker Nodes via Helm

Cribl's leader and workergroup Helm charts provide a fast way to deploy a distributed Cribl Stream environment to a Kubernetes cluster.

For up-to-date details on Prerequisites, Deploying, Upgrading, and running distributed on a Free License, see the Cribl Helm Charts repo's Readme.

K8s Leader Deployment

The rest of this page outlines how to deploy a Cribl Stream Leader Node (or Single instance) to AWS via Kubernetes, using a Cribl-provided Leader Helm chart.

This chart is a work in progress, provided as-is. Cribl expects to further develop and refine it.

Cribl recommends deploying the Leader on stable, highly available infrastructure, because of its role in coordinating all Worker instances.

Deprecation Notice

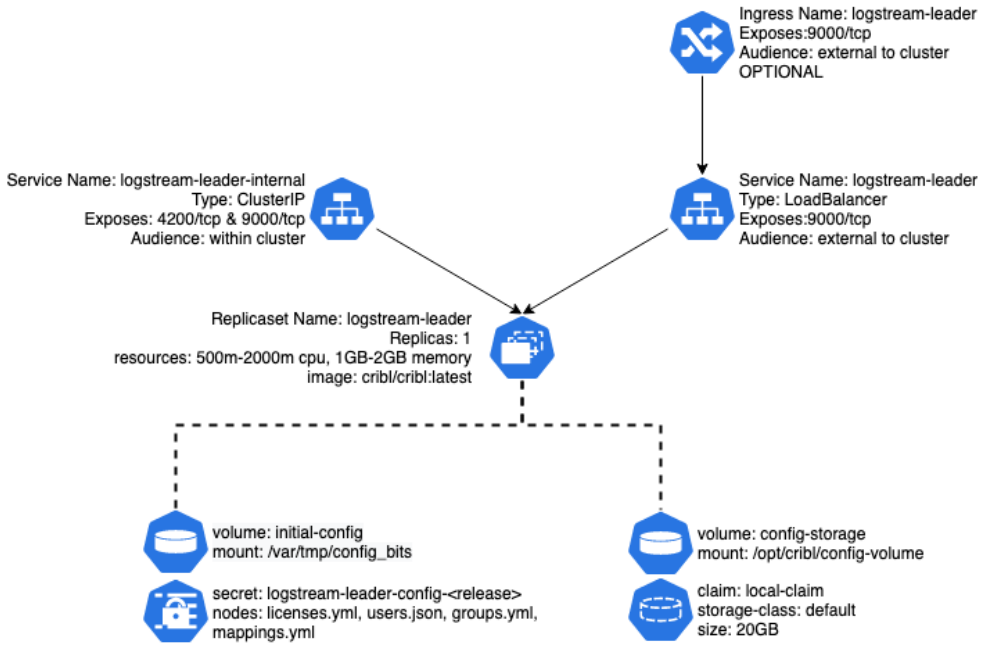
This chart replaces the `logstream-master` chart, which was deprecated as of v.2.9.9. See Migration below for instructions on migrating to this new chart to access features newly provided in this and future versions.

New Capabilities

- Supports Cribl Stream v.4.3.1.

Deployment

As built, Cribl's chart will deploy a Cribl Stream Leader server for Cribl Stream, consisting of a deployment, two services, and a number of persistent volumes.



Deployment schematic

Note that this chart creates two load-balanced services:

- The main one (named after the Helm release), which is intended as the primary service interface for users.
- The "internal" one (named `<helm-release>-internal`), which is intended for the worker-group-to-leader communication.

By default, this chart installs only a Cribl Stream Leader Node. To also deploy Cribl Stream Worker Groups/Fleets via Helm, you can use the Set Up Worker Groups/Mappings override described below.

You can also use Cribl's separate logstream-workergroup chart. For details, see Kubernetes Deployment: Worker Group/Fleet in this documentation.

AWS and Kubernetes Prerequisites

This section covers both general and specific prerequisites, with a bias toward the EKS-oriented approach that Cribl uses for its own deployments.

Set Up AWS CLI

Install the AWS CLI, version 2, following AWS' instructions.

Next, create or modify your `~/.aws/config` file to include (at least) a `[profile]` section with the following SSO (single-sign-on) details:

~/.aws/config

```
[profile <your-profile-name>]
sso_start_url = https://<your-domain>/start#/
sso_region = <your-AWS-SSO-region>
sso_account_id = <your-AWS-SSO-account-ID>
sso_role_name = <your-AWS-role-name>
region = <your-AWS-deployment-region>
```

Set Up kubectl

You will, of course, need `kubectl` set up on your local machine or VM. Follow Kubernetes' installation instructions.

Add a Cluster to Your kubeconfig File

You must modify your `~/.kube/config` file to instruct kubectl what cluster (context) to work with.

1. Run a command of this form: `aws --profile <profile-name> eks update-kubeconfig --name <cluster-name>`
   This should return a response like this: `Added new context arn:aws:eks:us-west-2:424242424242:cluster/<cluster-name> to /Users/<username>/.kube/config`
2. In the resulting `~/.kube/config` file's `args` section, as the new first child, insert the profile argument that you provided to the aws command. For example:

~/.kube/config

```
args:
- --profile=<profile-name>
- --region
[...]
```

3. Also change the `command: aws` pair to include the full path to the `aws` executable. This is usually in `/usr/local/bin`, in which case you'd insert: `command: /usr/local/bin/aws`.

This section of `~/.kube/config` should now look something like this:

```
args:
- --profile=<profile-name>
- --region
- us-west-2
- eks
- get-token
- --cluster-name
- lab
command: /usr/local/bin/aws
env:
- name: AWS_PROFILE
  value: <profile-name>
```

With these AWS and Kubernetes prerequisites completed, you're now set up to run `kubectl` commands against your cluster, as long as you have an active aws SSO login session.

Next, do the Helm setup.

Install Helm and Cribl Repo

1. You'll need Helm (preferably v.3.x) installed. Follow the instructions here.
2. Add Cribl's repo to Helm, using this command: `helm repo add cribl https://criblio.github.io/helm-charts/`

Persistent Storage

The chart requires persistent storage. It will use your default StorageClass, or (if you prefer) you can override `config.scName` with the name of a specific StorageClass to use.

Cribl has tested this chart primarily using AWS EBS storage, via the CSI EBS driver. The volumes are created as `ReadWriteOnce` claims. For details about storage classes, see Kubernetes' Storage Classes documentation.

AWS-Specific Notes

If you're running on EKS, Cribl highly recommends that you use Availability Zone–specific node groups. For details, see eksctl.io's Autoscaling documentation.

Do not allow a single node group to spans AZs. This can lead to trouble in mounting volumes, because EBS volumes are AZ-specific.

See other EKS-Specific Issues on our GitHub repo.

Configure the Chart's Values

You'll want to override some of the chart's default values. The easiest way is to copy this chart's default `values.yaml` file from our repo. save it locally, modify it, and install it in Helm:

1. Copy the **raw** contents of: https://github.com/criblio/helm-charts/blob/master/helm-chart-sources/logstream-leader/values.yaml
2. Save this as a local file, for example: `/bar/values.yaml`
3. Modify values as necessary (see Values to Override in the Helm Charts docs).
4. Install your updated values to Helm, using this command: `helm install -f /bar/values.yaml`

Match Versions

Cribl recommends that you use the same Cribl Stream version on Worker Nodes/Edge Nodes versus the Leader Node. So if, for any reason, you're not yet upgrading your Workers to the version in the Leader's default `values.yaml` > `criblImage.tag`, be sure to override that `criblImage.tag` value to match the version you're running on all Workers.

EKS-Specific Values

If you're deploying to EKS, many annotations are available for the load balancer. Set these as values for the `service.annotations` key. Internally, we typically use the annotations for logging to S3, like this:

values.yaml [excerpt]

```
service.beta.kubernetes.io/aws-load-balancer-access-log-enabled: "true"
service.beta.kubernetes.io/aws-load-balancer-access-log-emit-interval: "5"
service.beta.kubernetes.io/aws-load-balancer-access-log-s3-bucket-name: "<bucket
service.beta.kubernetes.io/aws-load-balancer-access-log-s3-bucket-prefix: "ELB"
```

For an exhaustive list of annotations you can use with AWS's Elastic Load Balancers, see the Kubernetes Service documentation.

Basic Chart Installation

With the above prerequisites and configuration completed, you're ready to install our chart to deploy a Cribl Stream Leader Node. Here are some example commands:

- To install the chart with the release name `logstream-leader`:
  `helm install logstream-leader cribl/logstream-leader`
- To install the chart using the storage class `ebs-sc`:
  `helm install logstream-leader cribl/logstream-leader --set config.scName='ebs-sc'`

Post-Install/Post-Upgrade

Cribl Stream will not automatically deploy changes to the Worker Nodes/Edge Nodes. You'll need to commit and deploy changes to all of your Worker Groups/Fleets.

Change the Configuration

If you don't override its default values, this Helm chart effectively creates a Single-instance deployment of Cribl Stream, using the standard container image. You can later configure Distributed mode, licensing, user passwords, etc., all from the Cribl Stream UI. However, you also have the option to change these configuration details upfront, by installing with value overrides. Here are some common examples.

Apply a License

If you have a Standard or Enterprise license, you can use the `config.license` parameter to add it as an override to your install:

```
helm install logstream-leader cribl/logstream-leader --set config.license="<long encoded license string redacted>"
```

Run Distributed on a Free License

If you do not specify a license with `config.license`, and you want to run Distributed, you'll need to go to Cribl Stream's **Settings** > **Licensing** page and accept the Free license. (The Free license allows one Worker Group/Fleet.)

If your Helm configuration includes the `config.groups` option, the Cribl Stream Leader Node will be configured as a distributed Leader. If you omit that option, it will be configured as a single instance. (You can

later use Cribl Stream's **Settings** > **Distributed Settings** page to select **Mode:** `Leader`.)

Set the Admin Password

Normally, when you first install Cribl Stream and log into the UI, it prompts you to change the default admin password. You can skip the password-change challenge by setting your admin password via the `config.adminPassword` parameter:

```
helm install logstream-leader cribl/logstream-leader --set config.adminPassword="<new password>"
```

Set Up Worker Groups/Mappings

As mentioned above, the chart's default is to install a vanilla deployment of Cribl Stream. If you are deploying as a Leader, you can use the `config.groups` parameter to define the Worker Groups/Fleets you want created and mapped. Each group in the list you provide will be created as a Worker Group/Fleet, with a Mapping Rule to seek a tag with that Worker Group's name in it:

```
helm install logstream-leader cribl/logstream-leader --set config.groups={group1,group2,group3}
```

The example above will create three Worker Groups/Fleets/Fleets – `group1`, `group2`, and `group3` – and a Mapping Rule for each.

Migrate from the logstream-master Chart

Here is how to migrate from the deprecated `logstream-master` chart to `logstream-leader`.

Export Your Configuration

You'll need to "export" your data from the existing `logstream-master` pod. And first, you'll need to get the current pod's name, as well as its namespace. The easiest way to do this is to run `kubectl get pods -A` and then look pods that start with the release name you used when you ran `helm install`. For example, if you installed with the following command:

```
helm install ls-master cribl/logstream-master
```

...you'd look for a pod name that started with `ls-master`.

Once you've identified your pod and namespace, you can export your configuration using a combination of `kubectl` and `tar`:

```
kubectl exec <pod name> -n <namespace> -- bash -c "cd /opt/cribl/config-volume; tar
```

This command executes the tar based back up of the config-volume, and outputs it to a local tar file (`cribl_backup.tar`).

"Re-Hydrate" the Backup on the logstream-leader Chart

Exploding the tarball onto the new persistent volume is a one-time event. Once the config volume is restored, you'll make changes to the config via the Cribl Stream UI or API. Either approach will change the config on disk, which you wouldn't want to overwrite the next time the pod restarts. You can manually re-hydrate the backup by installing the logstream-leader chart, and then running the following command:

```
cat cribl_backup.tar| kubectl -n <namespace> exec --stdin <pod name> -- bash -c "cd /
```

This will restore the data into the config volume (which is mounted as `/opt/cribl/config-volume`). If you want to double-check that, run:

```
kubectl -n <namespace> exec <pod name> -- bash -c "ls -alR /opt/cribl/config-volume"
```

After this, you want to **delete** the active pod, allowing the new one to come up with the restored configuration. To do this, you'd run the following `kubectl` command:

```
kubectl -n <namespace> delete <pod name>
```

This will cause the pod to exit, but the deployment will replace it with a new pod which will use the same config persistent volume.

Reconfigure the Worker Groups/Fleets

Now that you've got a new working leader chart, you need to tell the workers to connect to the new leader instead of to the old `logstream-master` instance. This is a simple `helm upgrade` operation. You'll need to use the same command string that you used to install, changing the word `install` to `upgrade`. But change the value of `config.host` to the new service that was created for the logstream-leader install. (You can

change `config.host` either via the `--set` option or in the `values.yml` file.) For example, if you ran the `logstream-leader` install with the release name `ls-lead`, like this:

```
helm install ls-lead -f <values file> cribl/logstream-leader
```

...you'd run `kubectl get service -n <namespace> | grep ls-lead` to get the two services that it created, and you'll want the name of the one that ends in `-internal`. In this case, that name would be `ls-lead-leader-internal`.

Assume that for your workergroup install, you used a release name of `ls-wg1`, and a values file named `my-values.yml` with the following contents:

```
config:
  host: logstream-master-internal
  group: kubernetes
  token: <token>
  rejectSelfSignedCerts: 0
```

...then you'd replace the `host` value in this file with `ls-lead-leader-internal`, and then run:

```
helm upgrade ls-wg1 -f my-values.yml -n <namespace>
```

The upgrade **should** replace all the existing workergroup pods with newly reconfigured ones. However, if you notice any workergroup pods with an AGE value indicating that it was started before the upgrade command, simply kill those pods, and they will re-spawn with the new configuration.

Preload Configuration

The `extraConfigmapMounts` and `extraSecretMounts` options enable you to preload configuration files into the leader chart, via ConfigMaps and Secrets that you've created in your Kubernetes environment. However, because ConfigMaps and Secret mounts are read-only, you can't simply mount them into the configuration tree.

Therefore, you must mount them to a location outside of the `/opt/cribl` tree, and then copy the files into the tree at startup. This copying can be accomplished using environment variables, as we'll see below.

Both ConfigMaps and Secret mounts can be made writable, but the K8s documentation recommends against this.

Configuration Locations

The chart creates a single configuration volume claim, `config-storage`, which gets mounted as `/opt/cribl/config-volume`. All Worker Group/Fleet configuration lives under the `groups/` subdirectory. If you have a Worker Group/Fleet named `datacenter_a`, its configuration will live in `/opt/cribl/config-volume/groups/datacenter_a`. See Configuration Files section for details on file locations.

Use Environment Variables to Copy Files

The cribl container's `entrypoint.sh` file looks for up to 30 environment variables assumed to be shell-script snippets to execute before Cribl Stream startup (`CRIBL_BEFORE_START_CMD_[1-30]`). It also looks for up to 30 environment variables to execute after Cribl Stream startup (`CRIBL_AFTER_START_CMD_[1-30]`).

The variables in each set need to be in order, and cannot skip a number. (The `entrypoint.sh` script breaks the loop the first time it doesn't find an env var, so if you have `CRIBL_BEFORE_START_CMD_1` skipping to `CRIBL_BEFORE_START_CMD_3`, then `CRIBL_BEFORE_START_CMD_3` will not be executed.)

The chart uses this capability to inject the license and to set up groups. We'll use this same capability to copy our config files into place. So if you've provided the `config.license` and `config.groups` variables (occupying the first two slots), you'll need to start with `CRIBL_BEFORE_START_CMD_3`. In the examples below, we'll start with `CRIBL_BEFORE_START_CMD_3`, assuming that a `config.license` and `config.groups` have been set.

Figure Out Which Variable to Use

The easiest way to figure out which environment variable you need to use is to deploy the chart with all the options you plan to use (that is, to use the `helm install` command with options that you plan to use for your deployment). Then check the pod definition for `CRIBL_*` environment variables. For example, if you used the following install command:

```
% helm install lsms -f ../leader-values.yaml -n logstream-ht cribl/logstream-leader
```

You can now get the pod's name:

```
% kubectl get pods -n logstream-ht
NAME                                    READY   STATUS    RESTARTS   AGE
lsms-leader-659bfccdd6-xsz67            1/1     Running   0          52m
```

And then you can use `kubectl describe` to get the relevant environment variables:

```
% kubectl describe  pod/lsms-leader-659bfccdd6-xsz67 -n logstream-ht  | egrep "CRIBL_
CRIBL_BEFORE_START_CMD_1:      if [ ! -e $CRIBL_VOLUME_DIR/local/cribl/licenses.yml
CRIBL_BEFORE_START_CMD_2:      if [ ! -e $CRIBL_VOLUME_DIR/local/cribl/mappings.yml
CRIBL_AFTER_START_CMD_1:       [ ! -f $CRIBL_VOLUME_DIR/users_imported ] && sleep 20
```

From that, you can tell that we already have a `CRIBL_BEFORE_START_CMD_1` and `CRIBL_BEFORE_START_CMD_2`, so our next logical variable should be `CRIBL_BEFORE_START_CMD_3`.

Preload Scenario

Here's a preload scenario that includes a sample ConfigMap, `extraConfigmapMounts`, copy command, and copy-once flag.

The ConfigMap

Let's say we want to preconfigure a collector job in the `group1` Worker Group. The job will be called `InfrastructureLogs`, and it will read ELB logs from an S3 bucket. First, we'll need a `jobs.yml` file, like this:

```
InfrastructureLogs:
  type: collection
  ttl: 4h
  removeFields: []
  resumeOnBoot: false
  schedule: {}
  collector:
    conf:
      signatureVersion: v4
      enableAssumeRole: true
      recurse: true
      maxBatchSize: 10
      bucket: <my infrastructure logs bucket>
      path: /ELB/AWSLogs/${aws_acct_id}/elasticloadbalancing/${aws_region}/${_time:%
      region: us-west-2
      assumeRoleArn: arn:aws:iam::<accountid>:role/LogReadAssume
    destructive: false
    type: s3
  input:
    type: collection
    staleChannelFlushMs: 10000
    sendToRoutes: false
    preprocess:
      disabled: true
    throttleRatePerSec: "0"
    breakerRulesets:
      - AWS Ruleset
    pipeline: devnull
    output: devnull
```

We'll need this loaded into a ConfigMap object, so we'd run kubectl to create a ConfigMap from the directory where our `jobs.yml` file resides:

```
kubectl create configmap job-config --from-file <containing directory> -n <deployment namespace>
```

So if that file is in a directory called `./config-dir`, and we're deploying the leader chart into the `logstream` namespace, we'd create it like this:

```
kubectl create configmap job-config --from-file ./config-dir -n logstream
```

extraConfigmapMounts Config

In our `values.yaml` file, we need to specify the ConfigMap and where to mount it:

```
extraConfigmapMounts:
  - name: job-config
    configMap: job-config
    mountPath: /var/tmp/job-config
```

This example will mount the files in the ConfigMap into the pod's `/var/tmp/job-config` directory.

Copy the Config Files

You could simply define, in the `values.yaml` file (or via `--set`):

```
env:
  CRIBL_BEFORE_START_CMD_3: "cp /var/tmp/job-config /opt/cribl/config-volume/groups/
```

However, there are two potential problems with that:

1. There is no guarantee that the destination directory tree will be there. (The first time a pod spins up, it won't be.)
2. If the pod has crashed and spun up anew, blindly copying will overwrite any changes previously made. This is rarely desirable behavior.

File Copying Pattern

Since we might want to copy multiple configuration files in one shot, it makes sense to use some sort of "flag file" to ensure that we copy the files only once. The script snippet to copy the `jobs.yaml` file looks like this, formatted for readability:

```
FLAG_FILE=/opt/cribl/config-volume/job-flag
if [ ! -e $FLAG_FILE ]; then
  mkdir -p /opt/cribl/config-volume/groups/group1/local/cribl # ensure the directory
  cp /var/tmp/job-config/jobs.yml /opt/cribl/config-volume/groups/group1/local/cribl
  touch $FLAG_FILE
fi
```

This looks to see if the file `/opt/cribl/config-volume/job-flag` exists, and if it doesn't, creates the directory tree, copies the config file(s), and then creates the job flag file. However, we need to format it a little differently to easily encompass it in the `env` variable:

```
env:
  CRIBL_BEFORE_START_CMD_3: "FLAG_FILE=/opt/cribl/config-volume/job-flag; if [ ! -e
```

Once you run `helm install` with this in the `values.yaml` file, you can do `kubectl exec` on the pod to execute a shell:

```
kubectl exec -it <pod name> -- bash
```

...and then look at `/opt/cribl/config-volume/groups/group1/local/cribl/jobs.yml` to verify that it is in place.

Uninstall the Infrastructure

To spin down deployed pods, use the helm uninstall command – where `<release-name>` is the namespace you assigned when you installed the chart:

```
helm uninstall <release-name>
```

You can append the `--dry-run` flag to verify which releases will be uninstalled before actually uninstalling them:

```
helm uninstall <release-name> --dry-run
```

Known Issues

- Cribl's current architecture supports **only** TCP ports in Worker Groups'/Fleets' `service > ports` configuration. This restriction might be removed in future versions.
- The upgrade process from pre-2.4.0 versions creates an `initContainer`, which will run prior to any instance of the Cribl Stream pod. Because the coalescence operation will not overwrite existing data, this is not a functional problem. But depending on your persistent-volume setup, the `initContainer`'s precedence might cause pod restarts to take additional time while waiting for the volume claims to release. The only upgrade path that will have this issue is 2.3.* -> 2.4.0. In the next iteration, we'll remove the `initContainer` from the upgrade path.
- The upgrade process leaves the old `PersistentVolumes` and `PersistentVolumeClaims` around. This is, unfortunately, necessary for this upgrade path. In follow-on versions, we will remove these volumes from the chart.
- See EKS-specific issues on our GitHub repo.

3.3.2. Kubernetes Worker Deployment

Boot a fully provisioned Worker Group via Helm.

This page outlines how to deploy a Cribl Stream Worker Group to AWS via Kubernetes, using a Cribl-provided Helm chart.

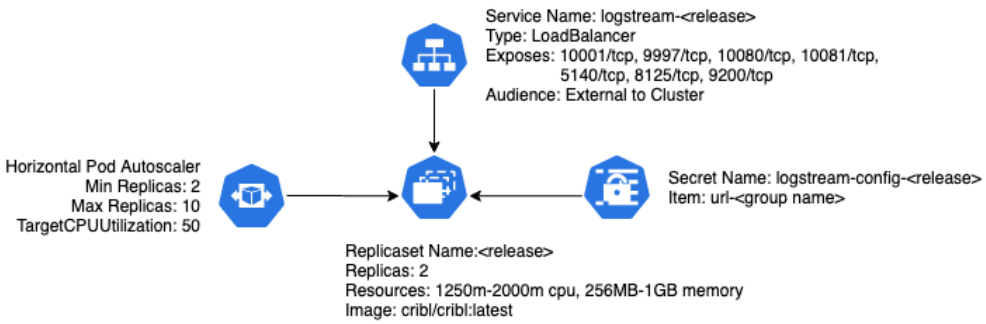
This chart will deploy only a Cribl Stream Worker Group, whose functioning depends on the presence of a Cribl Stream Leader Node. To deploy the Leader, see Kubernetes Leader Deployment.

New Capabilities

- Supports Cribl Stream v.4.3.1.

Deployment

As built, Cribl's chart will deploy a simple Worker Group for Cribl Stream, consisting of a deployment, a service, a horizontal pod autoscaler configuration, and a secret used for configuration.



Deployment schematic

AWS and Kubernetes Prerequisites

This section covers both general and specific prerequisites, with a bias toward the EKS-oriented approach that Cribl uses for its own deployments.

Set Up AWS CLI

Install the AWS CLI, version 2, following AWS' instructions.

Next, create or modify your `~/.aws/config` file to include (at least) a `[profile]` section with the following SSO (single-sign-on) details:

~/.aws/config

```
[profile <your-profile-name>]
sso_start_url = https://<your-domain>/start#/
sso_region = <your-AWS-SSO-region>
sso_account_id = <your-AWS-SSO-account-ID>
sso_role_name = <your-AWS-role-name>
region = <your-AWS-deployment-region>
```

Set Up `kubectl`

You will, of course, need `kubectl` set up on your local machine or VM. Follow Kubernetes' installation instructions.

Add a Cluster to Your `kubeconfig` File

You must modify your `~/.kube/config` file to instruct `kubectl` what cluster (context) to work with.

1. Run a command using this format: `aws --profile <profile-name> eks update-kubeconfig --name <cluster-name>`
   This should return a response like this: `Added new context arn:aws:eks:us-west-2:424242424242:cluster/<cluster-name> to /Users/<username>/.kube/config`
2. In the resulting `~/.kube/config` file's `args` section, as the new first child, insert the profile argument that you provided to the `aws` command. For example:

/.kube/config

```
args:
- --profile=<profile-name>
- --region
[...]
```

3. Also change the `command: aws` pair to include the full path to the `aws` executable. This is usually in `/usr/local/bin`, in which case you'd insert: `command: /usr/local/bin/aws`.

This section of `~/.kube/config` should now look something like this:

```
      args:
      - --profile=<profile-name>
      - --region
      - us-west-2
      - eks
      - get-token
      - --cluster-name
      - lab
      command: /usr/local/bin/aws
      env:
      - name: AWS_PROFILE
        value: <profile-name>
```

With these AWS and Kubernetes prerequisites completed, you're now set up to run `kubectl` commands against your cluster, as long as you have an active aws SSO login session.

Next, install Helm and the Cribl repository.

Install Helm and Cribl Repo

1. You'll need Helm (preferably v.3.x) installed. Follow the instructions here.
2. Add Cribl's repo to Helm, using this command: `helm repo add cribl https://criblio.github.io/helm-charts/`
3. Display the default values available to configure Cribl's `logstream-workergroup` chart: `helm show values cribl/logstream-workergroup`

Configure the Chart's Values

You'll want to override some of the values you've just displayed. The easiest way is to copy this chart's default `values.yaml` file from our repo. save it locally, modify it, and install it in Helm:

1. Copy the **raw** contents of: https://github.com/criblio/helm-charts/blob/master/helm-chart-sources/logstream-workergroup/values.yaml
2. Save this as a local file, for example: `/foo/values.yaml`
3. Modify values as necessary (see Values to Override in the Cribl Helm Charts docs). To see the full scope of values available, run: `helm show values cribl/logstream-workergroup`.

4. Install your updated values to Helm, using this command: `helm install -f /foo/values.yaml`

Match Versions

Cribl recommends that you use the same Cribl Stream version on Leader Nodes versus Worker Group/Fleet Nodes. So, if you're not yet upgrading your Leader to the version in the current `values.yaml` > `criblImage.tag`, be sure to override that `criblImage.tag` value to match the version you're running on the Leader.

Set Worker Processes Statically

For all container-based Worker Groups, Cribl recommends that you directly specify the Worker **Process count** using a positive integer (like `+3`). This convention prevents the overprovisioning of Worker Processes that can occur with dynamic values (like the default `-2` setting).

To access **Process count** in Stream, from a Worker group select **Group Settings** > **System** > **Worker Processes** (Distributed deployments) or **Settings** > **System** > **Service Processes** (Single-instance deployments).

Set a Maximum Number of Worker Processes

To provision a Kubernetes container with a specific number of Worker Processes, use the `CRIBL_MAX_WORKERS` environment variable. Setting a maximum amount of Worker Processes on a Kubernetes node helps to prevent overloading the node with more CPUs than it can handle.

See Sizing and Scaling for more information on this environment variable and example configurations.

Install the Chart

With the above prerequisites and configuration completed, you're ready to install our chart to deploy a Cribl Stream Worker Group/Fleet. Here are some example commands:

- To install the chart with the release name `logstream-wg`:
  `helm install logstream-wg cribl/logstream-workergroup`
- To install the chart using the Cribl Stream Leader `logstream.lab.cribl.io`:
  `helm install logstream-wg cribl/logstream-workergroup --set config.host='logstream.lab.cribl.io`
- To install the chart using the Cribl Stream Leader `logstream.lab.cribl.io` in the namespace `cribl-helm`:
  `helm install logstream-wg cribl/logstream-workergroup --set config.host='logstream.lab.cribl.io' -n cribl-helm`

Upgrade

You upgrade using the `helm upgrade` command. But it's important to ensure that your Helm repository cache is up to date, so first issue this command:

```
helm repo update
```

After this step, invoke:

```
helm upgrade <release> -n <namespace> cribl/logstream-workergroup
```

For the example above, where the release is `logstream-wg` and is installed in the `cribl-helm` namespace, the command would be:

```
helm upgrade logstream-wg -n cribl-helm cribl/logstream-workergroup
```

This Helm chart's upgrade is idempotent, so you can use the upgrade mechanism to upgrade the chart, but you can also use it to change its configuration (as outlined in Change the Configuration).

Optional: Kubernetes API Access

Versions 2.4.0+ include access mechanisms for Worker Groups to access the Kubernetes API.
The `values.yaml` file provides three relevant options:

- `rbac.create` – Enables the creation of a Service Account, Cluster Role, and Role Binding (which binds the first two together) for the release.
- `rbac.resources` – Specifies the Kubernetes API resources that will be available to the release.
- `rbac.verbs` – Specifies the API verbs that will be available to the release.
- `rbac.extraRules` – Additional rulesets for the cluster role.

For more information on the verbs and resources available, see Kubernetes' Using RBAC Authorization documentation.

Change the Configuration

Once you've installed a release, you can get its `values.yaml` file by using the `helm get values` command. For example, assuming a release name of `logstream-wg`, you could use this command:

```
helm get values logstream-wg -o yaml > values.yaml
```

This will retrieve a local `values.yaml` file containing the values in the running release, including any values that you overrode when you installed the release.

You can now make changes to this local `values.yaml` file, and then use the `helm upgrade` operation to "upgrade" the release with the new configuration.

For example, assume you wanted to add an additional TCP-based syslog port, listening on port 5141, to the existing `logstream-wg` release. In the `values.yaml` file's `service` > `ports` section, you'd add the three key-value pairs shown below:

values.yaml (excerpt)

```
service:
  [...]

  ports:
  [...]
  - name: syslog
    port: 5141
    protocol: TCP
```

Then you'd run:

```
helm upgrade logstream-wg cribl/logstream-workergroup -f values.yaml
```

Remember, if you installed in a namespace, you need to include the `-n <namespace>` option to any `helm` command. You'll still have to create the source in your Cribl Stream Leader, and commit and deploy it to your Worker Group/Fleet.

Use Persistent Storage for Persistent Queueing

The `extraVolumeMounts` option makes it feasible to use persistent volumes for Cribl Stream persistent queueing. However, Cribl does not recommend this combination – there is variability in persistent-storage implementations, and this variability can lead to problems in scaling Worker Groups/Fleets. However, if you choose to implement persistent volumes for queueing, please consider these suggestions:

1. Use a shared-storage-volume mechanism. We've worked with the EFS CSI driver for AWS, and it works fairly well (although it can be tedious to configure).
2. Understand your Kubernetes networking topology, and how that topology interacts with your persistent-storage driver. (For example, if you're on AWS, ensure that your volumes are available in all Availability Zones that your nodes might run in.)
3. Monitor the Worker Group/Fleet pods for volume issues. The faster you can see such issues and react, the more likely that you'll be able to resolve thema.

Uninstall the Infrastructure

To spin down deployed pods, use the helm uninstall command – where `<release-name>` is the namespace you assigned when you installed the chart:

```
helm uninstall <release-name>
```

You can append the `--dry-run` flag to verify which releases will be uninstalled before actually uninstalling them:

```
helm uninstall <release-name> --dry-run
```

Notes on This Example

- If you installed in a namespace, you'll need to include the `-n <namespace>` option in any `helm` command.
- In the above syslog example, you'd still need to configure a corresponding syslog Source in your Cribl Stream Leader, and then commit and deploy it to your Worker Group(s)/Fleet(s).

Known Issues

- The chart currently supports **only** TCP ports in `service` > `ports` for Worker Groups/Fleets. This limitation might be removed in future versions.
- See EKS-specific issues on our GitHub repo.

3.3.3. Considerations For Cribl Stream On Kubernetes

Kubernetes can be a powerful platform for deploying Cribl Stream, offering scalability and flexibility. However, there are specific use cases where Kubernetes might not be the optimal choice. This guide will explore the factors to consider when deciding whether Kubernetes is the right fit for your Cribl Stream deployment. We'll also discuss workarounds and best practices to ensure a smooth integration.

Understanding the Challenges of Dynamic Workloads and HP Autoscaling

To maximize the benefits of Cribl Stream's integration with Kubernetes, it's essential to understand its optimal use cases and potential limitations.

Optimal Use Cases

Cribl Stream, when deployed on Kubernetes, excels at handling pull-based Sources, where data is readily available for collection. This is because Kubernetes's containerized environment and dynamic scaling capabilities align well with data Sources where collection is on demand or scheduled.

By actively pulling data from Sources like Collector Sources, Cribl Stream running on Kubernetes ensures timely data ingestion, and minimizes the risk of data loss. This proactive approach also enables Cribl Stream to handle a large number of Sources efficiently, making it ideal for environments with many log files or syslog servers.

Less-Ideal Use Cases

Cribl Stream Workers running on Kubernetes can effectively handle data streams from push-based Sources, provided they are provisioned appropriately with fixed resources and sufficient overhead to accommodate average and peak data volumes. However, challenges can arise when dealing with senders that experience frequent, significant fluctuations in data volume, especially when using auto-scaling with scale-in policies.

Kubernetes environments, with their dynamic scaling capabilities, can be powerful tools to accommodate these fluctuations. However, the ephemeral nature of Kubernetes pods, particularly when managed by Horizontal Pod Autoscaler (HPA), can introduce complexities. HPA automatically scales the number of pods based on defined metrics, such as CPU utilization. While this is beneficial for resource optimization, it can lead to unexpected behavior in certain scenarios.

When a sudden spike in data volume occurs, HPA may scale up by creating new pods to handle the increased load. However, if the traffic spike is short-lived, these newly created pods may be terminated prematurely to conserve resources. This can disrupt ongoing data processing tasks, leading to data loss or processing delays.

Additionally, the constant creation and destruction of pods can introduce latency and overhead, impacting overall system performance.

Consider the following when deploying Cribl Stream within Kubernetes environments.

General Kubernetes Best Practices

When managing large Cribl deployments within Kubernetes, it's essential to be aware of potential limitations inherent to large Kubernetes clusters. To ensure optimal performance and stability, consider the best practices outlined in the Kubernetes documentation. These guidelines address critical aspects like resource management, network configuration, and monitoring, which become increasingly important as your Kubernetes environment scales.

Tuning Cribl for Kubernetes

Cribl Stream leverages Worker Processes to efficiently handle data ingestion and processing tasks. By configuring the maximum number of Worker Processes per pod, you can optimize resource allocation and prevent overloading.

Kubernetes containers use resource limits that map to shares of the CPU and Memory. Although a Kubernetes container has visibility of the entire host CPU, it can only use the resources allocated to the pod based on the configured limits. For details, see Resource Management for Pods and Containers.

To ensure optimal performance and avoid overloading your Kubernetes pods, consider the following:

- **Set the Maximum Worker Processes:**
  Use the `--set env.CRIBL_MAX_WORKERS=NUMBER_WORKER_PROCESSES` configuration setting to specify the maximum number of Worker Processes per pod. While Cribl cannot directly determine the number of CPUs within a container, this setting allows you to increase the maximum number of Worker Processes, helping to optimize resource allocation and avoid excessive load. This setting helps balance resource utilization and prevent excessive load on individual pods.
- **Determine the Optimal Worker Process Count:**
  - **Self-Hosted Environments:** Calculate the available CPU cores on your host nodes and set the Worker Process count accordingly. To avoid overloading your nodes, it's recommended to deploy a limited number of Cribl Stream pods per node. A 1:1 mapping, where each node hosts a single Cribl Stream pod, is often a good starting point. For details, see Sizing and Scaling.
  - **Cloud Environments:** Refer to your cloud provider's instance type specifications or leverage auto-scaling mechanisms like HPA to dynamically adjust the number of pods based on demand.

Persistent Queue Considerations for Kubernetes Deployments

Persistent queuing in Cribl Stream on Kubernetes requires careful consideration of autoscaling and storage performance.

Autoscaling

To ensure data durability and prevent unexpected data loss, it's crucial to carefully manage autoscaling when using persistent queues in Cribl Stream on Kubernetes.

- **Avoid Automatic Scale-In:** Disable automatic scale-in or limit it to manual intervention. This prevents unexpected pod terminations, which can lead to data loss.
- **`StatefulSet` Deployment:** Use the `StatefulSet` deployment mode of the Worker Group chart. `StatefulSet` ensures that pods are assigned to specific volumes, maintaining data consistency.

Storage Performance

To ensure optimal performance and data integrity, use high-performance storage for persistent queues in Cribl Stream on Kubernetes.

High-Performance Storage: Use Elastic Block Store (EBS block) storage for the `CRIBL\_VOLUME\_DIR`. EBS storage is resilient and has minimal risk of data loss or corruption. EBS volumes can be moved to a new Kubernetes host (in the same Availability Zone (AZ)) in the event of a host failure or termination.

Avoid Shared Storage: While shared storage solutions like Elastic File System (EFS) can be flexible, they may not provide the necessary performance for persistent queuing. EBS volumes, while less flexible, offer better performance and reliability.

Additional Considerations

- **Volume Mount Configuration:** Ensure `CRIBL\_VOLUME\_DIR` is set, and set to the mount point of the PVC defined in the volumeClaimTemplates configuration. Enabling `CRIBL\_VOLUME\_DIR` ensures that the worker GUID is consistent on each startup.
- **Monitoring:** Continuously monitor PQ usage, including storage utilization and performance metrics, to identify potential bottlenecks.
- **`ExtraVolumeMounts`:** While the Kubernetes `extraVolumeMounts` option allows for persistent volume usage, Cribl doesn't recommend it due to potential issues arising from variations in persistent storage implementations. Additionally, `extraVolumeMounts` is a requirement for non-root Kubernetes environments like Anthos and OpenShift, which can make the setup more complex.

General Reminders

- **Start small:** Begin with a small-scale deployment and gradually scale up as needed. This allows you to fine-tune your configuration and identify any potential bottlenecks.
- **Monitor performance:** Closely monitor the performance of your Cribl Stream deployment, including CPU usage, memory usage, and network traffic.
- **Test thoroughly:** Conduct thorough testing in a controlled environment to validate the performance and scalability of your Cribl Stream deployment.

3.4. Docker Deployment

You can use the following `docker-compose.yml` to stand up a Cribl Stream distributed deployment of a Leader and one or more Workers:

docker-compose.yml

```
services:
  master:
    image: cribl/cribl:latest
    environment:
      - CRIBL_DIST_MODE=master
      - CRIBL_DIST_MASTER_URL=tcp://${CRIBL_DIST_TOKEN:-criblmaster}@0.0.0.0:4200
      - CRIBL_VOLUME_DIR=/opt/cribl/config-volume
    ports:
      - "19000:9000"
    volumes:
      - "~/cribl-config:/opt/cribl/config-volume"
  workers:
    image: cribl/cribl:latest
    depends_on:
      - master
    environment:
      - CRIBL_DIST_MODE=worker
      - CRIBL_DIST_MASTER_URL=tcp://${CRIBL_DIST_TOKEN:-criblmaster}@master:4200
    ports:
      - 9000
```

When you run the `docker compose` command, the `~/cribl-config` local directory is created automatically for use as a persistent configuration store for Cribl Stream.

If you prefer to use ephemeral storage, simply delete line 8 (the `CRIBL_VOLUME_DIR` definition) and lines 11–12 (the `volumes` configuration) before running the `docker-compose` command.

Cribl recommends deploying the Leader on stable, highly available infrastructure, because of its role in coordinating all Worker instances.

Running as a Non-Root User

You can run the Cribl image as a non-root user within a container using Docker's `--user` option or the user setting in Compose. You can specify any desired `UID` (User ID).

To ensure correct functionality, you must set the `CRIBL_VOLUME_DIR` environment variable to a location the non-root user can write to. This is because the software requires write permissions to directories like `/opt/cribl/state`, `/opt/cribl/log`, and `/opt/cribl/local`. Failure to set `CRIBL_VOLUME_DIR` will result in a warning and potential functional issues.

If you mount a persistent volume, setting `CRIBL_VOLUME_DIR` to the mount point is strongly recommended for optimal performance and reliability. While `/tmp/cribl_data` might be used, a dedicated persistent volume ensures data integrity and prevents potential data loss or corruption.

We recommend specifying `CRIBL_VOLUME_DIR` whenever running as a non-root user to avoid unexpected behavior.

See example below:

docker-compose.yml

```
services:
  master:
    image: cribl/cribl:latest
    user: 999:999
    environment:
      - CRIBL_DIST_MODE=master
      - CRIBL_DIST_MASTER_URL=tcp://${CRIBL_DIST_TOKEN:-criblmaster}@0.0.0.0:4200
      - CRIBL_VOLUME_DIR=/opt/cribl/config-volume
    ports:
      - "19000:9000"
    volumes:
      - "~/cribl-config:/opt/cribl/config-volume"
  workers:
    image: cribl/cribl:latest
    user: 999:999
    depends_on:
      - master
    environment:
      - CRIBL_DIST_MODE=worker
      - CRIBL_DIST_MASTER_URL=tcp://${CRIBL_DIST_TOKEN:-criblmaster}@master:4200
      - CRIBL_VOLUME_DIR=/tmp/
    ports:
      - 9000
```

Deploying Hybrid Workers

With a Leader on Cribl.Cloud, encryption is enabled by default. Set the hybrid Worker's `CRIBL_DIST_MASTER_URL` environment variable to begin with the `tls://` protocol. For example:

```
CRIBL_DIST_MASTER_URL=tls://<token>@main-<Organization-name>.cribl.cloud:4200
```

When you include an auth token in `CRIBL_DIST_MASTER_URL` to deploy managed Cribl Stream or Edge Nodes, it can include only alphanumeric characters or the underscore (`_`). Do not include `<`, `>`, `"`, `` ` ``, `\r`, `\n`, `\t`, `{`, `}`, `|`, `\`, `^`, or `'`.

Selecting the Number of Workers

To deploy a Leader Node, plus (e.g.) two Workers already configured and wired up to the Leader, use this command:

```
docker compose up -d --scale workers=2
```

To deploy a different number of Workers, just change the `workers=2` value.

If you are deploying the Leader and Workers on the same machine or VM, and the Leader is crashing with two workers, make sure you are allocating enough memory to Docker.

Default Image, OS, and Port Assignments

By default, the above command pulls the freshest stable image (tagged `cribl/cribl:latest`) from Cribl's Docker Hub. Our Docker images are currently built on Ubuntu 20.04.6.

Launching Docker containers with the above `docker-compose.yml` file will default to the following URLs and ports:

- Leader URL: `http://localhost:19000`
- Worker URLs: `http://localhost:<automatically-assigned-host-ports>`

With virtual machines, the VMs' IP addresses would replace `localhost`. The automatic assignment of available host-OS ports to the Workers prevents port collisions. **Within** the Docker container, these ports will forward over TCP to port 9000. To see the ports assigned on the OS, enter:

```
docker ps
```

You should see results like these:

```
CONTAINER ID   IMAGE                 COMMAND                  CREATED          STATUS
a3de9ea8f46f   cribl/cribl:latest    "/sbin/entrypoint.sh…"   12 seconds ago   Up 10 s
40aa687baefc   cribl/cribl:latest    "/sbin/entrypoint.sh…"   12 seconds ago   Up 10 s
df362a65f7d1   cribl/cribl:latest    "/sbin/entrypoint.sh…"   13 seconds ago   Up 11 s
```

The host-OS ports are shown on the left, forwarding to the container-internal ports on the right. You can use the `docker_workers_N` ports if you want to log directly into Workers. In the above example:

- Worker1 URL: `http://localhost:63411`
- Worker2 URL: `http://localhost:63410`

Adding Port, Forwarding, and Protocol Assignments

To specify additional ports in a distributed deployment, add them to the `docker-compose.yml` file's `workers` > `ports` section:

docker-compose.yml (modified)

```
version: '3.8'
services:
  [...]
  workers:
    image: cribl/cribl:latest
    depends_on:
      - master
    environment:
      - CRIBL_DIST_MODE=worker
      - CRIBL_DIST_MASTER_URL=tcp://${CRIBL_DIST_TOKEN:-criblmaster}@master:4200
    ports:
      - 9000
      - <Additional ports go here>
```

You can specify port forwarding, and TCP versus UDP protocol, in the same keys:

```
    ports:
      - 9000
      - "10060/tcp"
      - "10070/tcp"
```

Updating the Docker Image

Cribl recommends that you always use our latest stable container image wherever possible. This will provide bug fixes and security patches for any vulnerabilities that Cribl has discovered when scanning the base image OS, dependencies, and our own software.

Note that the sample `docker-compose.yml` provided above automatically specifies the latest stable image at:

```
image: cribl/cribl:latest
```

You can explicitly pull the latest stable image with this CLI command:

```
docker pull cribl/cribl:latest
```

Updating the Packaged OS

Cribl strongly recommends that you monitor and patch vulnerabilities in the packaged OS. The base OS might have been updated with fixes for new vulnerabilities discovered after Cribl published its container images. This is especially important if you choose to keep an earlier Cribl image in production.

You can update the base OS image by updating the package, as shown in the following `Dockerfile`.
This example assumes you're updating Cribl's `latest` image:

```
FROM cribl/cribl:latest
RUN apt-get update && \
    apt-get -y upgrade dpkg
```

4. CrowdStream

CrowdStream is a special Cloud-hosted version of Cribl Stream, available through CrowdStrike Falcon LogScale. This collaboration is tailored to forward data from a wide range of sources into LogScale for XDR analysis and log management.

En route, you can process events using all of Cribl Stream's options for aggregating, sampling, redacting, cloning, and otherwise shaping and directing your data. CrowdStream provides parallel options to route data to cost-effective Amazon S3 storage, and to S3 data lakes, for later replay and analysis.

Getting Started

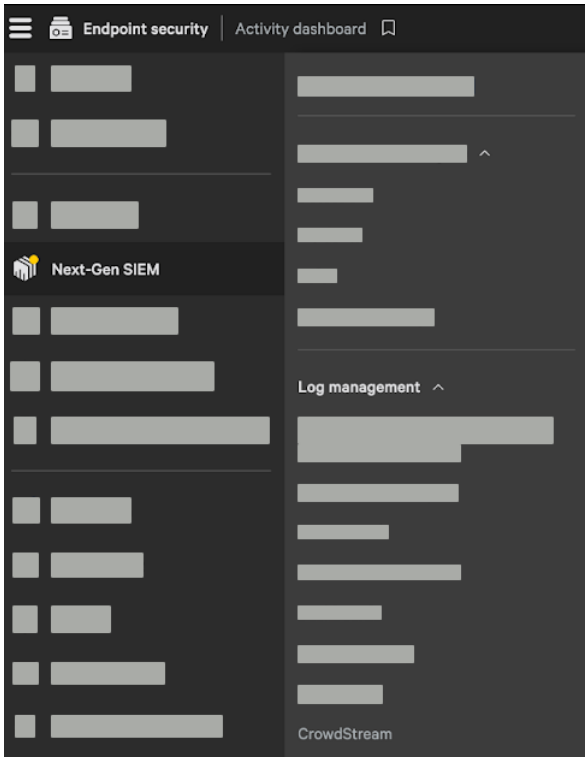
These steps assume that you've set up your CrowdStrike Falcon LogScale account, obtained your corresponding API token.

You can get access to CrowdStream in two ways:

- Through Falcon Next-Gen SIEM interface
- Through Falcon LogScale interface

To log into CrowdStream from Next-Gen SIEM interface:

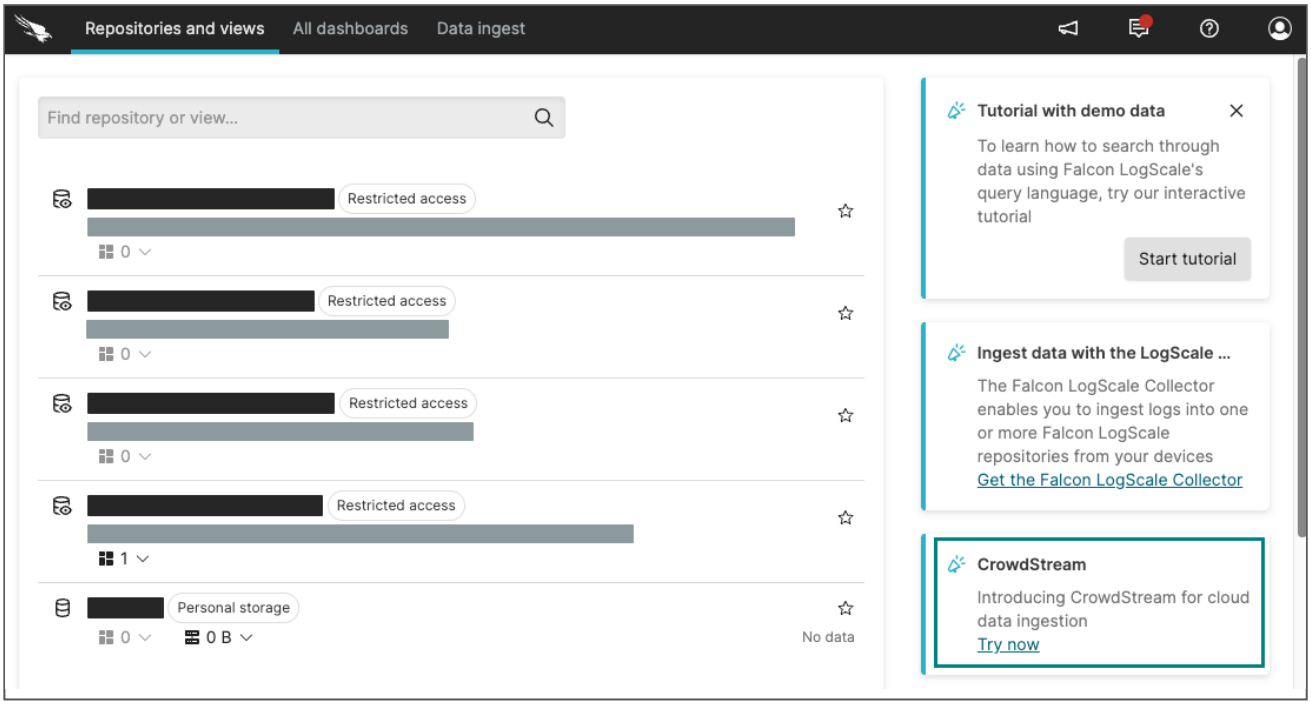
1. In the left menu, select **Next-Gen SIEM**
2. Then, under **Log management** select **CrowdStream**.



Navigating from Next-Gen SIEM to CrowdStream

To log into CrowdStream from LogScale interface:

1. Log into LogScale.
2. On the **CrowdStream** tile at right, select **Try now**.

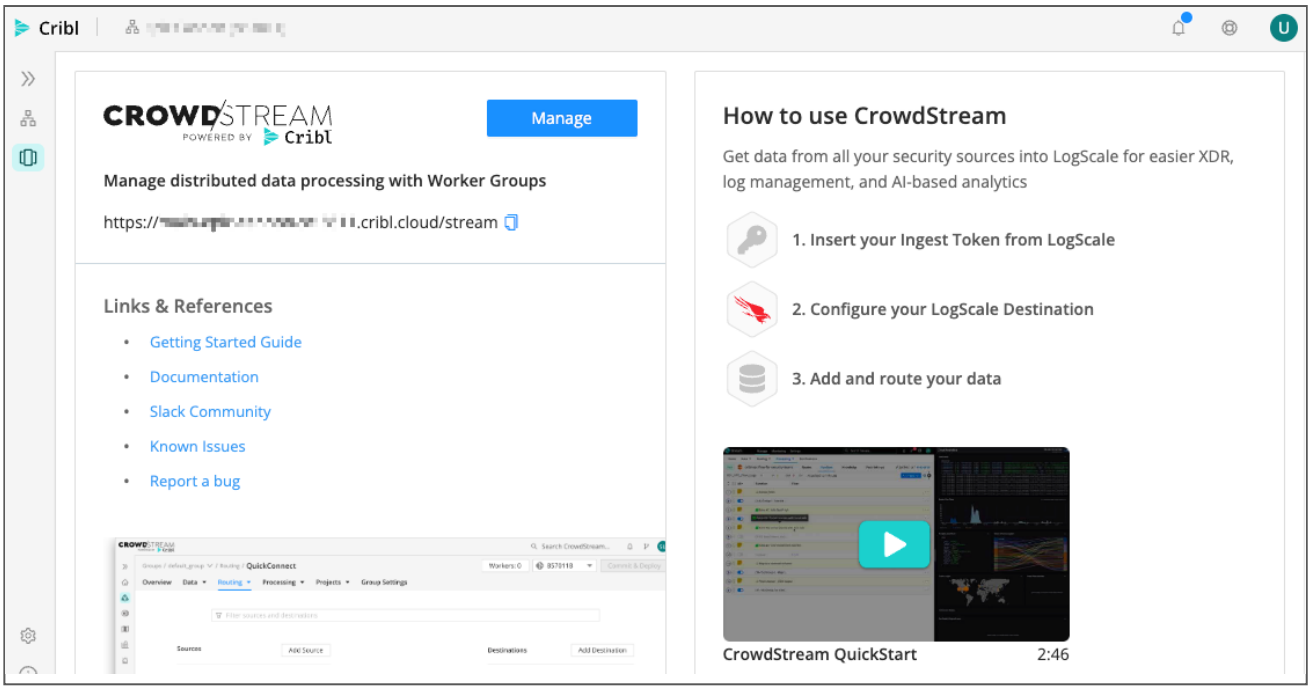


Navigating from LogScale to CrowdStream

3. On the resulting page, select **Log in**.

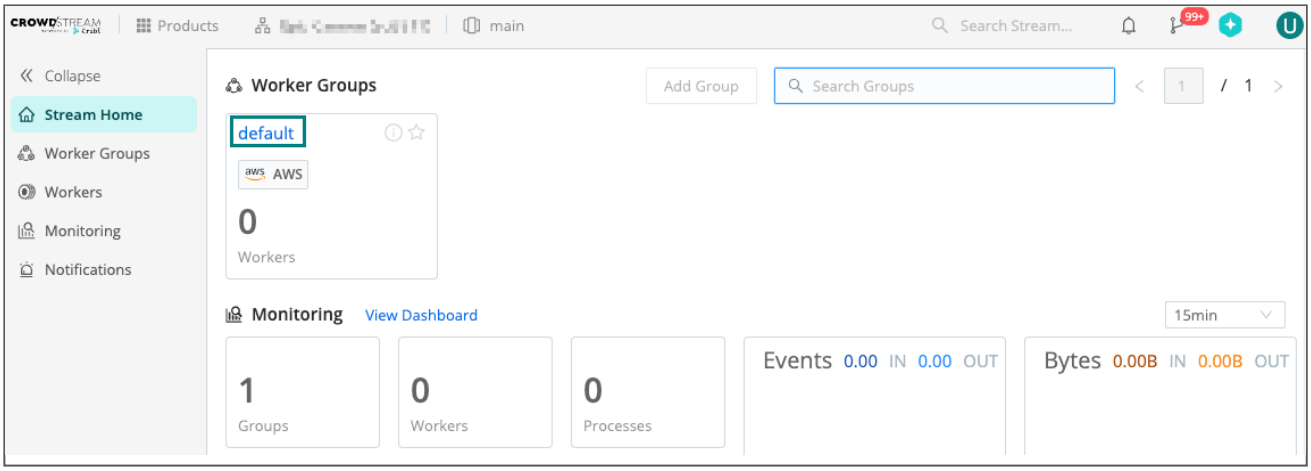
Regardless of your login method, you should now see the CrowdStream home page.

4. Select **Manage** on the **CrowdStream** tile.



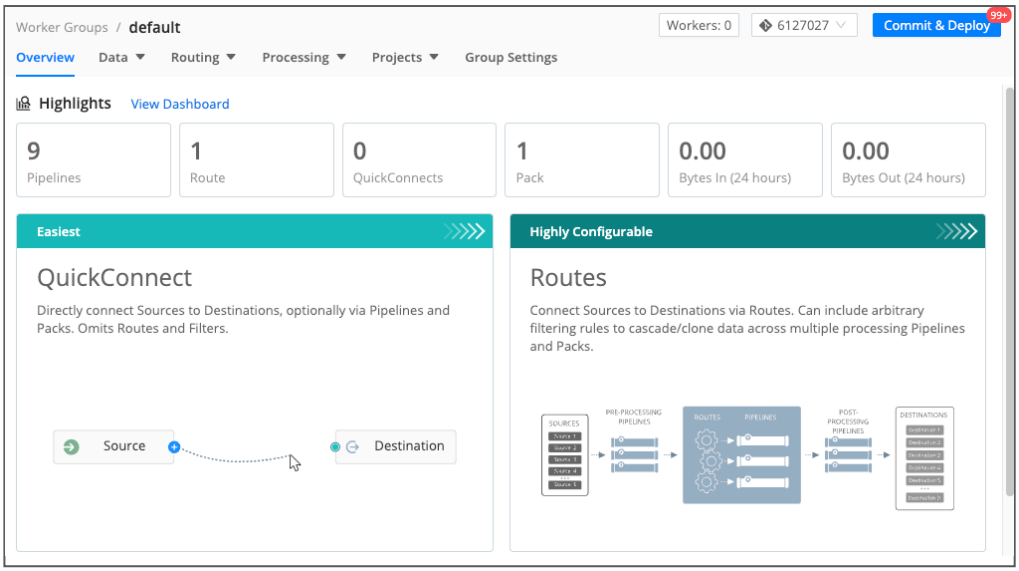
Selecting the CrowdStream app

5. On CrowdStream's home page, under **Worker Groups**, select the **default** Group.
   (A Worker Group is a collection of processing instances that share the same configuration. For details, see Cribl Stream's Distributed Deployment topic.)



Selecting the **default** Group

6. To configure this Group, you can choose between the **QuickConnect** or **Routes** tiles. How to choose? See the next section.



Group **Overview** page

For More Information

- Cribl.Cloud Launch Guide

Simple or Complex Routing?

Your first choice is how simply or intricately you want to configure data flow from the first data Source you set up. CrowdStream offers two user interfaces:

- QuickConnect (the left tile shown above) provides a simple visual UI. You drag and drop connections from Sources on the left to Destinations on the right. Each connection can include as much or as little intermediate processing as you like. To remove a connection, just drag it off the Destination (you'll get a confirmation modal). The only practical limitation here is that data flow through every Source -> Destination connection must be parallel and independent.
- Data Routing (the right tile shown above) provides fine-grained control, via a more traditional UI that you configure across separate modals and pages. You build a Routing table with conditional processing. This can cascade and clone data across multiple processing Routs, according to the arbitrary filtering rules and sequence that you define.

So the trade-off between these two options is ease of use versus flexibility. These two options are separate, but not mutually exclusive: You can set up simultaneous data flows through QuickConnect and Data Routes.

You can also move Sources, and their connections to Destinations, between the two UIs. So one obvious option is to configure your first data flow in QuickConnect, and then move to the Routing UI as your familiarity and needs expand.

Here is a lightning-fast (one-minute) preview of **all** the configuration steps below, in QuickConnect:

We couldn't verify the security of your connection.

Access to this content has been restricted. Contact your internet service provider for help.

Navigate Between User Interfaces

To work in QuickConnect, select the left tile shown above, or open the **Worker Groups** and select **Routing** > **QuickConnect**.

To work in the Routing UI, select the right tile shown above, or open the **Worker Groups** submenu and select **Routing** > **Data Routes** .

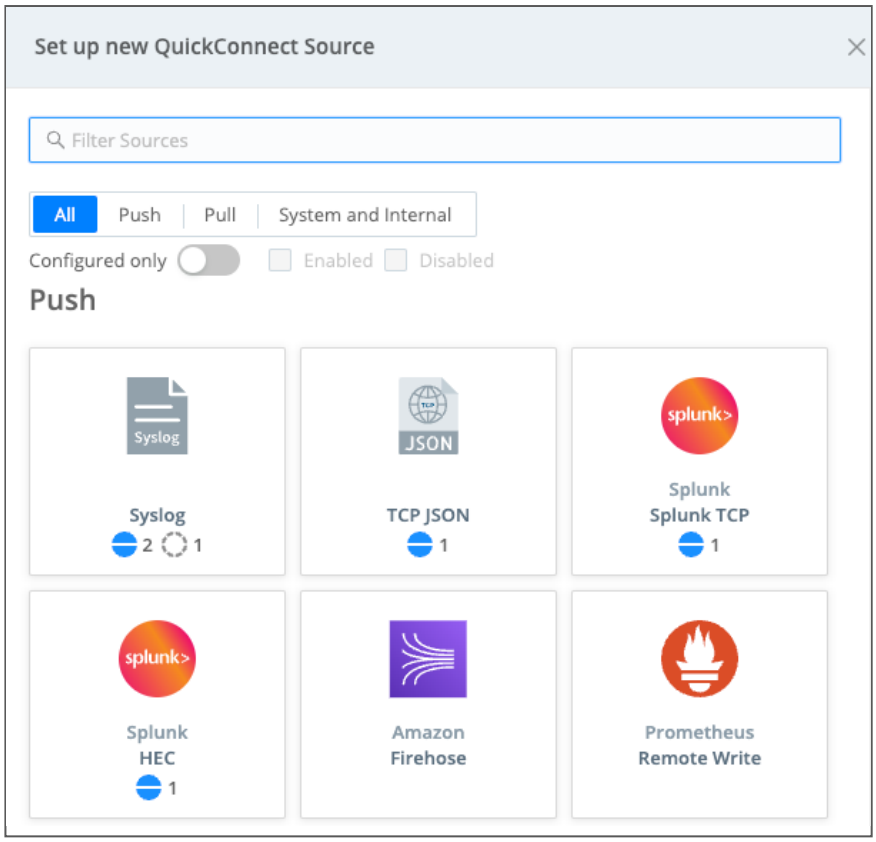
Configure a Source

A CrowdStream Source is a model of an upstream service sending data into the system. In this model, you configure authentication and/or other needed parameters.

You can configure multiple instances of a given Source type, each with different parameters. You can also attach processing that's specific to each instance. CrowdStream provides the Datagen Source type to generate sample inbound events for development and testing.

Using QuickConnect

In QuickConnect, select **Add Source** on the left (Sources) side. In the resulting left drawer, search for and select your desired Source type to begin configuring a new instance of that Source.



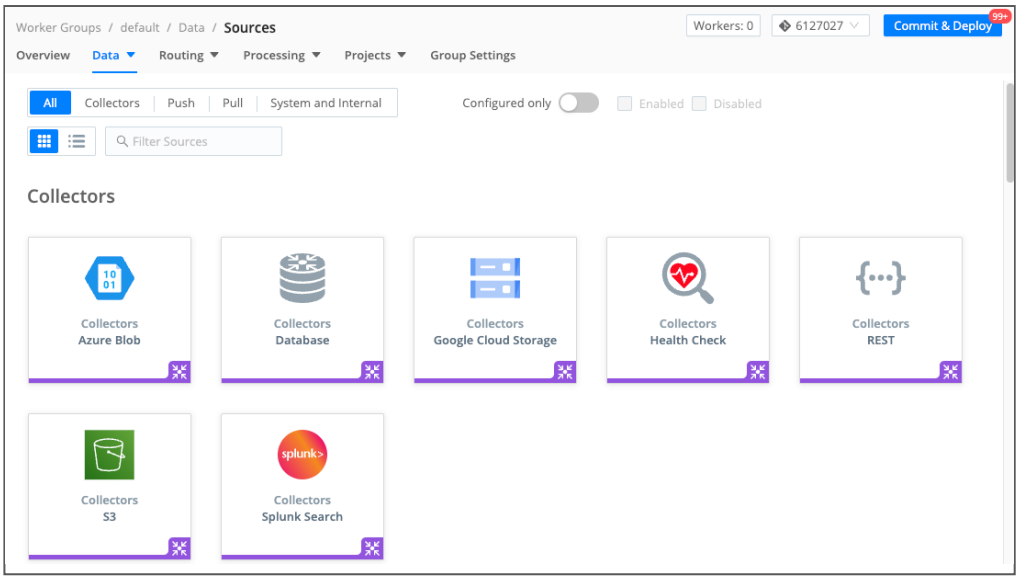
Selecting a Source through the QuickConnect UI

To configure (or reconfigure) a Source that's already present in QuickConnect, hover over its tile and select **Configure**. Note that for multiple Sources of the same type, tiles will display stacked until you hover over the stack.

Using Data Routes

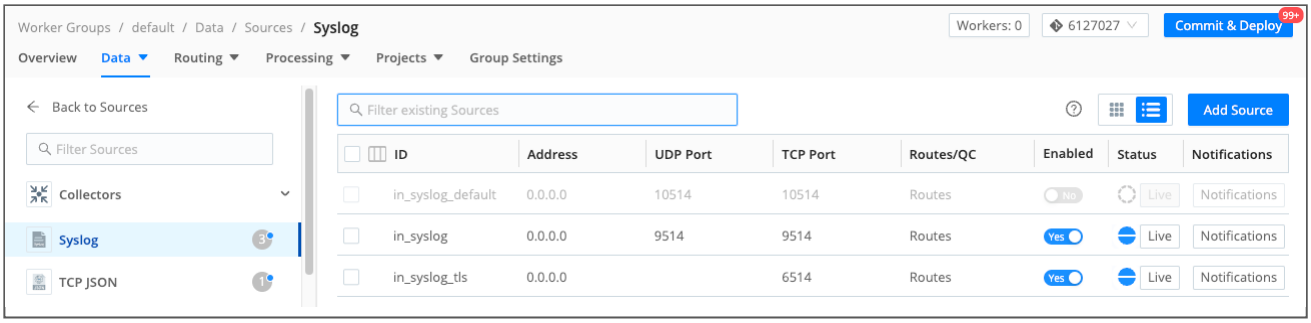
To use the Routing UI, on the **Worker Groups** submenu select **Data**, then **Sources**. On the resulting **Sources** page, search for your desired Source type, then select its tile to begin configuring a new instance of that Source.

(After you click through to a Source, the same set of peer Sources will be available in the left nav.)



Sources page

Select an existing Source's row here to access its configuration, or select **Add Source** to configure a new instance of that Source.



Manage Syslog Sources UI

To get data flowing, jump ahead to commit and deploy your new configuration.

For More Information

- Sources
- Using Datagens
- QuickConnect
- Routes

Configure a Destination

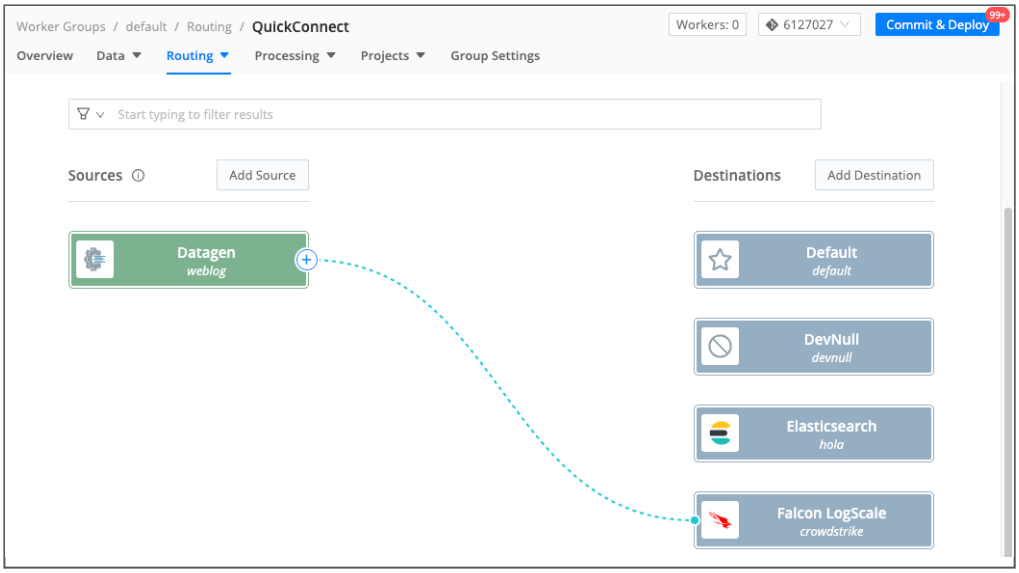
A CrowdStream Destination is a model of a downstream receiver of events, enabling you to configure authentication and/or other needed parameters.

As with Sources, you can configure multiple instances of a given Destination type, each with different parameters. You can attach processing that's specific to each instance. CrowdStream provides the following Destinations:

- CrowdStrike Falcon LogScale – Set up your LogScale endpoint, token, and other parameters here.
- Amazon S3 Compatible Stores – Route full-fidelity data to cost-effective storage for later replay and analysis.
- Data Lakes > Amazon S3 – Store full-fidelity data for later retrieval or analysis. Compatible with Cribl Search (a separate product).
- DevNull – This output simply consumes and discards events, to facilitate development and testing.

Using QuickConnect

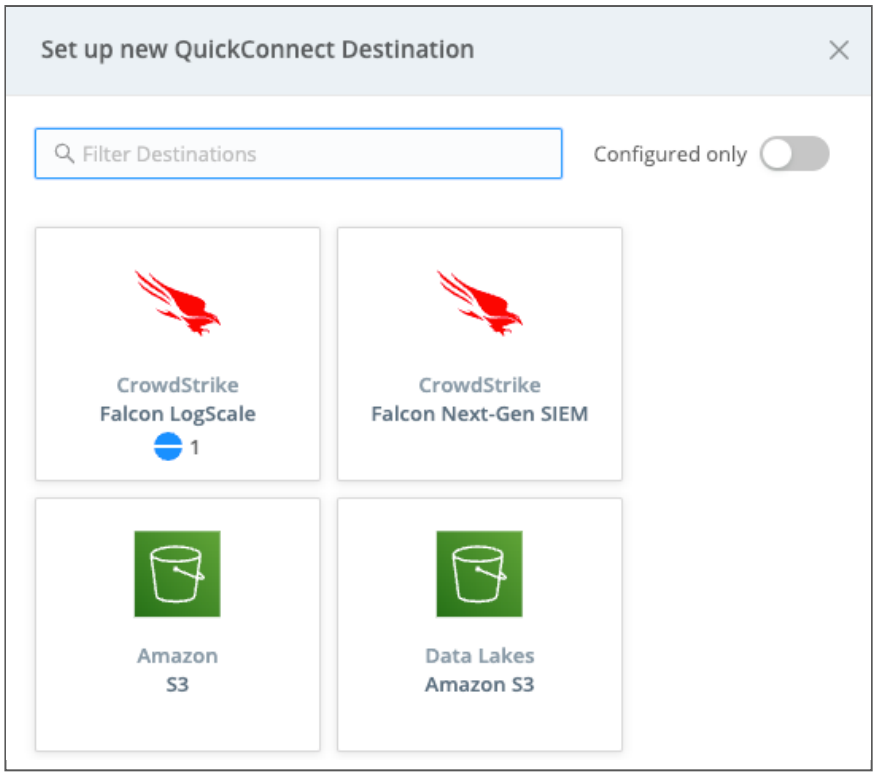
To connect a configured Source to a Destination tile already present on the right, just drag from the Source and drop the connector onto the Destination. A pop-up will prompt you to configure the connection via a Passthru, Pipeline or Pack (explained below).



Multiple Destinations added to QuickConnect

To configure (or reconfigure) the Destination, hover over its tile and select **Configure**. For multiple Destinations of the same type, tiles will display stacked until you hover over the stack.

To add a new Destination, select **Add Destination** on the right (Destinations) side. In the resulting right drawer, search for and select your desired Destination type to begin configuring a new instance of that Destination.

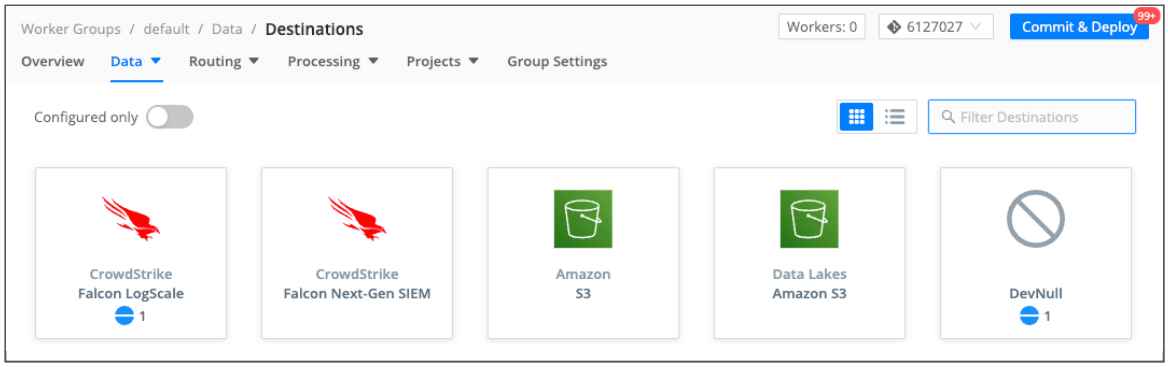


Selecting additional Destinations in QuickConnect

Using Data Routes

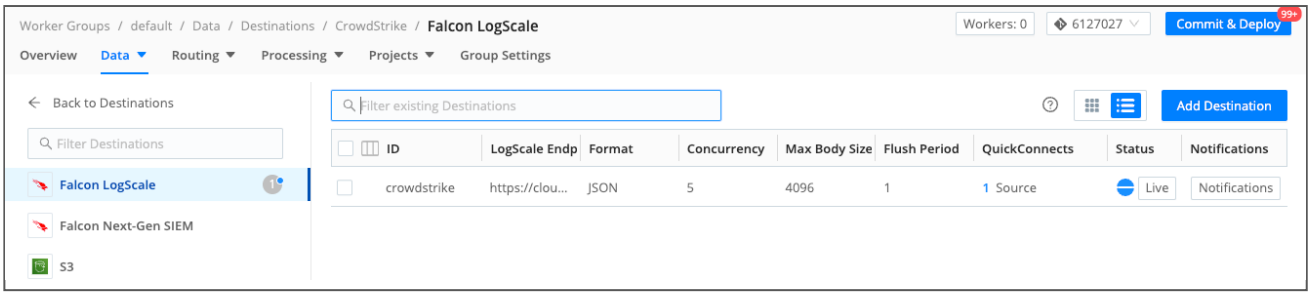
To use the Routing UI, on the **Worker Groups** submenu select **Data**, then **Destinations**. On the resulting **Destinations** page, search for your desired Destination type, then select its tile to begin configuring it.

(After you click through to a Destination, the same set of peer Destinations will be available in the left nav.)



Destinations page

Select an existing Destination's row here to access its configuration, or slect **Add Destination** to configure a new instance of that Destination.



Manage LogScale Destinations UI

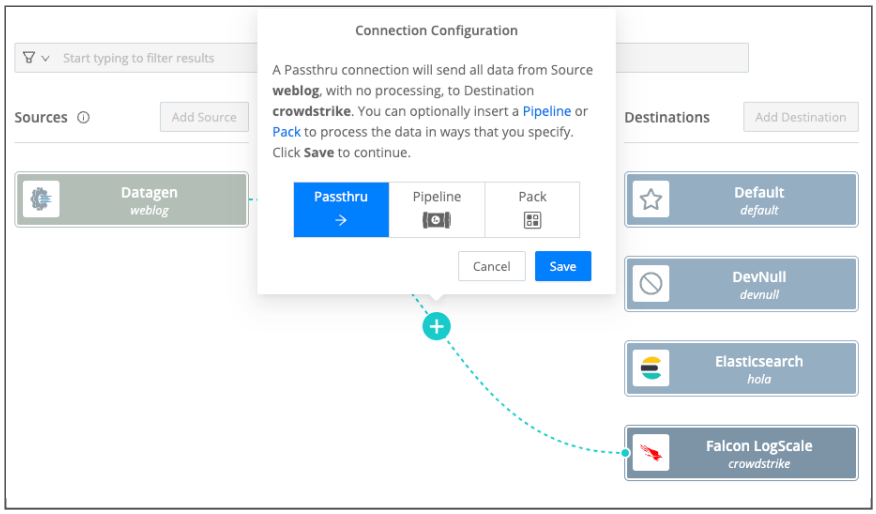
To get data flowing, jump ahead to commit and deploy your new configuration.

For More Information

- See the individual Destination topics linked at the head of this section.

Connect: Passthru, Pipeline, or Pack

In QuickConnect, as soon as you drag and drop a Source -> Destination connection, a pop-up dialog will prompt you to select a connection type: **Passthru**, **Pipeline**, or **Pack**. (In Data Routes, you'll make the same choices elsewhere.)



Connection-type selector in QuickConnect

What are these options?

- A **Passthru** establishes a simple direct connection between a Source -> Destination pair.
- A Pipeline hosts a stack of Functions to process your data, in the order you arrange them.

- A Pack is a microcosm of a whole CrowdStream configuration, designed to share configs between Worker Groups or deployments. A Pack can encapsulate its own Pipelines, Routes, Knowledge libraries, and sample data (but not data Sources or Destinations). A Pack can snap in wherever you can use a Pipeline.

So let's unpack Pipelines, where you'll define most of your event processing.

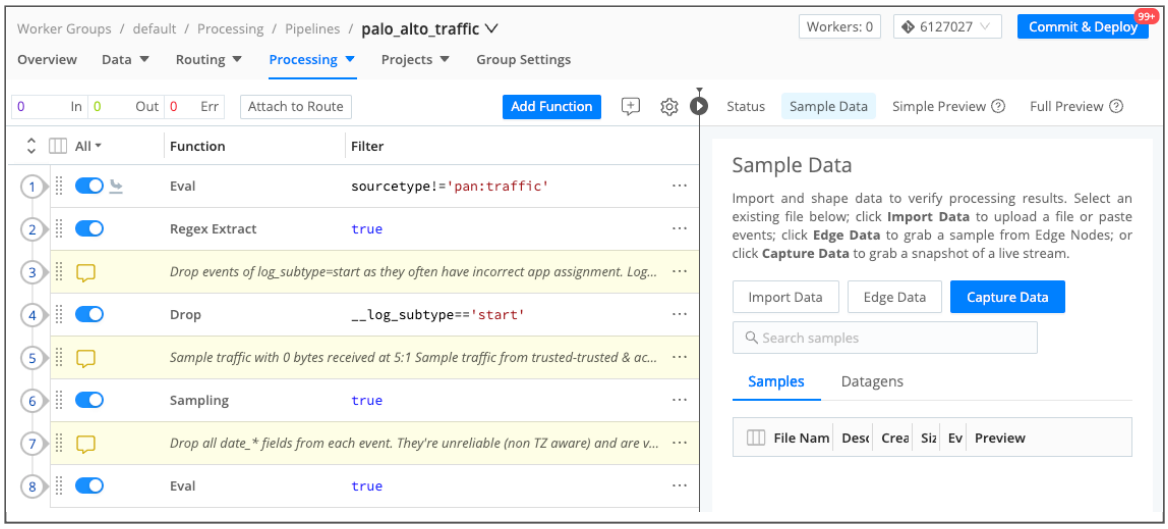
Pipeline Options

When you first create a new Pipeline, it's empty, making it equivalent to **Passthru**. CrowdStream provides a set of out-of-the-box Pipelines for specific purposes. As you can see below, one of these is a **Passthru** Pipeline. This similarly contains no Functions – making it the Data Routes UI's equivalent of QuickConnect's **Passthru** button.

For these reasons, it's easy to start with an empty Pipeline, and then add Functions as you need them.

A Pipeline, as you populate it, is a stack of processing Functions and optional comments. Use the accordions on the left to expand or collapse each Function. Use the toggles on the left to enable/disable each Function – preserving structure as you develop and debug.

Use the right **Sample Data** pane to preview how the Pipeline's current state transforms a set of events. (Controls here enable you to capture live data, save it to sample or datagen files, and reload those files.)



A Pipeline's Functions stack

Although you'll configure most data shaping in processing Pipelines between Sources and Destinations, you can also attach a pre-processing Pipeline to any Source instance, and a post-processing Pipeline to any Destination instance. Use these options when you need to "condition" the specific data type handled by a particular inbound or outbound integration.

Connect via QuickConnect

To select a connection type in QuickConnect, select the appropriate button in the pop-up dialog shown above. To accept the default **Passthru** option, select **Save**. Your Source and Destination will now be connected.

If you select **Pipeline**, you'll see an **Add Pipeline to Connection** modal. Here, you can choose an existing Pipeline, or select **Add Pipeline** to define a new one. Then select **Save** here to establish the connection.

Selecting **Pack** opens an **Add Pack to Connection** modal that works exactly the same way.

Whichever option you choose here, your connection between this Source and Destination is now complete.

To get data flowing, jump ahead to commit and deploy your new configuration.

Connect via Data Routes

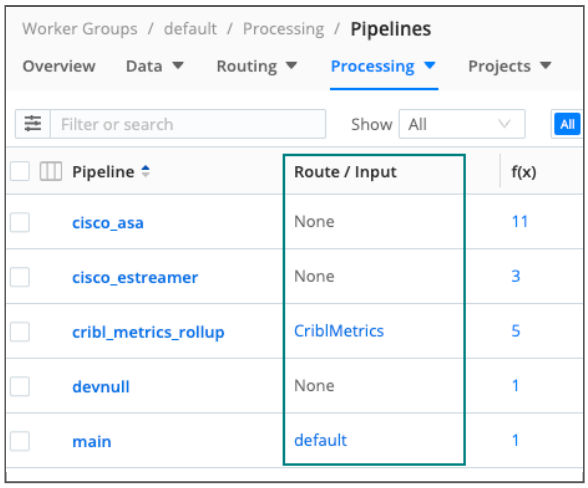
The Data Routes UI enables you to finely configure multiple, interdependent connections between Sources and Destinations. Events clone and cascade across a Routing table, based on the filtering rules and sequence you define.

In exchange for this flexibility, you sacrifice QuickConnect's one-stop, snap-together UI metaphor. After configuring your Sources and Destinations – which you've already done above – you need to connect them by separately setting up at least one Pipeline and one Route.

Pipelines Access

On the **Worker Groups** submenu, select **Processing**, then **Pipelines**. In addition to the minimal **Passthru** Pipeline identified above, other simple building blocks here include **main** (which initially contains only a simple Eval Function) and **devnull** (which contains a single Function that just drops events).

Out-of-the-box Pipelines are already connected to Routes. On the **Pipelines** page, the **Route/Input** columns displays the connected Route, as shown here. But as our final connection step, let's next look at how to connect up everything (Source, Pipeline, Destination) in a Route.



Checking Pipelines Route connections

For More Information

- Refine Data with Functions walks you through configuring CrowdStream's built-in Pipeline Functions to perform common processing tasks like parsing, masking, adding, deleting, and renaming event fields.

Configure a Route

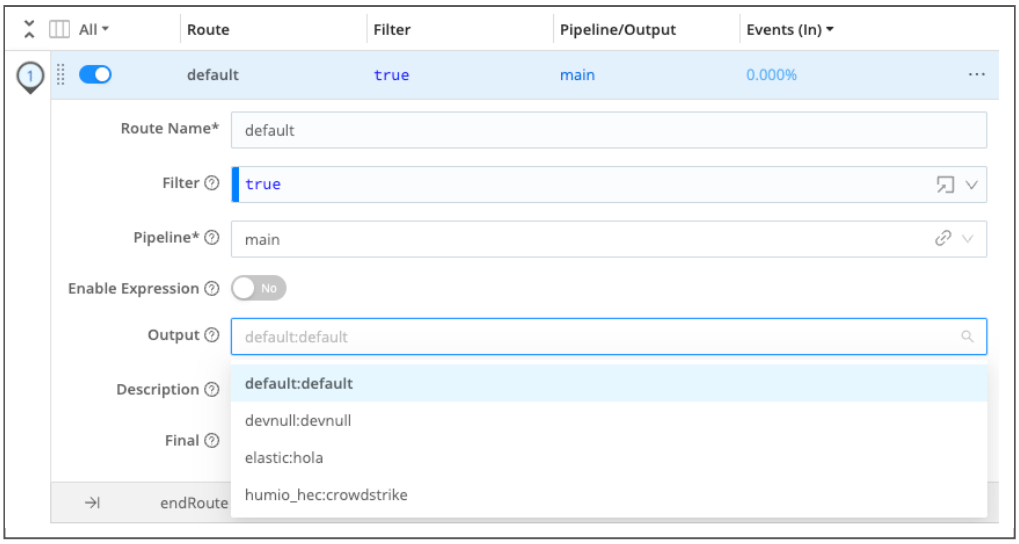
In the Data Routes UI, a Route is where you complete a data-flow connection. Each Route connects exactly one Pipeline with exactly one Destination.

This combination can consume data from one, multiple, or all the Sources you've configured on the Data Routes side. (QuickConnect Sources are separate, but you can open those Sources' configs to move them to the Data Routes UI.) This is governed by the filtering we'll see below.

To open the Routing table, on the **Worker Groups** submenu, select **Routing**, then **Data Routes**.

CrowdStream ships with one starter Route named **default**. It's configured as follows:

- The **Filter** expression is set to **true**. This simple, default expression makes data from **all** active Sources available to this Route. (See finer filtering options below.)
- The **Pipeline** drop-down is where you set the 1:1 Pipeline:Route connection. This starter Route's Pipeline defaults to **main**, but you can select any one other configured Pipeline.
- The **Output** drop-down defines the single Destination for this Pipeline:Route connection. If this isn't already set to your LogScale Destination, you'll most likely want to select that here. (Note that each option displayed on this list corresponds to the unique, arbitrary **Output ID** set on one **instance** of a Destination type. So some names might initially be unfamiliar.)



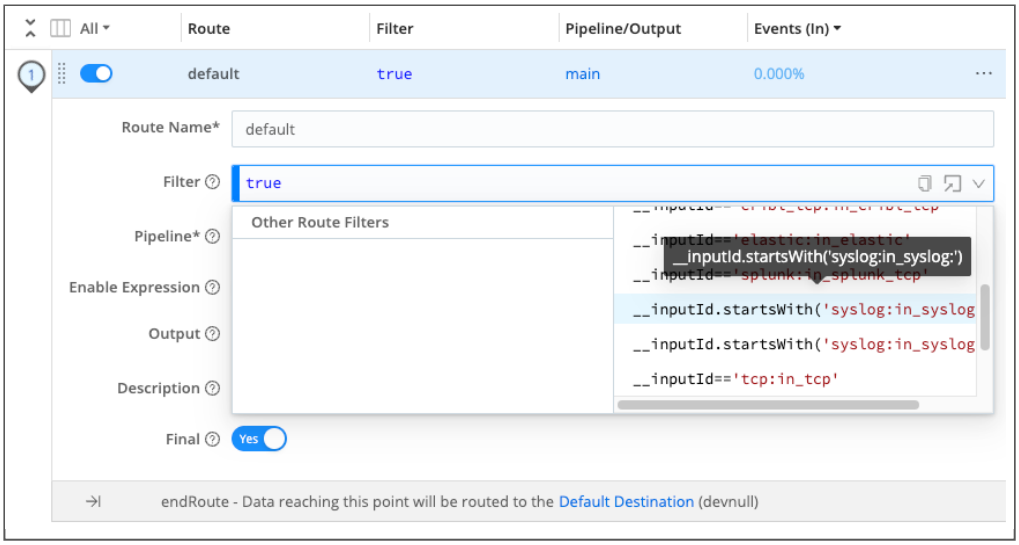
Changing a Route's Destination (Output)

To get data flowing, jump ahead to commit and deploy your new configuration.

Filter a Route's Input Data

When you want a Route to ingest data from only one Source, or a subset of Sources, you expand its **Filter** expression beyond the default **true** catch-all.

Filter is itself a drop-down. Open it to select among typeahead suggestions for several common inbound data types.



Tuning a Route's Filter expression

You can select one of these expressions and then modify it, using the same `__inputId` syntax. In the example expression below, note that the identifier after the `:` is – as with the **Output** options we saw above – the arbitrary name of one Syslog Source instance:

```
__inputId.startsWith('syslog:in_syslog:')
```

For More Information

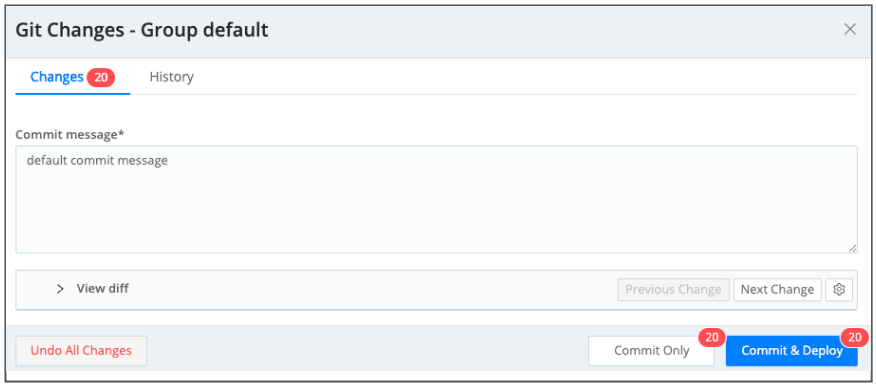
- Cribl Expression Syntax > Filters

Commit/Deploy Config Changes

To get data flowing as you expect, you'll always need to use CrowdStream's built-in Git version-control integration to commit your configuration changes and deploy them to your event-processing Worker instances. After any significant configuration change, you'll be prompted with Group-level **Commit & Deploy** button at the upper right

Depending on your version-control settings, **Commit** and **Deploy** might appear as separate buttons.

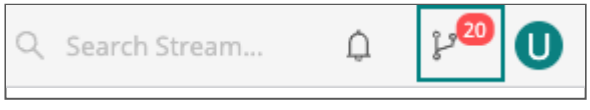
Selecting either flavor of the **Commit** button will display a confirmation modal like this. You can either accept the default commit message, or enter a specific message. Then be sure to select the appropriate buttons to both commit **and** deploy your changes.



Confirming a commit

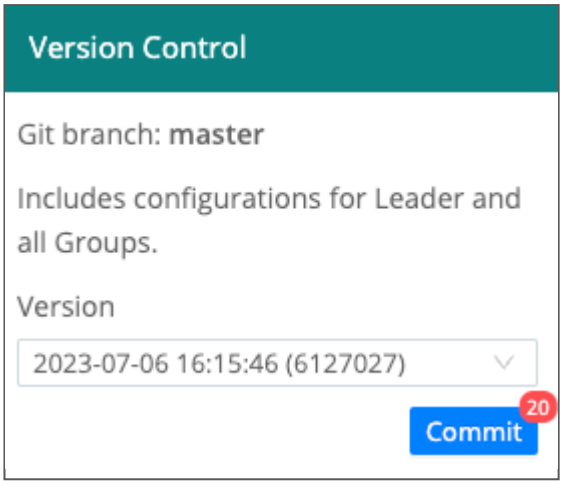
Data should now start flowing through the Workers. (You can check this by selecting the top nav's **Monitoring** link. This takes you to read-only dashboards, so remember to select **Manage** when you want to return to configuration options.)

In return for clearing all the red-dot prompts, your reward will be one more red dot, on the top nav's CrowdStream-wide Version Control button. This is because CrowdStream sees the preceding deploy to Workers as a change to record (commit) on the **Leader's** configuration.



Leader commit prompt

This top-level commit isn't necessary to enable data flow, but it backs up and safeguards your overall configuration. Select the button to display one final confirmation prompt:



Confirming a commit on the Leader

Select **Commit** here, and your configuration is complete!

For More Information

- Version Control > Committing Changes
- Version Control > Collapse Actions
- Monitoring

Moving Ahead with CrowdStream

To quote a fundamental treatise on SecOps: you know all the rules by now, and the fire from the ice. To delve deeper into CrowdStream's data shaping and routing options, follow these links to conceptual overview and reference topics.

5. Reference Architectures

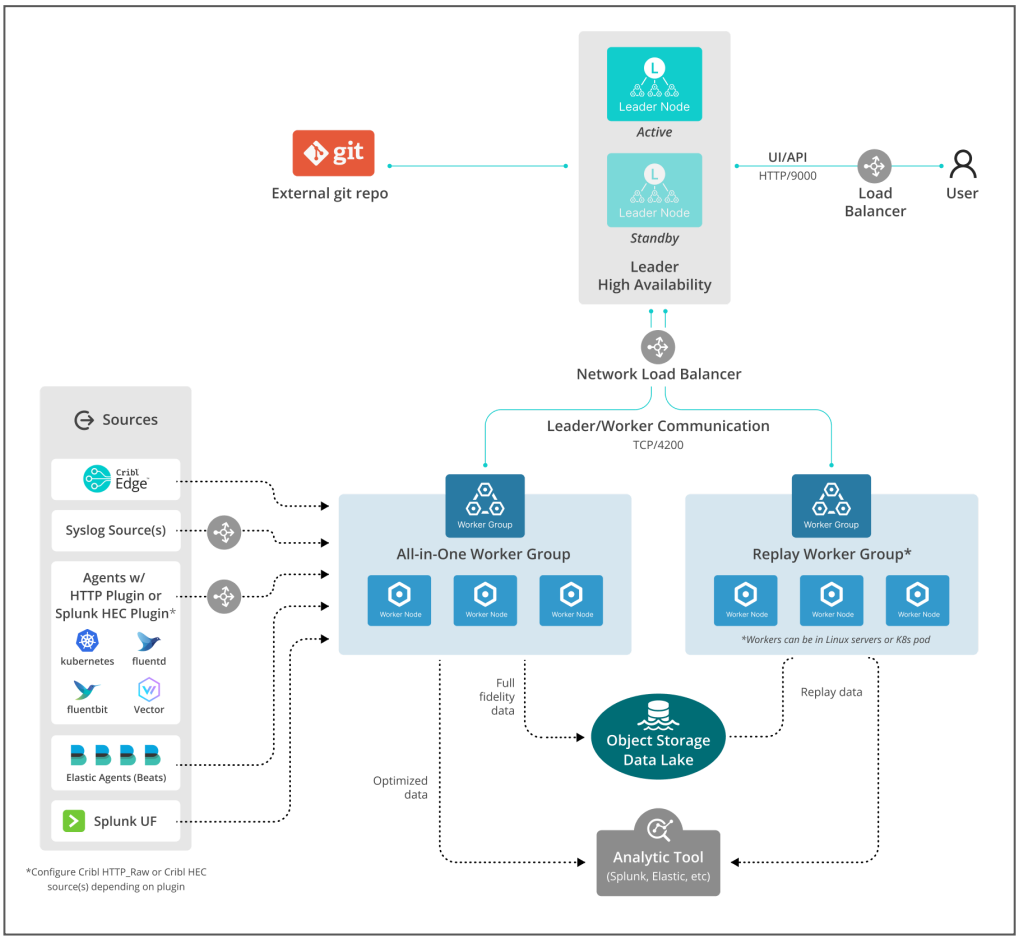
This section hosts a growing collection of diagrams representing possible Cribl Stream deployment architectures for different use cases. Please see the considerations, details, and disclaimers accompanying each diagram:

- All-in-One Reference Architecture
- Syslog to Cribl Stream Reference Architecture
- Multiple Agents Reference Architecture
- Comprehensive Reference Architecture
- Comprehensive Hybrid Cloud Reference Architecture

For a still broader view of interoperation among all Cribl products, see also our Cribl Reference Architecture, Full-Suite.

5.1. All-In-One Reference Architecture

This reference architecture shows one possibility for ingesting and replaying diverse data types from multiple senders. The Sources shown at left are just representative examples. The replay workers at right could be hosted on Linux servers, in Kubernetes Pods, etc.



All-in-one reference architecture

Download an editable version of this diagram in SVG or draw.io format. Download Cribl stencils here.

Sizing Considerations

- An all-in one Worker Group works best with fewer than 2000 Sources (agents, syslog senders, and so forth).
- Syslog over TCP should be under 200 GB/day from any one sender.
- Account for up to 50% bursts in traffic.

Load Balancers

The load balancer in front of the Leader UI can be an Application Load Balancer or a Network Load Balancer.

The load balancer between the Cribl Workers and the Cribl Leader listening on port 4200 must be a Network Load Balancer or equivalent.

Leader High Availability

Configuring Leader high availability requires a standby server, a load balancer (details here) between users and the Cribl UI port, and a Network Load Balancer between the Cribl Leader and Workers.

Leader high availability is optional. Many customers opt instead for a single Leader, and a remote Git repo for scheduled backups. If the Leader becomes unavailable, you can use the Git repo to provision a new Leader, restoring configuration from a backup.

However, a single Leader is reliable only when Workers are running Cribl Sources that fully leverage a shared-nothing architecture (such as Raw HTTP, Splunk HEC, Elasticsearch API, Amazon S3 Source, etc). Here, Workers can process data even if the Leader is unavailable. A Leader without failover will not reliably support Collectors, which require a Leader's ongoing orchestration.

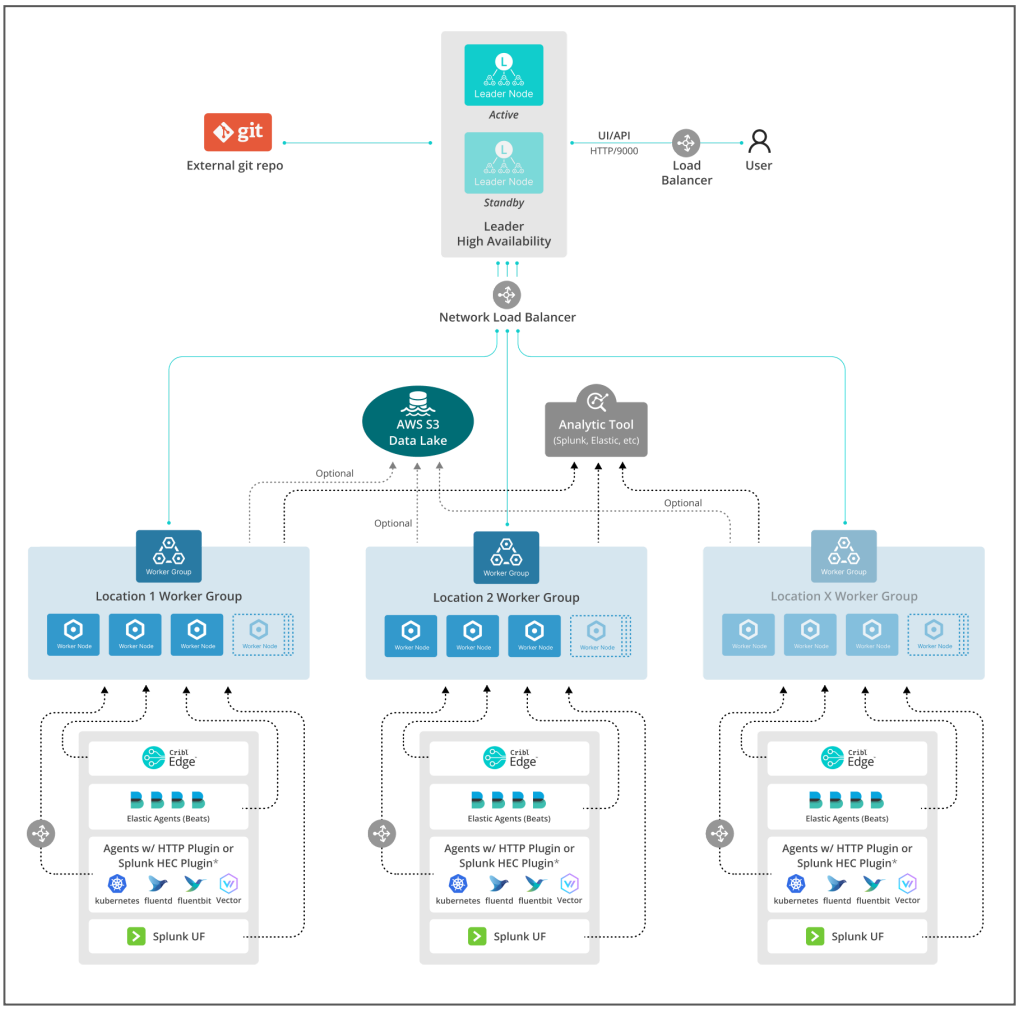
Disclaimers

All product names, logos, brands, trademarks, registered trademarks, and other marks listed in this document are the property of their respective owners. All such marks are provided for identification and informational purposes only. The use of these marks does not indicate affiliation, endorsement, or ownership of the marks or their respective owners.

This document is provided "as is" with NO EXPRESS OR IMPLIED WARRANTIES OR REPRESENTATIONS. It is intended to aid users in displaying system architecture, but might not be applicable or appropriate in all circumstances. You should not act on any information provided until you have formed your own opinion through investigation and research. Cribl is not responsible for any use of this document or the information provided herein.

5.2. Multiple Agents Reference Architecture

This reference architecture shows one Cribl Stream deployment possibility for ingesting data from a large quantity of agents. Here, a single basic configuration is replicated across multiple Worker Groups, organized by geographic location.



Multiple agents reference architecture

Download an editable version of this diagram in SVG or draw.io format. Download Cribl stencils here.

Single or Multiple Worker Groups?

The multiple-Groups architecture shown here is one approach. It might or might not be desirable for your use case.

Pros of using multiple Worker Groups:

- Configuration granularity.

- Can use Packs to export/reuse configurations across Groups.

Cons of using multiple Worker Groups:

- Multiple configurations to maintain (even if shared via Packs).

General Sizing Considerations

Size based on data throughput (in+out), and on number of incoming TCP connections.

Sizing Examples

Below are two scenarios demonstrating how to determine the number of Stream Worker Processes you'll need to allocate. Both scenarios assume the same distribution of chatty versus medium-chatty agents, but with a different balance of throughput volume versus agents volume.

How Many Events per Second?

We assume three tiers of "chatty" agents, based on events per second. You'll probably recognize your senders from these definitions:

- Chatty agents (100 EPS/agent) – Size 150 agents/vCPU. (Examples are domain controllers or intermediary agents.)
- Medium-chatty agents (30 EPS/agent) – Size 250 agents/vCPU. (Most servers will fall into this medium category.)
- Low-volume agents (3 EPS/agent) – Size 5000 agents/vCPU (Examples are workstations.)

For the most accurate sizing, obtain EPS reports from your current observability tools.

Using the Scenarios

In each scenario, to size based on the number of agents directly feeding Cribl Stream, take the **largest** vCPU count from the pair of volume versus ports calculations.

Scenario 1

40 TB/day throughput, 40,000 agents, 10% of them very chatty, 90% medium-chatty.

- Sizing for volume (non-hyperthreaded CPU cores): 205 Worker Processes.
- Sizing from TCP ports (non-hyperthreaded CPU cores): (0.10 x 40,000 / 150) + (0.90 x 40,000 / 250) = (27 + 144) = 171.

- Result: Allocate **205** Worker Processes, the larger of the two.

Scenario 2

4 TB/day throughput, 20,000 agents, 10% of them very chatty, 90% medium-chatty.

- Sizing from vCPUs (non hyperthreaded CPU Cores): 11 Worker Processes.
- Sizing from TCP ports (non-hyperthreaded CPU Cores): (0.10 x 20,000 / 150) + (0.90 * 20,000 / 250) = (14 + 72) = 86.
- Result: Allocate **86** Worker Processes, the larger of the two.

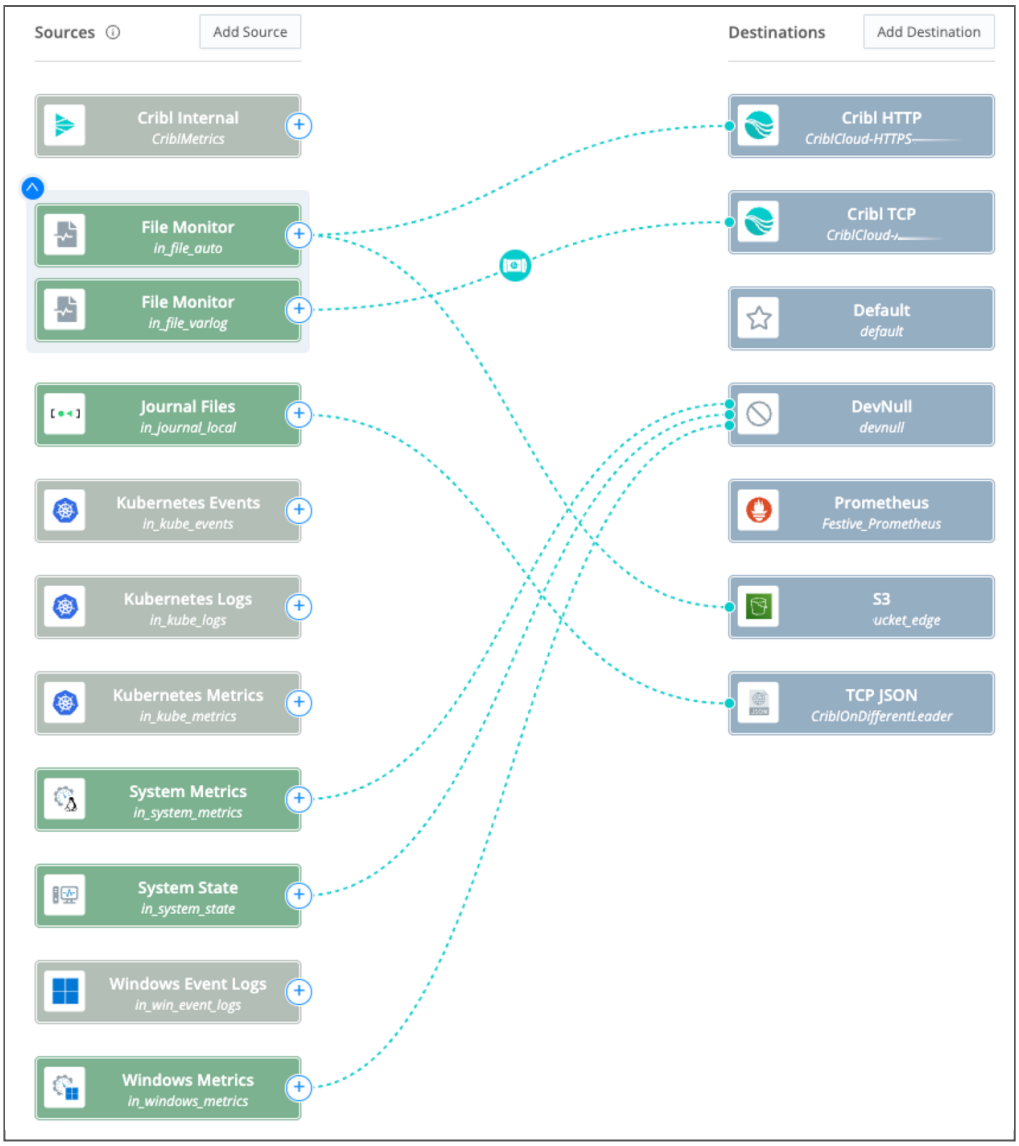
Cribl Edge Configuration

You can configure Cribl Edge to send data to Cribl Stream via a Cribl HTTP, Cribl TCP, or TCP JSON Destination.

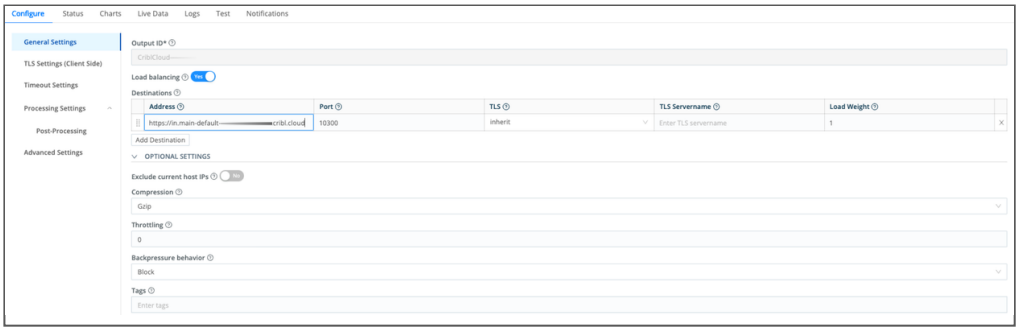
Cribl HTTP is ideal for environments where the Edge Nodes and the Cribl Stream Workers are managed by the same Leader. Cribl HTTP is particularly well-suited to scenarios where the data must traverse a proxy. (The proxy will reduce throughput performance, so monitor throughput when traversing a proxy.) You should always enable this Destination's load-balancing option. When you use a Cribl HTTP Destination/Source pair to connect the applications, license metering occurs **only** when the data is collected by the Edge Node, so you are billed only once.

Cribl TCP is also available for environments where the Edge Nodes and the Cribl Workers are managed by the same Leader. Its limitation is vulnerability to "pinning" on persistent connections. When you use this Destination, you should always enable its load-balancing option. With Cribl TCP, as with Cribl HTTP, license metering occurs **only** when the data is collected by the Edge Node, so you are billed only once.

TCP JSON is ideal for environments where the Edge Nodes are managed by a **different** Leader than the Cribl Stream Workers. Neither Cribl HTTP nor Cribl TCP will work in this scenario. You should always enable this Destination's load-balancing option.



Edge UI, showing connections to all three Destinations



Example Cribl TCP Destination config

Elastic Agent Configuration

The configuration to use in `filebeat.yml` depends on your agent's version.

Versions 8.x+

```
setup.ilm.enabled: false
```

Versions 7.15 Through 7.17

```
output.elasticsearch:
hosts: ["https://<your-host-here>.com:9200/elastic"]
```

Or:

```
output.elasticsearch:
hosts: ["<server-name-here>:9200/elastic", "<another-server-name-here>:9200/elastic"]
```

Versions 7.14 and Earlier

```
output.elasticsearch:
hosts: ["[https://<your-host-here>.com:9200](https://<your-host-here>.com:9200)"]
```

Or:

```
output.elasticsearch:
hosts: ["<server-name-here>:9200", "<another-server-name-here>:9200"]
```

Configure the agent's `worker` setting to avoid TCP pinning. See the `worker` configuration option in Configure the Elasticsearch Output.

Splunk Forwarder Configuration

Here are configurations for a few different scenarios.

Setting `blockOnCloning` to `false` ensures that if either Cribl Stream or Splunk becomes unavailable, the other system will continue receiving data without dropping events. This prevents potential data loss

or interruptions in transmission.

Send All Data to Cribl Stream

Default `outputs.conf` to forward all inputs to the `stream` servers:

```
[tcpout]
defaultGroup=stream
blockOnCloning=false

[tcpout:stream]
server=10.1.1.200:9997,10.1.1.201:9997
sendCookedData=true
blockOnCloning=false
```

Send to Splunk and Cribl Stream

This `outputs.conf` bifurcates all data to both Splunk and Cribl, by configuring `defaultGroup` with two `tcpout` values.

```
[tcpout]
defaultGroup=splunk,stream
blockOnCloning=false

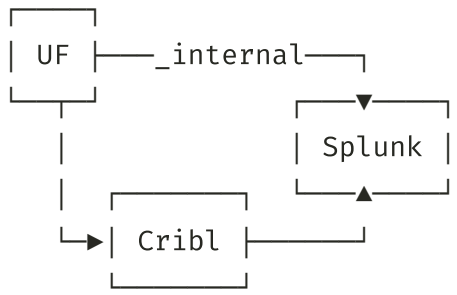
[tcpout:splunk]
server=10.1.1.197:9997,10.1.1.198:9997
blockOnCloning=false

[tcpout:stream]
server=10.1.1.200:9997,10.1.1.201:9997
sendCookedData=true
blockOnCloning=false
```

Bypass Internal Logs

The Splunk Universal Forwarder will send the `splunkd.log` and `metrics.log` sources to any configured `tcpout` stanza. This is because both monitor stanzas have `_TCP_ROUTING = *`. In certain scenarios, it's desirable for the internal logs to bypass Cribl Stream, sending them directly to Splunk.

For example:



In this scenario, configure your settings as follows.

`outputs.conf`:

```
[tcpout]
defaultGroup=stream
blockOnCloning=false

[tcpout:splunk]
server=10.1.1.197:9997,10.1.1.198:9997
blockOnCloning=false

[tcpout:stream]
server=10.1.1.200:9997,10.1.1.201:9997
sendCookedData=true
blockOnCloning=false
```

`inputs.conf` for internal logs:

```
# splunkd.log and metrics.log will get sent to Splunk

[monitor://$SPLUNK_HOME/var/log/splunk/splunkd.log]
_TCP_ROUTING = splunk

[monitor://$SPLUNK_HOME/var/log/splunk/metrics.log]
_TCP_ROUTING = splunk
```

`inputs.conf` for all other logs:

```
# datasource.log will get sent to Cribl by default

[monitor:/path/to/log/datasource.log]
index = ds_index
sourcetype = sourcetype
```

Fluent Bit Configuration

Here are sample configurations for three different ways to ingest Fluent Bit data.

Splunk HEC Source on Cribl Workers

Fluent Bit reference

```
[OUTPUT]
Name cribl
Match *
host <HOST>
port 8088
Cribl_HEC_Token xxxxxxxx-xxxx-xxxx-xxxx-xxxxxxxxxxx
Cribl_HEC_Send_Raw On #optional: to raw instead of event endpoint
TLS On
TLS.Verify Off #optional
```

Raw HTTP Source on Cribl Workers

Fluent Bit reference

```
[OUTPUT]
Name http
Match *
Host cribl_worker_load_balanced_vip
Port 10443
URI /optional/uri/for/filtering/in/cribl
Format json_lines
Header Authorization <Cribl-generated token>
Header X-Key-B Value_B
```

TCP JSON Source on Cribl Workers

Fluent Bit reference

```
[OUTPUT]
Name tcp
Format json_lines
Workers 2
tls on #optional for tls setting
json_date_key date
json_date_format epoch

# Note: Use mTLS, because this plugin doesn't appear to support authTokens
```

Cribl Destination Considerations

Adjust Cribl Destinations' **Advanced Settings** > **Max connections** setting (where available) to limit the load on receivers. E.g.: For a Splunk Load Balanced Destination, if you have 5 Worker Groups sending data to the same Splunk indexer cluster, with 25 indexers, set **Max connections** to between `5-10`.

Load Balancers

The load balancer in front of the Leader UI can be an Application Load Balancer or a Network Load Balancer.

The load balancer between the Cribl Workers and the Cribl Leader listening on port 4200 must be a Network Load Balancer or equivalent.

Leader High Availability

Configuring Leader high availability requires a standby server, a load balancer (details here) between users and the Cribl UI port, and a Network Load Balancer between the Cribl Leader and Workers.

Leader high availability is optional. Many customers opt instead for a single Leader, and a remote Git repo for scheduled backups. If the Leader becomes unavailable, you can use the Git repo to provision a new Leader, restoring configuration from a backup.

However, a single Leader is reliable only when Workers are running Cribl Sources that fully leverage a shared-nothing architecture (such as Raw HTTP, Splunk HEC, Elasticsearch API, Amazon S3 Source, etc). Here, Workers can process data even if the Leader is unavailable. A Leader without failover will not reliably support Collectors, which require a Leader's ongoing orchestration.

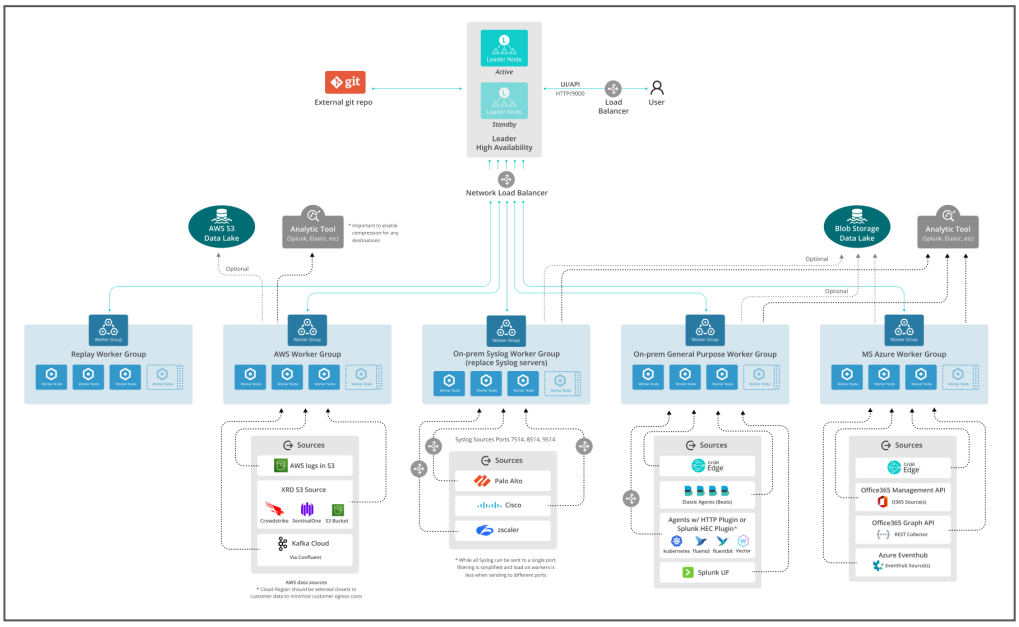
5.3. Comprehensive Reference Architecture

This reference architecture shows one Cribl Stream deployment possibility for sending data to a diverse mix of destinations, such as data centers, while minimizing data egress costs. The multiple Worker Groups might be organized functionally, or by geographic location.



Comprehensive reference architecture

Download an editable version of this diagram in SVG or draw.io format. Download Cribl stencils here.

This architecture shows on-prem Worker Groups and primary/standby Leaders. For a Cribl.Cloud-centric alternative, see Comprehensive Hybrid Cloud Reference Architecture.

Division of Labor

In this architecture, you manage all components.

You also manage a remote Git repo. You manage commit, push, deploy, and backup operations through the Cribl Leader.

The Replay Worker Group can be on-demand, and provisioned when heavy replays are planned.

General Sizing Considerations

Size based on data throughput (in+out), and on number of incoming TCP connections.

Destination Considerations

Adjust Destinations' **Advanced Settings** > **Max connections** setting (where available) to limit the load on receivers. E.g.: For a Splunk Load Balanced Destination, if you have 5 Worker Groups sending data to the same Splunk indexer cluster, with 25 indexers, set **Max connections** to between `5-10`.

Load Balancers

The load balancer in front of the Leader UI can be an Application Load Balancer or a Network Load Balancer.

The load balancer between the Cribl Workers and the Cribl Leader listening on port 4200 must be a Network Load Balancer or equivalent.

Leader High Availability

Configuring Leader high availability requires a standby server, a load balancer (details here) between users and the Cribl UI port, and a Network Load Balancer between the Cribl Leader and Workers.

Leader high availability is optional. Many customers opt instead for a single Leader, and a remote Git repo for scheduled backups. If the Leader becomes unavailable, you can use the Git repo to provision a new Leader, restoring configuration from a backup.

However, a single Leader is reliable only when Workers are running Cribl Sources that fully leverage a shared-nothing architecture (such as Raw HTTP, Splunk HEC, Elasticsearch API, Amazon S3 Source, etc). Here, Workers can process data even if the Leader is unavailable. A Leader without failover will not reliably support Collectors, which require a Leader's ongoing orchestration.

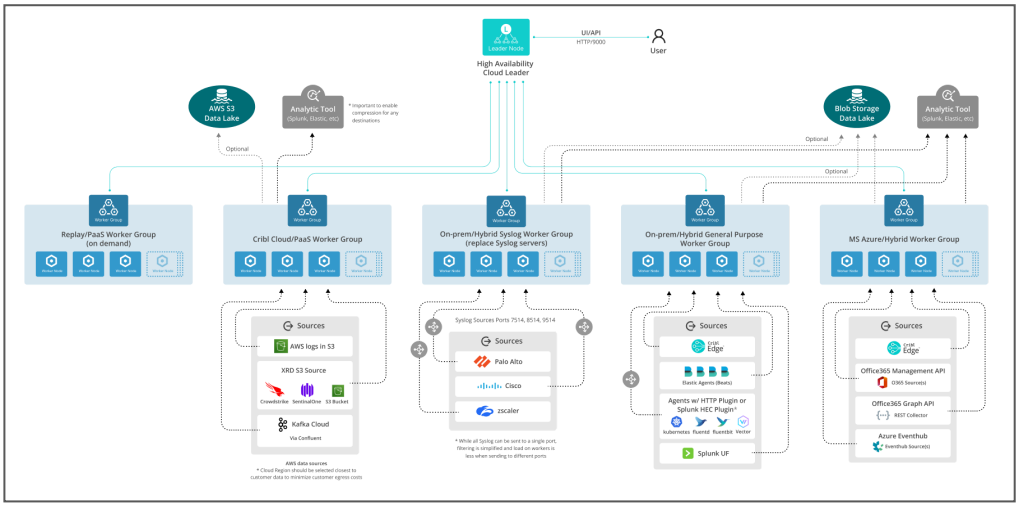
Cribl is not responsible for any use of this document or the information provided herein.

5.4. Comprehensive Hybrid Cloud Reference Architecture

This reference architecture shows one Cribl Stream deployment possibility for sending data to a mix of analytics tools and data lakes. Data is processed by a mix of Cribl-managed/PaaS (platform as a service) and hybrid Worker Groups, all coordinated by a Cribl.Cloud Leader with failover. The multiple Worker Groups are organized functionally, by Destination type. One Cribl-managed Group in Cribl.Cloud is reserved for on-demand replay from data lakes.



Comprehensive hybrid Cribl.Cloud reference architecture

Download an editable version of this diagram in SVG or draw.io format. Download Cribl stencils here.

This architecture shows Cribl.Cloud Leaders with a mix of Cribl-managed and customer-managed (hybrid) Workers. For a fully on-prem alternative, see Comprehensive Reference Architecture.

Division of Labor

Cribl.Cloud maintains high-availability Leader infrastructure on your behalf.

Cribl.Cloud also maintains secure copies of the Leader's configurations for all Worker Groups (Cribl-managed/PaaS and hybrid).

Even on Cribl-managed/PaaS Worker Groups, configuring and administering Pipelines, Routes, etc., remains your responsibility.

General Sizing Considerations

Size based on data throughput (in+out), and on number of incoming TCP connections.

Destination Considerations

On Cribl-managed/PaaS Groups, enable compression on all Destinations that support it, to minimize data egress volume and costs.

Adjust Destinations' **Advanced Settings** > **Max connections** setting (where available) to limit the load on receivers. E.g.: For a Splunk Load Balanced Destination, if you have 5 Worker Groups sending data to the same Splunk indexer cluster, with 25 indexers, set **Max connections** to between `5-10`.

Disclaimers

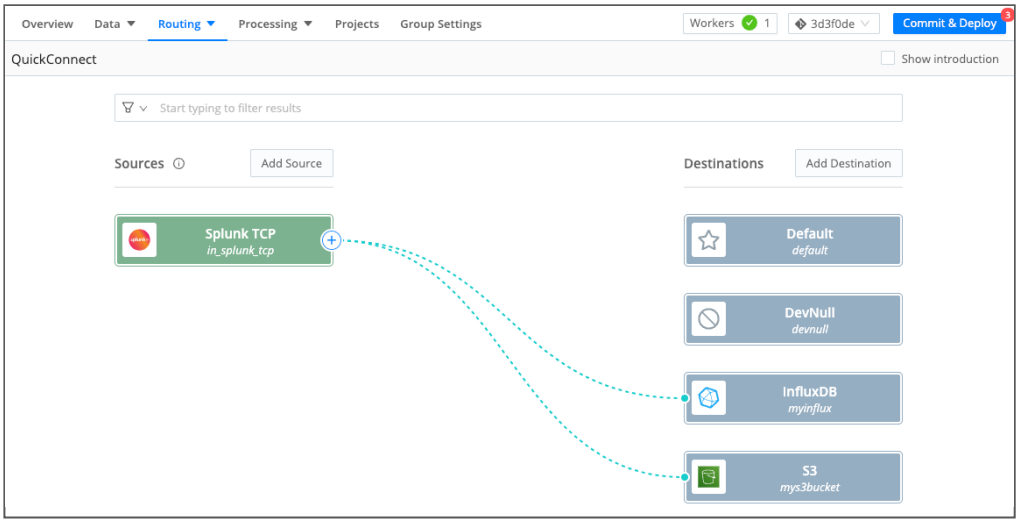
You should not act on any information provided until you have formed your own opinion through investigation and research. Cribl is not responsible for any use of this document or the information provided herein.

6. QuickConnect

The QuickConnect visual rapid-development UI enables you to visually connect Cribl Stream inputs (Sources) to outputs (Destinations) through simple drag-and-drop.

You can insert Pipelines or Packs into the connections, to take advantage of Cribl Stream's full range of data-transformation Functions. Or you can omit these processing stages entirely, to send incoming data directly to Destinations – with minimal configuration fuss.

QuickConnect was designed as a simple, quick way to prototype, test, and send data flowing through Cribl Stream. But it's also entirely suitable for configuring a production deployment, if your needs are restricted to sending data through parallel paths, and you don't need to use Routes. (See QuickConnect Versus Routes to help you clarify that choice.)

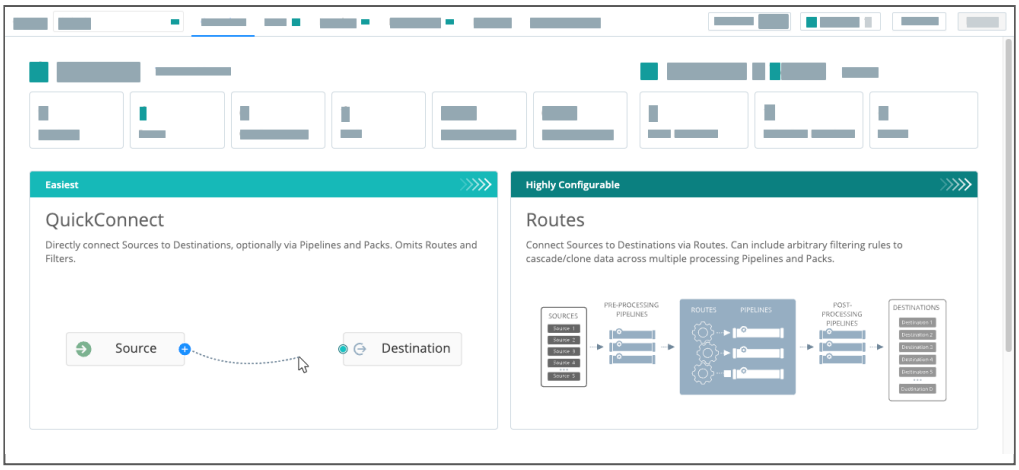


QuickConnect UI

You also have the option to start with simple direct connections, and later add Pipelines and/or Packs processing power at up to three stages of each connection.

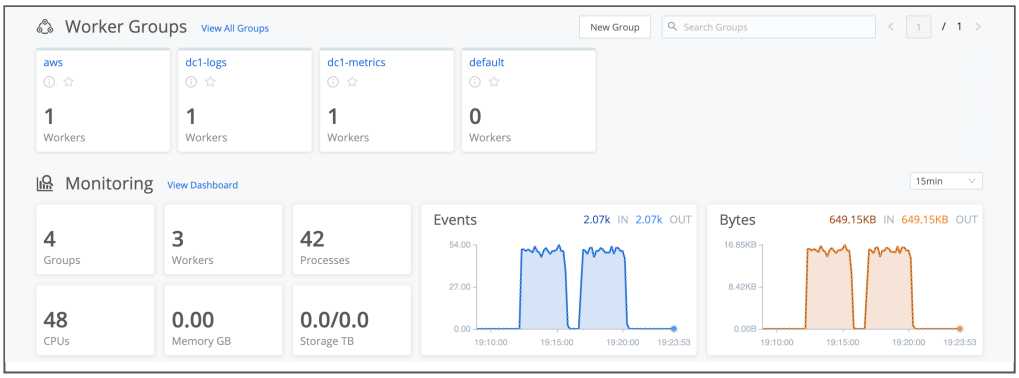
Initiate QuickConnect

When you display the home page of a Cribl Stream single instance or Worker Group, you'll see tiles that prompt you to choose between the **QuickConnect** versus **Route** configuration. Select the left tile to start using QuickConnect.



QuickConnect versus Routing

To display this landing page in a Distributed deployment, you must first select a Worker Group. In the sidebar, select **Worker Groups**, and then select the `default` or a different Worker Group. Or, select a Worker Group's tile on the Distributed landing page, as shown here.



Selecting a Worker Group

You can switch to the Routes configuration at any time from the **Worker Groups** submenu by selecting **Routing** > **Data Routes**. To toggle back, select **Routing** > **QuickConnect**.

QuickConnect Versus Routes

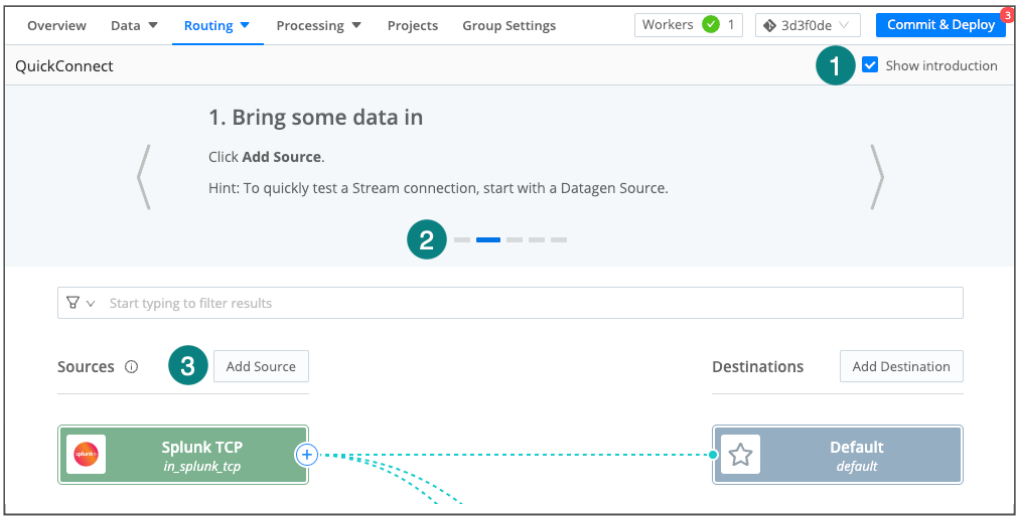
QuickConnect provides access to most of Cribl Stream's configuration options, with a few restrictions (in exchange for the simplified visual interface):

- QuickConnect completely bypasses Routes – which is why every QuickConnect path is independent and parallel. There is no Route-level data filtering, and you forego the Cribl Stream Routing table's options to clone and cascade data across Pipelines.
- Most Sources are available to fully configure. However, you'll need to use **Routing** > **Data Routes** to configure Collector Sources.

- Each supported Source's config can be created in either QuickConnect or Routes, and will reside only in that context. But you can switch a config between the two contexts, or you can create an identical config on the opposite side.
- All Destinations are available to fully configure.
- Everything you configure in QuickConnect exists separately from everything you configure in Data Routes. (But remember that you can use the **Routing** menu to toggle between contexts, and then replicate a QuickConnect configuration on the Data Routes side, or vice versa.)

Use QuickConnect

QuickConnect is designed to be nearly self-documenting, with **Introduction** help text available at the top of the UI. Here's a little extra help on help, keyed to the orange, numbered callouts in the screenshot:



QuickConnect Introduction/help carousel

1. Use the **Show introduction** check box at the upper right to toggle the help text on and off.
2. Use the dashed buttons to advance or rewind the help text's carousel (whose position is independent of your connection state).
3. Once you've added at least one Source, the **New Source** button (mentioned in the help text) becomes an **Add Source** button beside the **Sources** header.

Enable Sources and Destinations

When you add Sources and Destinations, their configuration options will open in a drawer. Fill in a unique **Input ID**, and any other required fields marked by an asterisk (*). Then select **Save**.

Switch Contexts

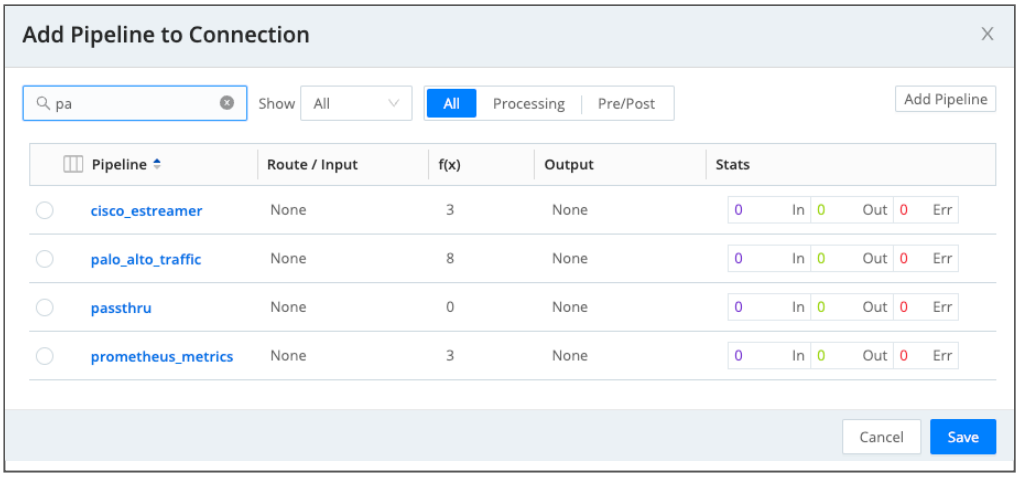
If you switch an **existing** Source to QuickConnect – for example, one of the preconfigured Sources that ship with Cribl Stream – you'll see a confirmation message. This is due to QuickConnect's independence from the Routes interface – you need to confirm your choice to move the existing configuration from the Data Routes world to the QuickConnect world.

If you switch an existing Source config to QuickConnect, its data will no longer flow through its configured Route.

You can also go the opposite way: move a Source originally configured in QuickConnect to the Routing interface. In the Source's drawer or config modal, select the **Connected Destinations** left tab, and then select the resulting tab's **Send to Routes** button. Here again, you'll need to confirm your choice before proceeding.

Select a Pipeline or Pack

When you add or modify a connection line, the **Connection Configuration** modal will prompt you to select a **Passthru**, **Pipeline**, or **Pack** connection. Selecting either **Pipeline** or **Pack** will open an **Add...** modal like this:



Adding a Pipeline

Here, you're using the radio buttons at left to select among already-configured Pipelines or Packs. **Resist the temptation to select a bold blue Pipeline or Pack name.** (Doing so will open the Pipeline's or Pack's config in a new modal, which might offer more configuration than you bargained for.)

Instead, select the radio button to the left of the Pipeline or Pack you want to select. (Or select some black text around the center of your desired Pipeline's/Pack's row, which will fill in its radio button.) Then click **Save** to confirm your choice and close the modal.

If you've attached Tags to your Pipelines or Packs, you can use the filter field to search against them. Use the format: **TAGS/tag_name**.

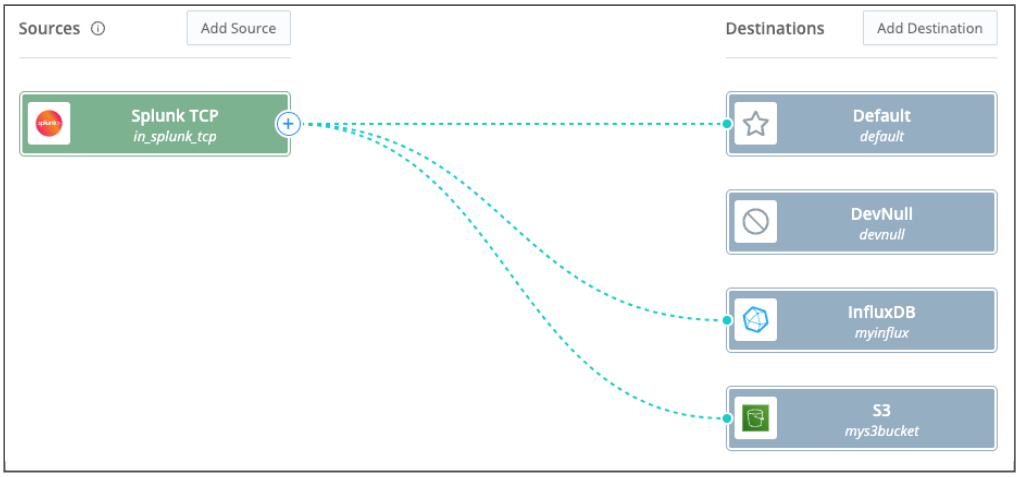
Edit a Pipeline

If you want to modify a Pipeline, this is where you do want to select its blue link in the **Add Pipeline to Connection** modal. For the options available here, see Pipelines.

Multiple Connections

You can drag multiple connection lines between a given Source/Destination pair. (You might do this, for example, to configure parallel Pipelines to handle different data types.)

Also, you can connect one Source to multiple Destinations, or multiple Sources to one Destination. Let's isolate examples of both, from the screen capture we started with:



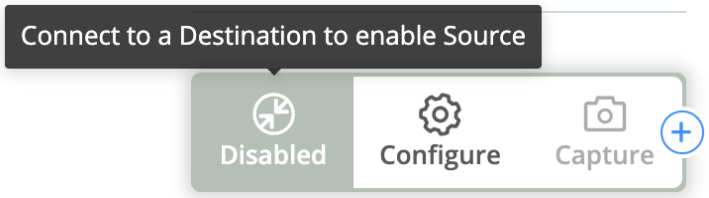
Multiple connections out, multiple connections in

Source/Destination Tile Hover Options

Once you've configured a Source or Destination, hovering over its tile will display options like these:

Tile on-hover options

The leftmost button is an indicator of the Source's/Destination's state. Live means healthy; disabled, error, or warning states will also appear here. Note that a Source will appear as **Disabled** until you connect it to a Destination.



A Source not connected to a Destination

Selecting the middle **Configure** button reopens the Source's Destination's configuration drawer, where you can address any problems or simply update the configuration.

The right **Capture** button captures a sample of data flowing through the Source or Destination, in a drawered version of the Source's/Destinations's config modal > Live tab. (Not to be confused with a healthy tile's left **Live** indicator.)

Group Connections

Once you've configured two or more copies of the same Source or Destination type – for example, to support different configurations of one integration or protocol – QuickConnect stacks their tiles together to keep the display clean.

2 similar Destinations, stacked

The number at the stack's upper right shows how many tiles it contains.

Hovering over a stack doesn't change its options...until you select it. This will expand all the tiles in the group, so each tile can now reveal the on-hover options described earlier.

You can drag multiple connection lines from, or to, the same stack. If you drag or modify a connection from or to a stacked group, the UI will prompt you whether to similarly expand the group to access individual tiles.

7. Workspaces

Workspaces offer a multi-tenancy capability, enabling you to create multiple isolated instances in your Cribl.Cloud Organization. This lets you strengthen your security, and fulfill compliance and isolation requirements.

Each Workspace offers a dedicated virtual private cloud (VPC) that acts as a separate environment within your Organization.

A centralized interface allows you to manage all your Workspaces and control access for Members and Teams to individual Workspaces.

Workspaces require Cribl.Cloud with certain plan tiers. For details, see Pricing.

An example use case scenario for creating multiple Workspaces is setting up separate environments for different business units in an enterprise. Data management, security, development, and any other units can have their own federated Workspaces, with completely separate members and permissions lists. This way, they can work in isolation without risk of interference and with increased focus.

Limitations

You can create up to 5 Workspaces per Organization.

If you need more Workspaces in your Organization (up to 50), contact Cribl Support to discuss extension options.

Workspaces require Cribl.Cloud with certain plan tiers. For details, see Pricing.

View Workspace Details

Workspaces provide a set of information that you can use when configuring data flow through their Worker Nodes.

View Access Details

To view detailed access information of your Workspace, in the sidebar, select **Workspace** and then **Access**.

This page presents a summary of information about your Cribl.Cloud Organization, as well as the **Cribl.Cloud URL** for the current Workspace.

Cribl.Cloud URL

Cribl.Cloud URL is a static address associated with the load balancer that is in front of the Leader. customer-managed (hybrid) Worker Nodes will connect to this address on port 4200, while the Leader UI is served from this address on port 443.

You can use this URL for certain API calls and certain Collection operations coordinated by the Leader.

Stream Worker Group Details

Stream Worker Group Details provides information about Cribl-managed Worker Groups in Cribl.Cloud, if any are provisioned.

If no Worker Group is provisioned, you can select **Provision Now** to provision infrastructure for the Group. After a lag, the Group will be ready to process data, and this modal's remaining fields will populate.

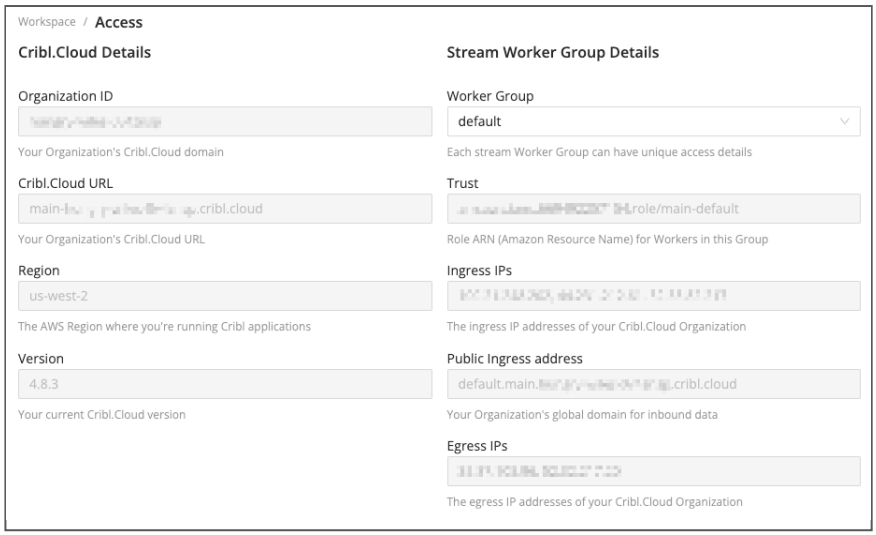
For a provisioned Worker Group, you see the following information:

Field	Description
Trust	Role ARN for Workers in this Worker Group. You configure these ARNs on the Trust tab.
Ingress IPs	The IPv4 addresses of Worker Groups' load balancers, also used when receiving data from Push Sources. These addresses will remain constant, so you can build firewall rules around them.
Public Ingress address	Each Group's domain for inbound data. This address prepends the Group name to the Organization's global domain name. It does not append ports per data type – you can obtain these from the Data Sources tab.
Egress IPs	Your Cribl.Cloud Organization's current public IP addresses. These addresses are Group-specific and also dynamic: Cribl will occasionally update them when we need to rescale core infrastructure.

Public Ingress address and **Egress IPs** are used for both outbound connections from the Workers and Pull Sources.

Egress IPs are not static.

If you need a static egress IP, contact Cribl Support.



Access Details modal for a provisioned Group

Configuring Stream Groups (beyond the `default` Group) requires certain plan tiers. For details, see Pricing. For details about creating and provisioning Groups, see Cribl.Cloud Worker Groups.

View Data Sources

To view detailed access information about a Workspace's Data Sources, in the sidebar, select **Workspace** and then **Data Sources**.

The **Data Sources** page lists ports, protocols, and data ingestion inputs that are open and available to use, including pre-enabled Sources. Use the **Group** drop-down to filter these details per Cribl-managed Worker Group in Cribl.Cloud. For details, see Available Ports and TLS Configurations.

For each existing Source listed here, Cribl recommends using the preconfigured endpoint and port to send data into Cribl Stream.

Get ARN

To get the ARN (Amazon Resource Name) for your Workspace, in the sidebar, select **Workspace** and then **Trust**.

You can copy and paste the **Worker ARN**s listed in the **Trust** page to attach a Trust Relationship to an AWS account's IAM role. Use the **Group** drop-down to display the ARN for any Group of Cribl-managed Stream Worker Groups in Cribl.Cloud.

Attaching a Trust Relationship enables the `AssumeRole` action, providing cross-account access. For usage details, see the AWS Cross-Account Data Collection topic's **Account B Configuration** section.

This option applies only to your Cloud Workers. You cannot use this technique to enable access to customer-managed hybrid Workers.

Set Up ACL

To set up Access Control List (ACL) Rules, in the sidebar, select **Workspace** and then **Access Control List**.

ACL Rules (IPv4 CIDR ranges) let you restrict data sent to your data sources. The Rules you define here are global to all Cribl-managed Worker Groups in Cribl.Cloud in the current Workspace.

The default `0.0.0.0/0` rule (modifiable) imposes no limits. End a rule with `/32` to specify a single IP address, or with `/24` to enable a whole CIDR block from `x.x.x.0` to `x.x.x.255`.

Select **Save** after adding, modifying, or removing rules. Each change takes up to 5 minutes to propagate. Cribl.Cloud will display a banner, notifying you that rules edits are temporarily disabled to prevent conflicts. A successful update proceeds silently – you will not see a confirmation message.

The **ACL** options apply only to Cribl-managed Workers. You cannot use them to set access rules on customer-managed hybrid Workers.

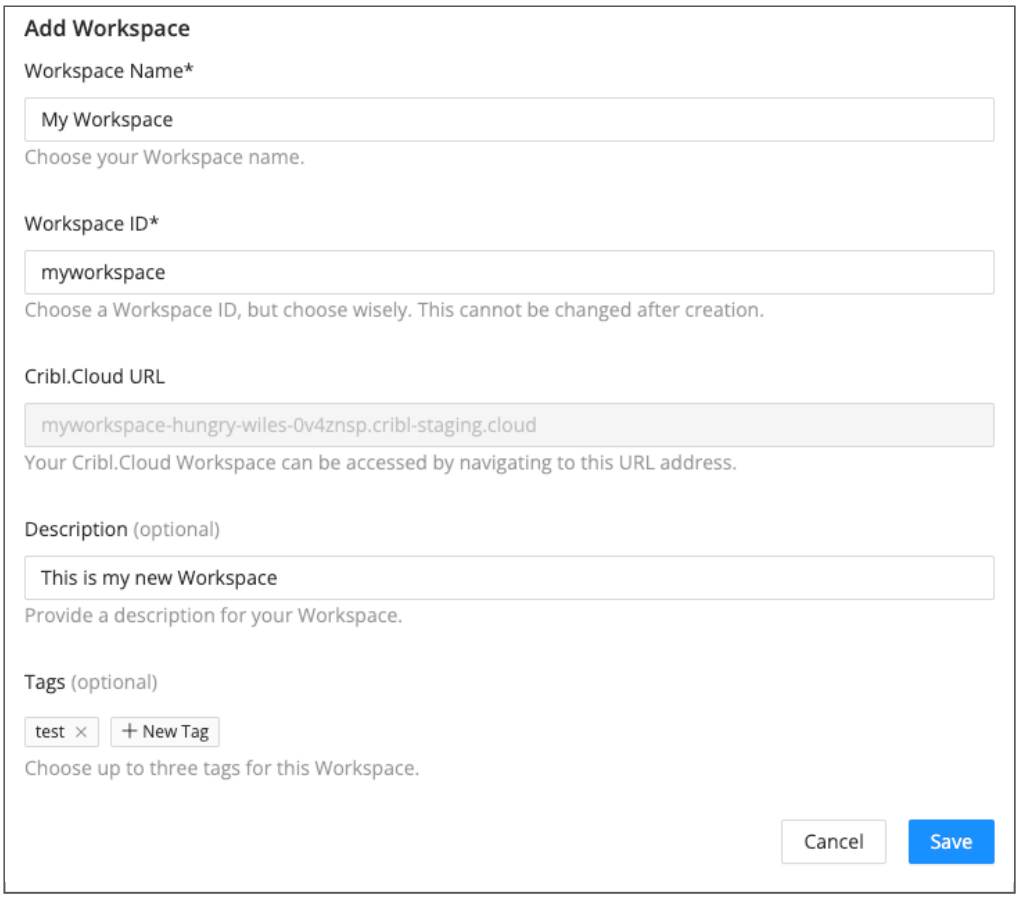
7.1. Configuring Workspaces

Add New Workspace

To create a new Workspace:

1. On the top bar, select your current Workspace name. This opens a modal with a list of all Workspaces you have access to.
2. Select **Add Workspace**.
3. Fill the form with the following information:

Field	Description	Notes
Workspace Name	Human-readable name for the Workspace.	
Workspace ID	Internal ID for the Workspace. This ID will be part of the Workspace's Cribl.Cloud URL.	**Cannot be changed** once the Workspace is created.
Description	Additional Workspace description.	Optional
Tags	Up to 3 tags you can use to filter Workspaces.	Optional



4. Confirm with **Save**.

The Workspace can take up to several minutes to spin up. While the process continues, you can navigate away and keep working with your Cribl.Cloud instance as usual.

Edit or Delete a Workspace

To edit a Workspace:

1. On the top bar, select your current Workspace name. This opens a modal with a list of all Workspaces you have access to.
2. Next to the Workspace you want to edit, select **Settings** in the **Actions** column.
3. Here you can change the name, description, and tags of a Workspace. However, you can't change the Workspace ID after it has been created.
4. Confirm with **Save**.

On the same page you can select **Delete Workspace** to remove it. You will need to manually type the name of the Workspace as a security measure.

Only Members with the Organization Owner permission can delete Workspaces.

8. Projects

Projects (also called Stream Projects) diversify who can use Cribl Stream, and how:

- Projects create isolated spaces for teams and users to share and manage their data. Project editors get a streamlined visual UI.
- Cribl admins can filter users' access to specific data and Destinations – scoping the access to match what's relevant to those users' work.

This self-service approach to Cribl Stream data can benefit its immediate users, by offering them accelerated access to relevant data, with minimal configuration requirements. It can also benefit their peers.

Project editors get isolated data flows, and they can customize them to meet their needs, with no impact on other Cribl Stream users across their organization. Data can be forked into (for example) full-fidelity versus redacted views, to match different groups' authorization and needs.

You can also isolate data and permissions at a higher level by using Workspaces (available in Cribl.Cloud). Workspaces offer a separate VPC (virtual private cloud) that acts as a separate environment that contains not only Cribl Stream, but all Cribl products. See Workspaces for more details.

Breaking Change

Any Projects you created in v.4.1.x are deleted when you upgrade to v.4.2. You must re-create your Projects after you upgrade. You should also delete and re-create any Subscriptions that carry over during the upgrade.

In Cribl Stream 4.2 and later, Projects/Subscriptions rely entirely on the fine-grained Members/Permissions access control first introduced in Stream 4.2. See Adding Users to Projects for details.

Use-Case Scenario

Imagine that a Cribl administrator wants to filter data from a shared set of firewall Sources, splitting the data between her organization's Security and Ops teams. A requirement is that each team's data should be isolated, with neither team having access to the other team's data. The Security team uses Splunk, while the Operations team uses Elasticsearch.

Projects enable this filtering and isolation. Each team gets secure access to its own sets of data, and each team's data transformations and configuration changes don't affect the other team's data or configs. Additionally, data capture and samples are isolated to each project.

Requirements

Enabling Projects requires certain plan/license tiers. For details, see Pricing..

Projects' Subscriptions can ingest data only from Cribl Stream Sources configured as **Send to Routes**, not from QuickConnect Sources. (This is despite Projects' QuickConnect-like Project view, introduced below.)

Components

This feature relies on the following building blocks:

- Subscriptions
- Data Projects
- Roles and Permissions

Data Projects

The **Data Projects** tab is where Cribl admins can add and configure Projects, share access to those Projects, and associate Subscriptions with specific Destinations.

Admins see an expanded version of the same drag-and-drop visual UI that Project editors can use to connect configured Subscription with configured Destinations.

Each project maintains its own independent processing Pipelines, data capture and sample data.

Subscriptions

Each Subscription filters a subset of a Worker Group's incoming data to expose to Project editors, along with processing options for that data.

Members and Permissions

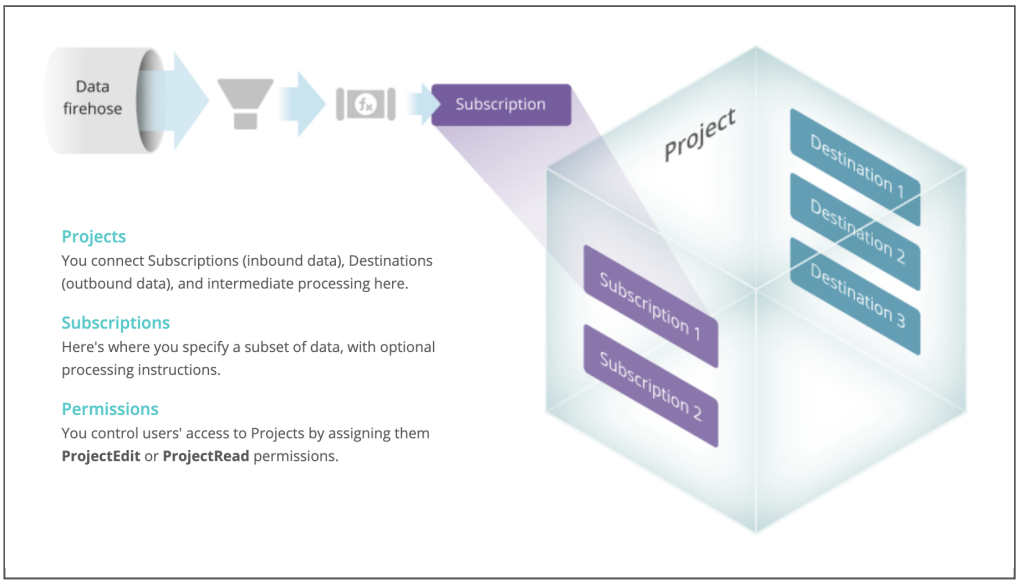
Projects work with the Members and Permissions authorization system. Cribl Stream admins – users who hold the Stream- or Worker Group-level `Admin` or `Editor` Permission, or the legacy `stream_admin` Role – can create and configure Projects and Subscriptions. They can access resources outside individual Projects to build the Projects.

As a Stream Admin, you also control users' access to Projects and Subscriptions. For details, see Adding Users to Projects.

How the Components Fit Together

The components' names and relationship are easiest to remember in terms of the publish/subscribe model long used by Cribl Stream integrations like Kafka or Google Cloud Pub/Sub:

- A **Project** is a microcosm of a whole Cribl Stream deployment – gathering together Subscriptions' incoming data, routing/processing, Destinations, and authorized users.
- A **Subscription** specifies a subset of available data to retrieve, and how to import the data.



How Subscriptions and Projects filter incoming data

Get Started with Projects

You interact with Projects in either of two ways, depending on your Cribl Stream Permissions.

As a Project Editor

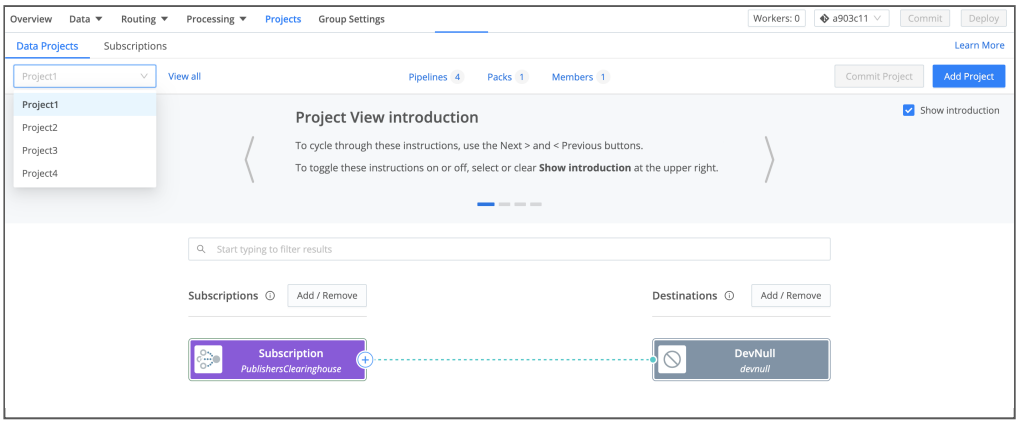
When you log into Cribl Stream and navigate to a Group, you'll find your Projects and Subscriptions already set up for you in a convenient visual UI.

You can adjust your Projects' data flow by connecting Subscriptions to Destinations. You can insert and configure Pipelines, and can insert Packs, that are part of the Project. You can also commit your configuration changes to Git. This all works the same way as in QuickConnect.

As a Cribl Admin

To access Projects configuration options:

1. Navigate to a Worker Group. (Projects and their components are configured per Group, providing a first layer of isolation).
2. Select **Projects** in the submenu to see two menu options: **Data Projects** and **Subscriptions**.
3. See the following pages for details on configuring each of these components for Project editors.



Accessing the Project view

8.1. Configure Projects

Projects define the data that the Project's users can consume, where that data can be sent, and who has access to the Project. A Project associates specific Subscriptions with specific Destinations. For fine-grained access control, you can share each Project with specific Members and Teams.

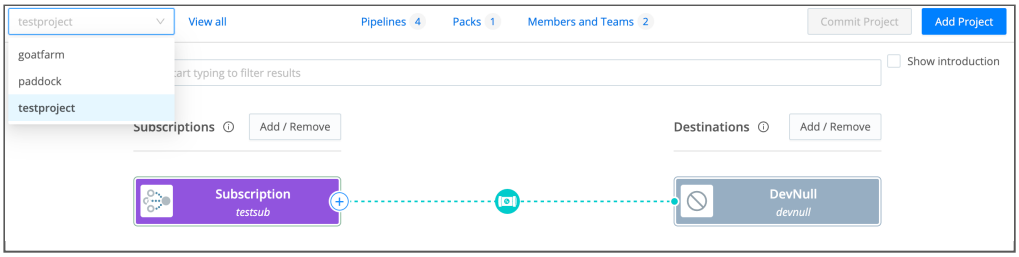
By connecting incoming data sources (Subscriptions) to specific Destinations, Projects function like a Route's Output selection. We expand on this similarity in Subscriptions and Routes.

Access Projects

From your Worker Group's **Manage** submenu, select **Projects** to open the default **Data Projects** page.

This is the "Project view," an expanded version of the UI in which Project editors will manage connections among the resources you define here. From left to right, the options in this administrator's view are:

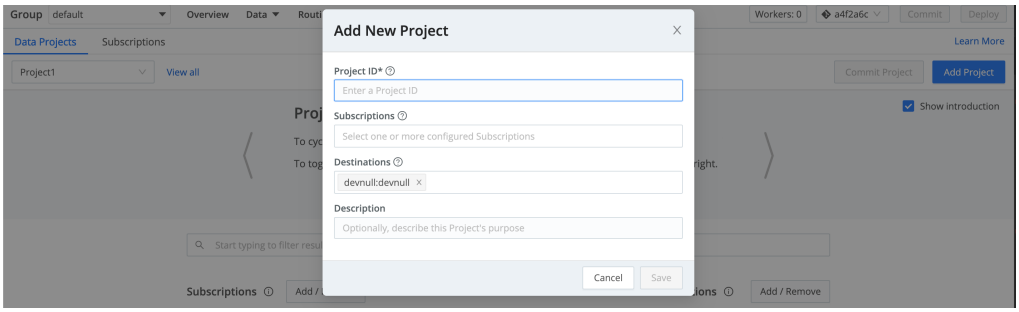
- Projects drop-down list: To bring a different Project into the Project view, select it here.
- **View all** link: Select to open the **All Projects** modal, where you can configure and share existing Projects.
- **Pipelines** link: Select to open a modal where you can manage Pipelines that are scoped to this Project.
- **Packs** link: Works the same way as the **Pipelines** link. The modal will show only Packs that are part of this Project. For Project editors, Packs will be read-only resources – Project editors can insert or remove Packs, but not modify them.
- **Members and Teams** link: Select to open a drawer where you can grant Members and/or Teams access to the Project.
- **Commit Project** button: Commit changes from this Project to Git.
- **Add Project** button: Creates a new Project. Covered just below.



Accessing the Project view

Configure a New Project

1. From the Project view shown above, select **Add Project** to open the **Add New Project** modal shown below.



Configuring a new Project

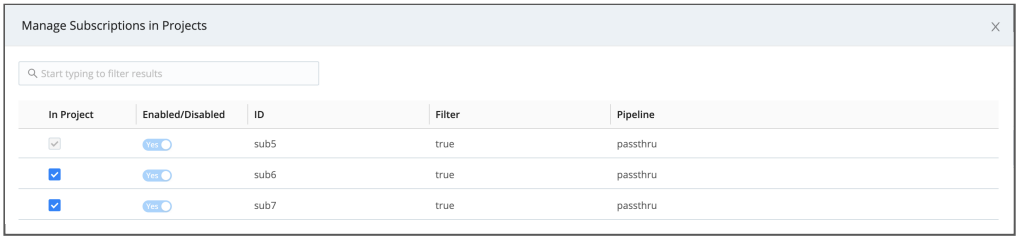
2. Assign this Project a unique **Project ID**. (This can include letters, numbers, `_`, and `-`. IDs are case-sensitive, so entering the same characters with different capitalization will create a separate ID.)
3. Select one or more configured **Subscriptions**. (You can access only Subscriptions that are already configured in this Project. But you can reopen this modal later to add newly configured Subscriptions. Also, the Subscriptions UI enables you to add Subscriptions to Projects.)
4. Select one or more configured **Destinations** that will have access to this Project's data. (You can access only Destinations that are already configured in this Project – but you can configure and add more Destinations in the next section.)
5. Optionally, add a **Description** of the Project's purpose.
6. Select **Save** to finish configuring your Project.
7. Commit and deploy your changes.

To view **Live Data** on your configured **Destination**, you must **Commit** and **Deploy** your changes.

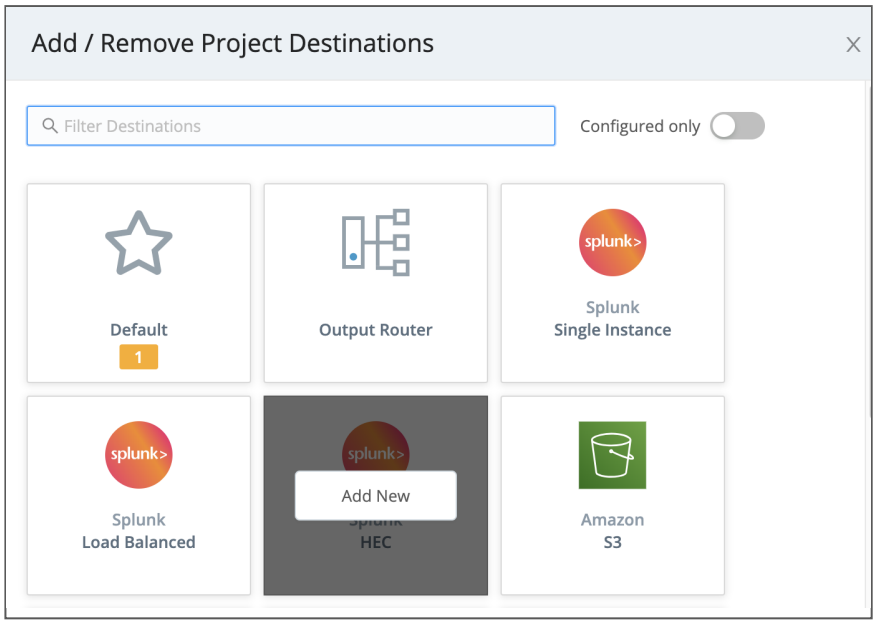
Test a Project (Manage Data Flow)

After you return to the Project view, make sure your desired Project has focus in the upper-left drop-down list. You can now use the Project view's visual UI to expand the Project and enable its data flow. The options here include:

- Connect the Project's already configured Subscriptions and Destinations, optionally adding a Pipeline or Pack to each connection.
- Select **Subscriptions** > **Add / Remove** to open a drawer where you can expose any Subscription you've already configured in the Project, remove Subscriptions from the Project view, or add new Subscriptions.



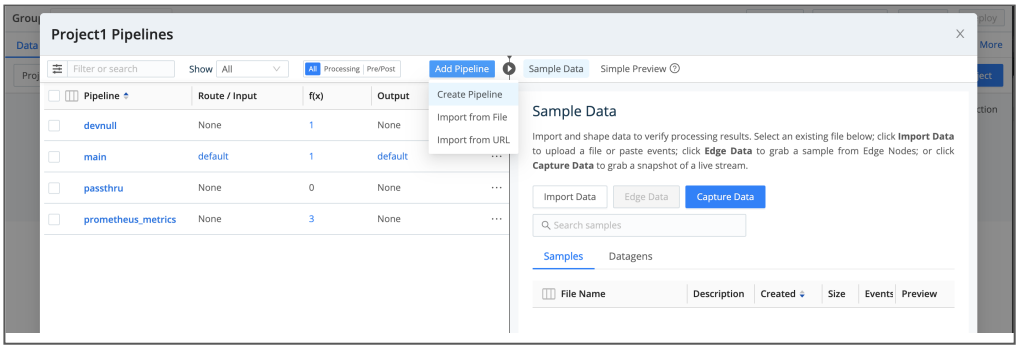
- Select **Destinations** > **Add / Remove** to open a drawer where you can expose and configure any Destination type available in your Cribl Stream deployment. (Any Destination that you add here will automatically be added to the Project's configuration modal when you next reopen it.)



As you configure and test your Project, beware of high ingestion rates that could overwhelm downstream receivers. To prevent dropped events, enable Persistent Queues on Destinations that support them.

Enable Pipelines and Packs

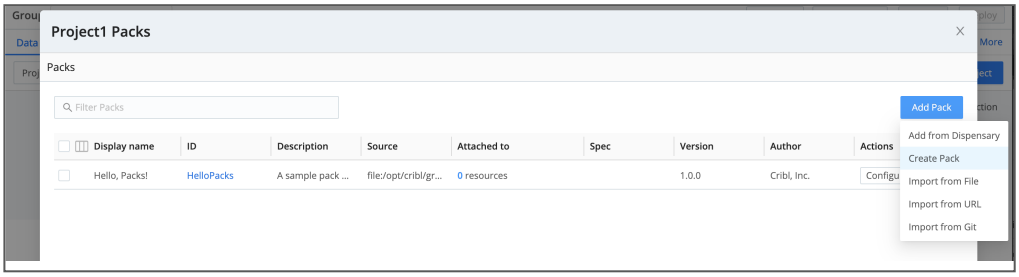
Each Project that you configure opens with a basic set of Pipelines and one default Pack. To manage these, select the upper **Pipelines** or **Packs** link, respectively. Each opens a modal similar to Cribl Stream's standard Pipelines or Packs UI, with access to standard Sample Data and Preview options on the right.



Managing Project Pipelines

To offer Project editors additional processing resources to insert on Subscription/Destination connections, select the modal's **Add Pipeline** or **Add Pack** button. You can then enable new Pipelines and Packs in the Project, with these constraints:

- You can create a new Pipeline or Pack here. It will be available only in the current Project.
- You can import an existing Pipeline or Pack. Any modifications that you make here will similarly be scoped to the current Project.
- To import an existing Pipeline from your Cribl Stream deployment, you must export it as JSON, then select the **Import from Pipeline** drop-down option shown above. (You can also **Import from URL**.)
- You can import Packs from an exported JSON file, a URL, or the Dispensary or Git options shown on the drop-down below.

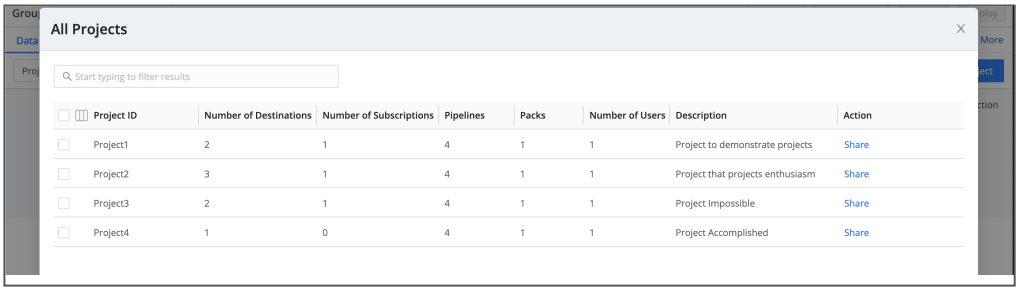


Adding Project Packs

Edit a Project

To update an existing Project, select the Project view's upper-left **View all** link. From the resulting **All Projects** modal, select the Project's row to reopen its configuration in a modal similar to the **Add New Project** modal covered above.

You can also select any row's **Share** link to open a drawer in which to manage users' access to the Project.



View all > All Projects modal

Access Project Metrics

You can access the following metrics on your Projects:

- Events and bytes in/out of Subscriptions.
- Bytes in/out of Pipelines, Packs, and Destinations.
- Events in/out/dropped through Pipelines, Packs, and Destinations;

To tap these metrics, enable Cribl Stream's internal CriblMetrics Source. This Source's defaults are different for Cribl.Cloud versus on-prem deployments.

Cribl.Cloud Leaders and Groups

For Cribl.Cloud Leaders, and Worker Groups of Cribl-managed Workers in Cribl.Cloud, Projects' metrics are always available to the CriblMetrics Source. This availability is not configurable.

On-Prem Leaders and Groups

For on-prem Leaders, and customer-managed (hybrid or on-prem) Worker Groups, Projects' metrics are disabled by default. (As with other on-prem exclusions, we provide this default to optimize performance.) However, you can easily make these metrics available to the CriblMetrics Source.

See Controlling Metrics for general instructions on modifying defaults at the Leader, Worker Group, or single-instance level. From the **Disable field metrics** list, remove the `project` metric. Then save, commit, and deploy your changes.

8.2. Configure Subscriptions

You use a Subscription's **Filter** expression to specify a subset of a Worker Group's overall incoming data stream to forward to Destinations. Optionally, you can also specify a Pre-processing Pipeline to condition that data before it leaves the Subscription.

You gather Subscriptions into Projects, where you match them up with Destinations and share them with authorized users.

A Project can contain multiple Subscriptions, and each Subscription can be associated with multiple Projects. Each Project's copy of the Subscription will share the same configuration, but will have independent data flow.

Subscriptions and Routes

From the UI similarity, you've probably noticed that Subscriptions look and function much like Routes. There are both similarities and differences – which we'll consider in reverse order.

Subscriptions/Routes Differences

Compared to Routes, Subscriptions present these exceptions:

- Subscriptions lack a Route's **Output** or **Output Expression** field. (Instead, you associate Subscriptions with Projects, where Project editors can process the data and send it to Destinations.
- Subscriptions have no **Final** flag. So a Subscription is similar to a Route with the **Final** toggle switched off.
- Subscriptions do not relay backpressure upstream to data senders. (This is by design, to prevent any Subscription from affecting data flow through parallel Subscriptions, Projects, or Routes/Pipelines.) If any backpressure occurs, a Subscription will drop data.

Subscriptions/Routes Similarities

A further link to Cribl Stream's Data Routes interface is that Subscriptions can ingest data **only** from Sources configured (at the Cribl Stream product level) as **Send to Routes**. (Subscriptions and Projects cannot ingest data from QuickConnect Sources, despite the similarity of Projects' visual UI (the Project view).

This also means that Subscriptions tap exactly the same overall flow of inbound data that Data Routes do, in parallel. So there are cases where, after you've configured Subscriptions to ingest certain data, you might want to configure a Pipeline at the top of the Routing table to drop the same data. This will prevent Cribl Stream from processing the same events twice.

Usage Tips

Compared to sending the same data flow through Routes, adding Subscriptions can have a performance impact, because each Subscription creates a copy of the data that Cribl Stream needs to process. Therefore, your resource requirements could change with the number of Subscriptions you add.

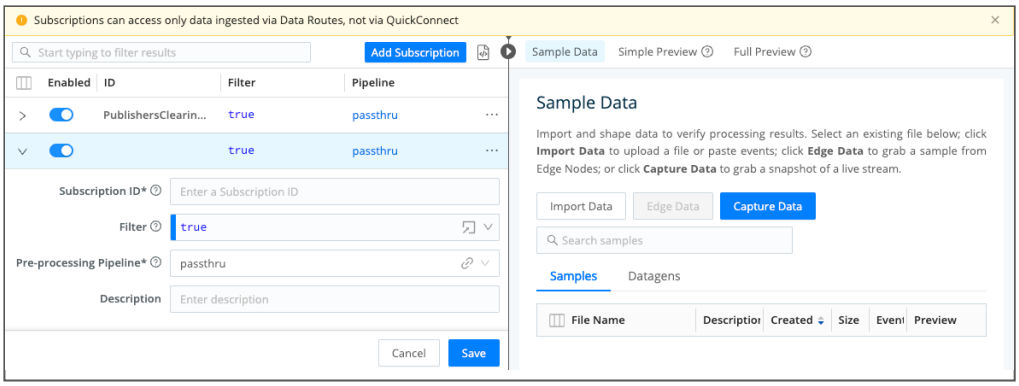
Please work with your Cribl Solutions Engineer to select an architecture that best balances your needs for performance versus segmented data/configuration access.

Cribl recommends that you configure a separate Subscription – and corresponding Pipeline(s) – for each data type you ingest. This enables you to filter by data type in the Subscription's definition, and again in individual Pipeline Functions.

Access Subscriptions

From your Worker Group's submenu, select **Projects**, and then select **Subscriptions**.

Any Subscriptions you've already configured will appear here. Expand the accordions to access each Subscription's configuration.



Configuring a new Subscription

Configure a New Subscription

1. Select **Add Subscription** to open the configuration options described below.
2. Assign this Subscription a unique **Subscription ID**. (This can include letters, numbers, `_`, and `-`. IDs are case-sensitive, so entering the same characters with different capitalization will create a separate ID.)
3. Modify the **Filter** by replacing the default `true` with a JavaScript expression that selects a subset of events to filter through this Subscription. (Your expression can specify an upstream sender, a data type, the presence of particular fields, etc. For examples, see Cribl Expression Syntax.)
4. Modify (as needed) the Source's default `passthru` Pre-processing Pipeline.
5. Optionally, add a **Description** of the Subscription's purpose.

6. Optionally, assign the Subscription to one or more Projects. (You can also import Subscriptions from individual Projects' configurations, and can control Subscriptions' visibility in the Project view.)
7. Select **Save** to save the new Subscription to the Subscriptions table.
8. Commit and deploy your changes.

A Subscription must specify a Pre-processing Pipeline, even if this is the default `passthru`, which performs no processing.

Add and Preview More Subscriptions

On the **Subscriptions** page, you can select **Add Subscription** to define multiple Subscriptions. These stack on the left, like Routes in Cribl Stream's Routing table.

Note these further similarities to the Routing table:

- Each Subscription's blue title bar has a toggle that you can use to disable the Subscription from gathering data, while preserving its configuration.
- On the right, you can capture, import, and save sample data, and. You can use these samples to preview how your Subscriptions transform incoming data.

Edit a Subscription

To update an existing Subscription, just select its accordion in the Subscriptions table. This will reopen the same configuration options outlined above.

8.3. Add Users To Projects

As a Stream admin, you control Members' access to individual Projects by assigning Permissions to those Members, as outlined below.

Breaking Change

In Cribl Stream 4.2 and later, Projects and Subscriptions rely entirely on the fine-grained Members/Permissions access control first introduced in Stream 4.2. The 4.1.x `project_user` Role and `ProjectSourceSubscribe` Policy, which provided access to all Projects, are now retired. To migrate Projects configured in v.4.1.x, you'll find those projects' users visible in Stream as Members. Assign them appropriate new Permissions, as outlined here.

Project-Level Permissions

You can share a Project with a Cribl Stream Member or Team using the following Permissions, with some constraints inherited from the Member's Permissions at higher levels (Cribl Organization, Cribl Stream, and Worker Group).

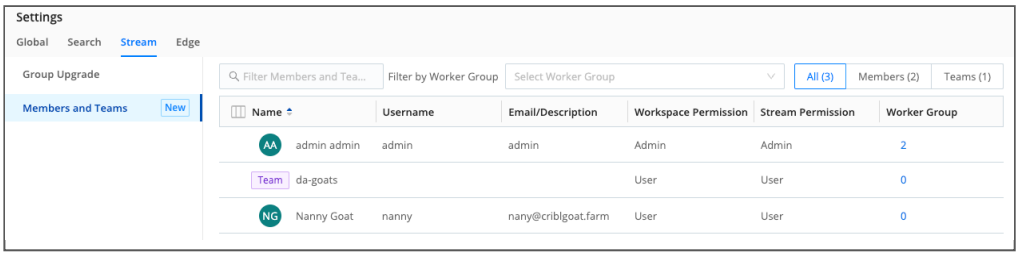
Permission	Description
Maintainer	Admin-level Permission. Allows freely editing or deleting the Project and its settings. (Shared, by inheritance, only with Members/Teams who have the `Admin` or `Editor` Permission at higher levels.)
Editor	Can configure connections among the Project's Subscriptions, Packs, and Destinations, but cannot modify or delete these resources. Can create, modify, and delete Pipelines within the Project. (**Use this Permission to share a Project with** Project editors.)
Read Only	Can view Project and Subscription settings and connections, but not modify or delete them. (Designed specifically for support personnel. Members/Teams who have the product-level `Read Only` Permission will inherit, and will be locked to, this Permission.)
No Access	Self-explanatory: a Member's default state on a Project that has not (yet) been shared with them.

Members or Teams who have the `User` Permission at the top (Organization) level are the most malleable at the Project level. These are the Members/Teams with whom you can readily share a Project-specific `Editor` Permission, to authorize them as a Project editor.

Share a Project (Example)

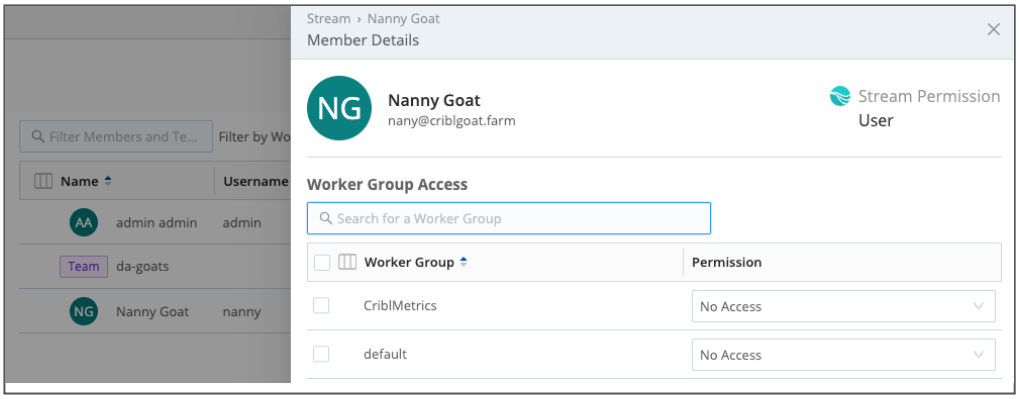
To share a Project with an eligible Cribl Stream Member or Team:

1. Select **Settings** > **Stream** > **Members and Teams**.
2. Make sure each applicable Member or Team has the `User` **Workspace Permission**, and the `User` **Stream Permission**. (Select an existing Member's row to adjust their Permissions.)



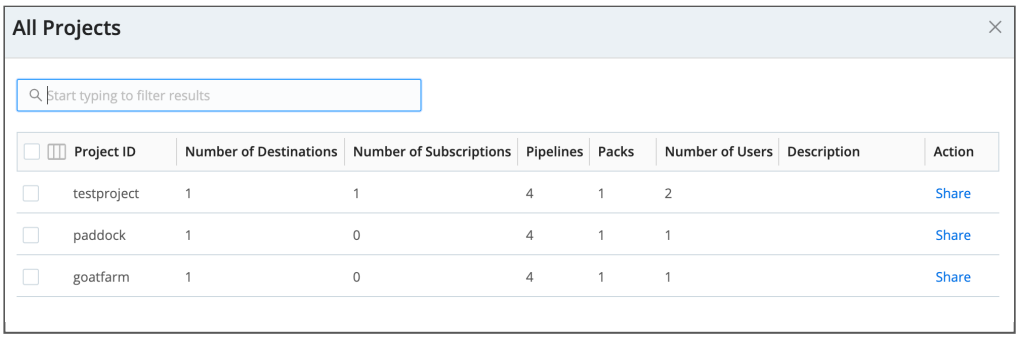
Stream Settings > Members and Teams

3. Select each applicable Member and Team's row to open their details drawer.

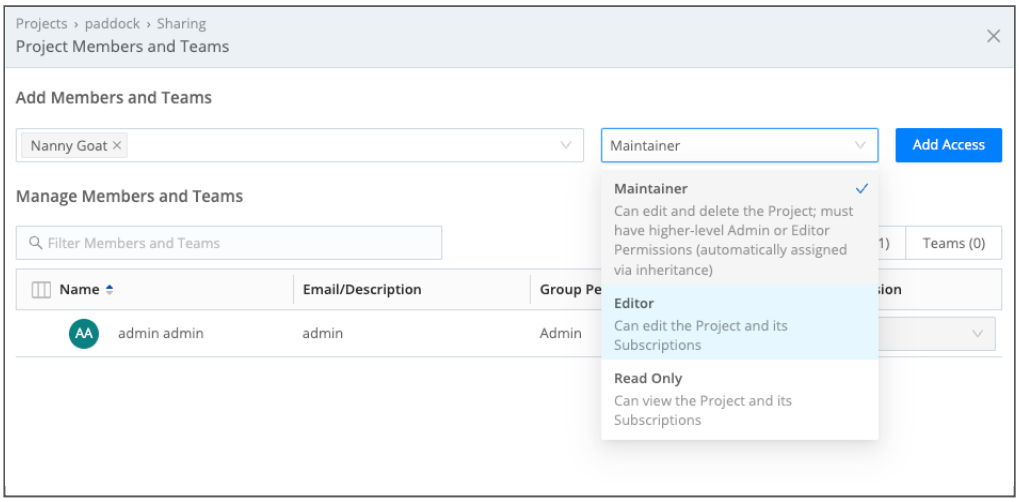


Stream Members > User Details

4. Grant the Member or Team a `User` Permission on the applicable Project's parent Worker Group. (Higher Permissions offered on this drop-down are not applicable to Project editors.)
5. In the sidebar, select **Worker Groups** and select the same Worker Group.
6. Select **Projects** > **Data Projects** > **View all**.



7. Select the Project's **Share** link to open the **Project Members and Teams** drawer. Here, you can see all the Group's Members and Teams with whom this Project can be (or has been) shared.
   You can also open an individual Project's **Sharing** drawer directly from the Project view. Give this Project focus in the Project view, then select the **Members and Teams** link at the top.
8. Grant each applicable Member or Team an `Editor` Permission on the Project. (The alternative `Read Only` Permission is intended for support users. It does not enable configuring connections or Pipelines.)



Project Sharing drawer – assigning `Editor` Permission

9. Select **Save** to confirm your changes, then select outside the drawer to close it.
10. Commit your changes, and deploy the Group if prompted.

These Members and Teams who now have Project `Editor` Permissions – and no higher Stream Permissions – view data filtered through the Projects UI. They also have read access to Cribl Stream Data Monitoring and Notifications.

You can reopen the same drawer to modify Members' Permission levels. To remove a Member from the Project, assign them `No Access`.

9. Administering

9.1. Licensing

Every Cribl Stream download package comes with a Free license that allows for processing of up to 1 TB/day. This license requires sending anonymized Telemetry Data to Cribl.

Enterprise, Standard, and Sales Trial licenses are entitled to a defined, per-license daily ingestion quota. These licenses do not require sending telemetry metadata.

This page applies only to on-premises deployments. For basic information about Cribl.Cloud Enterprise and Standard plans, see Cloud Pricing.

Manage Licenses

Check Licenses

To check your license type, restrictions, and/or expiration date:

1. In the sidebar, select **Settings**.
2. On the **Global** tab, select **Licensing** to see these details.

Add or Renew Licenses

On the Leader (or in a Single-instance deployment), after submitting your newly untarred Cribl Stream software's registration page, you can add and manage licenses at **Settings** > **Global** > **Licensing**. Select **Add License** to paste in a license key provided to you by Cribl.

This applies to Cribl Stream Standard and Enterprise licenses, which must be renewed annually. Free licenses are already onboard the download package, need not be added or managed here, and do not expire.

Licenses in Airgapped Deployments

If your environment does not allow internet connectivity, you'll need to bypass the registration Web form when you deploy or upgrade Cribl Stream. To do so:

1. On the Leader's (or single instance's) host, navigate to `$CRIBL_HOME/local/cribl`.
2. Create a file named `license.yml`.

3. Paste in your license key in this format, then save the result:

```
licenses:
- <your-license-key-here>
```

Expiration/Renewal Notifications

In Cribl Stream 4.3 and later, the UI will prompt you to renew your paid license by displaying banner and drawer notifications, starting 30 days before license expiration. When you see these prompts, verify your license's expiration date and contact Cribl Sales at sales@cribl.io to renew.

Beyond these default notifications, you can configure custom License-Expiration Notifications. You can send these to PagerDuty, or to other external services via webhook.

License Quotas

Track Data Ingestion

To track your data ingestion volume over the last 30 days:

1. In the sidebar, select **Monitoring**.
2. Select **System** and then **Licensing**. This shows you the dashboard with your license consumption.

For higher-fidelity metrics, you can enable the Cribl Internal Source's CriblMetrics option to forward metrics to your metrics Destination of choice, and run a report on `cribl.total.in_bytes`.

Exemptions from License Quotas

Cribl does not require a separate license for sending data from Cribl Stream to Cribl Stream, such as sending from one Worker Group managed by Leader Node A to a different Worker Group managed by Leader Node B. In such situations, you can use the same license on Leader Node A and on Leader Node B.

- Data generated by Cribl Internal Sources normally does not count against your ingestion quota.
- Edge Node events that you drop in any Pipeline do not count against your ingestion quota.

If you are connecting Workers/Edge Nodes in a Cribl Stream Cloud hybrid deployment, you are granted additional exemptions to prevent double billing (in Cribl Edge, these exemptions also apply to customer-managed deployments):

- Data transferred between Cribl Stream Workers via the Cribl HTTP and Cribl TCP Sources does not count against your ingestion quota.

- Data that Cribl Edge sends to Cribl Stream from the Cribl HTTP and Cribl TCP Destinations counts against quota only in Cribl Edge.
- Data generated by Datagens does not count against your ingestion quota.

License Quotas with Compressed S3 Buckets

If you pull data from compressed S3 buckets, the license quota is applied to the uncompressed size of the file objects.

Enforce License Quotas

If your data throughput exceeds your license quota:

- Free and Standard licenses enforce data ingestion quotas through limits on the number of Worker Groups/Fleets and Worker/Edge Node Processes.
- Enterprise license keys turn off all enforcement.
- When an Enterprise or Standard license expires, Cribl Stream will attempt to fall back to a trial or free license, or – only if that fails – will block incoming data. For details, see Combining Licenses.

License Types

Cribl offers several Cribl Stream license types including Enterprise, Standard, and Free. For a current list of available license types and a detailed comparison of what's included in each, see Cribl Pricing.

Combine Licenses

Multiple licenses can coexist on one instance. When two or more Standard or Enterprise licenses are present, the effective ingestion quota for the deployment will be equal to the sum of their individual ingestion quotas.

When multiple *license types* coexist, the effective license is determined by the following priority order:

1. Enterprise or Standard licenses that have not expired.
2. Sales Trial licenses.
3. Free licenses.

License Expiration

When an Enterprise or Standard license expires, you can remove the old license to fall back to the Sales Trial or Free type. An expired Sales Trial license will fall back to a Free license, but you must remove the Sales Trial license and restart the Leader.

To delete your expired license:

1. In the sidebar, select **Settings**.
2. On the **Global** tab, select **Licensing**.
3. Locate your expired license, and select **Delete license**.
4. Restart the Leader.

Upon expiration of a paid license, if there is no fallback license, Cribl Stream will backpressure and block all incoming data.

Licensing in Distributed Deployments

With licenses that limit the number of Worker Processes/Edge Nodes, Cribl Stream will attempt to balance or rebalance Worker Processes (threads) as evenly as possible across all licensed Worker Nodes.

You configure licensing only on the Leader Node. (See Managing Licenses – Adding and Renewing.) The Leader will push license information down to Worker Groups as part of the heartbeat (Stream, Edge). There is no need to configure or store licenses directly on Worker Nodes.

Temporary License Restriction on Worker Node Startup

When you first start a Worker Node, it will use the default license. As a result, you might see a log entry warning about a limit on Worker Processes:

```
{
  "time": "2023-02-10T15:11:48.609Z",
  "cid": "api",
  "channel": "cribl",
  "level": "warn",
  "message": "number of worker processes has been limited by the license",
  "requested": 14,
  "licenseLimit": 10,
  "source": "cribl.log"
}
```

You can ignore this warning message. The license won't limit Worker Processes once the Leader passes the production license to the Worker.

Convert an On-Prem License to a Cribl.Cloud Billing Plan

You can convert on-prem Cribl Stream licenses to a Cribl.Cloud billing plan. This lets you keep your on-premises deployments of Cribl Stream, but manage all of the environment licenses in one interface.

For more details and setup steps, visit Connecting On-Premises Leaders to Cribl.Cloud Billing.

Telemetry Data

A **Free** license requires sharing of telemetry **metadata** with Cribl. Cribl uses this metadata to help us understand how to improve the product and prioritize new features.

Telemetry payloads are sent from all Cribl Stream nodes (Leader and Workers), to an endpoint located at `https://cdn.cribl.io/telemetry/`.

Test the Telemetry Endpoint's Connectivity

To manually test connectivity to the telemetry endpoint, especially if you are needing to configure a proxy, you can use the following command:

```
curl https://cdn.cribl.io/telemetry/
```

Expected response:

```
cribl /// living the stream!
```

If you get a 302 response code, check whether you've omitted the URL's trailing `/`.

Disable Telemetry

With an Enterprise or Standard license, you have the option to disable telemetry sharing from on-prem Cribl Stream. With a Free license, disabling telemetry will cause Cribl Stream to block inbound traffic within 24 hours.

If you would like an exception to disable telemetry in order to deploy in your environment, please contact Cribl Sales at sales@cribl.io, and we will work with you to issue licenses on a case-by-case basis.

Once you have received a license that removes the telemetry requirement, you can disable telemetry in Cribl Stream' at **Settings** > **Global** > **System** > **General Settings** > **Upgrade & Share Settings** > **Share telemetry with Cribl**. Set the toggle to `No`.

Metadata Shared Through Telemetry

Your Cribl Stream instance shares metadata with Cribl per interval (roughly, every minute).

Details sent for nodes in any mode:

- Version
- OS Distribution/Version
- Kernel Version
- Instance's GUID
- License ID
- Earliest, Latest Time
- Number of Events In and Out, overall and by Source type and Destination type
- Number of Bytes In and Out, overall and by Source type and Destination type
- Number of Open, Closed, Active Connections
- Number of Routes
- Number of Pipelines
- Runtime Environment Indicators (AWS and Kubernetes)

Additional details sent for Leader nodes (when Cribl isn't sending managed node data):

- Runtime Environment
- OS Distribution / Version
- Version
- Kernel Version

How We Use Telemetry Data

With telemetry enabled, Cribl software sends usage data directly to Cribl. We securely store and encrypt this data on Cribl-managed servers, with restricted access.

Cribl fully anonymizes and aggregates this usage data in our systems of analysis. There, we use the aggregated metrics to improve Cribl products and services by analyzing circumstances around disruptions, opportunities for ingest efficiencies, and ways to optimize performance. Access is restricted to only those Cribl employees and contractors who require anonymized data to perform their jobs.

Cribl collects License IDs only to ensure that all data is being sent by a Cribl product. These IDs cannot be used to personally identify any user of Cribl software or Cribl.Cloud services.

For further details, see the Cribl Privacy Policy.

Troubleshooting Resources

Cribl University offers a Troubleshooting Criblet on Switching from Free to Enterprise. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Troubleshooting Criblets and Advanced Troubleshooting short courses.

9.2. Version Control

Tracking, backing up, and restoring configuration changes for single-instance and distributed deployments

---

Cribl Stream integrates with Git clients and remote repositories to provide version control of the Cribl Stream configuration. This integration offers backup and rollback for single-instance and distributed deployments.

These options are separate from the Git repo responsible for version control of Worker configurations, located on the Leader Node in distributed deployments. We cover all these options and requirements on this page.

Cribl.Cloud deployments do not currently support integration with external Git clients or remote repos.

Install Git (Local or Standalone/Single-Instance)

To verify that `git` is available, run:

```
git --version
```

The minimum version that Cribl Stream requires is: **1.8.3.1.** If you don't have `git` installed, see the official Git installation site.

Git is a hard requirement for certain Cribl Stream features.

Distributed Deployments

For distributed deployments, `git` **must** be installed and available locally on the host running the Leader Node.

All configuration changes must be committed before they are deployed. The Leader notifies Workers that a new configuration is available, and Workers pull the new configuration from the Leader Node.

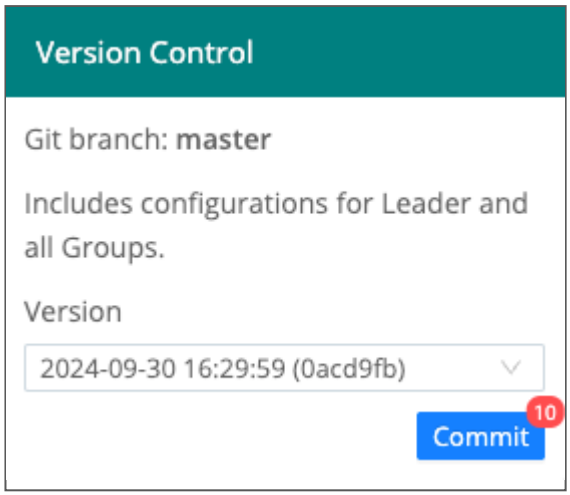
Licensing Dashboard

Even on single-instance deployments, the Monitoring > Licensing dashboard will display configuration change markers only if you have `git` installed.

Commit Changes

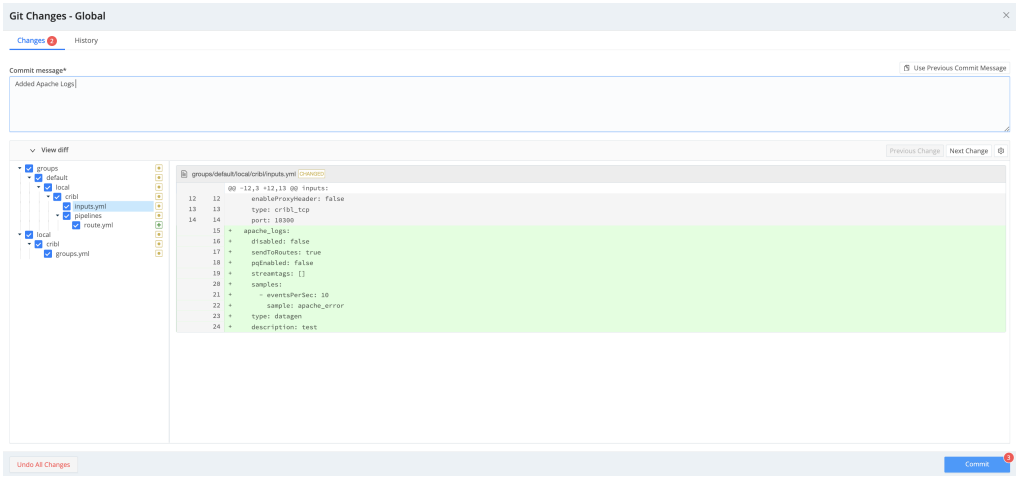
Once you have installed Git, you can commit configuration changes using the `git` CLI. You can also commit changes interactively, using the Cribl Stream UI.

Pending commits have a red dot indicator, as shown in this image. Select **Commit** to proceed.



Changes pending commit

Next, in the resulting **Commit Changes** modal, you can verify the diffs in the configuration changes. To reuse your preceding commit message, select the **Use Previous Commit Message** button. Other options here include clearing check boxes for individual files to exclude them from the commit (as shown below), and selecting **Undo** to reverse the changes instead of committing them.



Reviewing a pending commit

When you're ready to commit to your changes, select **Commit**. Look for a **Commit successful** confirmation message at the lower right.

Commit and Deploy Controls

Distributed mode includes Worker Group-specific **Commit** and **Deploy** controls. These controls function differently from the global **Commit** button.

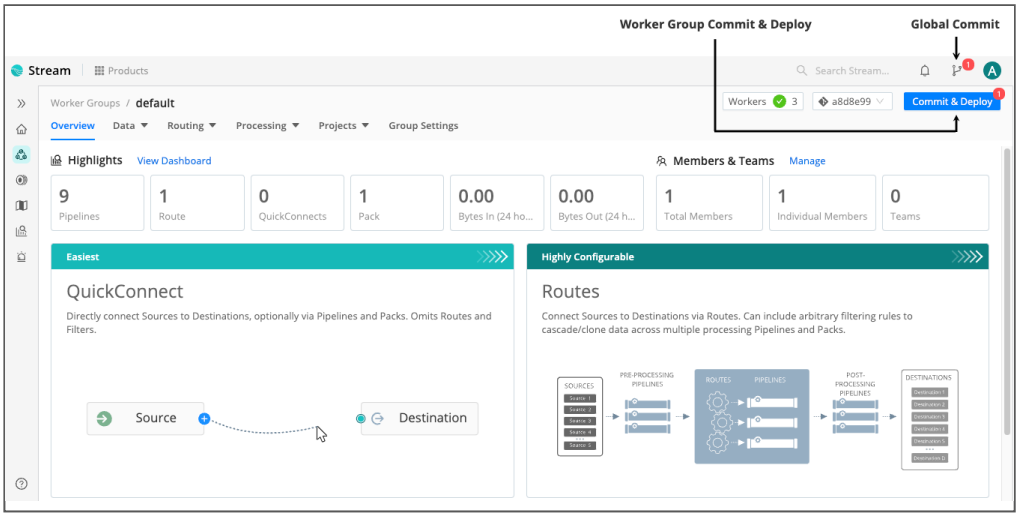
The global **Commit** button:

- Commits configurations for *all* Worker Groups and for the Leader Node.
- Does not deploy configurations.

The Worker Group **Commit** and **Deploy** buttons:

- Commit and deploy configurations for the currently selected Worker Group only.

These controls will appear slightly differently depending on whether you have changes committed but not yet deployed, and on whether you've enabled the Collapse actions setting.



Commit and Deploy controls in the user interface

Revert Commits

If you want to revert a commit, you can do it:

- In Cribl Stream UI
- Via `git` CLI

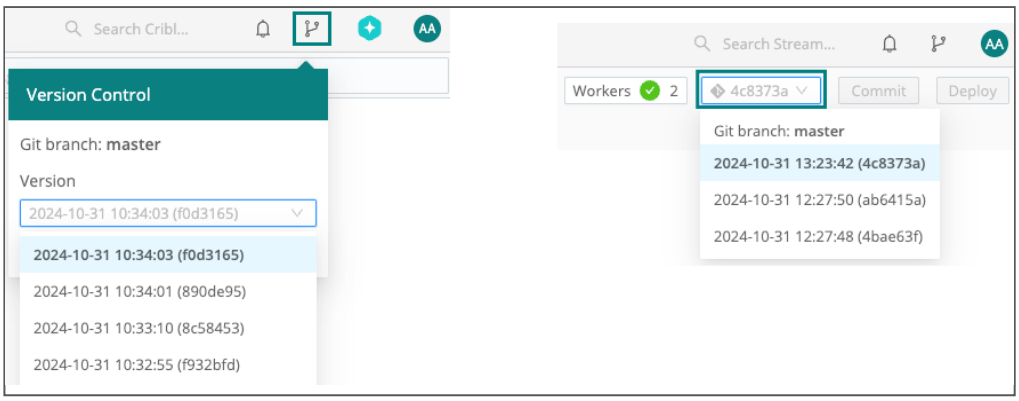
Revert Commits in the UI

Reverting a commit in the UI proceeds slightly differently for Single-instance and for Distributed deployments. In a Distributed deployment, you revert commits for each Worker Group separately.

To revert a commit in the UI:

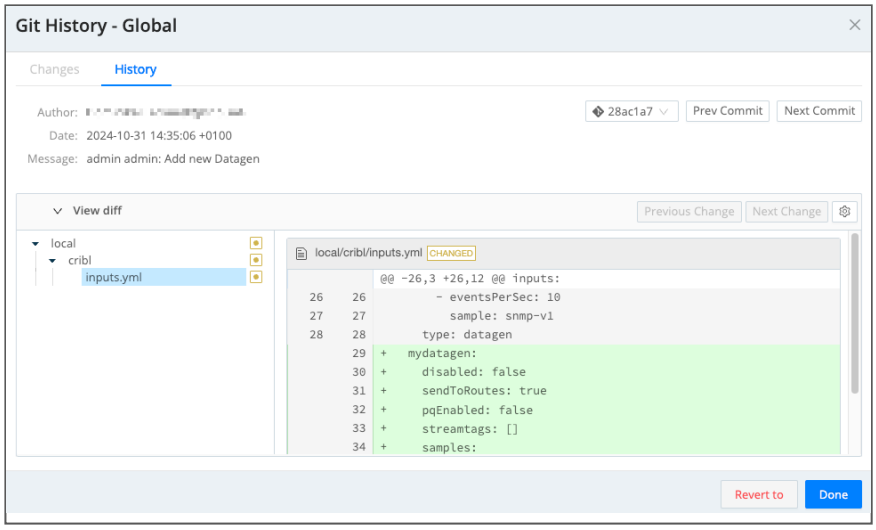
1. If you are on a Distributed deployment, in the sidebar, select **Worker Groups**, then select the Worker Group you want to revert the commit for.
2. Select the commit you want to revert. To do this:

- in a Distributed deployment, use the drop-down listing commits,
- in a Single-instance deployment, open the **Version Control** menu on the top bar. (Note that you're not selecting a single commit to roll back, but the *commit to roll back to*.)



Selecting commit to revert in Single-instance (left) and Distributed (right) deployment

3. Then, in the resulting **Git History** modal, verify the diffs in the configuration changes and select **Revert to**.



Diff preview before reverting a commit

4. Confirm the revert. This will cause Cribl Stream to restart.

Revert Commits via CLI

To revert a commit via CLI:

1. Make sure you have committed all your recent configuration changes.
2. Stop Cribl Stream.
3. In your terminal, navigate to your `$CRIBL_HOME` location (typically, `/opt/cribl`).

4. Run `git log` to get a list of most recent commits and find the hash of the commit you want to revert.
5. Run `git revert <commit-hash>` to revert this commit.
   If you want to revert more than one commit, list all their hashes as arguments for `git revert`.

   Running `git revert` will create one or more new "Revert" commits that record the change in your git history.

6. Restart Cribl Stream.

Support For Remote Repositories

Cribl supports Git remote repositories (but they are not required) for version control of all configuration changes.

This feature requires certain license tiers. For details, see Pricing.

You can configure a Leader Node with Git remote push capabilities through the Cribl Stream CLI, or through the Cribl Stream user interface. From Settings, select the **Global** tab, then select **System** > **Git Settings**.

To create a repo, see these tutorials:

- Setting Up a Repository (CLI instructions, host-agnostic, from Atlassian).
- Creating a New Repository (specific to the GitHub Web UI).
- Create a Repo (longer GitHub-specific tutorial, also covers committing changes).

Remote Formats Supported

Remote URI schema patterns should match this regex: `(?:git|ssh|ftps?|file|https?|git@[-\w.]+):(\/\/)?(.*?)(\.git\/?)?$`

You can find a list of supported formats in this external article: What are the supported git url formats?

For example:

- GitHub or other providers: `<protocol>://git@example.com/<username>/<reponame>.git`
- Local Git servers: `git://<host.xyz>:<port>/<user>/path/to/repo.git`

Secure Local Configuration and Remote Repos

Make a local backup of your whole `$CRIBL_HOME` directory before you set a remote repo. This safeguards your Cribl Stream configuration against being overwritten by a misconfigured remote.

Create each new remote as an empty repo, with no README file and no commit history. (See the following GitHub and GitLab examples.)

Some files that are used by Cribl Stream (both Leader and Worker Groups) contain sensitive keys; examples are `cribl.secret` and `...auth/ssh/git.key`. These will be pushed to the remote repo as part of the entire directory structure under version control. Ensure that this repo is secured appropriately.

Connect to a Remote Repo over HTTPS (Recommended)

Cribl recommends connecting to a remote repo over HTTPS. The following examples show a token-based and a password-based HTTPS connection to GitHub.

Example: Connect to GitHub over HTTPS with a Personal Access Token

1. Create a new GitHub repository.
   For best results, create a new empty repo, with no README file and no commit history. (This will prevent `git push` errors.) Note the username and email associated with your login on the repo provider.
2. Create a personal access token with **repo** scope.
3. Copy the token to your clipboard.
4. In Cribl Stream, from Settings, select the **Global** tab, then select **System** > **Git Settings**.
5. In the **Remote** tab, select **Authentication type**: **None**.
6. Fill in the **Remote URL** field with your username and repo name. Use the format below:
   `https://<username>:<token>@github.com/<owner>/<repository>.git`

For additional details, see the GitHub Creating a Personal Access Token tutorial.

For GitHub repos specifically, use only personal access tokens in the **Remote URL** field. GitHub announced its end of support for plaintext passwords as of August 13, 2021.

Example: Connect to GitHub over HTTPS with Username and Password

1. Create a new GitHub repository.
   For best results, create a new **empty** repo, with no readme file and no commit history. (This will prevent `git push` errors.) Note the username and email associated with your login on the repo provider.
2. In Cribl Stream, from Settings, select the **Global** tab, then select **System** > **Git Settings**.
3. In the **Remote** tab, select **Authentication type**: **Basic**.
4. Enter your credentials in the **User** and **Password** fields.

Connect to a Remote with SSH

You can set up SSH keys from the CLI, or upload keys via the UI. If you have a passphrase set, this functionality is available only through the CLI - see Encryption: Configuring Keys with the CLI. The example below outlines the UI steps.

Example: Connect to GitHub with SSH

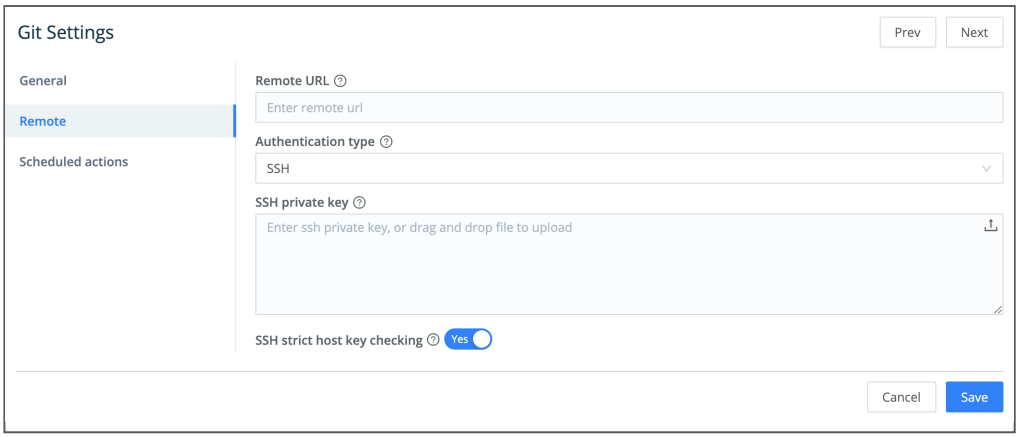
1. Create a new GitHub repository.
   For best results, create a new **empty** repo, with no readme file and no commit history. (This will prevent `git push` errors.) Note the user name and email associated with your login to the repo provider.
2. Add an SSH public key to your GitHub account.
3. In Cribl Stream, from Settings, select the **Global** tab, then select **System** > **Git Settings**.
4. In the **Remote** tab, fill in the **Remote [repo] URL**. In the generic example below, replace `<username>` with your user name on the repo provider:
   - **Remote URL**: `<protocol>://git@github.com:<username>/<reponame>.git`
   - For GitHub specifically, the URL/protocol format must be: `git@github.com:<user>/<reponame>.git`
   - A specific (fictitious) GitHub example: `git@github.com:johndoe/leadsheets.git`
5. Paste in the **SSH private key**.

The key will paste in with an appended newline below it. Do not delete this newline before you save the Remote Settings, or else you will trigger an error of the form: `fatal: Could not read from remote repository.`

6. As the user running Cribl Stream, run this command to add the GitHub keys to `known_hosts`:

```
ssh-keyscan -H github.com >> ~/.ssh/known_hosts
```

For additional details, see the GitHub Connecting to GitHub with SSH tutorial.



Cribl Stream Git settings

GitLab Notes

For repos hosted on GitLab, we recommend that you:

- Create a new empty (blank) project, with no README file and no commit history. (Clear the **Initialize repository with a README** check box.)

  This will prevent `git push` errors by creating a project with no branch, not even `main`. When you later push the Cribl Stream `master` branch, that will create a corresponding `master` branch on the GitLab remote with no conflicts.

- Create a GitLab project access token for authentication. See the GitLab documentation, which also covers project bot conventions.
- With project bots, the first token's username is set to `project_{project_id}_bot`. The password is the alphanumeric token.
- Create the token with `write_repository` scope.
- Specify a remote URL in HTTPS format. For example: `https://localgitlab.<yourdomain.ext>/<yourusername>/cribl.git`
- If you do see a `main` branch in the Cribl Stream UI, do not select it. Leave the branch at `master`, then use the Stream UI's **Commit** and **Push** commands. This will create the desired `master` branch on GitLab's remote.

The GitLab **Repository Settings** > **Push Rules** section includes these two settings of interest:

- As needed, enable **Check whether author is a GitLab user**.

- Understand the consequences of of enabling **Prevent committing secrets to Git**. This blocks commits of `.pem` and `.key` files. If you have certificates or SSH keys configured, this will break commits from Cribl Stream, throwing only a generic `API Error` in the UI. Check your `git` CLI client for more-specific diagnostics.

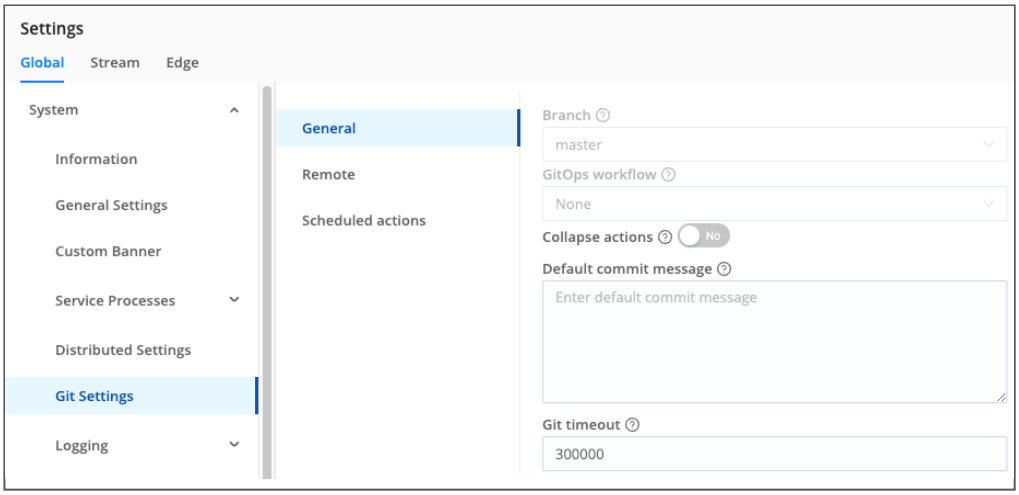
Additional Git Settings

From Settings, select the **Global** tab, then select **System** > **Git Settings**. Select the **General** tab to modify the following additional Git configurations, all of which are optional:

- **Branch**, **GitOps workflow**: These drop-downs are available to configure GitOps.

  See the GitOps documentation for details and precautions.

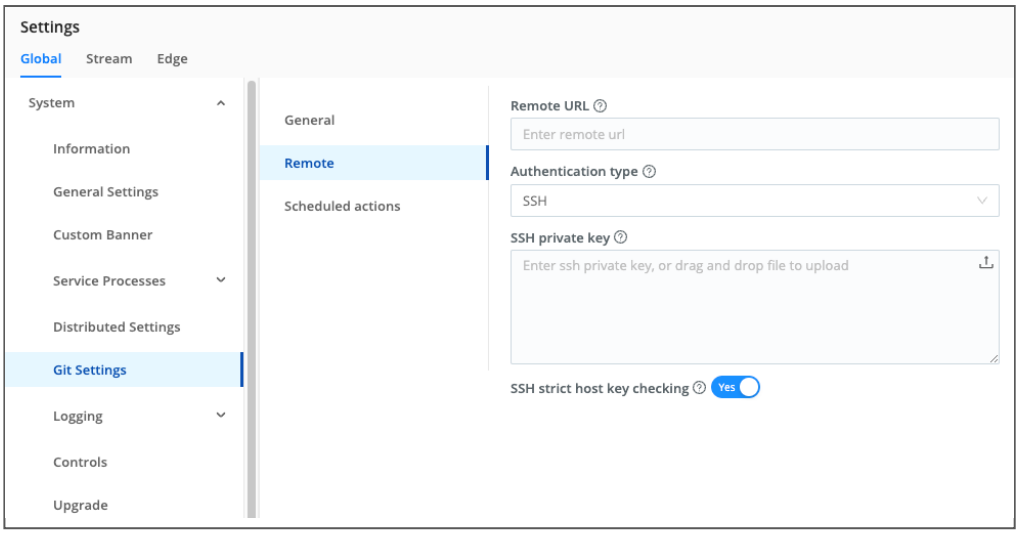
- **Collapse actions**: Combine multiple Git buttons to one, to reduce repetitive clicks. See Collapse Actions below.
- **Default commit message**: Enter a placeholder message to apply to all commits from Cribl Stream. This also reduces clicks.
- **Git timeout**: Maximum time (in milliseconds) to wait for Git processes to complete before killing them. If a Leader instance hangs, try lowering this value from the default `300000` (300 seconds = 5 minutes). However, avoid very low values (like `1000` ms), which might time out even when Git processes are working properly. Enter `0` to wait indefinitely.



Git Authentication Type settings

On the **Git Settings** > **Remote** tab, you can change the **Authentication Type** from its **SSH** default to **Basic** authentication. This displays two additional fields:

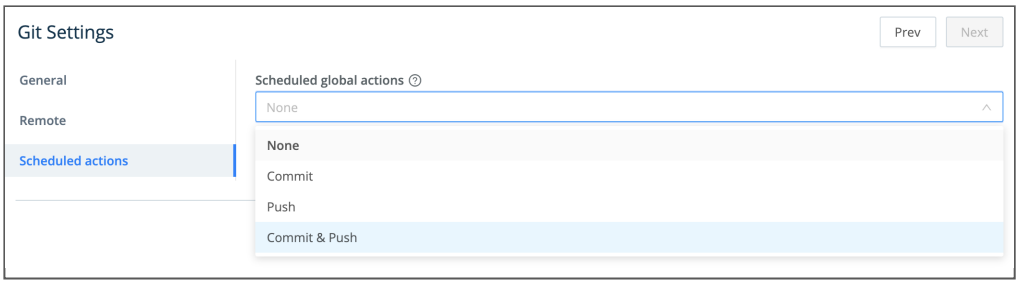
- **User**: Username on the repo.
- **Password**: Authentication password (for example, a GitHub personal access token).



Git Authentication Type settings

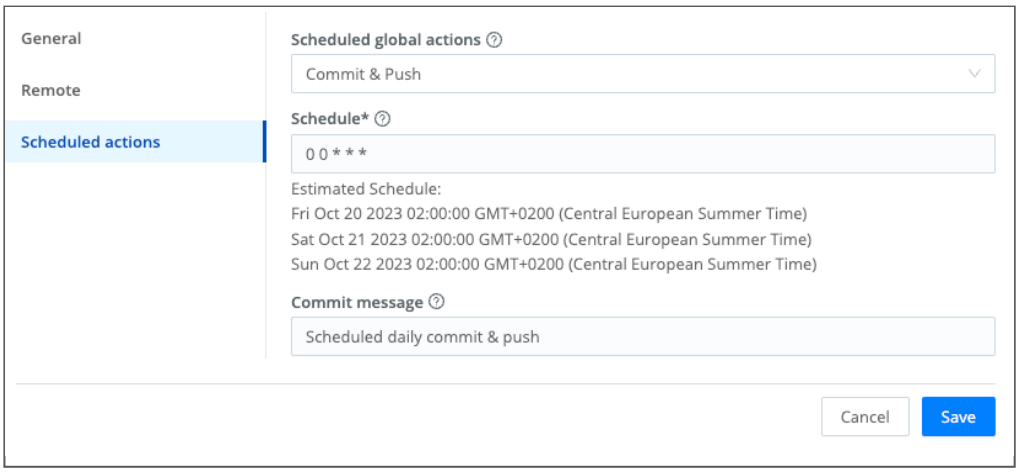
GitHub (specifically) does not support Basic authentication.

On the **Git Settings** > **Scheduled Actions** tab, you can schedule a **Commit**, **Push**, or **Commit & Push** action to occur on a predefined interval.



Git Scheduled Actions selection

For the selected action type, you can define a cron schedule, and a commit message distinct from the **General** tab's **Default Commit Message**. Then select **Save**.

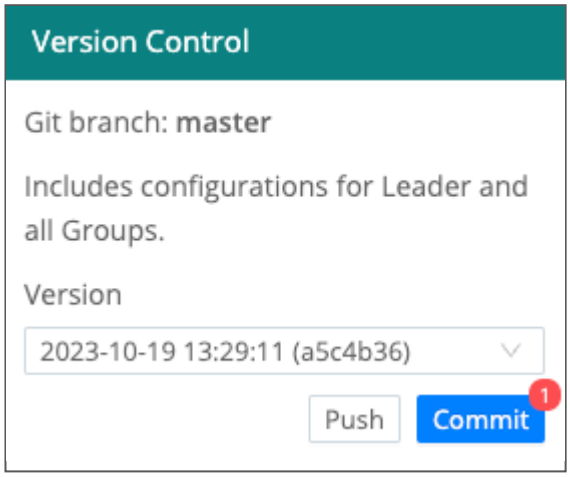


Saving a Git Scheduled Action

You can schedule only one type of action. To swap to a different type, select it from the **Scheduled global actions** drop-down, and resave. To turn off scheduled Git commands, select **None** from the drop-down, and resave.

Push Configs to a Remote Repo

Once you've configured a remote, a **Git Push** button appears in the **Global Config** dialog. You can use this to copy committed configuration changes to your remote.

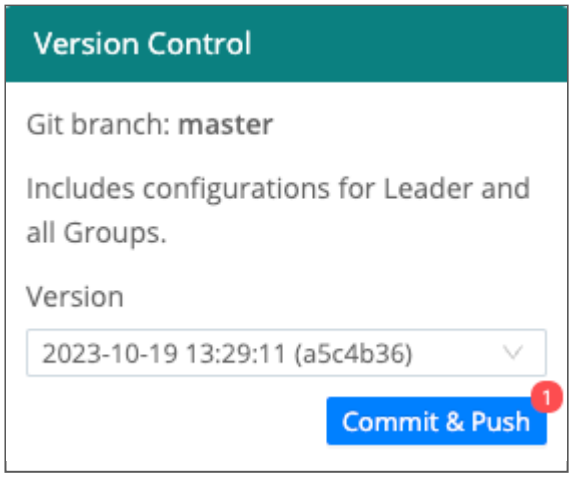


Git Push button

The branch indicator will normally read `master`, as shown above, unless you have enabled GitOps with an appropriate license.

Collapse Actions

If you enabled the **Git Settings** > **Collapse Actions** option, you will be offered a combined **Commit & Push** button in the **Global Config** dialog.



Git combined actions button

At the Group level, enabling **Collapse Actions** adds a combined **Commit & Deploy** option to the modal you see after clicking **Commit** for the Group config.

Enabling **Collapse Actions** with a remote repo simplifies the **Commit Changes** confirmation dialog. It substitutes just a commit **Message** text box, with **OK** and **Cancel** buttons - omitting the diff view. Don't enable this option if you prefer to inspect configuration changes before committing.

Back Up Configs Out of Band

Once you've configured your remote repo, changes to all Cribl Stream config files under the `$CRIBL_HOME` directory will normally be backed up to your remote whenever you select the above **Git Push** or **Commit & Push** UI buttons. The exceptions are:

- Any configuration files you've chosen to store outside `$CRIBL_HOME`.
- Any configuration files residing in paths you've added to `.gitignore`.

To back up these files to your remote, you'll need to either:

- Change the above paths/settings, or
- Use an external `git` client to manually push them.

Troubleshooting Push Errors

To resolve errors commonly encountered when pushing to a remote repo, see:

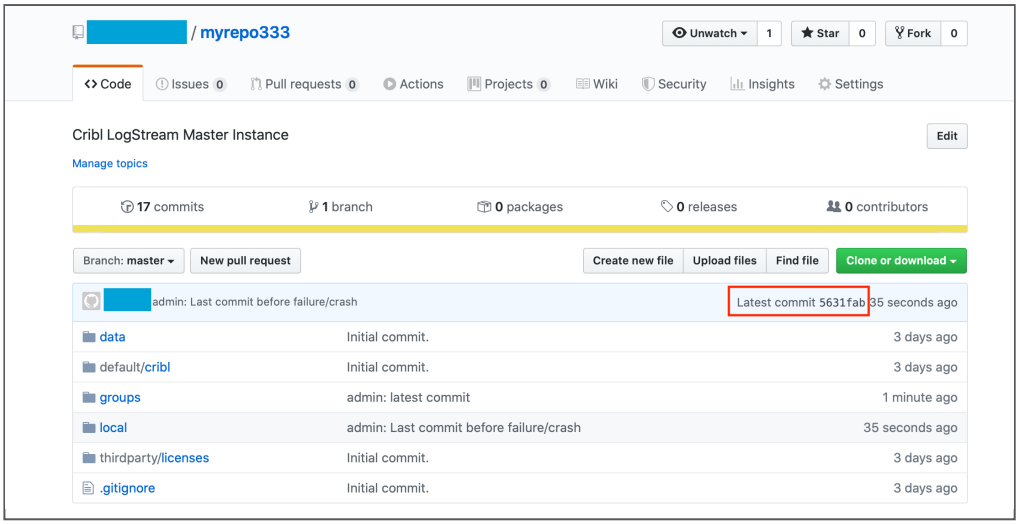
- Git Push Errors
- Git Remote Repos & Trusted CAs

Troubleshooting Resources

Cribl University offers a Troubleshooting Criblet on Commit & Deploy best practices and error recovery. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses - but Cribl's training is always free of charge.) Once logged in, check out other useful Troubleshooting Criblets and Advanced Troubleshooting short courses.

Restore Leader from a Remote Repo

If a remote repo is configured and has the latest known good Leader configuration, this section outlines the general steps to restore the config from that repo.



Restoring from remote repo

Let's assume that either the entire `$CRIBL_HOME` directory of the Leader is corrupted, or you're replicating the remote repo's config onto a fresh instance. Let's also assume that the remote repo has the form: `git@github.com:<username>/<reponame>.git`.

1. **Important**: In a directory of choice, untar the **same Cribl Stream version** that you're trying to restore, but do not start it.

Make sure you download the **matching** Cribl Stream version. The Cribl Download page foregrounds current version of Cribl Stream, but provides a link to this archive of prior releases.

2. Change directory into `$CRIBL_HOME` and initialize `git`:

```
# git init
```

3. If you are using SSH key authentication, specify the key using the following command:

```
GIT_SSH_COMMAND='ssh -i </path/to/github/repo>.key -o IdentitiesOnly=yes'
```

As an alternative to executing `GIT_SSH_COMMAND` on the fly, you can set your key in `$CRIBL_HOME/.git/config` with: `git config core.sshCommand "ssh -i /path/to/key"`

Or set it globally with: `git config --global core.sshCommand "ssh -i /path/to/key"`

4. Ensure that you have proper access to the remote repo:

```
# git ls-remote git@github.com:<username>/<reponame>.git
56331fabb4822eaec4ca0ffd008d6e9974c1e419f       HEAD
5631fabb4822eaec4ca0ffd008d6e9974c1e419f        refs/heads/master
```

5. Next, add/configure the remote:

```
# git remote add origin git@github.com:<username>/<reponame>.git
```

6. Now set up your local branch to exactly match the remote branch:

```
# git fetch origin
# git reset --hard origin/master
```

7. Finally, to confirm that the commits match, run this command while in `$CRIBL_HOME`:

```
# git show --abbrev-commit
```

You should see output indicating that `HEAD` points to both `master` and `origin/master`, as in this example:

```
commit 5631fab (HEAD -> master, origin/master)
Author: First Last <email@example.com>
Date:   Fri Jan 31 10:16:07 2020 -0500

    admin: Last commit before failure/crash
......
```

Step 6 above pulls in all the latest configs from the remote repo. Step 7 confirms the local repo matches the remote. You should now be able to start the Leader as normal. Once up and running, Workers should start checking in after about 60 seconds.

Verify cribl.secret

The `cribl.secret` file - located at `$CRIBL_HOME/local/cribl/auth/cribl.secret` - contains the secret key that is used to encrypt sensitive settings on configuration files (for example, AWS Secret Access Key). Make sure this file is properly restored on the new Leader, because it is required to make encrypted conf file settings usable again.

.gitignore File

A `.gitignore` file specifies files that `git` should ignore when tracking changes. Each line specifies a pattern, which should match a file path to be ignored. Cribl Stream ships with a `.gitgnore` file containing a number of patterns/rules, under a section of the file labeled `CRIBL SECTION`.

.gitignore

```
# Do NOT REMOVE CRIBL and CUSTOM header lines!
# DO NOT REMOVE rules under the CRIBL section as they may be reintroduced on update.
# You can ONLY comment out rules in the CRIBL section.
# You can add new rules in the CUSTOM section.
### CRIBL SECTION -- DO NOT REMOVE ###
default/ui
default/data/ui
/bin/
/lib/
/log/
/pid/
data/uploads
/diag/
**.tmp
/state/
**/local/cribl/messages.yml
**/local/edge/messages.yml
**/default/cribl/lakes.yml
**/local/cribl/lakes.yml
/thirdparty/
*.cpuprofile
**/auth/ssh/git.key
ha-version.txt
### CUSTOM SECTION -- DO NOT REMOVE ###

<User-defined patterns/rules go here>
```

Worker Deployment: How to Handle Customer-Defined `.gitignore` Exclusions

The `bundler` object in `cribl.yml` allows you to deploy files to GitOps that are usually excluded via gitignore, like `cribl.secret` and `secrets.yml`. This facilitates loading custom secrets per environment and Group. However, these files are never committed to GitOps. Instead, a customer-managed logic (outside GitOps) ensures the appropriate secret files are dropped during deployment for each environment and group. This approach safeguards sensitive information while leveraging the `bundler's` functionality within your GitOps workflow.

To leverage this functionality for deployment-critical files, configure `cribl.yml` using the `bundler.bundleGitIgnoredPatterns` setting. This ensures essential files reach Workers, even if they are not tracked with version control due to customer-specific `.gitignore` rules.

Example: Use `.gitignore` with `bundler`

For example, if you want to exclude your Cribl secret from Git, add `local/cribl/auth/cribl.secret` to `.gitignore`.

You can then add the same path to `bundler` to ensure it is deployed to GitOps during deployment.

```
bundler:
  bundleGitIgnoredPatterns:
    - 'local/cribl/auth/cribl.secret'
```

If you want to avoid tracking custom certificates as well, use the path for the directory in which the secrets/certificates reside: `local/cribl/auth`.

```
bundler:
  bundleGitIgnoredPatterns:
    - 'local/cribl/auth'
```

CRIBL Section

Do Not Remove CRIBL SECTION or CUSTOM SECTION Headers

Under the `CRIBL SECTION` header, Cribl Stream specifies the files that Git will ignore by default. Further files for Git to ignore should be listed under the `CUSTOM SECTION` header.

Do **not** add any lines to the `CRIBL SECTION` block, because the next update will just overwrite them anyway. Do not remove any lines either. The only modifications that will survive updates are commented lines.

Do not remove any section header lines, or unexpected behavior might occur on update.

CUSTOM Section

User-defined, custom patterns/rules can be **safely defined** under the `CUSTOM SECTION`. Cribl Stream will **not** modify the contents of `CUSTOM SECTION`.

Good candidates to add here include large lookup files - especially large binary database files. For details, see Git Push Errors: Large Files Detected.

Files Skipped with .gitignore

If you have files that you've set `.gitgnore` to skip, you will need to back them up and restore them by means other than Git. For example, you can periodically copy/rsync them to a backup destination, and then restore them to their original locations after you complete the steps above.

Files specified in `.gitignore` are not only excluded from pushes to the remote repo, but are also excluded from Worker Group config bundles. When Workers load a new config that references a skipped (and missing) file, this can produce unexpected results, and usually errors.

For example, if you add `**/auth/certs/leader*` to `.gitignore`, this will prevent the `leader.crt` and `leader.key` files from leaking to Worker Nodes in config deployments.

Configs that you `.gitignore` in this way on the Leader will not persist on Workers after they receive their next deploy. However, these configs will be available in the next few rolling backup bundles in `state/`.

Commit and Deploy Using the API

You can automate commit and deploy commands by using Cribl Stream API requests. The following examples show how to do so for a Worker Group configuration.

About the Examples

- The API calls below include Worker Group names as path parameters.
- The `curl` commands assume that you have set the `$token` environment variable to match the value of a bearer token. See Authentication for alternative approaches; adapt the example commands to suit your chosen approach.

Commit Changes

To commit pending changes to your configured repo, adapt and run the following API call:

```
POST /api/v1/version/commit
```

```
{"message":"a descriptive commit message","group":"<worker_group_name>"}
```

You will receive a JSON response with some details about the commit:

```
{"items":[{"branch":"master","commit":"abcd1234","summary":{"changes":"1","insertions
```

From that response, you'll need to extract the commit ID (`abcd1234`) to use in the second deploy API call below.

Commit Example

Here, let's commit all pending changes to the default Worker Group:

```
curl -X POST -H "Authorization: Bearer $token" -H "Content-Type: application/json" "l
```

Deploy Changes

To deploy your committed config changes to Worker Groups, adapt and run the following API call. As the `version` value, you'll need the commit ID you received in the commit response above:

```
PATCH /api/v1/master/groups/<worker_group_name>/deploy
```

```
{"version":"abcd1234"}
```

A successful response payload looks like this:

```
{"items":[{"description":"Default Worker Group","tags":"default","configVersion":"5b8
```

Deploy Example

Here, let's deploy the previously committed configuration to the `default` Worker Group:

```
curl -X PATCH -H "Authorization: Bearer $token" -H "content-type: application/json"
```

Selectively Commit Changes

If you want to commit only a subset of configuration changes, adapt and use the following payload:

```
POST /api/v1/version/commit

{
  "message":"descriptive commit message",
  "group":"default",
  "files":["groups/default/data/samples/sample-g0aT.json","groups/default/local/crib
}
```

Selective Commit Example

Let's selectively commit a sample data file, and the updated YAML listing of all sample files, to the `default` Worker Group:

```
curl -X POST -H "Authorization: Bearer $token" -H "Content-Type: application/json" "
```

View Large Diffs

For large diffs that have more than 1000 lines, the **Commit Changes** modal in the Cribl Stream user interface displays the message "Diff too big to be displayed." Likewise, if you use the `GET /api/v1/version/diff` or `GET /api/v1/version/show` API endpoints to retrieve a large diff, the response includes the "Diff too big to be displayed" message as well as `"isTooBig": true`.

To view a large diff, add the `diffLineLimit` query parameter to a `GET /api/v1/version/diff` or `GET /api/v1/version/show` request to specify the maximum number of lines to display. For example:

```
curl -X GET -H "Authorization: Bearer $token" -H "Content-Type: application/json" "h
```

You can also set `diffLineLimit` to `0` to disable the line limit and retrieve the complete diff. For example:

```
curl -X GET -H "Authorization: Bearer $token" -H "Content-Type: application/json" "h
```

9.3. GitOps

With Cribl Stream's GitOps features, you can manage Cribl Stream configuration with standard version-control systems and CI/CD flow. You can separate development from production configurations, and thus, safely build and continuously deploy your observability pipelines. The production environment will be read-only, and thus strongly protected against unauthorized or unintended changes. This intentionally restrictive approach is a good fit for some but not all organizations.

The GitOps workflow described here assumes that your development, staging, and production environments are identical or nearly identical. If, on the other hand, your development environment differs significantly from production (in its branching structure, for example, or if users have wide latitude for experimentation), you should consider solutions other than GitOps.

GitOps requires a Distributed Cribl Stream deployment with a certain license tier.

Cribl.Cloud does not support GitOps.

How to Use This Doc

This doc has three sections.

- Work through all three sections, in order, once.
- Once you have done that, you are finished with the first two sections, Preparing Your Git Repo and Preparing Cribl Stream.
- Next, incorporate the HTTP request from the third section (GitOps Workflow) into your CI/CD tool infrastructure.
- From then on, your normal production routine will be to just repeat the GitOps Workflow (that is, the third section) again and again.

You'll perform setup steps in the Cribl Stream UI, in your Git management system, and at the command line. Screenshots are in light mode for Cribl Stream, and in dark mode for GitHub examples.

Environment and branch names have been chosen to help you keep track of what you're doing – if you decide to use different ones, exercise care. We've chosen names that always make it clear whether we're talking about environments or about branches:

- Development and Production will be your Cribl Stream environments.
- `dev` and `prod` will be the branches in your Git repo.

Procedures begin with instructions that are agnostic to the Git management system you want to use, whether that is free GitHub, GitHub Enterprise, GitLab, Bitbucket, or a self-hosted Git server. The detailed instructions that follow are for use with free GitHub. If you're using one of the other Git management systems, you'll need to substitute appropriate instructions for the ones that begin "To do this in GitHub …"

Check out Cribl's free GitOps sandbox for a "deep dive" and to work through a practical example.

If you encounter either of the following situations, see the linked appendix:

- You need to upgrade your GitOps-enabled Cribl Stream deployment.
- You are not using systemd, and need to override the defaults using environment variables.

Preparing Your Git Repo

The procedure in this section only needs to be done once. When you've completed it, you can prepare Cribl Stream for GitOps.

Creating SSH Public and Private Keys

You'll use SSH to connect to your Git management system; Cribl does **not** recommend using basic authentication for GitOps.

At the command line, generate public and private SSH keys, specifying Ed25519 as the key type:

```
ssh-keygen -t ed25519 -C "your_email@example.com"
```

Verify that the `~/.ssh/` directory contains both of the newly-generated keys:

- `id_ed25519` (the private key that Cribl Stream will use).
- `id_ed25519.pub` (the public key that your Git management system will use).

Copy the public SSH key to your clipboard:

```
cat ~/.ssh/id_ed25519.pub
```

Associate the public key with your Git management account.

To do this in GitHub:

1. If you do not have a GitHub account, create one.

2. Sign in to your GitHub account.
3. On the SSH and GPG keys page, click **New SSH key**.
4. Paste the key in the **Key** field.
5. Click **Add SSH key**.

Creating a Private Git Repo

You need to create a dedicated, private Git repo – your Development environment will write to it, and your Production environment will sync to it. Create a private repo named `cribl`.

To do this in GitHub:

1. In GitHub, select **Create new...** on the top bar, and choose **New repository**.
2. Name the repo `cribl`.
3. Change the repo from **Public** to **Private**.
4. Select **Create repository**. The new repo's landing page will open.

Preparing Cribl Stream

The procedure in this section only needs to be done once. When you've completed it, you can move on to testing and using GitOps.

Setting Up Your Environments

In your distributed Cribl Stream deployment, set up two separate environments, one named `Development` and the other named `Production`. Cribl strongly recommends that you use systemd to manage the `cribl` service.

Complete the following steps in **both** environments:

- Create one Cribl Leader and two Cribl Workers.
- On the Leader, install a Cribl Enterprise License.
- On the Leader, install `git` using the following command (or the equivalent for your OS):
  `sudo yum install git -y`

Then, in the Production environment:

- On the Leader, install `jq` – the GitOps workflow instructions below use `jq`.
  - Run this command (or the equivalent for your OS):
    `sudo yum install jq -y`

- Note the Production Leader's IP address for use later on.

Configuring Your Production Leader

First, you'll ensure that your Production Leader and your Git repo can communicate; then, you'll put your Production Leader into read-only mode.

Creating the `gitops` User

1. Create a new Local User called `gitops`.
2. On the Production Leader's local filesystem, temporarily record the password for the `gitops` User. This password well be referred to as `GITOPS_USER_PASSWORD` in later steps.
3. Associate the default `gitops` Role with the `gitops` User. (See Adding Roles.)
    - This Role allows only to `POST` to the `/version/sync` endpoint of the Cribl API (in the API Reference, see **versioning**).

Adding a Secret to Git

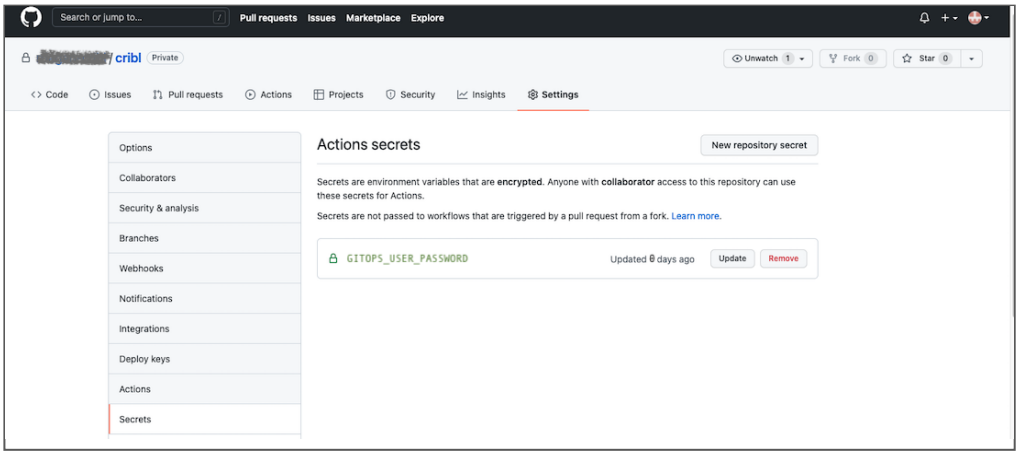
Your Git repo needs to be able to communicate with your Production Leader. This requires that you store a secret in your Git management system. We'll use `GITOPS_USER_PASSWORD` as the secret.

From the Production Leader, upload the `GITOPS_USER_PASSWORD` to the Git management system (or perform an equivalent operation) now.

To do this in GitHub:

1. In the GitHub site for your repo, navigate to **Settings** > **Secrets and variables** > **Actions**.
2. Click **New repository secret** and follow the prompts.

When done, you should see a `GITOPS_USER_PASSWORD` row under **Actions secrets**:



Connecting Your Production Environment to Your Git Repo

In Cribl Stream, in the UI for the Production Leader, select **Settings** in the sidebar, then select **Global** > **Git Settings**.

In the **Remote** tab:

1. In **Remote URL**, enter the URL for your private Git repo.
    - On GitHub, the **Remote URL** will look like this: `git@github.com:<your_GitHub_username>/cribl.git`
2. Make sure that in the **Authentication type** drop–down, `SSH` (the default) is selected.
3. In **SSH private key**, copy and paste the private key (`~/.ssh/id_ed25519`).

The key will paste in with an appended newline below it. Do not delete this newline before you save the Remote Settings, or else you will trigger an error of the form: `fatal: Could not read from remote repository.`

4. Toggle **SSH strict host key checking** off. This will allow the remote repository to accept your host key information. If you miss this step, you will trigger an error.
5. Click **Save**.
6. Toggle **SSH strict host key checking** on again.
7. Click **Save** (again!).
8. **Commit** and **Push**.

Check your private Git repo – in the `master` branch, you should now see your commit.

Setting Up the `prod` Branch

In this section, we'll set up the Git `prod` branch; later on, we'll set up `dev`.

Recall that your Git repo has one branch, named `master`. Now, rename `master` to `prod`.

To do this in GitHub:

1. In your GitHub repo's landing page (for example, `https://github.com/<your_Git_username>/cribl`), select the **1 branch** tab. (That's what the branches tab will be named, assuming that the sole branch is `master`).

The branches tab

2. In the `master` branch's row, select ••• at far right, then select **Rename branch**, and rename `master` to `prod`.

Now, configure your Cribl Stream instance to be using the `prod` branch:

1. In Cribl Stream, select **Settings** > **Global** > **Git Settings**.
2. In the **General** tab, set **Branch** to `prod`.
3. Save.

Making the Production Leader Read-Only

In a terminal on the Production Leader, become root:

```
sudo su -
```

Add `systemctl` overrides to set environment variables that will (a) make the Production Leader read-only upon startup, and (b) set the branch to `prod`.

1. Use `systemctl` to open the `override.conf` file in an editor:

   ```
   systemctl edit cribl
   ```

2. When prompted, add the following overrides:

   ```
   [Service]
   Environment=CRIBL_GIT_OPS=push
   Environment=CRIBL_GIT_BRANCH=prod
   ```

3. Restart:

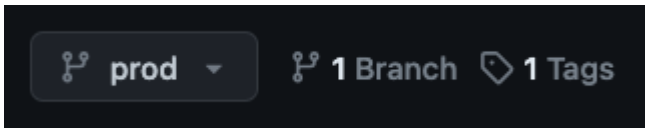
   ```
   systemctl daemon-reload && systemctl restart cribl
   ```

Creating the dev Branch

Recall that your Git repo has one branch, named `prod`. Now, create a new branch named `dev`, **from your existing** `prod` branch.

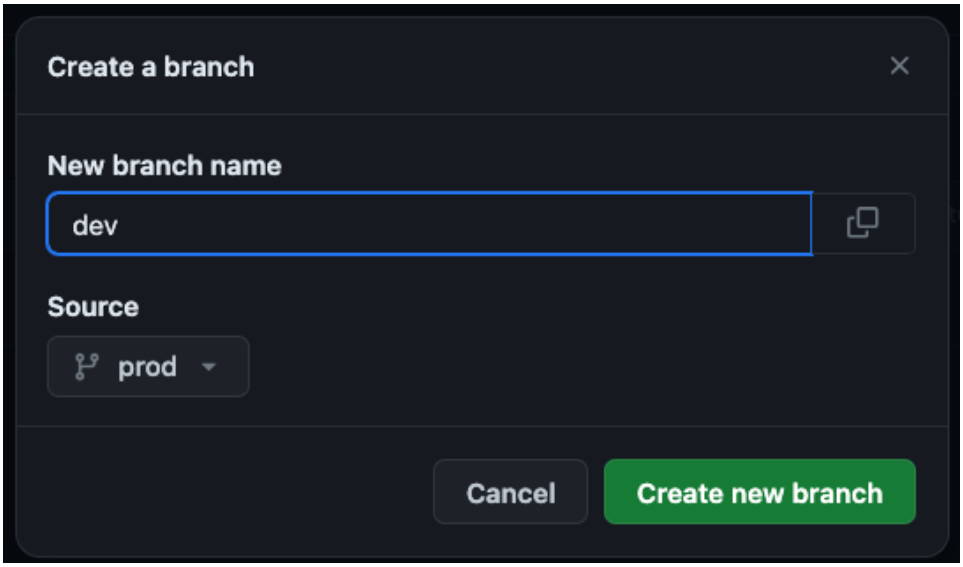
To do this in GitHub:

1. In your GitHub repo's landing page (for example, `https://github.com/<your_Git_username>/cribl`), select the **1 branch** tab. (That's what the branches tab will be named, assuming that the sole branch is `prod`).



The branches tab

2. Click **New branch** to open the **Create a branch** modal.
3. Make sure that **Source** is set to `prod`.
4. In the **New branch name** field, enter `dev`.



Creating the `dev` branch

5. Click **Create new branch** to close the modal.
6. Back in the **Branches** tab, click **Overview** to refresh the tab – you should now see both the `prod` and `dev` branches listed.

Configuring Your Development Leader

First, you'll point your Development Leader to the `dev` branch in the remote repo. Then, you'll ensure that one or more users exist that can push configs to that repo.

Pointing Your Development Leader to Its Branch

In Cribl Stream, in your Development Leader's UI, select global **Settings** (lower left) > **Git Settings**.

In the **Remote** tab:

1. In **Remote URL**, enter the URL for your private Git repo – and if the URL includes a Git username, this should be `gitops`, the one you created above.
    - On GitHub, the **Remote URL** will look like this: `git@github.com:<your_GitHub_username>/cribl.git`
2. Make sure that in the **Authentication type** drop–down, `SSH` (the default) is selected.
3. In **SSH private key**, copy and paste the private key (`~/.ssh/id_ed25519`).

> The key will paste in with an appended newline below it. Do not delete this newline before you save the Remote Settings, or else you will trigger an error of the form: `fatal: Could not read from remote repository.`

4. Toggle **SSH strict host key checking** off. This will allow the remote repository to accept your host key information. The remote host's information is stored in `~/.ssh/known_hosts`. If you miss this step, you will trigger an error.
5. Click **Save**.
6. Toggle **SSH strict host key checking** on again.
7. Click **Save** (again!), but do not **Commit** or **Push** yet.

In the **General** tab:

1. Set **Branch** to `dev`.
2. Leave **GitOps Workflow** set to `None`.
3. Click **Save**, but do not **Commit** or **Push** yet.

Restart the Development Leader. When it comes back up, it will be able to write to your Git repo.

Setting Up Users to Push to the Remote Repo

You will need one or more users capable of pushing configs to the remote repo. There is more than one way to achieve this. Your choice will depend on the needs of your organization.

- Any user with the `admin` Role already has ability to push to the remote repo. If this is your preferred approach, skip to the next section.
- If you prefer to allow one or more **regular** users to push to the remote repo, **without** having the power of the `admin` Role, you can create such users by completing the procedure below.

First, edit the `roles.yml` file to make a new `push_to_remote` Role. (We're using the command line here because you cannot perform this operation in the UI.)

1. SSH into the Leader Node.
2. `cd` into your `$CRIBL_HOME/local/cribl` directory.
3. Open or create the `roles.yml` file in a text editor.
4. Without changing the existing text in the file, paste in the following snippet:

```
push_to_remote:
  policy:
    - POST /version/sync
    - POST /version/commit
    - POST /version/push
    - GET /system/settings/git-settings
  description: Members with this role can push configs to a remote repo.
```

5. Restart Cribl Stream.

Next, back in the UI, create a new `config_pusher` User.

1. In global **Settings** (lower left) > **Access Management** > **Local Users**, click **Add User** to open the User creation modal.
2. Name the new Local User `config_pusher`.
3. In addition to the usual configuration steps, use the **Roles** drop-down to associate the `push_to_remote` Role with the `config_pusher` User.
4. Click **Save**.
5. **Commit** and **Push**.

Verify That Your New User Can Push to the Remote Repo

1. Log out, then log back in as `config_pusher`.
2. The **Version Control** drop-down should now display a **Push** button.

Later, when you are ready to push new configs to the remote repo, click this new **Push** button.

GitOps Workflow

If you've completed the above preparatory sections, your GitOps workflow is ready go. Here's an overview, with links to detailed procedures.

- Work in the Development Environment: All your commits and testing happen in the Development environment first; you push changes to the `dev` branch in your Git repo.
- Merge Changes from dev to prod: When you are satisfied that your changes are ready for production, you create a pull request that brings the `prod` branch up-to-date with `dev`. This is all in your Git management system, and changes nothing in your Cribl Stream Production environment.
- Sync Your Production Leader to Git: For your changes to take effect in production, you will send an HTTP request to the `/version/sync` endpoint of the Cribl API, on the Production Leader. Once you are in production, it will be your CI/CD infrastructure – not you – that sends the request. This will cause the Production Leader to pull in the latest changes from your Git repo's `prod` branch – without violating the Production Leader's read-only status.

The procedures include a harmless test task so that you can validate your setup and acquire a feel for the workflow.

Working in the Development Environment

In this step, you'll make changes in the Development environment, and subsequently propagate them to Production. To test this with a minimal unit of work, start by adding a Route.

In Cribl Stream, in the Development Leader's UI, navigate to **Routing** > **Data Routes**.

1. Click **Add Route**.
2. Configure the new Route as follows:

Name	Filter	Pipeline	Output
`test-gitops`	`true`	`devnull`	`devnull:devnull`

3. Click **Commit**.
4. In the **Git Changes** modal, add a commit message and click **Commit & Deploy**.
5. Finally, push the changes to your remote repo via the **Global Config** dialog, whose appearance will vary depending on how you've configured **Git Settings** > **Collapse Actions**. Make sure the dialog says that the **Git branch** you're pushing to is `dev`, as configured above.

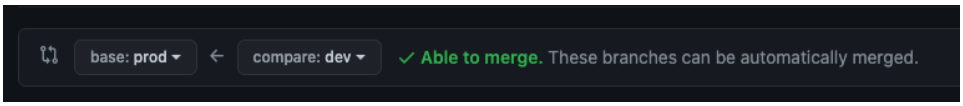
Merging Changes from `dev` to `prod`

In your Git management system's `dev` branch, you should see the new `route.yml` appearing in the `/groups/<group_name>/local/cribl/` directory.

Merge the changes from the `dev` branch to `prod` now.

To do this in GitHub:

1. Click **Compare & pull request**. Be sure that the `base` drop-down says `prod` and the `compare` drop-down says `dev`.



Comparing `dev` to `prod`

2. Add some comments.
3. Click **Create pull request**. The UI should say that you want to `merge 1 commit into prod from dev`.
4. If GitHub detects conflicts, fix them.
5. Have the appropriate person on your team review the pull request.
6. You (or the appropriate person) should now click **Merge pull request**, then **Confirm merge**.

If the merge is successful, GitHub will display a confirmation message. Your committed changes have now been merged from `dev` to `prod`.

Syncing Your Production Leader to Git

Your changes so far have all been done in the Development environment. Meanwhile, you have committed to the `dev` branch, and pushed to the `prod` branch **in your Git management system** – but your Production **environment** has not changed.

Since, for safety's sake, you made the Production environment read-only, you can neither write to it nor update it via a UI. Instead, the following must happen:

- You will send an HTTP request to the `/version/sync` endpoint of the Cribl API, on the Production Leader (in the API Reference, see **versioning**). Once you are in production, it will be your CI/CD infrastructure – not you – that sends the request.
- This will cause the Production Leader to pull in the latest changes from your Git repo's `prod` branch – without violating the Production Leader's read-only status.

Below you'll see a script you can use to send the HTTP request.

- This script is generic, and will require you to adapt it to work with the Git management system you're using.
- Once you run the script, you should see the changes you made in your Development environment (in this example, the new Route) in the Production environment, too.

Syncing to Git: Generic Script

Substitute your Production Leader's IP address and the `gitops` User's password for the placeholders.

```
#!/bin/bash

# Authenticate and Save the Token.
TOKEN=$(curl http://<Production_Leader_IP_address>:9000/api/v1/auth/login \
     -H 'Content-Type: application/json' \
     -d '{"username":"gitops","password":"$GITOPS_USER_PASSWORD"}' 2>/dev/null | \
     jq -r .token)

# Set up the Authentication Header
export AUTH_HEAD="Authorization: Bearer $TOKEN"

# Make the notification call
curl -X POST "http://<Production_Leader_IP_address>:9000/api/v1/version/sync" -H "ac
```

Making the HTTP Request from CI/CD

Now that you have run one of the above scripts to prove that your GitOps workflow works, you should incorporate the script's HTTP request into your CI/CD setup. Once that is done, you're in production with GitOps! To develop, test, and push changes to production, just keep running through the whole GitOps workflow.

Appendix: Upgrading

Upgrading a Cribl Stream GitOps deployment is essentially a variation on the day-to-day GitOps workflow described in the previous section, with the key difference that you take the Production environment out of, then put it back into, read-only mode.

Once you have begun the upgrade, **do not** make any changes unrelated to the upgrade process, in either the Development or Production environment, until the upgrade process is complete. For example, do not start creating any new Routes or Pipelines.

First, in your Development environment:

1. Validate that Cribl Stream is working as expected, and that the latest changes have been pushed to the `dev` branch in your Git repo.
2. Stop the Cribl Stream Leader and back up `$CRIBL_HOME` (the Cribl install directory).
3. Use the UI to upgrade the Leader and Workers.
4. Create a PR to merge the `dev` branch into `prod`. Merge the PR.

Next, in your Production environment:

1. Stop the Cribl Stream Leader and back up `$CRIBL_HOME` (the Cribl install directory).
2. Take your Production environment **out of read-only mode** according to the instructions below.
3. Use the UI to upgrade the Leader and Workers – but **do not** commit changes after the upgrade.
4. Put the Leader **back into read-only mode** according to the instructions above.
5. Sync the Production environment to the `prod` branch in your Git repo.

Finally, confirm that all Workers in both environments have the latest configuration.

Taking the Production Leader Out of Read-Only Mode

In a terminal on the Production Leader, become root:

```
sudo su -
```

Comment out the `systemctl` overrides that set environment variables that (a) had made the Production Leader read-only upon startup, and (b) had set the branch to `prod`.

1. Use `systemctl` to open the `override.conf` file in an editor:

   ```
   systemctl edit cribl
   ```

2. When prompted, comment out the Git-related overrides as shown:

   ```
   [Service]
   # Environment=CRIBL_GIT_OPS=push
   # Environment=CRIBL_GIT_BRANCH=prod
   ```

3. Restart:

   ```
   systemctl daemon-reload && systemctl restart cribl
   ```

9.4. Worker Group Settings

A Worker Group's General Settings allows you to configure teleporting, throughput throttling, logging, upgrading, and security at the Worker Group level.

To edit a Worker Group's General Settings:

1. Select the Worker Group, then select **Worker Group Settings**.
2. Configure the following settings per Worker Group.

General Settings

Worker Group Configuration

You can configure the following options on this tab:

Description: Optionally, add or edit a description of the Worker Group's purpose.

Tags: Use tags to organize Worker Groups into logical categories. Then, you can search by tags on the **View all Groups** (Stream) or **View all Fleets** (Edge) interface. This search filters the list of Worker Groups, showing only those with the tag you entered.

Enable teleporting to Workers: Use this toggle to enable or disable authenticated access to Workers' UI from the Leader (Stream, Edge).

In Cribl Stream 4.1.2 and later, you can configure the following option in Shutdown Settings.

API Server Settings

General

You can set the following options for the API server.

Host: The hostname or IP address you want to bind the API server to. Defaults to:

- `127.0.0.1` for standalone Edge Nodes and Edge Fleets
- `0.0.0.0` for Leader, standalone Stream Workers, and Worker Groups.

You can override the value with the `CRIBL_API_HOST` environment variable.

Port: API port to listen to.

Defaults to:

- `9420` for standalone Edge Nodes and Edge Fleets
- `9000` for Leader, standalone Stream Workers, and Worker Groups.
-

You can override the value with the `CRIBL_API_PORT` environment variable.

TLS

For information on TLS options, see the documentation for any Source or Destination that supports TLS.

Advanced

See Authentication Controls.

Default TLS Settings

See the System-wide TLS Settings Including Ciphers.

Limits

The **Limits** tab provides access to controls for metrics, storage, metadata, jobs, the Redis cache and connections to it, and CPU settings.

Metrics

See Controlling Metrics Volume.

Storage

You can configure the following options for storage. In **General Settings**, open **Limits** and then select **Storage**:

Max sample size: Maximum file size, in binary units (`KB`, `MB`), for sample data files. Maximum: `3 MB`. Default: `256 KB`.

Min free disk space: The minimum amount of disk space on the host before various features take measures to prevent disk usage (KB, MB, etc.). Default: `5 GB`.

Max PQ size per Worker Process: Highest accepted value for the **Max queue size** option used in individual Sources' and Destinations' persistent queues. Default: `1 TB`. Consult Cribl Support before increasing beyond this value.

Metadata

Event metadata sources: List of event metadata sources to enable. No sources are enabled by default.

Jobs

Disable jobs/tasks: Set to `Yes` by default in Edge Fleets and `No` by default in Stream Groups. In Edge, Nodes no longer poll the Leader for upgrade jobs. Setting this to `Yes` in Edge reduces application load from the Leader.

Nodes running 4.4.4 and older still upgrade via jobs and will honor the Jobs settings, even with the **Disable jobs/tasks** toggle enabled.

Job Limits

Disable Jobs/Tasks: When enabled, the Worker Nodes won't poll the Leader for jobs/tasks. The job limits settings below will not affect Worker Nodes on version 4.5.0 and newer. Worker Nodes running 4.4.4 and older still use these jobs settings even if jobs/tasks are disabled here.

Concurrent Job Limit: The total number of jobs that can run concurrently. Defaults to `10`.

Concurrent System Job Limit: The total number of **system** jobs that can run concurrently. Defaults to `10`. Minimum `1`.

Concurrent Scheduled Job Limit: The total number of **scheduled** jobs that can run concurrently. This limit is set as an offset relative to the **Concurrent Job Limit**. Defaults to `-2`.

Skipped jobs indicate that a Group's **Concurrent Job Limit** has been reached or exceeded. Increase this limit to reduce the number of skippable jobs. For resource-intensive jobs, this might require deploying more Worker Nodes.

Task Limits

Concurrent Task Limit: The total number of tasks that a Worker Process can run concurrently. Defaults to `2`. Minimum `1`.

Concurrent System Task Limit: The number of system tasks that a Worker Process can run concurrently. Defaults to `1`. Minimum `1`.

Max Task Usage Percentage: Value, between `0` and `1`, representing the percentage of total tasks on a Worker Process that any single job may consume. Defaults to `0.5` (50%).

Task Poll Timeout: The number of milliseconds that a Worker's task handler will wait to receive a task, before retrying a request for a task. Defaults to `60000` (60 seconds). Minimum `10000` (10 seconds).x

Completion Limits

Artifact Reaper Period: Interval on which Cribl Stream attempts to reap jobs' stale disk artifacts. Defaults to `30m`.

Finished Job Artifacts Limit: Maximum number of finished job artifacts to keep on disk. Defaults to `100`. Minimum `0`.

Finished Task Artifacts Limit: Maximum number of finished task artifacts to keep on disk, per job, on each Worker Node. Defaults to `500`. Minimum `0`.

Task Manifest and Buffering Limits

Manifest Flush Period: The rate (in milliseconds) at which a job's task manifest should be refreshed. Defaults to `100` ms. Minimum `100`, maximum `10000`.

Manifest Max Buffer Size: The maximum number of tasks that the task manifest can hold in memory before flushing to disk. Defaults to `1000`. Minimum `100`, maximum `10000`.

Manifest Reader Buffer Size: The number of bytes that the task manifest reader should pull from disk. Defaults to `4kb`.

Job Dispatching: The method by which tasks are assigned to Worker Processes. Defaults to `Least In-Flight Tasks`, to optimize available capacity. `Round Robin` is also available.

Job Timeout: Maximum time a job is allowed to run. Defaults to `0`, for unlimited time. Units are seconds if not specified. Sample entries: `30`, `45s`, `15m`.

Task Heartbeat Period: The heartbeat period (in seconds) for tasks to report back to the Leader/API. Defaults to `60` seconds. Minimum `60`.

Redis

Cache

Key TTL in seconds: Maximum time to live of a key in the cache (seconds). `0` indicates no limit. Defaults to `10 minutes`.

Max # of keys: Maximum number of keys to retain in the cache. `0` indicates no limit. Defaults to `0`.

Max cache size (bytes): Maximum number of bytes to retain in the cache. `0` indicates no limit. Defaults to `0`.

Service period (seconds): Frequency of cache limit enforcement. Defaults to every `30 seconds`.

Server assisted: Defaults to `No`. When toggled to `Yes`, the following control appears.

Client tracking mechanism: Mechanism for invalidation message delivery. In default mode, the server remembers which keys a client has requested and only sends invalidations for those, using more Redis server memory. In broadcast mode, it sends all invalidations, requiring more processing by Cribl Stream.

Connections

Reuse Redis connections: Toggle on if you want Cribl Stream to try to reuse Redis connections when multiple Redis Functions (or references to them) are present. When enabled, displays the following additional control:

- **Max number of connections**: The maximum number of identical connections allowed before Cribl Stream tries to reuse connections. Defaults to `0`, meaning unlimited connections are allowed (equivalent to leaving **Reuse Redis connections** toggled off). Setting a non-zero integer value forces Cribl Stream to try to reuse connections for each individual Worker Process (**not** to reuse connections **among** Worker Processes).

To understand why and when to employ these controls, see Reusing Redis Connections.

Other

CPU profile TTL: The time-to-live for collected CPU profiles.

Default managed node heartbeat period: How many seconds a managed Node will wait to send back a heartbeat to the Cribl control plane.

Config bundle download timeout: How many seconds a Cribl Stream Worker will wait for a successful Leader connection before canceling a download of a new configuration bundle. This timeout helps prevent Workers from hanging indefinitely when there are network issues or other delays during the download process. A `0` value means wait indefinitely, which could cause Workers to hang.

Proxy Settings

Use proxy env vars: Honors the `HTTP_PROXY/HTTPS_PROXY` environment variables. Defaults to `Yes`.

Cribl prioritizes environment variables for proxy settings in this order: Process, User, and System.

If your Cribl service is managed by a service manager other than systemd (such as upstart or init), the `Use proxy env vars` toggle might not behave as expected because Cribl might prioritize environment variables set by the service manager instead of using the proxy settings you intended.

Sockets

Directory: Holds sockets for inter-process communication (IPC), such as communications between a load-balancing process and a Worker Process. Defaults to `/tmp` (your system's temp directory).

Shutdown Settings

Drain timeout (sec): Determines how long a Cribl server will wait for writes to complete before the server shuts down on individual Worker Processes. If you notice that Workers are under-ingesting available data upon shutdown or restart, increase the `10`–second default. Acceptable range of values: minimum `1` second, maximum `600` seconds (10 minutes).

Worker Processes

For details about this left tab's **Process count**, **Minimum process count**, and **Memory (MB)** controls, see Sizing and Scaling.

Process count and **Minimum process count** are not configurable on Cribl Edge, where each Edge Node is automatically allocated `1` Worker Process.

The following controls are also available on this tab to optimize Worker Processes' throughput on startup.

Max connections at startup: Maximum number of connections accepted at Worker Process startup. Defaults to `1`. Enter a negative integer for unlimited connections.

Startup throttling duration (ms): Maximum time (in milliseconds) to continue throttling connections after Worker Process startup. Defaults to `10000` ms (10 sec.) Enter `0` to disable throttling.

Load throttle %: Sets a threshold to prevent overwhelming Workers. If 90% of a Worker Process' CPU utilization readings exceed this threshold over one minute, the process will reject new connections until the

CPU load stabilizes. Another process that is below the threshold will accept the connection the next time it is established. Defaults to `0%` (no throttling). Enter a percentage between `1-100` to enable throttling.

You can configure the CPU saturation threshold, but the 90% sampling trigger is not configurable. Also, `_raw stats > cpuPerc` values might diverge from your **Load throttle %** threshold. This is because `cpuPerc` is sampled and averaged once per minute, whereas the **Load throttle %** is evaluated every second, with a rolling 1-minute lookback sample. (These intervals are also not configurable.)

Enable heap snapshots: Defaults to `No`. Toggle to `Yes` for Cribl Stream to automatically create memory snapshots for Worker Processes when they approach or exceed memory limits. Only the two most recent heap snapshots are retained. Older snapshots are automatically deleted. This behavior cannot be modified.

The **Enable heap snapshots** is available for hybrid or on-prem deployments only. This setting should only be enabled if recommended by support or if you are experiencing out-of-memory issues. Be aware that enabling this setting may impact system performance and storage usage.

Other Settings

This page's remaining options work essentially the same way as their counterparts in **Settings** > **Global**. Use the following links for details about: logging levels/redactions, access management, security, scripts, and diagnostics.

9.5. Notifications Overview

With Notifications, you can set up alerts that notify Cribl Stream admins about issues that require their immediate attention.

Types of Notifications

In Cribl Stream, you can configure Notifications about:

- Sources (including Cribl Stream Collectors) with high, low, or no data flow rates.
- Destinations that are experiencing backpressure, reporting errors, or approaching their persistent queue threshold.
- Pending expiration of a Cribl Stream license.

Notifications are also sent as events to Cribl Stream internal logs – both application-wide, and with a filtered view available on affected Sources and Destinations. Cribl Stream stores these application-wide logs in `notifications.log` on the Leader Node. The Leader Node is also responsible for sending all Notifications.

License Requirements

Notifications require certain plan/license tiers. Without an appropriate license, the configuration options described below will be hidden or disabled in Cribl Stream. For more information on license types and a feature comparison, see our Pricing page.

Notifications and Targets

A Notification target allows you to specify where Cribl Stream delivers a Notification. Every Notification requires one or more targets.

Available target types include:

- Webhook
- PagerDuty integration
- Slack
- AWS SNS
- Email
- System Messages (default when you create a new Notification without a target).

For details, see Notification Targets.

When you create a new Notification, its default target type will be **System Messages**. When an event occurs in Cribl Stream to trigger a Notification condition, you will see an indicator in the **Messages** icon.

Select the icon to open the **Messages** drawer and view the Notification details.

Notifications and RBAC

Notifications work with Cribl Stream role-based access control. For users with non-administrative permissions, their assigned Roles and Policies determine the Worker Groups on which they can view Notification messages, configure Notifications, and configure targets.

Set up Notifications

To set up Notifications, you can create either the Notification or the target first — the order doesn't matter. In general, this is the process for creating a Notification:

- Create a Notification about a Source or Destination, or pending license expiration.
- Add or create a Notification target. See Targets Tab for more information. If you don't have a Notification target, the **Messages** icon will indicate you have a new Notification.
- Test the target to ensure it works.

Create a Notification about a Source or Destination

To create a Notification for a Source or Destination:

1. Navigate to your Worker Group.
2. Select Data and choose your Source or Destination.
3. In the **Notifications** column, select **Notifications**.

For specific information about configuring these options, see Source-State Notifications and Destination-State Notifications.

Create a Notification about License Expiration

To create a license-expiration Notification:

1. Navigate to **Settings** > **Global** > **Licensing**.
2. Select **Add Expiration Notification**.

License-expiration Notifications are only available for customer-managed instances of Cribl Stream. For specific information about configuring these options, see License-Expiration Notifications.

General

ID: Provide a unique ID for the Notification in this section. Cribl Stream enables the Notification by default, but you can disable the Notification by setting **Enabled** to `No`.

Configuration

Define the triggering condition for the Notification in this section. Conditions vary by Notification type, so consult one of the following topics for the relevant details:

- Source-State Notifications
- Destination-State Notifications
- License-Expiration Notifications

Select **Add Target** to add a preexisting target. Select **Create Target** to create a new target.

If you select or add an email Notification target, an additional set of configuration options appear. See Configuring Email Notifications for more information.

Metadata

Metadata fields are user-defined fields included in the Notification payload. All Notification types can contain metadata.

Select **Add field** here to add custom metadata fields to your Notifications in the form of key-value pairs:

- **Name**: Enter a name for this custom field.
- **Value**: Enter a JavaScript expression that defines this field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Once you've saved your Notifications, you can see Notification events specific to this Destination on the **Events** tab within the Destination configuration window. When you set Source-state Notifications, a corresponding **Events** tab is available on Source and Collector config modals. For a comprehensive view of all Notification events, see the system-wide Events Tab.

Manage Notifications

You can manage existing Notifications and targets by selecting **Notifications** in the sidebar. You can also reach this page by selecting an existing Notification in a Source or Destination modal or in **Settings** > **Global** > **Licensing**.

Notifications Tab

This tab lists all your configured Source-state and Unhealthy Destination Notifications, across all integrations, along with any configured license-expiration Notifications. You can't create new Notifications here, but you can disable or delete existing Notifications. For any individual Notification, select **View Events** to see events that have triggered the Notification.

To modify a Notification, select anywhere on its row.

Targets Tab

This tab is where you centrally configure and manage targets that are available across Cribl Stream – for all Sources, Destinations, and license-based Notifications. See Notification Targets for details.

To create a new target, select **Add Target**. To delete a target, select **Delete** in the appropriate row.

9.5.1. Source-State Notifications

In Cribl Stream, you can configure Notifications on Sources and Collectors to trigger under these conditions:

- High Data Volume
- Low Data Volume
- No Data

Read on for details about these conditions and how to configure appropriate Notifications.

High Data Volume

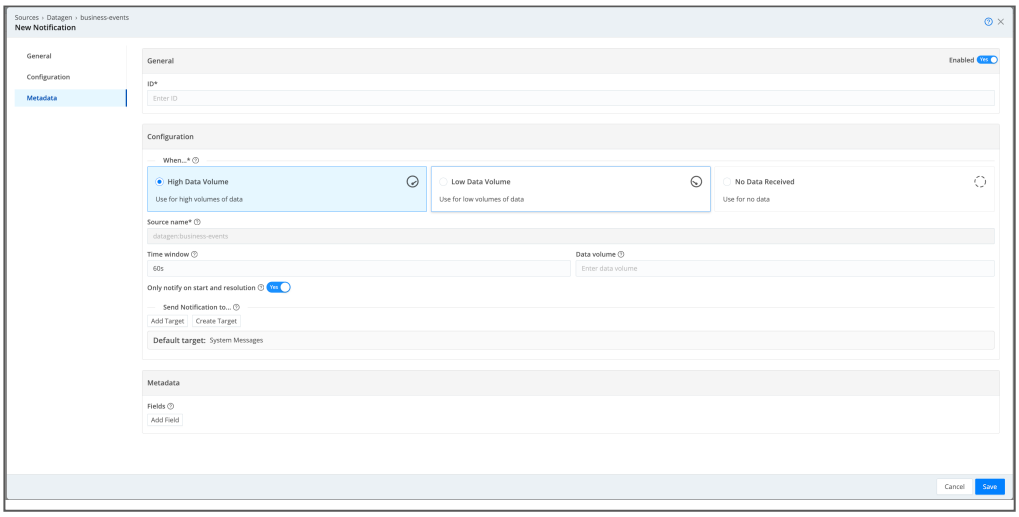
Cribl Stream will generate a Notification when incoming data over your configured **Time window** exceeds your configured **Data volume** threshold. This selection exposes the following fields:

Notification targets: The **Default target** is always locked to `System Messages`.

Source name: This field is locked to the Source on which you're setting this Notification.

Time window: This field's value sets the threshold period before the Notification will trigger. The default `60s` will generate a Notification when the Source has reported the trigger condition over the past 60 seconds. To enter alternative numeric values, append units of `s` for seconds, `m` for minutes, `h` for hours, and so forth.

Data volume: Enter the threshold above which a Notification will trigger. Accepts numerals with units like `KB`, `MB`, and so forth. For example: `4GB`. If you want the unit to be bytes, enter the numeral only, without a unit designator.



Configuring a high data volume Notification

Low Data Volume

Select the `Low Data Volume` tile to trigger Notifications when incoming data over your configured **Time window** is lower than your configured **Data volume** threshold.

This selection exposes the same additional fields as High Data Volume, except that here, the **Data volume** value defines a **floor** below which the Notification will trigger.

No Data

Select the `No Data Received` tile to trigger Notifications when the Source or Collector ingests zero data over your configured **Time window**.

This selection exposes the same additional fields as High Data Volume, except it omits the **Data volume** field. With no data entering the Source, there is no threshold to configure.

Source-State Notifications for Webhook Targets

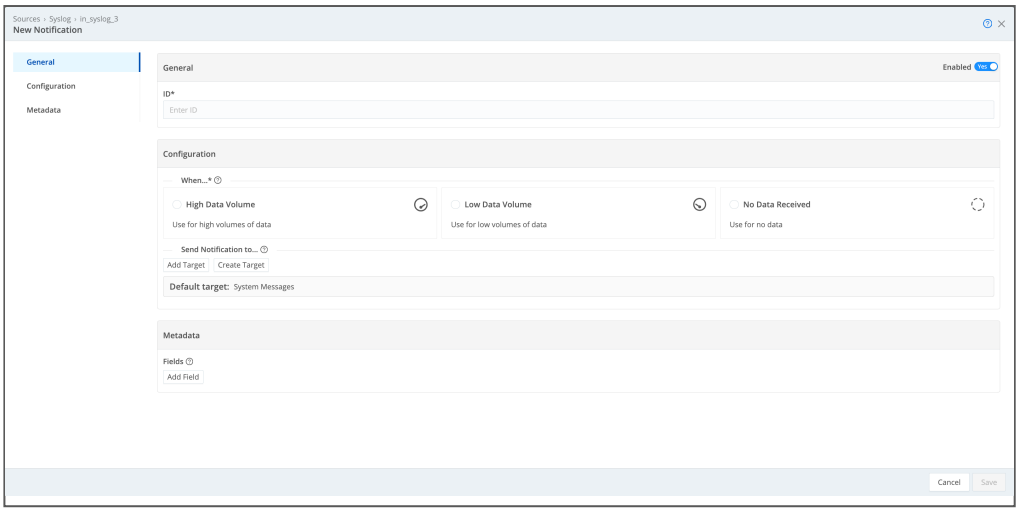
If you are sending a Source-state Notification to a Webhook Notification target, you can include a variety of expression fields in the target's **Source expression**. For more information, see:

- Fields Common to All Notification Types
- Source High Data Volume
- Source Low Data Volume
- Source No Data Received

Configure Source Notifications

To configure a Source-state Notification:

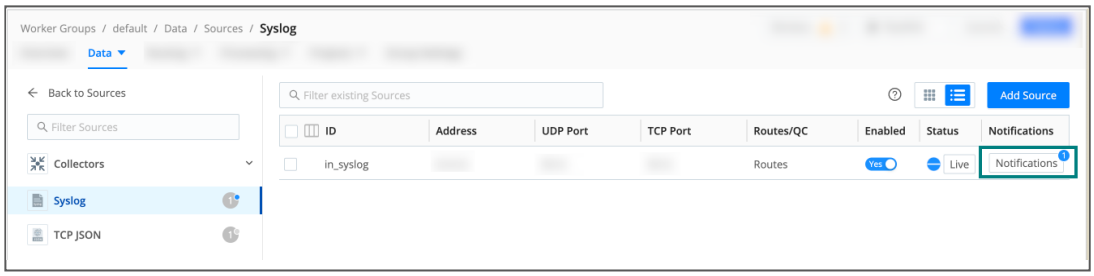
1. Configure and save the Source.
2. Access this Source's **Notifications** tab by one of the following methods:
    - Select the **Notifications** button on the Source page's appropriate row.
    - Reopen the Source's configuration modal and select its **Notifications** tab.
3. Select **Add Notification** to access the **New Notification** modal shown here.



Configuring a Source Notification

View Count of Configured Source Notifications

In the **List** view of a Source, you can quickly see how many Notifications are configured. The **Notifications** button will display a badge showing you the number of configured Notifications for the Source.



List view of a configured Source with Notifications

General

ID: Enter a unique ID for this Notification. Notifications are enabled by default, but you can disable the Notification by setting **Enabled** to `No`.

Configuration

When: Select one of the following Notification tiles:

- **High Data Volume**
- **Low Data Volume**
- **No Data Received**

You can create multiple Notifications for the same Source, but you must configure them separately.

Send notification to: Select **Add Target** to send this Notification to additional targets. You can add multiple targets.

- Use the resulting **Notification targets** drop-down to select any target you've already configured.
- Select **Create Target** to configure a new target.

See Notification Targets for details.

Default target is always locked to `System Messages`.

Source name: This field is locked to the Source on which you're setting this Notification.

Time window: This field's value sets the threshold period before the Notification will trigger. The default `60s` will generate a Notification when a Destination or Source has reported the trigger condition over the past 60 seconds. To enter alternative numeric values, append units of `s` for seconds, `m` for minutes, `h` for hours, and so forth.

Only notify on start and resolution: When this option is set to `Yes`, Cribl Stream will send a Notification at the onset of the triggering condition. On resolution, it will send a second Notification.

If you don't enable this option and a Source-state Notification's trigger condition persists beyond your configured **Time window**, Cribl Stream will send a new Notification, once per **Time window** interval.

Metadata

You can enter user-defined fields called *metadata*, which Cribl Stream includes in the notification payload. See Metadata for more information.

9.5.2. Destination-State Notifications

In Cribl Stream, you can configure Notifications on Destinations. You will receive a Notification to the set target when one of these conditions triggers:

- Backpressure activates on the Destination
- Persistent Queue Usage surpasses a set threshold
- The Destination is unhealthy

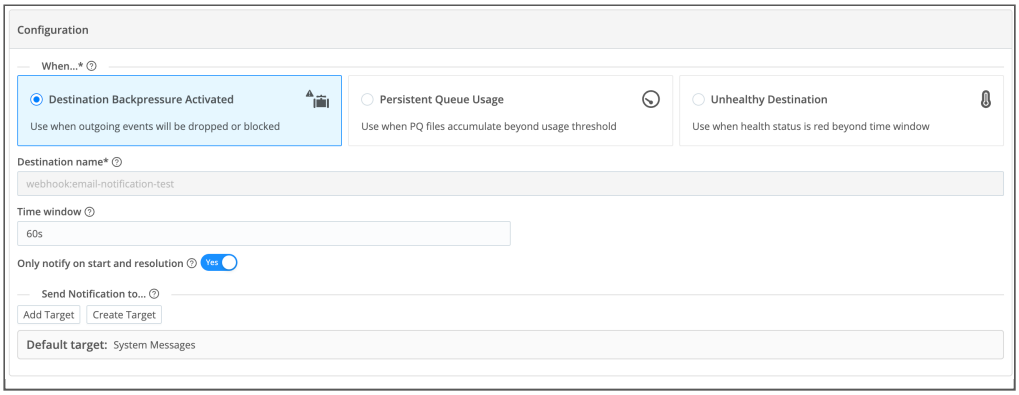
Read on for details about these conditions and how to configure appropriate Notifications.

Destination Backpressure Activated

Cribl Stream will generate a Notification when one of the following events occurs:

- The Destination's **Backpressure behavior** is set to `Block` or `Drop`, and backpressure causes outgoing events to block or drop.
- The Destination's **Backpressure behavior** is set to Persistent Queue, but its **Queue-full behavior** is set to either `Block` or `Drop new data`, and a filled queue causes the Destination to to block or drop outgoing events.

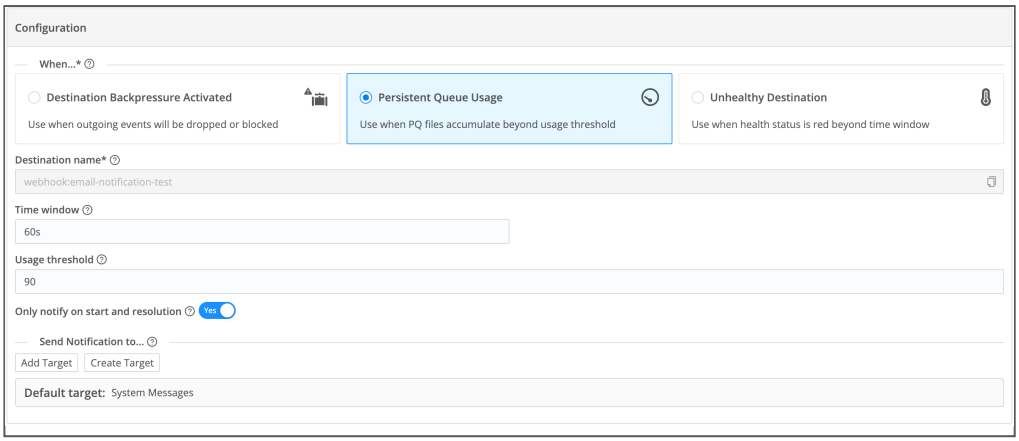
The threshold for the Notification to trigger is: Cribl Stream detected a blocked or dropped state during ≥ 5% of the trailing **Time window** that you configure in the Configuring Destination Notifications.



Backpressure Notification

Persistent Queue Usage

Cribl Stream will generate a `Persistent Queue usage has surpassed <threshold>%` Notification when the PQ accumulates files past the `<threshold>` percentage of capacity that you set in the **Usage threshold** field. This field appears only when you configure a Notification for **Persistent Queue Usage**.



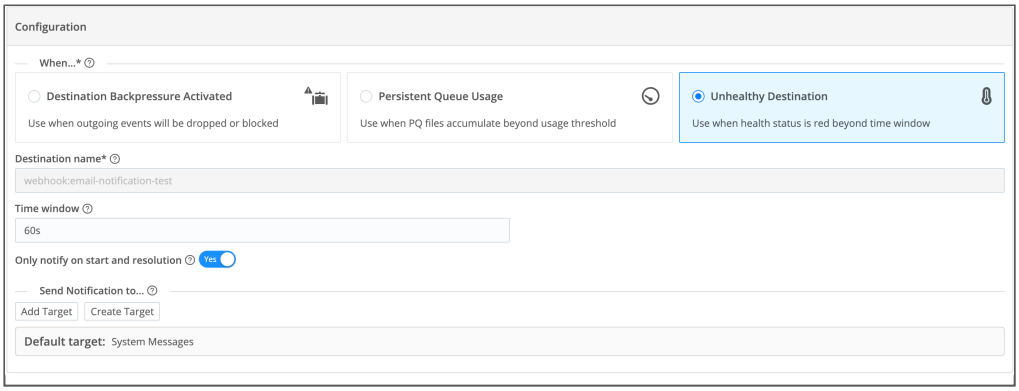
Persistent Queue Notification

Unhealthy Destination

Cribl Stream will generate a `Destination <name> is unhealthy` Notification when the Destination's health has been in red status (as indicated on the Monitoring page) over the trailing **Time window** that you configure in Configuring Destination Notifications.

The algorithm has slight variations among Destination types, but red status generally means that ≥ 5% of health checks, aggregated over the **Time window**, reported one of the following conditions:

- An error inhibiting the Destination's normal operation, such as a connection error.
- For multiple-output Destinations like Splunk Load Balanced or Output Router, > 50% of the Destination senders are in an error state.



Destination Unhealthy Notification

Destination-State Notifications for Webhook Targets

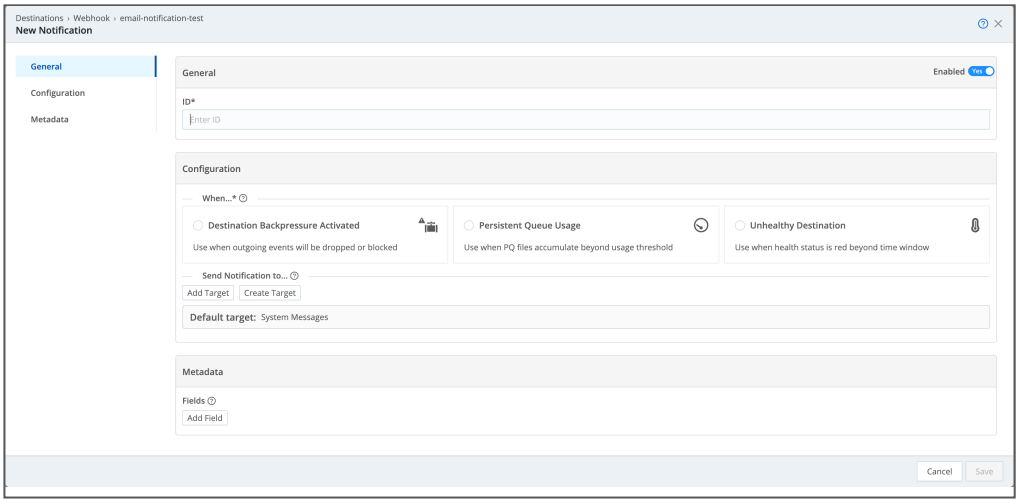
If you are sending a Destination-state Notification to a Webhook Notification target, you can include a variety of expression fields in the target's **Source expression**. For more information, see:

- Fields Common to All Notification Types
- Unhealthy Destination
- Destination Backpressure Activated

Configure Destination Notifications

To configure a Destination-state Notification:

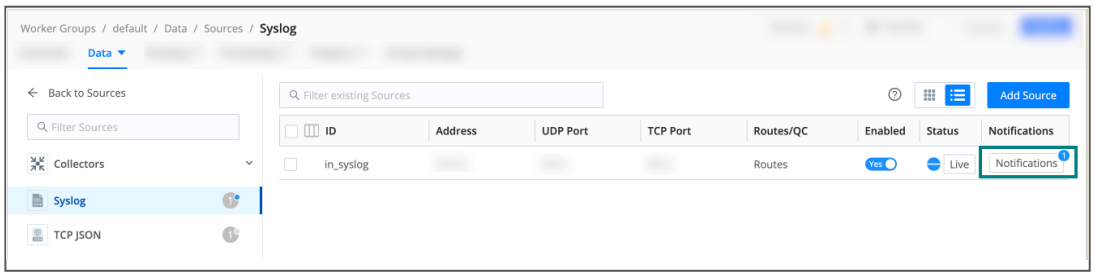
1. Configure and save the Destination.
2. Access this Destination's **Notifications** tab by one of the following methods:
    - Select the **Notifications** button on the Destination page's appropriate row.
    - Reopen the Destination's configuration modal and select its **Notifications** tab.
3. Select **Add Notification** to open the **New Notification** modal shown here.



Configuring a Destination Notification

View Count of Configured Destination Notifications

In the **List** view of a Destination, you can quickly see how many Notifications are configured. The **Notifications** button will display a badge showing you the number of configured Notifications for the Destination.



List view of a configured Source with Notifications

General

ID: Enter a unique ID for this Notification. Notifications are enabled by default, but you can disable the Notification by setting **Enabled** to `No`.

Configuration

When: Select one of the following Notification tiles:

- **Destination Backpressure Activated**
- **Persistent Queue Usage**
- **Unhealthy Destination**

You can set up multiple Notifications for the same Destination, but you must configure them separately.

Send Notification to: Select **Add Target** to send this Notification to additional targets. You can add multiple targets.

- Use the resulting **Notification targets** drop-down to select any target you've already configured.
- Select **Create Target** to configure a new target.

See Notification Targets for details.

Default target is always locked to `System Messages`.

Destination name: This field is locked to the Destination on which you're setting this Notification.

Time window: This field's value sets the threshold period before the Notification will trigger. The default `60s` will generate a Notification when a Destination or Source has reported the trigger condition over the past 60 seconds. To enter alternative numeric values, append units of `s` for seconds, `m` for minutes, `h` for hours, and so forth.

Only notify on start and resolution: When this option is set to `Yes`, Cribl Stream will send a Notification at the onset of the triggering condition and a second Notification to report its resolution.

If you don't enable this option and a Destination-state Notification's trigger condition persists beyond your configured Time window, Cribl Stream will send a new Notification, once per **Time window** interval.

Metadata

You can enter user-defined fields called *metadata*, which Cribl Stream includes in the notification payload. See Metadata for more information.

9.5.3. License-Expiration Notifications

To prevent interruptions in data throughput, you can configure a Notification that will be triggered two weeks before your Cribl Stream paid license expires, and then again upon expiration. (If the two-week Notification is cleared from the **Messages** tab between those dates, but the license has not been extended, it will trigger again.)

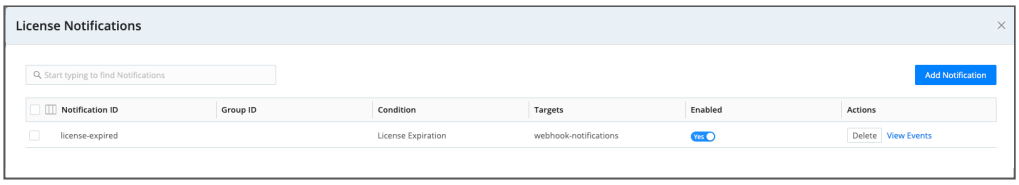
License-Expiration Notifications for Webhook Targets

If you are sending a license-expiration Notification to a Webhook Notification target, you can include a variety of expression fields in the target's **Source expression**. For more information, see:

- Fields Common to All Notification Types
- License Expiration

Configure License-Expiration Notifications

1. In the sidebar, select **Settings** > (**Global** >) **Licensing**.
2. Select **Add Expiration Notification** to access the **License Notifications** modal.



License Notifications modal

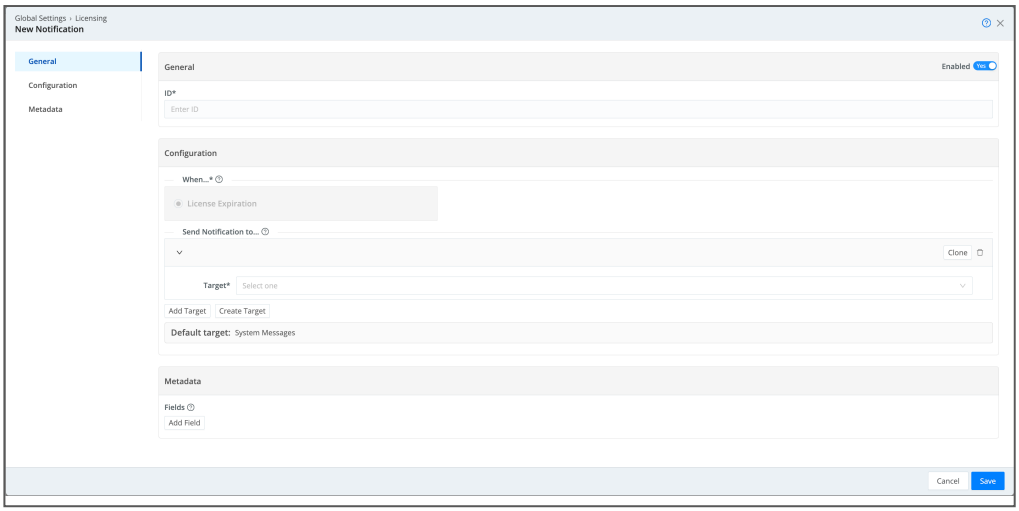
This modal shows existing license Notifications.

To modify a license-expiration Notification, select its row.

To delete a Notification, select **Delete**.

To view license-expiration events, select **View Events**.

Select **Add Notification** to to open the **New Notification** modal shown here.



Configuring a license expiration Notification

This **New Notification** modal provides General, Configuration, and Metadata tabs.

General

ID: Enter a unique ID for this Notification. Notifications are enabled by default, but you can disable the Notification by setting **Enabled** to `No`.

Configuration

When: This modal's triggering condition is locked to `License Expiration`.

Send notification to: This section contains a list of the targets receiving this Notification. The **Default target** is always locked to `System Messages`.

Select **Add Target** for each additional existing target that you want to send this Notification to. Select **Create Target** to create a new target for the Notification.

Metadata

You can enter user-defined fields called *metadata*, which Cribl Stream includes in the notification payload. See Metadata for more information.

9.5.4. Email Notifications

If you're a Cribl Stream admin, email notifications make it easy to receive alerts about any operational issues that require your attention, such as a particular Source or Destination condition or a pending license expiration.

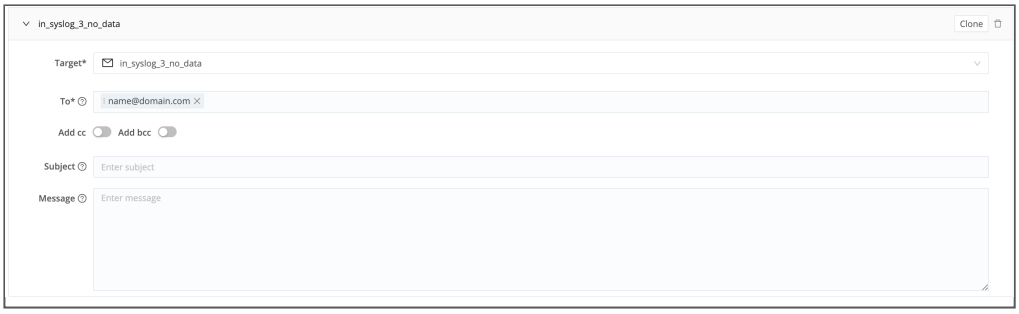
An email Notification requires two things — a configured Notification and an email Notification target. Cribl.Cloud Organizations using certain plan/license tiers also have access to a preconfigured email Notification target.

Email Notifications do not have an unsubscribe option. Recipients who do not want to receive particular email Notifications should contact their Cribl Stream admins.

Email Notifications are sent on a no-reply basis.

Configure Email Notifications

When you create a Notification for an email target, specify the recipients of the message, the subject line, and the contents of the message.



Email Notification with target selected

Target: The ID of the email target to which you want to send the Notification.

Select **Add target** to add an existing target.

Select **Create target** to create a new target. For information on configuring email Notification targets, see Email Notification Targets.

If the Notification already has a designated target, you can change the selection by selecting the drop-down.

When an email Notification target is selected, the following additional fields appear:

To: The email address of the recipient.

Add cc: When enabled, reveals a field where you can enter the addresses of additional recipients.

Add bcc: When enabled, reveals a field where you can enter the addresses of additional recipients that do not appear in the Notification email.

Cribl Stream does not limit the total number of recipients for a Notification, but your email service might set a limit.

Subject: The subject line of the email Notification. You can use variables in the subject line.

Message: The content of an email Notification. You can use variables in the body of the email message.

Email Notification Variables

Email variables are placeholders in the email template that get replaced with actual values when the email is sent. These variables can be:

- General-use variables, like `condition`, `worker_group`, or `timestamp`
- Special-purpose variables

You can use a variety of general-use and special-purpose variables in the subject or message body of an email Notification. Insert a variable name between two braces preceded by a `$`. For example: `${cribl_notification}`.

General-Use Email Variables

Variable	Description
`workspace`	Workspace name (Cribl.Cloud only).
`organization`	Organization ID (Cribl.Cloud only).
`timestamp`	Timestamp when the email is sent. For example: `2019-08-04 18:22:24 UTC`.
`cribl_notification`	User-defined notification ID.

Special-Purpose Email Variables

Variable	Usage	Example
`input`	Type and name of a Source or Collector.	`syslog:in_syslog_1`

Variable	Usage	Example
`output`	Type and name of a Destination.	`webhook:out_webhook_1`
`name`		Unique ID of a Source or Destination.
`bytes`	Quantity of data triggering the specified Notification.	`0`
`starttime`	Start time of an Event (in Epoch seconds).	`1706747185`
`endtime`	End time of an Event (in Epoch seconds).	`1706747294`
`health`	Health metric of the specified Source or Destination.	`0`
`_raw`	The `_raw` field of the Event triggering the Notification.	`_raw (Source ${name} in group ${__workerGroup} traffic volume greater than ${dataVolume} in ${timeWindow})`
`backpressure_type`	Backpressure behavior.	`1=BLOCKING, 2=DROPPING`
`queue_usage`	Percentage of capacity set in the **Usage threshold** field for a **Persistent Queue Usage** Notification.	`90`

Troubleshoot Email Notifications

The section details the troubleshooting steps you can take if an email Notification fails to reach its intended recipient.

Test the Email Notification Target

An email Notification can fail if the target is misconfigured. You can test your email Notification target by following this procedure:

1. Open the target (in **Notifications** > **Targets**).
2. Select **Test Target**.
3. Add one or more email addresses to the **Test Target** modal and select **Send Test Email**.

4. Check the designated inbox to verify receipt of the test message. If it does not arrive in the designated inbox, review the target configuration.

Check Notification Service Logs

A failed email Notification leaves a log entry. You can examine logs by following this procedure:

1. Select **Monitoring** > **Logs**.
2. In the drop-down on the left, select **Leader** > **Notifications Service**.
3. Examine any logs that have errors.

Check Notifications

Cribl Stream stores Notifications. You can check them by following this procedure:

1. Select **Monitoring** > **Notifications**.
2. In the search field, search for **cribl_notification** fields that correspond to the Notification ID of the failed Notification.

9.5.5. Notification Targets

A Notification target specifies the delivery method for a Notification. Every Notification requires one or more targets.

Available target types include:

- Webhook
- PagerDuty integration
- Slack
- AWS SNS
- Email

Add a Notification Target

To add a new Notification target:

1. In the Cribl Stream sidebar, select **Notifications**, and then select the **Targets** tab.
2. Select **Add Target** to open the **New Target** modal.
3. Give this target a unique **Target ID**.
4. Select the desired **Target type**.

Then configure the target as described in the appropriate page:

- Webhook
- PagerDuty
- Slack
- AWS SNS
- Email

When you create a Notification target in Cribl Stream, Edge, or Search, it will also be available to you in the other products. For example, if you create a Notification target in Cribl Stream, you can also access it in Cribl Edge and Cribl Search.

Notifications require certain plan/license tiers. Without an appropriate license, target configuration options will be hidden or disabled in Cribl Stream's UI.

Manage Notification Targets

You can manage targets by selecting **Notifications** > **Targets**.

Select any existing Notification target to open a modal where you can manage the target, using buttons at the bottom of the page.

Select **Delete Target** to delete an existing Notification target. You can also select multiple targets for deletion, using the check boxes on the left side of the modal.

Select **Clone Target** to copy an existing target. A modal will open so you can modify the configuration of the target you started with.

To edit any target's definition in a JSON text editor, select **Manage as JSON** at the bottom of the **Notifications** > **Targets** modal. You can directly edit multiple values, and you can use the **Import** and **Export** buttons to copy and modify existing target configurations as `.json` files.

Some targets have additional controls for target configuration. See the documentation for the target of interest for more information.

9.5.5.1. Webhook Notification Targets

With this option, you can send Cribl Stream Notifications to an arbitrary webhook. Select **Webhook** in the **New Target** modal to expose multiple left tabs, with the following configuration options:

General Settings

Target ID: Enter a unique ID used to identify the target. This will show in the **Target ID** column of the **Targets** tab. You can't change it later, so make sure you like it.

Configuration

The added options that appear on this first left tab are:

URL: The endpoint that should receive Cribl Stream Notification events.

To proxy outbound HTTP/S requests, see System Proxy Configuration.

Method: Select the appropriate HTTP verb for requests: `POST` (the default), `PUT`, or `PATCH`.

Format: Specifies how to format Notification events before sending them to the endpoint. Select one of the following:

- `NDJSON` (newline-delimited JSON, the default).
- `JSON Array`.
- `Custom`, which exposes these additional fields:
    - **Source expression**: JavaScript expression whose evaluation shapes the event that Cribl Stream sends to the endpoint – for example: `notification=${_raw}`. For other fields you can use, see Expression Fields. If empty, Cribl Stream will send the full Notification event as stringified JSON.
    - **Drop when null**: Toggle to `Yes` if you want to drop events where the above **Source expression** evaluates to `null`.
    - **Event delimiter**: Delimiter string to insert between individual events. Defaults to newline character (`\n`).
    - **Content type**: Defaults to `application/x-ndjson`. You can substitute a different content type for requests sent to the endpoint. This entry will be overridden by any content types set in this modal's **Advanced Settings** tab > **Extra HTTP Headers** section.

- **Batch expression**: Expression specifying how to format the payload for each batch. Defines a wrapper object in which to include the formatted events, such as a JSON document. This enables requests to APIs that require such objects. To reference the events to send, use the `${events}` variable. An example expression to send the batch inside a JSON object would be: `{"items" : [${events}] }`.

Expression Fields

When building the Source expression, you can use the following fields:

Fields Common to All Notification Types

- `starttime`: Beginning of the time bucket where this condition was reported. All Notifications have this field.
- `endtime`: End of the time bucket where this condition was reported. All Notifications have this field.
- `_time`: Timestamp when this Notification was created. All Notifications have this.
- `cribl_host`: Hostname of the (physical or virtual) machine on which this Notification was created. All Destination and Source Notifications have this.
- `cribl_notification`: Configured name/ID of this Notification. All Destination and Source Notifications have this.
- `origin_metadata`: Object containing metadata about the Notification's origin, with the following fields for all Destination Notifications:
  - `type`: "output".
  - `id`: ID of the affected Destination.
  - `subType`: Destination's type (where applicable).
- `origin_metadata`: Object containing metadata about the Notification's origin, with the following fields for all Source Notifications:
  - `type`: "input".
  - `id`: ID of the affected Source.
  - `subType`: Source's type (where applicable).

Unhealthy Destination

- `health`: Numeric value where `0`=green, `1`=yellow, `2`=red.
- `output`: Output ID of the affected Destination.
- `_raw`: "Destination `${output}` [in group `${__worker_group}`] is unhealthy".
- `_metric`: "health.outputs".

Destination Persistent Queue Usage

- `output`: Output ID of the affected Destination.
- `timeWindow`: The interval at which Notifications will be repeated.
- `usageThreshold`: The minimum persistent queue utilization (stated as a percentage) that will trigger Notifications.
- `_metric`: “system.pq_used”.
- `usage`: The persistent queue utilization (stated as a percentage) that triggered the Notification.

Destination Backpressure Activated

- `backpressure_type`: `1` for Block, `2` for Drop.
- `output`: Output ID of the affected Destination.
- `_raw`: “Backpressure ([dropping|blocking]) is engaged for destination `${output}` [in group `${__worker_group}`]”.
- `_metric`: “backpressure.outputs”.

Source High Data Volume

- `health`: Numeric value where `0`=green, `1`=yellow, `2`=red.
- `bytes`: Number of bytes received in the time bucket.
- `input`: Input ID of the affected Source.
- `_raw`: “Source `${input}` [in group `${__worker_group}`] traffic volume greater than `${dataVolume}` in `${timeWindow}`”.
- `_metric`: “total.in_bytes”.

Source Low Data Volume

- `health`: Numeric value where `0`=green, `1`=yellow, `2`=red.
- `bytes`: Number of bytes received in the time bucket.
- `input`: Input ID of the affected Source.
- `_raw`: “Source `${input}` [in group `${__worker_group}`] traffic volume less than `${dataVolume}` in `${timeWindow}`”.
- `_metric`: “total.in_bytes”.

Source No Data Received

- `health`: Numeric value where `0`=green, `1`=yellow, `2`=red.
- `_time`: Timestamp when this Notification was created.
- `input`: Input ID of the affected Source.
- `_raw`: "Source `${input}` [in group `${__worker_group}`] had no data for `${timeWindow}`".
- `_metric`: "total.in_bytes"

License Expiration

- `severity`: One of "warn" or "fatal".
- `title`: One of: "License expiring soon, data will stop flowing." Or: "License has expired. Data flow has been stopped.".
- `text`: One of: "License will expire on `${expirationDate}`, no external inputs will be read" after that time. Please contact sales@cribl.io to renew your license." Or: "License has expired."

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header.
- **Basic**: In the resulting **Username** and **Password** fields, enter HTTP Basic authentication credentials.

Post-Processing Settings

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates not authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Keep alive: By default, Cribl Stream sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Stream to close the connection immediately after sending a request.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB, but you can set this limit to as high as 500 MB (512000 KB).

High values can cause high memory usage per Worker Node, especially if a dynamically constructed URL causes this target to send events to more than one URL. The actual request body size might exceed the specified value because the target adds bytes when it writes to the downstream receiver. Therefore, we recommend that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass to all events as additional HTTP headers. Values will be sent encrypted. You can also add headers dynamically on a per-event basis in the `__headers` field; headers added by this method take precedence over headers defined in the **Extra HTTP headers** table.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Used to declare headers that are safe to log as plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

9.5.5.2. PagerDuty Notification Targets

This option sends Cribl Stream Notifications to PagerDuty, a real-time incident response platform, using Cribl Stream's native integration with the PagerDuty API. Select Select **PagerDuty** in the **New Target** modal to expose the following additional options on the modal's (single) **General Settings** left tab:

General Settings

Target ID: Enter a unique ID used to identify the target. This will show in the **Target ID** column of the **Targets** tab. It can't be changed later, so make sure you like it.

Configuration

Routing key: Enter your 32-character Integration key on a PagerDuty service or global ruleset.

Group: Optionally, specify a PagerDuty default group to assign to Cribl Stream Notifications.

Class: Optionally, specify a PagerDuty default class to assign to Cribl Stream Notifications.

Component: Optionally, a PagerDuty default component value to assign to Cribl Stream Notification. (This field is prefilled with `logstream`.)

Severity: Set the default message severity for events sent to PagerDuty. Defaults to `info`; you can instead select `error`, `warning`, or `critical`. (Will be overridden by the `__severity` value, if set.)

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

9.5.5.3. Slack Notification Targets

You can send Notifications to a Slack channel, using Slack's Incoming Webhooks.

You can also use a Webhook Destination to send specific event data to Slack for a team's attention. For more information, see our Slack/Webhook integration topic.

First, in your Slack workspace, use a Slack app to enable incoming webhooks.

Then, in the **New Target** modal, click **Slack** to expose the following additional options on the modal's (single) **General Settings** left tab:

General Settings

Target ID: Enter a unique ID used to identify the target. This will show in the **Target ID** column of the **Targets** tab. You can't change it later, so make sure you like it.

Configuration

Webhook URL: Add the full URL of your Slack Incoming Webhook. For example: `https://hooks.slack.com/services/T00000000/B00000000/XXXXXXXXXXXXXXXXXXXXXXXX`.

Retries

Honor Retry-After header: When toggled to `Yes` and the `retry-after` header is present, Cribl Stream honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. Cribl Stream always ignores `retry-after` headers that specify a delay longer than 20 seconds.

Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).

When toggled to `No` (the default), Cribl Stream ignores all `retry-after` headers.

Settings for failed HTTP requests: Automatically retries after unsuccessful response status codes, such as `429` (Too Many Requests) or `503` (Service Unavailable). Clicking **Add Setting** reveals a table where you can add retry parameters for individual failed HTTP requests. These include:

- **HTTP status code**: The individual status code for which the retry parameters apply.

- **Pre-backoff interval (ms)**: How long, in milliseconds, Cribl Stream should wait before initiating backoff. The maximum interval is 600,000 ms (10 minutes).
- **Backoff multiplier**: Base for exponential backoff. A value of `2` (default) means Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so forth.
- **Backoff limit (ms)**: The maximum backoff interval, in milliseconds, Cribl Stream should apply. Default (and minimum) is 10,000 ms (10 seconds); maximum is 180,000 ms (180 seconds).

Retry timed-out HTTP requests: When set to `Yes`, Cribl Stream to automatically retries HTTP requests that have timed out. Defaults to `No`. Enabling this option exposes the following settings:

- **Pre-backoff interval (ms)**: How long, in milliseconds, Cribl Stream should wait before initiating backoff. Maximum interval is `600,000 ms` (10 minutes).
- **Backoff multiplier**: Base for exponential backoff. A value of `2` (default) means Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so forth.
- **Backoff limit (ms)**: The maximum backoff interval, in milliseconds, Cribl Stream should apply. Default (and minimum) is 10,000 ms (10 seconds); maximum is 180,000 ms (180 seconds).

9.5.5.4. AWS SNS Notification Targets

You can send Notifications to an Amazon Simple Notification Service (SNS) topic. This gives you access to a broad array of Notification destinations, such as various AWS services, mobile push notifications, or text messages.

To add an Amazon SNS Notification target in Cribl Stream, select **Notifications** in the sidebar, and then select **Targets** > **Add Target** > **AWS SNS**.

General Settings

Target ID: Enter a unique ID used to identify the target. This will show in the **Target ID** column of the **Targets** tab. It can't be changed later, so make sure you like it.

Configuration

Destination type: Defaults to **Topic ARN**. The SMS section explains the **Phone number** option.

Region: Select the region associated with the Amazon S3 bucket.

Default Topic ARN: The default Amazon Resource Name (ARN) of the Amazon SNS topic to which you want to send Notifications. Cribl Stream expects the ARN in a format like this:

`arn:aws:sns:region:account-id:MyTopic`.

If you use a non-AWS URL, the format must be:

`{url}/myQueueName` – for example, `https://host:port/myQueueName`.

Must be a JavaScript expression (which can evaluate to a constant value), enclosed in quotes or backticks. Can be evaluated only at initialization time. For example, if you're referencing a Global Variable: `https://host:port/myQueue-${C.vars.myVar}`. This value can be overridden by the Notification event `__topicArn` field.

Phone number allowlist: A wildcard list of phone numbers that are allowed to receive SMS notifications. This is used when **Destination type** is set to **Phone number**.

Authentication

Auto: This default option uses the AWS instance's metadata service to automatically obtain short-lived credentials from the IAM role attached to an EC2 instance, local credentials, sidecar, or other source. The

attached IAM role grants Cribl access to authorized AWS resources. Can also use the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. Works only when running on AWS.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Worker Nodes not in an AWS VPC, like those running a private cloud.

The **Manual** option exposes these additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

The values for **Access key** and **Secret key** can be a constant, or a JavaScript expression (such as `${C.env.MY_VAR}`) enclosed in quotes or backticks, which allows configuration with environment variables.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The Secret option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Stream's secrets manager. To store a new, reusable secret, select **Create**.

Assume Role

Enable for SNS: Toggle to `Yes` to define an IAM Role to use, instead of automatically detecting one locally.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Post-Processing

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.

- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Maximum number of retries: The maximum number of retries before the output returns an error. The retries use an exponential backoff policy.

Endpoint: The SNS service endpoint. If empty, defaults to AWS' Region-specific endpoint. Otherwise, it must point to an SNS-compatible endpoint.

Signature version: Signature version to use for signing SNS requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

SMS Notifications

You can use an Amazon SNS Notification target to send text messages (SMS) to a list of phone numbers. To do this, you'll need to set up a allowlist of phone numbers that are permitted to receive Notifications.

1. Select **Notifications** in the sidebar, and then select **Targets** > **Add Target**.
2. Enter a unique **Target ID**.
3. Set the **Target type** to **AWS SNS**.
4. Set **Destination type** to **Phone number**.
5. Set **Region** to the region of the Amazon S3 bucket.
6. In **Default Phone number**, enter a comma-separated list of phone numbers that are allowed to receive Notifications. This value can be overridden by the Notification event `__phoneNumber` field. You can use `*` as the wildcard character.
   For example: `+15555550123, +15555551***`.
7. If desired, use **Phone number allowlist** to specify a wildcard list of allowed phone numbers.
8. Configure the remaining sections of the AWS SNS Notification target as described earlier.
9. Select **Save**.

Now, when you set up Notifications, you can select the new Amazon SNS target and specify any phone number that matches the configured allowlist.

9.5.5.5. Email Notification Targets

You can send notifications by email, using an SMTP server of your choice. Once you have configured the email notification target, you can specify the recipients and customize the subject line and message content. See Email Notifications for details on configuring an email Notification.

To add an email Notification target in Cribl Stream, select **Notifications** in the sidebar, and then select **Targets** > **Add Target** > **Email**.

If you are a Cribl.Cloud user on a certain plan/license tier, you can use the default email Notification target. This target requires no configuration.

General Settings

Target ID: Enter a unique name to identify this email Notification target.

Configuration

Address: Identify the SMTP server by its hostname or IP address.

Port: Set the SMTP port. Use port `587` for SMTP Secure (SMTPS). Use `465` when SSL/TLS is enabled. You can also use port `2525` if your email service provider supports this port as a backup when other ports are blocked by a network provider or a firewall.

In Cribl.Cloud, orgs on a certain plan/license tier can use `system_email` – the default email notification target – and avoid configuring an SMTP server. If you **do** wish to configure an SMTP server in Cribl.Cloud, use any port other than port `25`.

Encryption type: Specify the encryption type used to secure SMTP communication. Options include:

- **STARTTLS**: Select this option to start the connection as plaintext, then upgrade it to a TLS-encrypted one if the server supports it. If the server doesn't support it, the connection remains plaintext.

  STARTTLS upgrades the connection to be encrypted but does not authenticate the server. Take additional steps to prevent man-in-the-middle attacks.

- **Require STARTTLS**: Select this option to require TLS. If the server doesn't support a secure connection, the connection will be dropped.
- **TLS (SMTPS)**: Select this option to use an encrypted connection from the start without requiring a subsequent connection upgrade.
- **None**: Select this option to use a plaintext connection.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path** or by another trusted CA (such as the system's CA).

From: Identify the email address of the sender.

Authentication

Username: The authentication principal (if required).

Password: The authentication credential (if required).

Test Email Notification Targets

When you finish configuring your email Notification target, you can manage it, using the following options.

Click **Save & Test Target** to save your target and open a modal where you can enter an email to test your email Notification target. After configuration, the button text changes to **Test Target**.

Default Email Notification Target for Cribl.Cloud Enterprise Orgs

For Cribl.Cloud Enterprise orgs, a default email Notification target is available for Cribl Stream, Edge, and Search. You can use this target to route any email Notification to any valid email address.

This target appears on the **Notifications** > **Target** page as `system_email`. You cannot modify or remove this target.

The `system_email` Notification target is managed by Cribl. It will be disabled in the unlikely event of abuse. If this target is disabled for a workspace, a log entry will appear in the Notifications Service logs. Select **Monitoring** > **Logs** > **Notifications Service** to view this log.

The `system_email` email Notification target is available only for Cribl.Cloud Enterprise organizations.

Send Domain for Cribl.Cloud Email Notifications

Every Cribl.Cloud workspace and organization has a unique address for its email Notification target. Messages sent using this target will have a sender's address in the form `do-not-reply@<workspace>-<org>.criblcloud.email`. To ensure delivery, recipients should add the `criblcloud.email` domain to their email allowlists.

9.6. Customizing The Interface

9.6.1. Custom Banners

Cribl admins can define a custom banner from the Leader. This will be displayed at the top of your Cribl Organization, above all Cribl apps. You can display one banner at a time.

Your banner can display warnings, requirements, neutral updates, or good news about new features or options. It can contain a mixture of text, a raw URL, or a URL with a friendly/short label. The banner does not appear unless you enable and configure it, as described here.

1. In the sidebar, select **Settings** > **Global**.
2. Select **System** > **Custom Banner**.
3. Toggle **Enable banner** on to expose the configuration options.
4. From the **Background color** dropdown, select a background color for your banner. You can also pick a custom color by selecting **+Add color** in the dropdown.
5. Optionally, toggle **Invert front color** to **Yes** to make the text on the banner white instead of black (typically, for darker custom banner colors).
6. In the **Banner message** field, enter a single-line message of up to 1,024 characters. (The displayed banner will truncate characters that cannot fit across one line of a given viewport.)
7. In the **Link URL** field, optionally enter a hyperlink to append to the message.
8. In the **Link display** field, optionally give your **Link URL** a text label. This can include up to 512 characters, but a long label can force-truncate the **Banner message**. A short label can help everything fit.
9. Select **Save** to display your banner.
10. Commit your changes from the Leader.

To hide the banner, toggle the **Enable banner** off, and again **Save** and commit your changes. Your banner's configuration will remain intact, ready to re-enable and/or revise when you're ready.

9.6.2. Custom Login Page

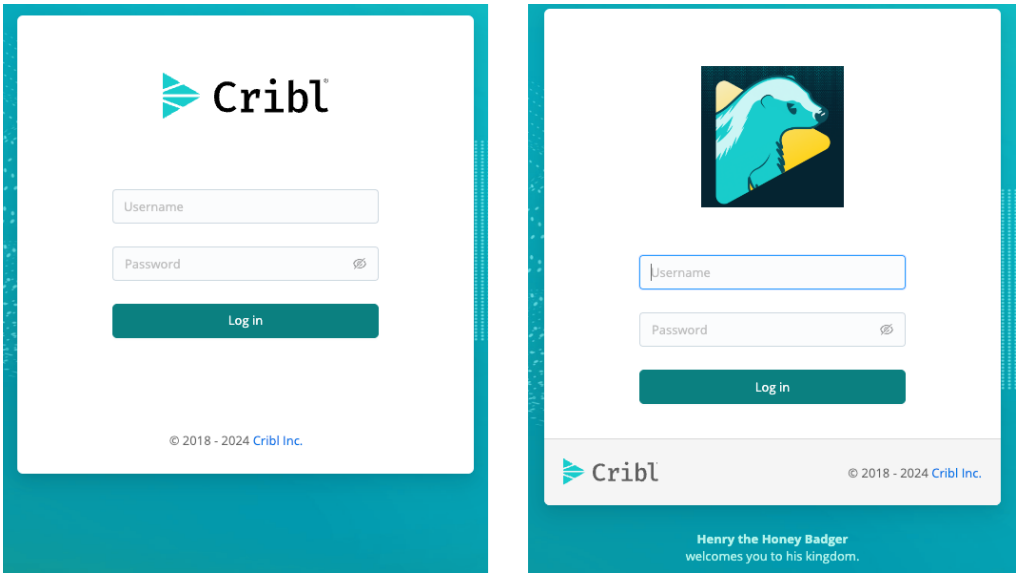
You can customize the look of the login page for all Cribl apps.

Custom login pages are available only in on-prem installations.

Configure Custom Login Page

To configure a custom login page:

1. In the Cribl Stream sidebar, select **Settings**, then **Global**.
2. Under **System**, select **General settings**.
3. Go to **Custom login page** and toggle **Enabled** to `Yes`.
4. In **Logo file**, select an image file that wll serve as a logo. The image must be no larger than 350x350px and under 2MB.
5. In **Content**, edit the provided HTML to modify the text block displayed under the login box.



Built-in and customized login pages

9.7. Scripts

Scripts are available only in on-prem deployments, not in Cribl.Cloud.

Admins can run scripts (for example, shell scripts) from within Cribl Stream by configuring and executing them at **Settings** > **Global** > **Scripts**. Scripts are typically used to call custom automation jobs or, more generally, to trigger tasks on demand. For example, you can use Scripts to run an Ansible job, or to place a call to another automation system, when Cribl Stream configs are updated.

With Great Power Comes Great Responsibility!

Scripts will allow you to execute almost anything on the system where Cribl Stream is running. Make sure you understand the impact of what you're executing before you do so!

Enable Scripts

For security reasons, using scripts is disabled by default on all new deployments. You can re-enable them by using the `limits` command (available since Cribl Stream 4.8.2).

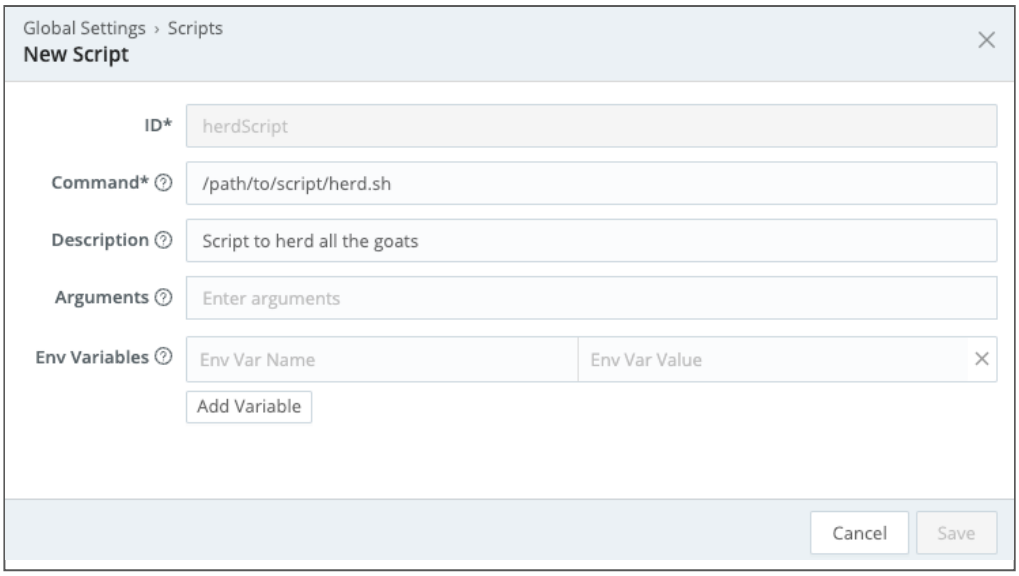
To control script availability, run:

```
# Enable scripts
./cribl limits -s true
# Disable scripts
./cribl limits -s false
```

When you enable or disable scripts, you need to restart the instance for the changes to take effect.

Add Scripts

To add a new script, select **Add Script** on the scripts settings page.



Settings > Scripts page

The **New Script** modal provides the following fields:

- **ID**: Unique ID for this script.
- **Command**: Command to execute for this script.
- **Description**: Brief description about this script. Optional.
- **Arguments**: Arguments to pass when executing this script.
- **Env variables**: Extra environment variables to set when executing script.

Scripts in Distributed Deployments

- Scripts can be deployed from the Leader Node, but can be **run** only locally from each Worker Node.
- If the Script command is referencing a file (for example, `herd.sh`), that file must exist on the Cribl Stream instance. In other words, the Script management interface cannot be used to upload or manage script files.

9.8. Upgrade

This page outlines how you can upgrade a Cribl Stream single-instance or distributed deployment along one of these supported upgrade paths, which apply to UI-based upgrades:

Current Version	Upgrade Path
4.x	4.x
3.x	3.x through 4.x
2.x	2.x through 4.x
1.7.x or 2.0.x	2.x.x, then 3.x or 4.x
1.6.x or below	1.7.x, then 2.x.x, then 3.x or 4.x

If you're upgrading Worker Nodes directly from the command line, you don't have to worry about a version upgrade path - there are no restrictions on the versions you can upgrade from or to.

Considerations

Here are some considerations to look at before you upgrade.

Upgrade to v.4.3.x using Leader-Managed Upgrades for Worker

Nodes

If a Leader is on Cribl Stream 4.3.x, you should upgrade all Worker Nodes to 4.3.x **before** making any config changes or committing and deploying to the Nodes.

If you have already committed and deployed to Nodes that are on a version earlier than 4.3.0, and the Leader is on 4.3.x, you won't be able to upgrade the Nodes. In this case, here are three workaround options:

- Revert and redeploy the last commit, then upgrade the Worker Nodes and deploy the most up-to-date changes; **or**
- Upgrade the Worker Nodes via command line or script; **or**
- Downgrade the Leader to v.4.2.2, and wait for a future release that will enable you to upgrade Worker Nodes across all Leaders and 4.x.x versions.

If you run into issues, contact support@cribl.io for resolution help.

General Upgrade Considerations

Cribl Stream does **not** support direct upgrades from any pre-GA version (such as a Cribl-provided test candidate) to a GA version. To get the GA version running, you must perform a new install.

Cribl.Cloud Upgrades

Cribl.Cloud automatically upgrades the Leader Node when a new version is released. If you have customer-managed (hybrid) Cribl.Cloud Worker Groups, you need to upgrade them manually.

We recommend keeping the Leader and Worker Groups on the same version for maximum compatibility. If the versions differ, the following setups are supported:

- **Minor versions**: A Worker Group that is one minor version behind the Leader Node (for example: Worker Group on version v4.5.1 and Leader on v4.6.0) **is supported**. However, features introduced in the new version will not function on the Worker Group.
  A greater version difference may cause compatibility issues and is **not supported**.
- **Patch versions**: Leaders and Worker Groups on different patch versions within the same minor version (for example: Worker Group on v4.5.0 and Leader on v4.5.1) **are supported**.

Requirements for Specific Version Upgrades

- If you're upgrading to v.3.5.4 or later, all Worker Nodes will need to be on the same version as the Leader. Leaders running v.3.5.4 and later test whether Worker Nodes are running a compatible version before deploying configs that could break Workers' data flow. The Leader will prompt you to upgrade these Nodes as needed. For details, see the Stream 3.5.4 release notes.
- Version 3.5.4 was also a compatibility breakpoint for the Cribl HTTP Source and Destination, and for the Cribl TCP Source and Destination. When running on Cribl Stream 3.5.4 and later, these two Sources can send data only to Nodes running v.3.5.4 and later, and these two Destinations can receive data only from Nodes running v.3.5.4 and later. When running on Stream 3.5.3 and earlier, these four integrations can similarly interoperate only with Nodes running v.3.5.3 and earlier.
- Before upgrading your Leader to v.4.0 and later, see Persisting Socket Connections to prepare the host to keep communications open from Workers.
- Cribl Stream 4.1 and later encrypt TLS certificate private key files when you add or modify them.
  See instructions just below for backing up your keys from earlier versions.

Safeguard Unencrypted Private Key Files for Rollback

Before upgrading from a pre-4.1 version, make a backup copy of all unencrypted TLS certificate private key files. Having access to the unencrypted files is essential if you later find that you need to roll back to your previous version.

To safeguard your unencrypted private keys, make a full backup of all Cribl config files. Files in the `auth/certs` directory are particularly important, such as those in:

- `groups/default/local/cribl/auth/certs/`
- `groups/<groupname>/local/cribl/auth/certs/`
- `cribl/local/cribl/auth/certs/`
- Etc.

Take appropriate precautions to prevent unauthorized access to these unencrypted private key files. If you need to roll back to a pre-4.1 version, see Restoring Unencrypted Private Keys.

Considerations for Firewalls/Web Proxies

You may encounter the “unsafe legacy renegotiation disabled” error when the Cribl Stream Leader attempts to connect to the CDN, preventing Worker Node upgrades.

This error occurs if your firewall or proxy (like PAN firewalls) doesn’t support the TLS Renegotiation Indication Extension (RFC 5746).

Ensure your firewall or proxy is compliant with RFC 5746. Contact your firewall/proxy vendor for update instructions.

Disable SNI Routing for Firewalls/Web Proxies

If you’re experiencing issues with proxies or firewalls between your Cribl Stream Workers and Leader, you can disable Server Name Indication (SNI) routing for specific Groups.

To disable SNI routing for a Group: Navigate to **Group Settings** > **General Settings** > **SNI** > **Disable SNI Routing** option. **Commit** and **Deploy** and then proceed with the upgrade. You must enable this setting for every Group that is behind a web proxy or firewall.

Standalone/Single-Instance

To upgrade a single-instance deployment from the UI, select **Settings** > **System** > **Upgrade**.

To upgrade a single-instance deployment using the command line:

1. Stop Cribl Stream.
2. Uncompress the new version on top of the old one.
   On some Linux systems, `tar` might complain with: `cribl/bin/cribl: Cannot open: File exists`. In this case, please remove the `cribl/bin/cribl` directory if it's empty, and untar again. If you have **custom functions** in `cribl/bin/cribl`, please move them under `$CRIBL_HOME/local/cribl/functions/` before untarring again.
3. Restart Cribl Stream.

Distributed Deployment

You can upgrade Leader and Worker Nodes with the command line interface (CLI) or the user interface (UI).

Upgrade and Rollback via the UI

Starting in Cribl Stream v.2.4.4, you can upgrade using the UI. When you choose to upgrade via the UI, Cribl Stream stops its own server, updates the installed package, and restarts Stream for you.

Here's how to access the Upgrade UI in Stream:

1. First, select **Settings** in the sidebar.
2. Select **Upgrade** depending on your deployment type:
   - In a single-instance deployment, select **System**, then **Upgrade**.
   - To upgrade the Leader Node, select **Global**, then **System** and **Upgrade**.
   - To upgrade a single Worker Group, select **Stream** then **Group Upgrade**.

You can also enable an automatic backup and rollback in case an upgrade fails.

These options will work only if all Stream instances (including Worker Processes) start at v.2.4.4 or higher. For other version-specific limitations, please see Known Issues.

Upgrade the Leader via the UI

To upgrade the Leader in a distributed deployment, go to **Settings** > **Global** > **System** > **Upgrade**.

When upgrading, you can choose to either download upgrade packages from Cribl's content delivery network (CDN), or from a filesystem location that you specify in the form of a path.

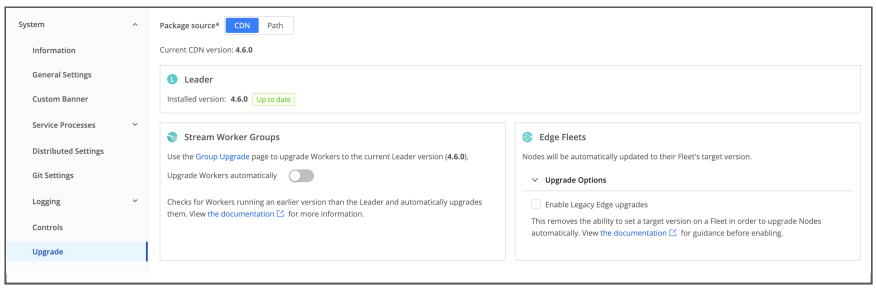
Select a Package Source

Here, you'll select between **CDN** and **Path** for your upgrade (in an on-prem, distributed deployment):

Package Source	Description	When You Select This Package Source
CDN	Downloads an installation package directly from Cribl's content delivery network.	With **CDN** selected, you can see the currently installed version and the version available on the CDN. The Leader will always upgrade to the current CDN version when you select **Upgrade**.
Path	You designate the path to the installation package in the **Path** field.	You must designate the correct paths for your Leader and Worker Groups, both version and architecture. For example, a Worker Group that contains ARM64 Workers will require an ARM64 installation package.

Use the buttons to choose the desired package source. Then, the UI will display settings and information appropriate for the package source you chose, as described in the respective Configure Stream Settings for CDN Upgrade and Configure Stream Settings for Path Upgrade sections below.

Configure Stream Settings for CDN Upgrade



Upgrade Stream using CDN

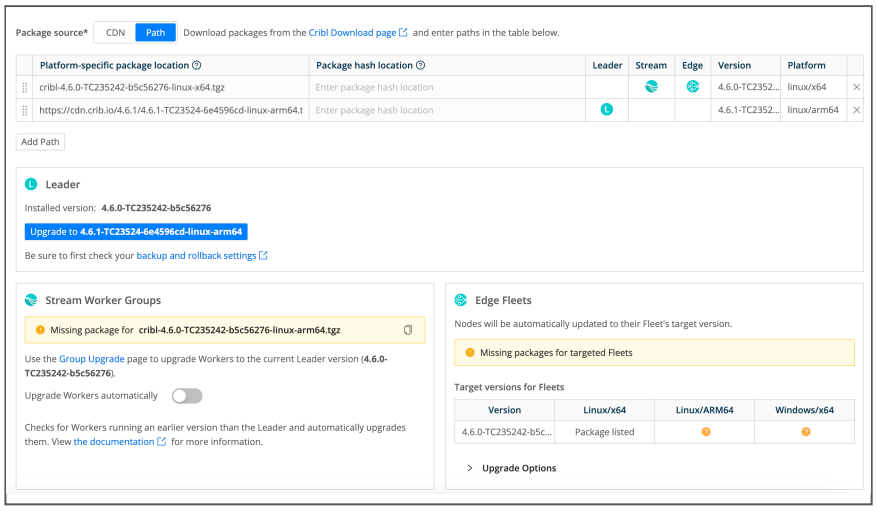
If you select **CDN** as your upgrade method, you will see the following options:

- **Current CDN version**: This lists the latest version of Cribl Stream available on the CDN.
- **Leader**: This shows the currently installed version of Cribl Stream on the Leader. If a newer version is available, you will be able to use the **Upgrade to** button.
- **Stream Worker Groups**: Provides a quick link to the Group Upgrade page if you want to upgrade Worker Groups individually.

In Cribl.Cloud, this area will only show hybrid Workers.

To automatically upgrade Workers to the Leader version, enable **Upgrade Workers automatically**. See Automatic Upgrades for more details.

Configure Stream Settings for Path Upgrade



Upgrade Stream using Path

With **Path** as your upgrade method, you'll see the following settings and information in the **Package Source** table:

- **Platform-Specific Package Location**: Enter or paste the path to the Cribl installation package. This can be either of the following:
  - An HTTP URL, for example `https://cdn.cribl.io/dl/4.1.0/cribl-4.1.0-6979aea9-linux-x64.tgz`
  - A local filesystem path, for example `myfolder/directory/cribl-package.tgz
- **Package Hash Location**: Enter either of the following:
  - An HTTP URL, for example `https://cdn.cribl.io/dl/4.1.0/cribl-4.1.0-6979aea9-linux-x64.tgz.sha256`
  - A local filesystem path to the hash that validates the package.

  Supports SHA-256 and MD5 formats. You can simply append `.sha256` to the contents of the **Platform-specific package location** field.

When Stream is running in FIPS mode, MD5 is not an acceptable hashing algorithm.

- **Leader**: Indicates the version the Leader will be upgraded to when an upgrade is available and you select the **Upgrade to** button.
- **Stream**: The version in this row will be used to upgrade the Stream Worker Group, because it matches the Leader's version.

- **Edge**: The version in this row will be used to upgrade Edge Fleets with a matching target version.
- **Version**: Displays the package version in this row.
- **Platform**: Displays the platform architecture for the package in this row.

Select **X** to immediately delete a row – there is no confirmation prompt.

> You can add multiple rows to this table to specify packages for different versions and platforms/architectures. To obtain the latest packages from https://cribl.io/download, use the drop-down list to specify each platform (for example, x64 versus ARM). When you stage these packages on your own servers, preserve the original file names.

Leader area: Shows you the currently installed Leader version and whether an upgrade is available. Check the backup and rollback settings before you upgrade.

Stream Worker Groups: Provides a quick link to the Group Upgrade page if you want to upgrade Worker Groups individually.

To automatically upgrade Workers to the Leader version, enable **Upgrade Workers automatically**.

The **Edge Fleets** area offers **Upgrade Options** for Edge. See Configuring Edge Settings for Path Upgrade for more information.

Missing Package Links

When you see this warning, it means there are Worker Groups that can't be upgraded due to a missing package path.

To add package links:

1. Select the **Copy** icon to add the link to your clipboard.
2. Paste the copied package link into a new **Platform-specific package location** field.
3. Add the appropriate path directory to the beginning of the installation package path (where your Cribl upgrade packages are located).
   For example: `myfolder/directory/cribl-package.tgz`
4. Select **Save** to add the upgrade package path and resolve the warning.

Automatic Upgrades

You can enable **Upgrade Workers automatically** in **Settings** > **Global** to check for Workers running an earlier version than the Leader, and automatically upgrade them to match the Leader.

Enable automatic upgrades has a different default state depending on the deployment type:

- In on-prem deployments, **Enable automatic upgrades** defaults to `No`, to prevent the Leader from automatically upgrading out-of-date Worker Nodes. Before you toggle this to `Yes`, upgrade the Leader itself to Cribl Stream's most recent version.
- In Cribl.Cloud deployments, **Enable automatic upgrades** defaults to `Yes`. This enables Cribl to automatically upgrade Worker Nodes to Cribl Stream's newest stable version. (Cribl-managed / Cribl.Cloud and customer-managed / hybrid Workers will auto-upgrade as soon as they see a new Leader version.) If you toggle this to `No`, you will need to explicitly upgrade each Worker.

When enabled, the automatic Worker upgrade process works like this:

1. The Leader pulls packages, and checks their hashes.
    - The Leader must be able to connect to the path.
    - The Leader must also have privileges to download the files.
    - If the path is an HTTP URL, the Leader copies the file to a known location in its filesystem.
    - If the package is already hosted on the Leader Node, specify its filesystem path.
2. Workers pull packages and check their hashes.
    - Workers pull from Cribl's content delivery network (CDN) and fall back to the Leader through HTTP, not directly from the Leader's filesystem.
    - Each Worker pulls the package that is appropriate for that Worker's platform and architecture.
3. Workers install the packages.

Upgrade Worker Groups via the UI

To upgrade a Worker Group:

1. Go to **Settings**, then **Stream**.
2. Select **Group Upgrade**.
3. Select the **Upgrade** button in a row to upgrade that Worker Group.

The **Upgrade Group** modal offers two states: Basic Upgrade and Advanced Upgrade.

Upgrading Workers from the Leader requires a Cribl Stream Standard or Enterprise license.

Basic Upgrade Configuration

In this default **Upgrade Group** modal, you can simply upgrade the whole Group, by selecting the modal's **Upgrade** button to confirm.

When one or more Workers can be upgraded in the Group, the **Upgrade** button will be enabled.

By selecting the **Upgrade** button, you can initiate the upgrade job with a task for each Worker that can be upgraded.

Cribl Stream will check to ensure that Workers are upgraded no higher than the Leader's version. Upgrades are performed as the user that was running Cribl Stream on each machine.

The **Worker Nodes** column will display a warning icon with a tooltip if the Group contains Workers that can't be upgraded for one or more of the following reasons:

- Workers are already running the current version.
- Workers running v.2.4.4 or older are too old to upgrade.

When none of the Workers in the Group can be upgraded, the **Upgrade** button will be disabled.

Advanced Upgrade Configuration

Select the modal's gear ( ) button to expose these additional options:

Quantity %: Specify what percentage of the Group's Workers to upgrade in this operation. If you enter a value less than the default `100%`, Cribl Stream will perform a partial upgrade, keeping the remaining Workers active to process data.

Rolling upgrade: This option upgrades Workers in batches, each sized according to the value in the **Quantity %** field. When enabled, this toggle also enables the modal's two remaining controls:

- **Retry delay (ms)**: How many milliseconds to wait between upgrade attempts. Defaults to `1000` ms (1 second).
- **Retry count**: How many times to retry a failed upgrade. Defaults to `5`.

After you confirm the Worker Group upgrade, the table on the Group Upgrade page will display an additional button on this Group's row:

- **View**: Select to display the upgrade task's status in the Job Inspector modal – select that modal's **System** tab to access details.

When you initiate an upgrade via the UI, the new package is untarred to `$CRIBL_HOME/unpack.<random-hash>.tmp`. This location inherits the permissions you've already assigned to `$CRIBL_HOME`.

Backup and Rollback

When you initiate an upgrade through the UI, Cribl Stream first stores a backup of your current stable deployment. If the upgrade fails, then by default, Stream will automatically roll back to the stored backup package. You can adjust this behavior in **Settings**.

Go to **Settings** > **Global**, then **System** and **General Settings**, then **Upgrade & Share Settings**.

Use the following controls to adjust backup and rollback behavior.

Cribl Stream can perform rollbacks only on Worker Nodes/instances that were running at least v.3.0.0 before the attempted upgrade.

Enable automatic rollback: Cribl Stream will automatically roll back an upgrade if the Cribl Stream server fails to start, or if the Worker Node fails to connect to the Leader. (Toggle to `No` to defeat this behavior.)

Rollback timeout (ms): Time to wait, after an upgrade, before checking each Node's health to determine whether to roll back. Defaults to `30000` milliseconds (30 seconds).

Rollback condition retries: Number of times to retry the health check before performing a rollback. Defaults to `5` attempts.

Check interval (ms): Time to wait between health-check retries. Defaults to `1000` milliseconds (1 second).

Backups directory: Specify where to store backups. Defaults to `$CRIBL_HOME/state/backups`.

Backup persistence: A relative time expression specifying how long to keep backups after each upgrade. Defaults to `24h`.

Upgrade and Rollback via the CLI

For a Distributed Deployment, this is the general upgrade order:

First, upgrade the Leader Node. Then, upgrade the Worker Nodes. Lastly, commit and deploy the changes on the Leader.

For distributed environments with a second Leader configured for failover, this is the upgrade order:

1. Stop both Leaders.
2. Upgrade the primary Leader.
3. Upgrade the second Leader.
4. Upgrade each Worker Node, respectively.

Upgrade the Leader Node via the CLI

1. Commit and deploy your desired previous version. (This will be your most recent checkpoint.)

Optionally `git push` to your configured remote repo.

2. Stop Cribl Stream.
    - Optional but recommended: Back up the entire `$CRIBL_HOME` directory.
    - Optional: Check that the Worker Nodes are still functioning as expected. In the absence of the Leader Node, they should continue to work with their last deployed configurations.
3. Uncompress the new Cribl Stream version on top of the old one.
4. Change ownership of the `cribl` directory as needed: `[sudo] chown -R cribl:cribl $CRIBL_HOME`
5. Restart Cribl Stream and log back in.
6. Wait for all the Worker Nodes to report to the Leader, and ensure that they are correctly reporting the last committed configuration version.

Upgrade from 4.1.0

When upgrading a Leader Node from version 4.1.0 using the UI, you may encounter the following error:

```
{"status":"error","message":"Protocol \"https:\" not supported. Expected \"http:\"","error":{"code":"ERR_INVALID_PROTOCOL"}}
```

To resolve this, configure the `no_proxy` directive to include the API's listening address on the Leader Node. To encompass all addresses, set `no_proxy` to `0.0.0.0`. This prevents internal traffic on the Leader Node from passing through the proxy server.

Here's an example `No_Proxy` configuration:

```
http_proxy=http://localhost:1234 https_proxy=http://localhost:1234 no_proxy=0.0.0.0 bin/cribl start
```

This extra step is due to changes in communication between the connection listener service and the API server via an `http` client.

Upgrade the Worker Nodes via the CLI

These are the same basic steps as when upgrading a single instance deployment, above:

1. Stop Cribl Stream on each Worker Node.
2. Uncompress the new version on top of the old one.
3. Change ownership of the `cribl` directory as needed: `[sudo] chown -R cribl:cribl $CRIBL_HOME`
4. Restart Cribl Stream.

Commit and Deploy All Changes from the Leader Node

1. Ensure that newly upgraded Worker Nodes report to the Leader with their **new** software version.
2. Commit and deploy the newly updated Leader configuration after all Workers have upgraded.

Successful upgrade confirmation

Breaking Change at v.3.2

Because of a breaking change at v.3.2, Leaders running v.3.2.x cannot upgrade (via the UI) Workers running versions prior to 3.2.0. The upgrade will fail with errors of the form: `Error checking upgrade path` and `Cannot read property 'greaterThan' of undefined.`

The workaround is to upgrade these Workers via the filesystem to v.3.2.0 or higher. The error does not affect upgrades of Workers running v.3.2.0+.

Manual Rollback

Using CLI commands, it's possible to explicitly roll back an on-prem Leader, and on-prem or hybrid Workers, to an earlier release. This works much like an upgrade.

Explicit rollback might be necessary if an automatic rollback fails. Otherwise, Cribl recommends first considering other options – an upgrade, or working with Cribl Support – before a manual rollback. Rollback can encounter these complications:

- Your current configuration might take advantage of dependencies not supported in an earlier release.

- Do not manually roll back any Cribl Stream instance running in a container. Instead, locate, download, and launch a container image hosting the earlier version you want.

Rollback Outline

We assume that you are rolling back to a previously deployed version that you know to be stable in your environment. The broad steps are:

1. Ideally, link your deployment to a Git remote repo. Commit and push your Leader's configuration to that remote. The repo will provide a stable location from which to recover your config, if necessary.
2. Stop the Leader instance. (From `$CRIBL_HOME/bin/`, execute `./cribl stop`.)
3. Also create a local backup of your Leader's whole `$CRIBL_HOME` directory.
4. Obtain the installation package for the earlier release and platform you need. (See the Rollback Example.)
5. Uncompress the earlier version to your original deployed directory. You can do this from the command line or programmatically (see the Rollback Example).

If installing to your existing target directory fails, try the same mitigations we list above for upgrades.

6. In a distributed deployment, Workers must not run a higher version than the Leader. Repeat steps 2, 3, and 5 above on all Workers (substituting "Worker" for "Leader").

Rollback Example

Although rollback can be partially scripted, you cannot discover earlier installation packages programmatically – the initial steps here require human intervention:

1. Stop and back up the Leader. (Follow steps 1–3 in the Rollback Outline.)
2. Open the **Cribl Past Releases** page: https://cribl.io/download/past-releases/.
3. Locate the earlier version that you want to restore.
4. Use the adjacent drop-down to select your target platform.
5. Right-click (or `Ctrl`-click) the corresponding **Download** button, and copy its URL to your clipboard. In this example, we've copied:
   `https://cdn.cribl.io/dl/4.1.0/cribl-4.1.0-6979aea9-linux-arm64.tgz`
6. Swap that URL into an untar command like the following. Run this command from the parent (typically `/opt/`) of your existing `$CRIBL_HOME` directory:
   `[sudo] curl -Lso - https://cdn.cribl.io/dl/4.1.0/cribl-4.1.0-6979aea9-linux-arm64.tgz | tar zxv`
7. Repeat the preceding steps to adjust all Workers to a compatible version.

Splunk App Package Upgrade Steps

See Deprecation note for v.2.1.

Follow these steps to upgrade from v.1.7, or higher, of the Cribl App for Splunk:

1. Stop Splunk.
2. Untar/unzip the new app version on top of the old one.
   On some Linux systems, `tar` might complain with: `cribl/bin/cribl: Cannot open: File exists`. In this case, please remove the `cribl/bin/cribl` directory if it's empty, and untar again. If you have **custom functions** in `cribl/bin/cribl`, please move them under `$CRIBL_HOME/local/cribl/functions/` before untarring again.
3. Restart Splunk.

Upgrade from Splunk App v.1.6 (or Lower)

As of v.1.7, contrary to prior versions, Cribl's Splunk App package defaults to Search Head Mode. If you have v.1.6 or earlier deployed as a Heavy Forwarder app, upgrading requires an extra step to restore this setting:

1. Stop Splunk.
2. Untar/unzip the new app version on top of the old one.
3. Convert to HF mode by running: `$SPLUNK_HOME/etc/apps/cribl/bin/cribld mode-hwf`
4. Restart Splunk.

9.9. Uninstalling

Removing an Cribl Stream installation, whether for a clean reinstall or permanently

---

Uninstalling the Standalone Version

- (Optional) To prevent systemd from trying to start Cribl Stream at boot time, run the following command: `sudo $CRIBL_HOME/bin/cribl boot-start disable`
  If you're running both Cribl Stream and Cribl Edge on the same host, be sure to execute this command in the same mode (Stream or Edge) and the same directory in which you originally ran `cribl boot-start enable`.
- Stop Cribl Stream (stopping the main process).
- Back up necessary configurations/data.
- Delete the `cribl` user: `userdel cribl`
- Delete the user group: `groupdel cribl`
- Remove the directory where Cribl Stream is installed.
- Directly delete any local files that Cribl Stream added while running, such as the `.dat` file and other local configs.
- Remove any leftover files in the system's temporary directory. On Linux, this is typically `/tmp`.
- If you've customized the **Helper processes socket directory** settings to change the default `/tmp` directory, adjust the cleanup accordingly. For the Leader, this setting is located in the **Distributed Settings** > **Leader Settings** > **Helper processes socket dir**. For the Worker Node, it is located in **System** > **General Settings** > **Sockets** > **Directory setting**.
- Remove any related configuration files and scripts, and disable the Cribl service if using a service manager.

In a Distributed deployment, repeat the above steps for the Leader instance and all Worker instances.

Uninstalling the Splunk App Version

- Stop Splunk.
- Back up necessary configurations/data.
- Remove the Cribl App in `$SPLUNK_HOME/etc/apps`.
- Remove the Cribl module in `$SPLUNK_HOME/etc/modules/cribl` (some versions).

10. Access Management

Cribl Stream provides a range of access-management features for users with different security requirements. Acccess management serves these common enterprise goals:

- **Security**: Limit the blast radius of inadvertent or intentional errors, by restricting each user's actions to their needed scope within the application.
- **Accountability**: Ensure compliance, by restricting read and write access to sensitive data.
- **Operational efficiency**: Match enterprise workflows, by delegating access over subsets of objects/resources to appropriate users and teams.

Where Can I Find Access Control Details?

See the following topics, according to your needs:

- Authentication: Authenticating users via local basic auth or external options (SSO, Splunk, LDAP).
- Members and Permissions: Fine-grained access control configurable at separate levels (Organization, product, Worker Group, and lower-level resources like Cribl Stream Projects and Cribl Search Datasets).
- Teams: Groups of Members who share the same Permissions.
- Local Users: Cribl Stream's original Role-based model for creating users, and for managing their access across a Cribl deployment.
- Roles: Cribl Stream's original RBAC model for managing Roles and Policies, and for assigning them to users.

Which Access Method Should I Use?

Cribl supports both the Members/Permissions and the legacy Users/Roles models, and these models are cross-compatible for many use cases. However, certain purposes require you to choose a specific model:

- **Cribl.Cloud** relies only on Members/Permissions. See Cribl.Cloud Organization-level Permissions starting at Inviting Members, and product- and lower-level Permissions starting at Product-Level Permissions.

  > Cribl.Cloud's Organization-level Permissions include an Owner superuser. This option has no counterpart at the on-prem (customer-managed) Organization level.

- **Stream Projects** and Subscriptions rely only on Members/Permissions. See Project-Level Permissions.
- **GitOps** integration authorization requires the legacy `gitops` Role. This legacy Role has no counterpart Permission.

- **Collectors**: The `collect_all` Role specifically enables creating, configuring, and running Collection jobs on all Stream Worker Groups. This legacy Role has no counterpart Permission.
- **Notifications**: The `notification_admin` Role specifically enables creating and receiving all Notifications. This legacy Role has no counterpart Permission.
- **Search granular resources** (Datasets, Dataset Providers, and search results) can be shared via Members/Permissions. For details, see the Cribl Search Sharing page.

10.1. Authentication

User authentication in Cribl Stream

Cribl Stream supports **local**, **Splunk**, **LDAP**, **SSO/OpenID Connect**, and **SSO/SAML** authentication methods, depending on license type.

Local Authentication

To set up local authentication:

1. In the sidebar, select **Settings**, then **Global**.
2. Under **Access Management**, select **Authentication**.
3. Choose **Local** as authentication **Type**.

You can then manage users through the **Settings** > **Global** > **Access Management** > **Local Users** page.
All changes made to users are persisted in a file located at `$CRIBL_HOME/local/cribl/auth/users.json`.

For Windows Edge Nodes, the changes are persisted in a file located at `C:\ProgramData\Cribl\local\cribl\auth\users.json`.

This is the line format, and note that both usernames and passwords are case-sensitive:

```
{"username":"user","first":"Goat","last":"McGoat","roles":
["admin"],"disabled":"false","passwd":"Yrt0MOD1w8OzyMYB8WMcEleOtYESMwZw2qIZyTvueOE"}
```

The file is monitored for modifications every 60s, and will be reloaded if changes are detected.

Adding users through direct modification of the file is also supported, but not recommended.

If you edit `users.json`, maintain each JSON element as a single line. Otherwise, the file will not reload properly.

Manual Password Replacement

Manual Password Replacement is for on-prem deployments only. For Cribl Stream in Cribl.Cloud, Cribl recommends setting up Fallback Access; if you do need to reset your password, you must contact Cribl.

To manually add, change, or restore a password, replace the affected user's `passwd` key-value pair with a `password` key, in this format: `"password":"<newPlaintext>"`. Cribl Stream will hash all plaintext password(s), identified by the `password` key, during the next file reload, and will rename the plaintext `password` key.

Starting with the same `users.json` line above:

```
{"username":"user","first":"Goat","last":"McGoat","roles":
["admin"],"disabled":"false","passwd":"Yrt0MOD1w8OzyMYB8WMcEleOtYESMwZw2qIZyTvueOE"}
```

...you'd modify the final key-value pair to something like:

```
{"username":"user","first":"Goat","last":"McGoat","roles":
["admin"],"disabled":"false","password":"V3ry53CuR&pW9"}
```

Within at most one minute after you save the file, Cribl Stream will rename the `password` key back to `passwd`, and will hash its value, re-creating something resembling the original example.

Set Worker/Edge Node Passwords

In a Distributed deployment (Edge, Stream), once a Worker/Edge Node has been set to point to the Leader Node, Cribl Stream will set each Worker/Edge Node's admin password with a randomized password that is different from the admin user's password on the Leader Node. This is by design, as a security precaution. But it might lead to situations where administrators cannot log into a Worker/Edge Node directly, and must rely on accessing them via the Leader.

To explicitly apply a known/new password to your Worker Node, you set and push a new password to the Worker Group. Here's how, in the Leader Node's UI:

1. On the top bar, select **Products**, and then select **Cribl Stream**.
2. Select the desired Worker Group.
3. On the Worker Group submenu, select **Group Settings**.
4. Select **Local Users**, then expand the desired user.
5. Update the **Password** and **Confirm Password** fields and select **Save**.

Every 10 seconds, the Worker/Edge Node will request an update of configuration from the Leader, and any new password settings will be included.

On Cribl.Cloud, Group Settings for customer-managed hybrid Workers include the above **Local Users** options, but Groups for Cribl-managed Workers in Cribl.Cloud do not. For alternatives, see the Cribl.Cloud Launch Guide and Cribl.Cloud SSO Setup docs.

Authentication Controls

You can customize authentication behavior at **Settings** > **Global** > **General Settings** > **API Server Settings** > **Advanced**. The options here include:

- **Logout on roles change**: If role-based access control is enabled, determines whether users are automatically logged out of Cribl Stream when their assigned Roles change. Defaults to `Yes`.
- **Auth-token TTL**: Sets authentication tokens' valid lifetime, in seconds. Defaults to `3600` (60 minutes = 1 hour); must be at least `1` sec.
- **Session idle time limit**: Sets how long (in seconds) Cribl Stream will observe no user interaction before invalidating user's session tokens. Defaults to `3600` (60 minutes = 1 hour); must be at least `60` sec.
- **Login rate limit**: Sets the number of login attempts allowed over a (selectable) unit of time. Defaults to `2/second`.
- **HTTP headers**: Enables you to specify one or more custom HTTP headers to be sent with every response.

Token Renewal and Session Timeout

Here is how Cribl Stream sets tokens' valid lifetime by applying the **Auth-token TTL** field's value:

- When a user logs in, Cribl Stream returns a token whose expiration time is set to {login time + **Auth-token TTL** value}.
- If the user is idle (no UI activity) for the configured token lifetime, they are logged out.
- As long as the user is interacting with Cribl Stream's UI in their browser, Cribl Stream continually renews the token, resetting the idle-session time limit back by the **Auth-token TTL** value.

The cribl.secret File

When Cribl Stream first starts, it creates a `$CRIBL_HOME/local/cribl/auth/cribl.secret` file. This file contains a key that is used to generate auth tokens for users, encrypt their passwords, and encrypt encryption keys.

Default local credentials are: `admin/admin`

Back up and secure access to this file by applying strict permissions – for example, `600`.

External Authentication

While configuring any external auth method, make sure you don't get locked out of Cribl Stream! Enable the **Fallback on fatal error** or **Allow local auth** toggle until you're certain that external auth is working as intended. If you do get locked out, refer back to Manual Password Replacement for the remedy.

All external auth methods require certain plan/license tiers. For details, see Pricing.

Cribl Stream Roles and role mapping are supported **only** with an Enterprise license. With a Standard license, all your external users will be imported to Cribl Stream in the `admin` Role.

This topic covers the following external authentication providers:

- Splunk Authentication
- LDAP Authentication

Authentication for Single Sign-On

Each authentication method that Cribl Stream supports for on-prem SSO has its own separate topic:

- SSO/OpenID Connect Authentication
- SSO/SAML Authentication

For deployments in Cribl.Cloud, see Cribl.Cloud SSO Setup.

Splunk Authentication

Splunk authentication is very helpful when deploying Cribl Stream in the same environment as Splunk. This option requires the user to have Splunk `admin` role permissions. To set up Splunk authentication:

Navigate to **Settings** > **Global** > **Access Management** > **Authentication** > **Type** and select **Splunk**. This exposes the following controls.

- **Host**: Splunk hostname (typically a search head).
- **Port**: Splunk management port (defaults to `8089`).
- **SSL**: Whether SSL is enabled on Splunk instance that provides authentication. Defaults to `Yes`.
- **Validate certificates**: When enabled, Cribl Stream will reject any certificate that the Certificate Authority (CA) for your system does not authorize. Although this control is off by default, Cribl strongly recommends that you enable it, except when you must allow untrusted (for example, self-signed) certificates.

- **Fallback on fatal error**: Attempt local authentication if Splunk authentication is unsuccessful. Defaults to `No`. If toggled to `Yes`, Cribl Stream will attempt local auth only **after** a failed Splunk auth. Selecting `Yes` also exposes this additional option:
    - **Fallback on bad login**: Attempt local authentication if the supplied user/password fails to log in on Splunk. This similarly defaults to `No`.

The Splunk search head does not need to be locally installed on the Cribl Stream instance.

For distributed deployments with an Enterprise License, the next (and final) step is to configure Role Mapping settings.

LDAP Authentication

You can set up LDAP authentication as follows:

Navigate to **Settings** > **Global** > **Access Management** > **Authentication** > **Type**, and select **LDAP**. This exposes the following controls.

- **Secure**: Enable to use a secure LDAP connections (`ldaps://`). Disable for an insecure (`ldap://`) connection.
- **LDAP servers**: List of LDAP servers. Each entry should contain `host:port` – for example, `localhost:389`.
- **Bind DN**: Distinguished Name of entity to authenticate with LDAP server – for example, `'cn=admin,dc=example,dc=org'`.
- **Password**: Distinguished Name password used to authenticate with LDAP server.
- **User search base**: Starting point to search LDAP for users – for example, `'dc=example,dc=org'`.
- **Username field**: LDAP user search field, such as `cn` or `(cn (or uid)`. For Microsoft Active Directory, use `sAMAccountName` here.
- **User search filter**: LDAP search filter to apply when authenticating users. Optional, but recommended: If empty, all users in your domain will be able to log in with the default Cribl Role. This example would enable only users in the `StreamAdmins` group to log in – they would then be mapped to any Roles specified in Role Mapping Settings:
  `(&(objectClass=user)(memberof=CN=StreamAdmins,OU=Groups,DC=cribl,DC=io))`
  This simpler filter example would enable anyone in a group called admin," who does **not** have a department attribute that starts with "123," to log in:
  `(&(group=admin)(!(department=123*)))`
- **Group search base**,
  Group member field,
  Group membership attribute,

Group search filter,
Group name field: These settings are used only for LDAP authentication with role-based access control. See Role-Based LDAP Authentication, below.

- **Connection timeout (ms)**: Defaults to `5000`.
- **Reject unauthorized**: Valid for secure LDAP connections. Set to `Yes` to reject unauthorized server certificates.
- **Fallback on fatal error**: Attempt local authentication if LDAP authentication is down or misconfigured. Defaults to `No`. If toggled to `Yes`, local auth will be attempted only **after** a failed LDAP auth. Selecting `Yes` also exposes this additional option:
    - **Fallback on bad login**: Attempt local authentication if the supplied user/password fails to log in on the LDAP provider. Defaults to `No`.

For distributed deployments with an Enterprise License, the next (and final) step is to configure Role Mapping settings.

Role-Based LDAP Authentication

When configuring LDAP authentication with role-based access control (RBAC), you **must** use the following settings to import user groups. (The UI does not enforce filling these fields. When using LDAP without roles, ignore them.)

- **Group search base**: Starting point to search LDAP for groups – for example, `dc=example,dc=org`.
- **Group member field**: LDAP group search field – for example, `member`.
- **Group membership attribute**: Attribute name of LDAP user object. Determines group member attribute's value, which defines group's allowed users. This field accepts `dn`, `cn`, `uid`, or `uidNumber`. If none of these are specified, falls back to `dn`.
- **Group search filter**: LDAP search filter to apply when retrieving groups for authorization and mapping to Roles – for example, `(&(cn=cribl*)(objectclass=group))`.
- **Group name field**: Attribute used in objects' DNs that represents the group name – for example, `cn`. Cribl Stream does not directly read this attribute from group objects; rather, it must be present in your groups' DN values. Match the attribute name's original case (upper, lower, or mixed) when you specify it in this field. In particular, Microsoft Active Directory requires all-uppercase group names – for example, `CN`.

For distributed deployments with an Enterprise License, the next (and final) step is to configure Role Mapping settings.

Role Mapping Settings

This section is displayed only on Distributed deployments (Edge, Stream) with an Enterprise License.
For details on mapping your external identity provider's configured groups to corresponding Cribl Stream user access Roles, see External Groups and Roles. The controls here are:

- **Default Role**: Default Cribl Stream Role to assign to all groups not explicitly mapped to a Role.
- **Mapping**: On each mapping row, enter an external group name (case-sensitive) on the left, and select the corresponding Cribl Stream Role in the right drop-down list. Click **Add Mapping** to add more rows.

10.2. Members And Permissions

Define and manage fine-grained access control across Cribl products and resources

---

Members and Permissions enable fine-grained access control and authorization. You can assign different access and capabilities (Permissions) to each user (Member) at multiple levels:

- Organization.
- Product: Stream, Edge, Search, or Lake.
- Group/Fleet.
- Resource: Cribl Stream Project, Cribl Search Dataset or Dataset Provider, and so on.

Availability

Permission-based access control is available on:

- On-prem Distributed deployments (Stream, Edge) with certain plan/license tiers.
- All Cribl.Cloud deployments, at the Organization level. (Cribl.Cloud with certain plan/license tiers also offers granular access control on products, Worker Groups, and lower-level resources.)

On on-prem Single-instance deployments, or Distributed deployments with other licenses, all users will have full `Admin`-level privileges.

Initial Permissions

When you first deploy Cribl Stream with the above prerequisites, you will be granted the Organization-level `Admin` Permission. Using this Permission, you can then assign additional Permissions to yourself and other Members, as outlined below in Organizations and Assigning Group-/Fleet-Level Permissions.

Cross-Compatibility

Members and Permissions are available as the successors to Cribl's original role-based access control (RBAC) model of Local Users and Roles/Policies. The earlier model is still supported across most of the Cribl product suite.

However, Cribl.Cloud invitations and Stream Projects have fully transitioned to the new model. For detailed differences between the two access control systems, see Which Access Method Should I Use?.

Known Issue

Existing Local Users display in **Settings** > **Global** > **Members and Teams** with the `No Access` Permission even if they've been assigned a higher Role. This is a display-only bug: These users' original Roles still function as configured. For details and fix progress, please see Known Issues.

Organizations

The Members and Permissions model uses the concept of Organization as a container for the deployment of a whole suite of Cribl products (Stream, Edge, and Cloud-only Search and Lake). To access the Organization-level Members UI as an Admin:

1. In the sidebar, select **Settings**, then **Global**.
2. Under **Access Management**, select **Members and Teams**.
3. Here, you can select an existing Member's row to change their access Permissions or other details, or select **Add Member** to grant a new user access to your Cribl Organization.

Invite Members

To invite new Members to your Organization:

1. In the sidebar, select **Settings**, and then select **Global**.
2. Under **Access Management** submenu, select **Members and Teams**.
3. Select **Add Member**.
4. Enter the new Member's information, email, and password.
5. Under **Workspace permission**, select the permission you want to grant to the new Member for the whole Organization.
6. If you chose the **User** permission, configure access for each Cribl product separately. An **Admin** permission automatically grants admin access to all products.
7. When finished, select **Save**.

For Cribl.Cloud's counterpart to this on-prem UI for managing Organization-level Permissions, see Inviting Members.

Members and Local Users

Members and Local Users are interchangeable: Members can be reconfigured using legacy Roles instead of Permissions, and anyone you add to **Local Users** will also show in **Members**.

Organization- and Product-Level Permissions

Each newly created Member starts out with **User** Permission at the Organization level, and with the self-explanatory **No Access** Permission on each product. You can use the toggles to assign the following Permission levels.

For Cribl.Cloud Organization-level Permissions, see Cribl.Cloud docs' Member Permissions section.

Organization-Level Permissions

Permission	Description
User	The most basic Permission. At the Organization level, gets the Member into the system, without conferring any access to peer Members, products, or lower-level resources. (Admins can freely assign these Members varying Permissions at lower levels.)
Admin	This is a superuser Permission. At the Organization level, allows creating, viewing, updating, and deleting all Members. (Automatically inherits Product-level `Admin` Permissions and resource-level `Maintainer` Permissions, which confer comparably broad capabilities.)

For Stream and Edge, the Product-level Permissions below apply to both Cribl.Cloud and on-prem deployments. For Cribl Search's more-specific Product-level Permissions, see Search Member Permissions. For Cribl Lake's Product-level Permissions, see Lake Permissions.

Product-Level Permissions (Stream and Edge)

Permission	Description
User	The most basic Permission. At the Product level, makes the Member assignable to Worker Groups and resources, with no initial access to any.
Read Only	At the Product level, this Permission is designed specifically to enable support personnel to help other users by viewing (but not modifying) their configurations. Allows viewing all Members, Worker Groups, Settings, Leader commits, and legacy Local Users and Roles, with no configuration capabilities. (A `Read Only` Permission at the Product level automatically inherits `Read Only` Permissions on all Worker Groups and lower-level resources.)

Permission	Description
Editor	Allows viewing all Groups and Monitoring pages. (Configuring these options requires `Admin`-level permission on the product and/or Worker Group.) Automatically inherits the `Editor` Permission on Worker Groups, and the `Maintainer` Permission on lower-level resources.
Admin	This is a superuser Permission at the Product level. It allows creating, viewing, updating, and deleting all Worker Groups and resources; managing Worker Group Mappings; adding, updating, and restarting Worker Nodes; and managing Notifications and Notification targets. (Automatically inherited from the Organization-level `Admin` Permission in on-prem deployments, and from the Org-level `Owner` Permission in Cribl.Cloud deployments. Automatically inherits `Admin` Permissions on all Worker Groups and `Maintainer` Permissions on lower-level resources.)

Once Members are in your Organization, you can assign or reassign the above Organization- and Product-level Permissions. Return to **Settings** > **Global** > **Members and Teams** and select the Member's row to reopen the same configuration modal.

Group- and Fleet-Level Permissions

Cribl Stream Permissions at the Worker Group level generally mirror those at the Product level:

Permission	Description
User	The most basic Permission. Gets the Member into the Worker Group, where Admins can then assign them access on individual resources. (Unless Members have a higher Permission at the Product level, they have no initial access to Worker Groups or resources.)
Read Only	Designed for support personnel. Allows viewing all Worker Group-level Settings, encryption keys, certificates, secrets, scripts, Sources, Destinations, Pipelines, Packs, Routes, QuickConnect connections, Knowledge objects, Notifications and Notification targets, Edge Subfleets and their Settings, and Stream Projects and Subscriptions, with no configuration capabilities. (Automatically inherited from a Product-level `Read Only` Permission. Automatically inherits `Read Only` Permissions on lower-level resources.)
Editor	Allows creating, viewing, updating, and deleting all Worker Group-level encryption keys, certificates, secrets, scripts, Sources, Destinations, Pipelines, Packs, Routes, QuickConnect connections, Knowledge objects, and Notifications and Notification targets. Allows committing configuration changes, but not deploying them. (An `Editor` Permission at the Product level automatically inherits `Editor` Permissions on all Worker Groups.)
Admin	Superuser Permission. Allows creating, viewing, updating, and deleting all Worker Group-level access management (Members' Permissions), Settings, encryption keys, key management system (KMS) settings, certificates, secrets, scripts, Sources, Destinations, Pipelines, Packs, Routes, QuickConnect connections, Knowledge objects, Notifications and Notification targets, and Stream Projects/Subscriptions.

Permission	Description
	Allows adding, updating, and restarting Worker Nodes. Allows committing and deploying configuration changes. On Edge, provides CRUD capabilities on Subfleets' Settings and access management identical to those on the parent Fleet. (Automatically inherited from the Product-level `Admin` Permission. Automatically inherits `Maintainer` Permissions on lower-level resources.)

Assigning Group-/Fleet-Level Permissions

To assign Permissions on a Worker Group:

1. In the sidebar, select **Settings**.
2. Select **Global**, then **Members and Teams**.
3. Make sure this Member has a **Workspace permission** level sufficient to support the Permission you want to assign on the Worker Group.
4. On the **Settings** submenu, select **Stream/Edge**, then **Members and Teams**.
5. Select each applicable Member's row to open their **Member Details** drawer.
6. Grant the Member the Permission level you want on this Worker Group.

Assigning Group-/Fleet-Level Permissions in only available in on-prem deployments, not in Cribl.Cloud.

Resource-Level Permissions

Certain Cribl products provide Permission-based access to particular resources.

Stream Projects

Stream Projects and Subscriptions rely entirely on the Members/Permissions access control system. These enable you to assign different users different levels of access on individual Projects.

The 4.1.x `project_user` Role and `ProjectSourceSubscribe` Policy, which provided access to all Projects, are retired in Cribl Stream 4.2.x and later. **This is a breaking change.** If you are upgrading with Projects configured in v.4.1.x, those Projects' users will be visible in Stream as Members, and you'll need to assign them new Permissions.

For details, see Adding Users to Projects.

Search Resources

For Permissions on Search resources, see the Search docs' Sharing topic.

Other Resources

Access to certain resources can be managed only via legacy Local Users and Roles.

GitOps integration: Authorization to enable and manage GitOps requires the legacy `gitops` Role. This legacy Role has no counterpart Permission.

Collectors: The `collect_all` legacy Role specifically enables creating, configuring, and running Collection jobs on all Stream Worker Groups. This Role has no counterpart Permission.

Notifications: The `notification_admin` legacy Role specifically enables creating and receiving all Notifications. This legacy Role has no counterpart Permission.

Inheritance

Members' Permissions at certain levels determine the Permissions that Admins can assign them at lower levels. Here is the current inheritance scheme:

- Members with the `Admin` Permission at the Organization level will be locked to the `Admin` Permission on Products, to the `Editor` Permission on Worker Groups, and to the `Maintainer` Permission on lower-level resources.
- Members with the Product-level `Editor` Permission will be locked to the `Editor` Permission on Worker Groups, and to the `Maintainer` Permission on lower-level resources.
- Members with the `User` Permission at each level can be assigned varying Permissions at the next level down. **`User` is the most malleable Permission.**
- On Stream Projects, the `Maintainer` Permission is available **only** to Members with higher-level `Admin` or `Editor` Permissions. (They're automatically assigned this Permission via inheritance.)
- Search resources are more flexible: Here, the `Maintainer` Permission can be shared with Members who have the `User` Permission at the Product level.
- Members with the Product-level `Read Only` Permission will be locked to the `Read Only` Permission on Worker Groups and on lower-level resources.

10.3. Teams

Teams are groups of Members who share the same Organization, Workspace, and product-level permissions. This allows you to efficiently manage access control by assigning permissions to the Team rather than configuring each Member individually.

Teams are available only in distributed deployments or in Cribl.Cloud.

Create a Team

To create and configure a Team:

Cribl.Cloud | On-Prem Deployment

1. On the top bar, select **Products**, and then select **Cribl**.
2. In the sidebar, select **Organization**, then **Members & Teams**.
3. Go to the **Teams** tab and select **Create Team**.
4. Provide a meaningful **Name** and optionally a **Description**.
5. If you have SSO configured in your Organization, in **Mapping ID**, you can provide an external ID for the Team. Use it when integrating with SSO to map Workspace roles with IDP groups.
6. Select the desired Workspace and access to assign to the Team. **Member** allows granular product-level permissions.
7. In **Team Members**, select the Members you want to add, then select **Add**. A Member must already exist to be added to a Team.
8. The table is updated to show the Members you've just added.
9. When finished, select **Save**.

The main Teams page displays the Teams configured on your Organization. You can edit them by clicking their row, or delete them as needed from the **Actions** column.

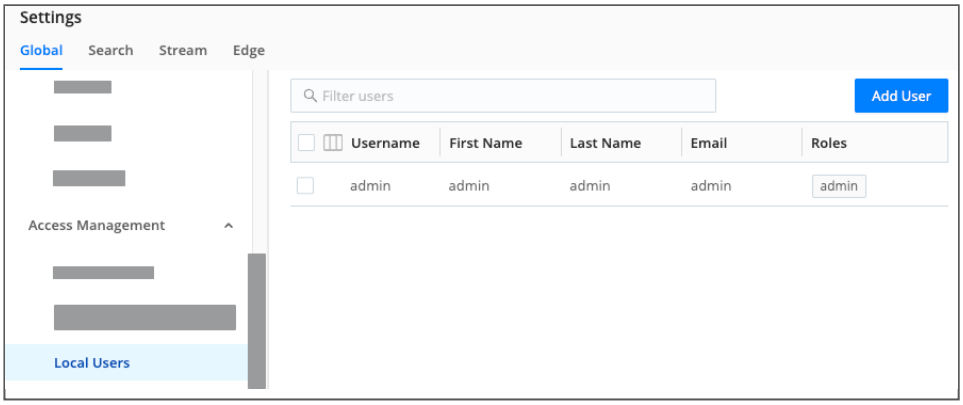
10.4. Local Users

This page covers how to create and manage Cribl Stream users, including their credentials and (where enabled) their access roles. These options apply if you're using the **Local** Authentication type, which is detailed here.

Creating and Managing Local Users

To create a new Local User:

1. In the sidebar, select **Settings**, then **Global**.
2. Under **Access Management**, select **Local Users**. The **Local Users** page will initially show only the default `admin` user. You are operating as this user.



Managing users

3. Select **Add User**.
4. Provide the new User with basic information and set their **Password**. Usernames and passwords are case-sensitive.
5. To prevent the user from currently logging in, toggle **Enabled** to **No**.

Logged-in users can change their own Cribl Stream password from the **Local Users** page, by clicking on their own row to open a **Local Users** modal that manages their identity.

Password Rules

All passwords must:

- Contain eight or more characters.
- Use characters from three or more of the following categories:
  - Lowercase letters.
  - Uppercase letters located after the first character in the password.

- Digits located before the last character in the password.
- Non-alphanumeric ASCII characters such as `#`, `!`, or `?`.
- Non-ASCII characters such as `ñ`, `€`, or emoji.

As of Cribl Stream version 4.5.0, these rules apply for all passwords, whether or not Cribl Stream is running in FIPS mode, with one exception:

- For Cribl Stream not running in FIPS mode, local users whose passwords existed before Cribl Stream 4.4.4 was released, can continue to use their passwords, even if those passwords do not satisfy the rules.
- When these users change to a new password, the new password must satisfy the rules.
- New users must create passwords that satisfy the rules.

If you get locked out of your account, you need to reset your password manually.

Adding Roles

If you've enabled role-based access control you can use the modal's bottom **Roles** section to assign access Roles to this new or existing user.

For details, see Roles. Role-based access control can be enabled only on distributed deployments (Edge, Stream) with certain plan/license tiers. With other license types and/or single-instance deployments (Edge, Stream), all users will have full administrative privileges.

Select **Add Role** to assign each desired role to this user. The options on the **Roles** drop-down reflect the Roles you've configured at **Settings** > **Global** > **Access Management** > **Roles**.

Note that when you assign multiple Roles to a user, the Roles' permissions are additive: This user is granted a superset of the highest permissions contained in all the assigned Roles.

By default, Cribl Stream will log out a user upon a change in their assigned Roles. You can defeat this behavior at **Settings** > **Global** > **General Settings** > **API Server Settings** > **Advanced** > **Logout on roles change.**

10.5. Roles

Define and manage access-control Roles and Policies

The Roles/Policies model exists in parallel with a more flexible Members/Permissions model, which will eventually replace it. Cross-compatible Default Roles and Default Policies support customers who still choose to configure Local Users with Roles and Policies. Your configured Local Users appear interchangeably in the new Members UI, and vice versa.

See Which Access Method Should I Use? for detailed differences between the two access control systems.

Availability

Role-based access control is available only on distributed deployments (Stream, Edge) with a certain plan/license tier.

On single-instance deployments or distributed deployments with other licenses all users will have full administrative privileges.

Known Issue

Existing Local Users display in **Settings** > **Global** > **Members and Teams** with the `No Access` Permission even if they've been assigned a higher Role. This is a display-only bug: These users' original Roles still function as configured. For details and fix progress, please see Known Issues.

RBAC Concepts

Cribl Stream's RBAC mechanism is designed around the following concepts, which you manage in the UI:

- **Roles**: Logical entities that are associated with one or multiple **Policies** (groups of permissions). You use each Role to consistently apply these permissions to multiple Cribl Stream **users**.
- **Policies**: A set of **permissions**. A Role that is granted a given Policy can access, or perform an action on, a specified Cribl Stream object or objects.
- **Permissions**: Access rights to navigate to, view, change, or delete specified **objects** in Cribl Stream.
- **Users**: You map Roles to Cribl Stream users in the same way that you map **user groups** to users in LDAP and other common access-control frameworks.

Users are independent Cribl Stream objects that you can configure even without RBAC enabled. For details, see Local Users.

Cribl Stream Roles can be integrated with external authorization/IAM mechanisms, such as LDAP and OIDC and mapped to their respective groups, tags, etc.

Using Roles

Cribl Stream ships with a set of default Roles, which you can supplement.

Default Roles

These Roles ship with Cribl Stream by default.

Organization-Level Roles

Note that some of the Roles below have no counterpart Permission in Cribl's newer Members/Permissions model.

Name	Description	Permission Equivalent
admin	Superuser – authorized to do anything in the system.	Organization Admin
gitops	Ability to sync the Cribl Stream deployment to a remote Git repository.	N/A
notification_admin	Read/write access to all Notifications.	N/A
user	Default Role that gets only a home/landing page to authenticate. This is a fallback for users who have not yet been assigned a higher Role by an admin.	Organization User
project_user	Read/write access to the simplified Stream Projects UI and related data Subscriptions. **Deprecated as of v.4.2.** Instead assign **Editor**, as the most comparable new Project-level Permission. The more-permissive **Maintainer**, and the more-restrictive **Read Only**, are also available Permissions.	Project Editor

Stream Roles

Name	Description	Permission Equivalent
stream_user	Basic Role for Stream.	Stream User.
stream_reader	Allows viewing all Members, Worker Groups, Settings, Leader commits, and legacy Local Users and Roles, with no configuration capabilities.	Stream Read Only.
stream_editor	Allows viewing all Groups and Monitoring pages.	Stream Editor.
stream_admin	Superuser Role at the Product level	Stream Admin.

Edge Roles

Name	Description	Permission Equivalent
edge_user	Basic Role for Edge.	Edge User.
edge_reader	Allows viewing all Members, Fleets, Settings, Leader commits, and legacy Local Users and Roles, with no configuration capabilities.	Edge Read Only.
edge_editor	Allows viewing all Groups and Monitoring pages.	Edge Editor.
edge_admin	Superuser Role at the Product level.	Edge Admin.

Worker Group–Level Roles

Name	Description	Permission Equivalent
owner_all	Read/write access to (and Deploy permission on) all Worker Groups.	N/A
editor_all	Read/write access to all Worker Groups.	N/A
reader_all	Read-only access to all Worker Groups.	N/A

Name	Description	Permission Equivalent
collect_all	Ability to create, configure, and run Collection jobs on all Worker Groups.	N/A

Cribl Search Roles

Name	Description	Permission Equivalent
search_user	Basic Role for Cribl Search.	Cribl Search User.
search_editor	Manage Datasets, Dataset Providers, Dashboards and settings.	Cribl Search Editor.
search_admin	Superuser Role at the Product level.	Cribl Search Admin.

Cribl **strongly recommends** that you do not edit or delete these default Roles. However, you can readily clone them, and modify the duplicates to meet your needs.

Initial Installation or Upgrade

When you first install Cribl Stream with the prerequisites to enable RBAC (Distributed deployment with a certain plan/license tier), you will be granted the **admin** Role. Using this Role, you can then define and apply additional Roles for other users.

You will similarly be granted the **admin** Role upon upgrading an existing Cribl Stream installation from pre-2.4 versions to v. 2.4 or higher. This maintains backwards-compatible access to everything your organization has configured under the previous Cribl Stream version's single Role.

Adding and Modifying Roles

To add a new Role:

1. In the sidebar, select **Settings**, then **Global**.
2. Under **Access Management**, select **Roles**.
3. Select **Add Role**.
4. Provide the Role **Name**.
5. Select **Policies** for this Role.

Adding and Removing Policies

The **Policies** section is an expandable table. In each row, you select a Policy using the left drop-down, and apply that Policy to objects (i.e., assign permissions on those objects) using the right drop-down.

Let's highlight an example from the above screen capture of Cribl Streams built-in Roles: The `editor_all` Role has the `GroupEdit` Policy, with permission to exercise it on any and all Worker Groups (as indicated by the `*` wildcard).

Policies on the left, objects on the right

To add a new Policy to a Role:

1. Select **Add Policy** to add a new row to the **Policies** table.
2. Select a Policy from the left column drop-down.
3. Accept the default object on the right; or select one from the drop-down.

To modify an already-assigned Policy, just edit its row's drop-downs in the **Policies** table.

To remove a Policy from the Role, select the **X** icon at right.

In all cases, click **Save** to confirm your changes and close the modal.

Default Policies

In the **Policies** table's left column, the drop-down offers the following default Policies:

Worker Group-Level Policies

Name	Description	Permission Equivalent
`GroupRead`	The most basic Worker Group-level permission. Enables users to view a Worker Group and its configuration, but not modify or delete the config.	Worker Group-level Read Only.
`GroupEdit`	Building on `GroupRead`, grants the ability to also change and commit a Worker Group's configuration.	Worker Group-level Editor.

Name	Description	Permission Equivalent
`GroupFull`	Building on `GroupEdit`, grants the ability to also deploy a Worker Group.	Worker Group-level Admin.
`GroupCollect`	Grants the ability to create, configure, and run Collectors on a Worker Group.	N/A
`GroupUser`	Access Worker Group.	Worker Group-level User.

Project-Level Policies

Name	Description	Permission Equivalent
`ProjectMaintain`	Grants ability to edit or delete the Project and its settings.	Project-level Maintainer.
`ProjectRead`	Can configure connections among the Project's Subscriptions, Packs, and Destinations, but cannot modify or delete these resources.	Project-level Read Only.
`ProjectEdit`	Can view Project and Subscription settings and connections, but not modify or delete them.	Project-level Editor.

Product-Level Policies

Name	Description	Permission Equivalent
`ProductUser`	Makes the Member assignable to Worker Groups and resources, with no initial access to any.	Product-level User.
`LimitedProductUser`	Similar to `ProductUser`, but omits the ability to read or act on all the endpoints within a Worker Group.	N/A
`ProductAdmin`	Superuser Permission at the Product level.	Product-level Admin.

Search Policies

Name	Description	Permission Equivalent
`DatasetMaintain`	Full access to Dataset configuration.	Search Datasets Maintainer.
`DatasetRead`	Can view and search, but not modify Dataset configurations.	Search Datasets Read Only.
`DatasetProviderMaintain`	Full access to Dataset Provider configuration.	Search Dataset Providers Maintainer.
`DatasetProviderRead`	Can view and search, but not modify Dataset Provider configurations.	Search Dataset Providers Read Only.
`SearchUser`	Search data and view results shared with the user	Search Product-level User.
`SearchMaintainer`	Manage Datasets, Dataset Providers, Dashboards and settings.	Search Product-level Editor.
`DashboardMaintain`	Can edit and delete a Search dashboard.	Search dashboard Maintainer.
`DashboardRead`	Can view and use a Search dashboard.	Search dashboard Read Only.

General Policies

Name	Description	Permission Equivalent
`*` (wildcard)	Grants **all** permissions on associated objects.	N/A

Internal Policies

The following policies are internal building blocks for Product-specific Policies. Do not add them directly to Roles.

Name	Description	Permission Equivalent
`Product`	N/A	N/A
`BaseProductUser`	N/A	N/A
`MaintainBase`	N/A	N/A
`SearchBase`	Similar to `SearchUser`: Can view Search resources shared with the Member.	N/A

Use Policies As-Is

By design, the default Policies that ship with Cribl Stream cannot be modified via the UI or API. Do not attempt to modify them by other means. Breaking the built-in model could undermine your intended access-control protections, opening your deployment and data to security vulnerabilities.

Objects and Permissions

In the **Policies** table's right column, use the drop-down to select the Cribl Stream objects on which the left column's Policy will apply. The objects available for selection are specific Worker Groups, or a wildcard representing all Worker Groups. For example:

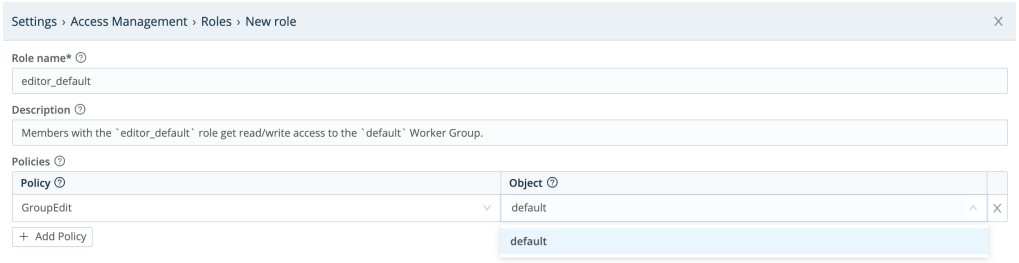
- `Worker Group <id>`
- `NewGroup2`
- `default` (Worker Group)
- `*` (all Worker Groups)

Extending Default Roles

Here's a basic example that ties together the above concepts and facilities. It demonstrates how to add a Role whose permissions are restricted to a particular Worker Group.

Here, we've cloned the `editor_all` Role that we unpacked above. We've named the clone `editor_default`.

We've kept the `GroupEdit` Policy from `editor_all`. But in the right column, we're restricting its object permissions to the `default` Worker Group that ships with Cribl Stream.



Cloning a default Role

You can readily adapt this example to create a Role that has permissions on an arbitrarily named Worker Group of your own.

Roles and Users

Once you've defined a Role, you can associate it with Cribl Stream users. For details, see Local Users.

Note that when you assign multiple Roles to a given user, the Roles' permissions are additive: This user is granted a superset of all the permissions contained in all the assigned Roles.

By default, Cribl Stream will log out a user upon a change in their assigned Roles. You can defeat this behavior at **Settings** > **Global** > **General Settings** > **API Server Settings** > **Advanced** > **Logout on roles change**.

External Groups and Cribl Stream Roles

You can map user groups from external identity providers (LDAP, Splunk, or OIDC) to Cribl Stream Roles, as follows:

1. In the sidebar, select **Settings**, then **Global**.
2. Under **Access Management**, select **Authentication**
3. Choose **LDAP**, **Splunk**, or **OpenID Connect** as authentication **Type**.
4. Configure your identity provider's connection and other basics. (For configuration details, see the appropriate Authentication section.)
5. Under **Role Mapping**, first select a Cribl Stream **Default role** to apply to external user groups that have no explicit Cribl Stream mapping defined below.
6. Next, map external groups as you've configured them in your external identity provider (left field below) to Cribl Stream Roles (right drop-down list below).
7. To map more user groups, select **Add Mapping**.
8. When your configuration is complete, select **Save**.

10.6. SSO

10.6.1. Cribl.Cloud SSO

10.6.1.1. Cribl.Cloud SSO Setup

With a Cribl.Cloud account on certain plan/license tiers, you can set up a Single Sign-On (SSO) integration between your identity provider and your Cribl.Cloud portal.

The general steps to set up a Single Sign-On (SSO) integration between your identity provider and your Cribl.Cloud portal are:

1. In your identity provider (IDP), configure user groups that map to Cribl.Cloud's Teams or to predefined Roles.
2. In your IDP, create an OIDC or SAML application.

   If creating an OIDC application, you must use backchannel authentication. Cribl.Cloud does not support front-channel authentication via OIDC.
3. Submit your app's configuration details to Cribl on your Cribl.Cloud portal's **Organization** > **SSO Management** page. (This will complete your SSO setup on the Cribl side.)
4. In your IDP, assign groups to your users, matching the Role that each group of users should have in Cribl.Cloud.
5. In your IDP, assign the OIDC/SAML app to the Organization's owner, and to other Cribl.Cloud users.

For detailed instruction on how to configure SSO using different IDPs, see:

- SSO with Okta and OIDC
- SSO with Okta and SAML
- SSO with Microsoft Entra ID and SAML

Additionally, refer to SSO Troubleshooting for help in resolving issues you may encounter when setting up SSO in Cribl.Cloud.

10.6.1.2. Configuring SSO Groups

In your IDP (identity provider), configure user groups that match Permissions for both Cribl.Cloud Organizations and individual products.

Linking IDP Groups with Teams

You can use Teams to automatically connect groups of Members with IDP users. This allows you to grant IDP users Workspace- or Product-level permissions.

For each Team, you can specify a **Mapping ID** to use as an external ID. In your IDP, create a group with the same ID to connect it to the Team and in this way automatically grant IDP users access with Workspace-level permissions.

To create a Team with an external ID, refer to Create a Team. To add an external ID to an existing Team:

1. On the top bar, select **Products**, and then select **Cribl**.
2. In the sidebar, select **Organization**, then **Members & Teams**, and then **Teams**.
3. Select the Team you want to configure.
4. In **Mapping ID**, provide an external ID for the team.
5. Confirm with **Save**.

IDP Group Naming

If you are not using Teams, or want to grant Organization-level permissions to IDP users, you can define groups that will be mapped to Cribl Roles based on their names.

In such a case, the names you define for groups in your IDP must include `Cribl` and the Role name (`Owner`, `Admin`, or `User`). They can include `Organization` or product name (`Stream`, `Edge`, or `Search`). If they don't contain a product name, the group is treated as an Organization name.

Even though IDP group names without Organization will be treated as Organization-level permissions, we recommend keeping Organization in the name for clarity.

You can use either the open or the closed format (with or without spaces) in group names. You can freely add prefixes or suffixes to Group Names that follow the formats in the examples above. Cribl will ignore these additions when mapping IDP groups to Cribl Roles. Examples:

- `SOME-LABEL-12345-CriblOrganizationOwner`

- `CriblOrganizationEditor-420`

Cribl.Cloud Role/Permission	IDP Group Name
Owner	Cribl Organization Owner /or/ CriblOrganizationOwner
Admin	Cribl Organization Admin /or/ CriblOrganizationAdmin
User	Cribl Organization User /or/ CriblOrganizationUser
Editor	**(Deprecated, will be mapped to Admin)** Cribl Organization Editor /or/ CriblOrganizationEditor
Read Only	**(Deprecated, will be mapped to User)** Cribl Organization Read Only /or/ CriblOrganizationReadOnly

Default Product Permissions

When you map external users to your Cribl Organization, their initial product-level Permissions follow a different inheritance pattern than Members configured within Cribl. This is to avoid downgrading product-level Permissions that Organization-level `User`s might already have.

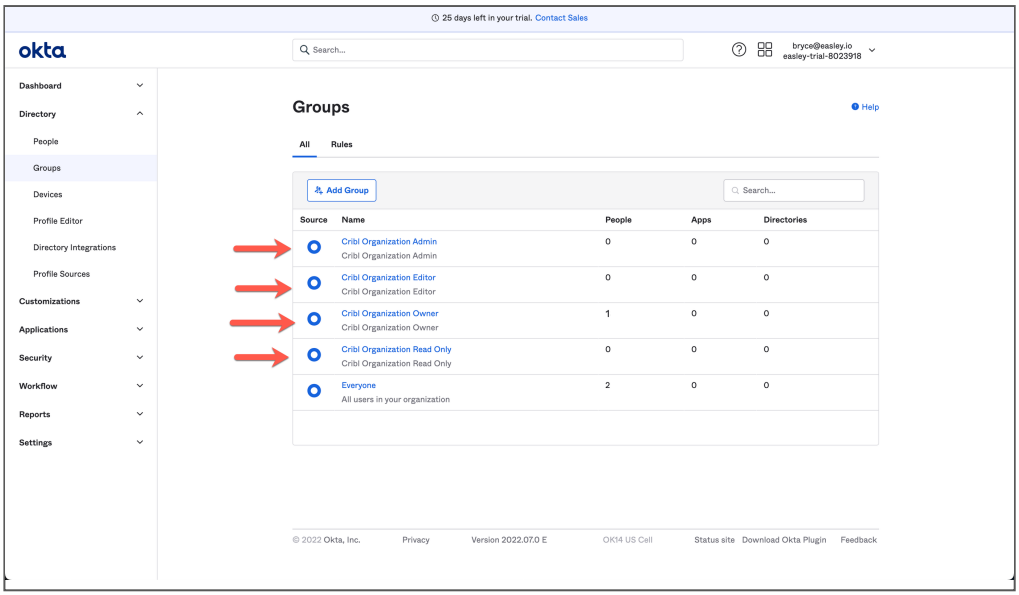
The defaults for mapped users are:

- Organization `Owner` or `Admin` inherits `Admin` Permission on all products.
- Organization `User` inherits `User` Permission on all products (except Cribl Lake, which inherits `No Access`).
- Organization `Editor` (deprecated) inherited `editor` legacy Roles on all products.
- Organization `Read Only` (deprecated) inherited `Read Only` Permission on Stream and Edge, and `User` Permission on Search.

Group Configuration Better Practices

- A Cribl.Cloud Organization's Owner Role can be shared and transferred among multiple users. This facilitates gradual ownership transfers, corporate reorganizations, and other scenarios.
- Those users should be in both the Owner and Admin groups in your IDP. (This enables them to acquire all needed permissions across Cribl's two corresponding Roles.)
- Aside from dual-assigning the Owners, you should assign every other user only one group in your IDP. (Cribl's Admin and Editor Roles include all the permissions of the Roles below them.)

Here’s an example of how groups configuration (at an early stage) might look in Okta’s UI:



Mapping Okta groups to Cribl.Cloud Roles

10.6.1.3. SSO With Okta And OIDC (Cribl.Cloud)

This page presents a walkthrough of setting up an OIDC SSO, using Okta as the example.

Cribl.Cloud supports only OIDC backchannel authentication, not front-channel.

This page is a guide for configuring SSO for a Cribl.Cloud deployment. For information about an on-prem installation, see SSO with Okta and OIDC (on-prem).

Set Up Fallback Access

Before you start configuring SSO, set up fallback access, so you are not locked out if issues with SSO occur.

In your Cribl.Cloud Organization, ensure that at least one Owner creates a local account, using an email domain that's separate from the corporate domain on which you're configuring SSO.

Bypassing SSO with Multiple Organizations

If you have SSO configured and you want to sign up for an additional Cribl.Cloud Organization, you need to bypass SSO. Otherwise, you will be forced to log into your existing Organization, because SSO does Home Realm Discovery and recognizes your email address.

In that case, edit your login URL and delete the word `identifier`. For example:

- Original URL: `https://login.cribl.cloud/u/login/identifier?state=<long_string_of_characters>`
- Edited URL: `https://login.cribl.cloud/u/login/?state=<long_string_of_characters>`

When you use this URL, instead of forcing you through SSO, Cribl.Cloud will ask for a username and password.

Create OIDC App Integration

To create your app integration:

1. In Okta, navigate to the **Applications** section and select **Create App Integration**.
2. Configure the app integration with the options below:
    - **Sign-in method**: `OIDC - OpenID Connect`

- **Application type**: `Web Application`

General Settings

3. Configure the app integration's **General Settings** with the options below:
   - **App integration name**: `Cribl.Cloud (OIDC)`
   - **Grant type**: Select `Authorization Code` and `Refresh Token`.
   - **Sign-in redirect URIs**:
     - `https://login.cribl.cloud/login/callback`
     - `https://manage.cribl.cloud/<organizationID>/organization/sso`
   - **Sign-out redirect URIs**: https://login.cribl.cloud/v2/logout

If your IDP is PingOne, you must also configure this (non-Okta) option:

- **Authentication options**: `Allow Client Secret`

Assignments

4. Configure the **Assignments** pane with the following options:
   - **Controlled access**: `Limited access to selected groups`
   - **Selected groups**: The groups you mapped in Configure Groups.
5. **Save** your application.
6. Now return to the **General** tab's **General Settings** section and in **Refresh token behavior**, select `Use persistent token`.

Sign On Tab

7. If you are *not* mapping Teams to IDP groups, you need to specify a groups claim filter. In the **OpenID Connect ID Token** section, select **Edit**, and set the **Groups claim filter** to: `groups` : `Starts with` : `Cribl`.
8. To obtain the **Issuer URL** that you'll need to provide to Cribl in the next section, change the value in the **Issuer** field from `Dynamic` to `Okta URL`.

This step concludes the setup procedure for Okta (or other IDP).

Submit Your App Info to Cribl

Next, provide Cribl with essential details about your application to implement the SSO setup on the Cribl side.

1. In Cribl Stream, on the top bar, select **Products**, and then select **Cribl**.
2. In the sidebar, select **Organization**, then **SSO Management**.
3. Above **Web Application Settings**, select **OIDC**.
4. The **Web Application Settings** are prefilled for you, so you only need to fill in the **Cribl Cloud SSO Settings** section with the following details from your IDP client configuration:
    - Client ID
    - Client Secret
    - Issuer URL. Copy the **Issuer** URL from the **Sign On** > **OpenID Connect ID Token** section of your Okta environment.

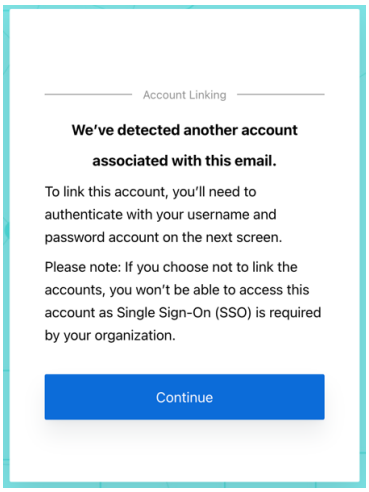
OIDC/Okta Chiclet Setup (Optional)

If you want to initiate login from your Okta instance with OIDC authentication configured, an Okta admin can configure an app integration as follows:

1. From Okta's left nav, select the **Applications** page.
2. Find the OIDC application created earlier in the OIDC/Okta Setup Example.
3. Select that application, and in the **General** tab's **General Settings** section, select **Edit**.
4. In the **Initiate login URI** field, enter `https://manage.cribl.cloud/login?connection=<organizationID>` (where `<organizationID>` is your Cribl.Cloud Organization's ID).
5. Confirm with **Save** to complete the chiclet.

Link Existing Users

If your Cribl.Cloud Organization has existing users who had been using a username and password to log in, upon first login with SSO, these users will see a prompt to link their identities. They should accept this prompt to ensure that their existing profile is linked with their SSO profile.



Prompt to link accounts

10.6.1.4. SSO With Microsoft Entra ID And SAML (Cribl.Cloud)

This page presents a walkthrough of setting up a SAML SSO, using Microsoft Entra ID as the example.

Set Up Fallback Access

Before you start configuring SSO, set up fallback access, so you are not locked out if issues with SSO occur.

In your Cribl.Cloud Organization, ensure that at least one Owner creates a local account, using an email domain that's separate from the corporate domain on which you're configuring SSO.

Bypassing SSO with Multiple Organizations

If you have SSO configured and you want to sign up for an additional Cribl.Cloud Organization, you need to bypass SSO. Otherwise, you will be forced to log into your existing Organization, because SSO does Home Realm Discovery and recognizes your email address.

In that case, edit your login URL and delete the word `identifier`. For example:

- Original URL: `https://login.cribl.cloud/u/login/identifier?state=<long_string_of_characters>`
- Edited URL: `https://login.cribl.cloud/u/login/?state=<long_string_of_characters>`

When you use this URL, instead of forcing you through SSO, Cribl.Cloud will ask for a username and password.

Create an Enterprise Application

From Microsoft Entra ID's left nav:

1. Select **Enterprise applications** and choose **All applications**, then **New application**.
2. Name your new app `Cribl.Cloud` (or any name you prefer).
3. Select **Integrate any other application you don't find in the gallery (Non-gallery)**.
4. Confirm with **Create**.

Assign Groups

Now, map your group from Cribl.Cloud to your SSO groups. From Microsoft Entra ID's left nav:

1. Select **Users and groups**, then select **Add user/group**.
2. Add the Cribl groups you created in Configure Groups. Do not configure Entra ID roles: access control will be handled by Cribl groups.

If Microsoft Entra ID is synchronized with your external Active Directory, you must set the groups claim: select `Groups assigned to the application` for association and set **Source attribute** to `sAMAccountName`.

Enable **Emit group name for cloud-only groups** to return the group names if it's defaulting to GUID or Object ID.

3. Click **Assign** after selecting Groups.

Configure Single Sign-On

From Microsoft Entra ID's left nav, select **Single sign-on**, then **SAML**, to open the **Basic SAML Configuration** page. Then, fill in the form with the information from Cribl.Cloud shown in the screenshot below:

1. In **Identifier (Entity ID)**, select **Add identifier** and enter the **Audience URI** value from the Cribl.Cloud SAML setup page.
2. In **Reply URL (Assertion Consumer Service URL)**, select **Add reply URL** and enter the two **Single Sign-on URL** values from Cribl.Cloud's SAML setup page.
3. Of these two URLs, identify the one with the `connection` query parameter, and select the check box to make it the **Default**.

SSO information for configuring Entra ID

Configure Attributes and Groups Claims

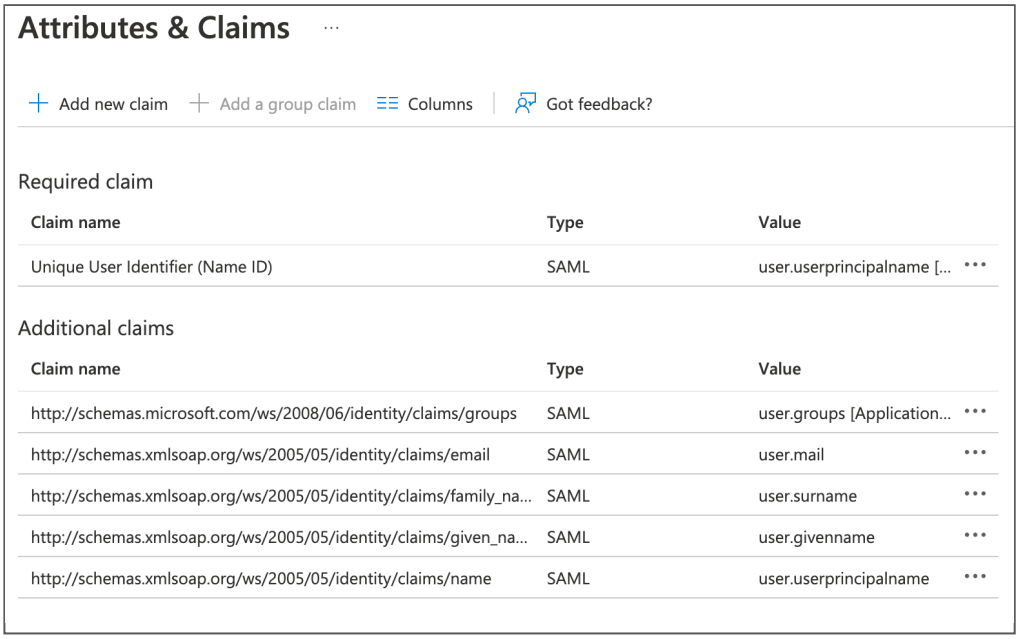
In Microsoft Entra ID, edit **User Attribute & Claims** as follows. Start with the claim names:

1. Change `surname` to `family_name`.

2. Change `emailaddress` to `email`.
3. Change `givenname` to `given_name`.

Next, add a group claim:

1. Select **Groups assigned to the application**.
2. Set the **Source attribute** to `Cloud-only group display names (Preview)`.
3. Accept the defaults for everything else, and save the new settings.



SAML Microsoft Entra ID Attribute

Submit Your App Info to Cribl

After you've created the SAML app integration in your IDP, provide Cribl with essential metadata about your application to implement SSO setup on the Cribl side.

1. In Cribl Stream, on the top bar, select **Products**, and then select **Cribl**.
2. In the sidebar, select **Organization**, then **SSO Management**.
3. Above **Web Application Settings**, select **SAML**.
4. Fill in the following fields with information from Entra ID:

Cribl.Cloud field	Entra ID
IDP Login/Logout URL	Login URL
IDP issuer	Microsoft Entra ID Identifier

Cribl.Cloud field	Entra ID
X.509 certificate (base64-encoded)	Certificate (Base64) under **SAML Certificates**

5. Select **Test Connection** to test the connection.
6. When you've verified the connection, select **Save** to complete your submission.

SAML/Entra ID Setup with My Apps Chiclet (Optional)

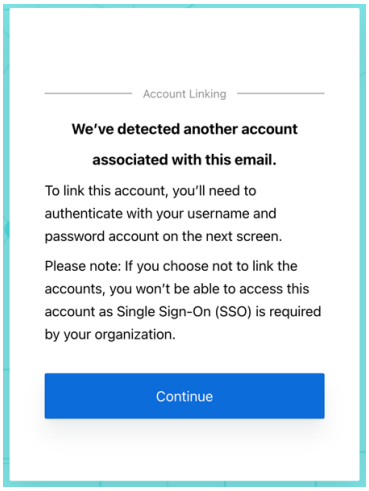
If you want to log into Cribl.Cloud via the Microsoft My Apps chiclet, complete the following procedure:

1. In Microsoft Entra ID, navigate to the enterprise application that you created to integrate SSO.
2. From the left nav, select **Single Sign-on**.
3. On the Enterprise Application's **Basic SAML Configurations** page, select **Edit**.
4. In the **Sign on URL (Optional)** section, enter the following URL: `https://manage.cribl.cloud/login?connection=<organizationID>` (where `<organizationID>` is your Cribl.Cloud Organization's ID).

You also need to allow self-service access to the Cribl App, or assign AD groups permissions to access the application.

Link Existing Users

If your Cribl.Cloud Organization has existing users who had been using a username and password to log in, upon first login with SSO, these users will see a prompt to link their identities. They should accept this prompt to ensure that their existing profile is linked with their SSO profile.



Prompt to link accounts

10.6.1.5. SSO With Okta And SAML (Cribl.Cloud)

This page presents a walkthrough of setting up a SAML SSO, using Okta as the example.

This page is a guide for configuring SSO for a Cribl.Cloud deployment. For information about an on-prem installation, see SSO with Okta and SAML (on-prem).

Set Up Fallback Access

Before you start configuring SSO, set up fallback access, so you are not locked out if issues with SSO occur.

In your Cribl.Cloud Organization, ensure that at least one Owner creates a local account, using an email domain that's separate from the corporate domain on which you're configuring SSO.

Bypassing SSO with Multiple Organizations

If you have SSO configured and you want to sign up for an additional Cribl.Cloud Organization, you need to bypass SSO. Otherwise, you will be forced to log into your existing Organization, because SSO does Home Realm Discovery and recognizes your email address.

In that case, edit your login URL and delete the word `identifier`. For example:

- Original URL: `https://login.cribl.cloud/u/login/identifier?state=<long_string_of_characters>`
- Edited URL: `https://login.cribl.cloud/u/login/?state=<long_string_of_characters>`

When you use this URL, instead of forcing you through SSO, Cribl.Cloud will ask for a username and password.

Create SAML 2.0 App Integration

To create your app integration:

1. In Okta, navigate to the **Applications** section of your Okta environment and select **Create App Integration**.
2. Create the app integration with **Sign-in method**: `SAML 2.0`.
3. Provide a name for your app and proceed with **Next**.

Configure SAML Settings

1. In the **Configure SAML** tab, in the **SAML Settings** section, you will use information you get from your Cribl.Cloud Organization. Configure the following options:
    - **Single sign-on URL** is the first of two URLs that your Cribl Organization's **SSO** > **SAML** tab lists under **Single Sign on URL**. For example: `https://login.cribl.cloud/login/callback?connection=<$organizationID>`
    - **Audience URI (SP Entity ID)** is located in your **SSO** > **SAML** tab under th same label. For example: `urn:auth0:cribl-cloud-prod:<$organizationID>`
    - **Application username**: `Email`

    The `nameidentifier` assertion in SAML responses must be the user's `Email`.
2. Select **Show Advanced Settings**. Navigate down and configure a single row of **Other Requestable SSO URLs**, as follows:
    - **URL** is required to test your connection. Get it from your Cribl.Cloud Organization's **SSO** > **SAML** tab, where it is the second **Single sign-on URL**. It will be in this format: `https://manage.cribl.cloud/api/assert`
    - **Index**: Set this to `0`.

Configure Attribute Statements

1. Configure **Attribute Statements** for these attributes, as shown below:

Name	Value
`email`	`user.email`
`given_name`	`user.firstName`
`family_name`	`user.lastName`

2. If you are *not* mapping Teams to IDP groups, you need to configure **Group Attribute Statements**:

Name	Filter
`groups`	Matches regex: `Cribl.*`

3. Save your app integration.

Submit Your App Info to Cribl

After you've created the SAML app integration in your IDP, provide Cribl with the essential metadata about your application to implement SSO setup on the Cribl side.

1. In Cribl Stream, on the top bar, select **Products**, and then select **Cribl**.
2. In the sidebar, select **Organization**, then **SSO Management**.
3. Above **Web Application Settings**, select **SAML**.
4. The **Web Application Settings** will be prefilled for you, and Cribl will also prefill the **SAML Assertion Mappings** based on the information you've registered with Cribl. So you only need to fill in the **SAML configuration** section with details from your IDP client configuration.
5. Return to your Okta environment to the **Sign On** tab and in the right pane, select **View SAML setup instructions**. Use the provided fields to fill in the information in Cribl.Cloud:

Cribl.Cloud field	Okta field
IDP Login/Logout URL	Identity Provider Single Sign-On URL
IDP issuer	Identity Provider Issuer
X.509 certificate (base64-encoded)	X.509 Certificate

SAML/Okta Chiclet Setup (Optional)

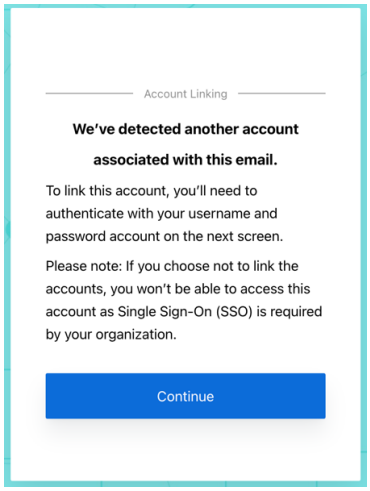
If you want to initiate login from your Okta instance with SAML authentication configured, an Okta admin can configure an app integration as follows:

1. From Okta's left nav, select the **Applications** page.
2. Select **Browse App Catalog**.
3. From the resulting catalog, use the search bar to find and select the `Bookmark App` application.
4. From that application's page, select **Add Integration**.
5. On the **General settings** page, enter an **Application label** that will identify this app as supporting Cribl.Cloud login. (`Cribl.Cloud` is a good choice, but the label is arbitrary.)
6. In the **URL** field, enter `https://manage.cribl.cloud/login?connection=<organizationID>` (where `<organizationID>` is your Cribl.Cloud Organization's ID).
7. Confirm with **Done**.
8. Select **Assign** and assign all of the Cribl.Cloud groups to the application.

9. The Cribl.Cloud chiclet should now be available for all users in the Cribl groups you've assigned.

Link Existing Users

If your Cribl.Cloud Organization has existing users who had been using a username and password to log in, upon first login with SSO, these users will see a prompt to link their identities. They should accept this prompt to ensure that their existing profile is linked with their SSO profile.



Prompt to link accounts

10.6.1.6. SSO Troubleshooting In Cribl.Cloud

Issues with enabling SSO typically result from incorrect or missing configuration. If your users are encountering problems logging in, make sure you have configured all the necessary fields (watch out for typos!):

- For SAML-based SSO, ensure that you have filled in the following fields correctly:
  - **IDP Login/Logout URL**
  - **IDP issuer**
  - **X.509 certificate (base64-encoded)**
- For OIDC-based SSO, verify the correctness of the following fields:
  - **Client ID**
  - **Client secret**
  - **Issuer URL**

Ensure all required users and groups are assigned to the application.

Make sure that the claims in your IDP are set up correctly. See our docs on Entra ID SAML and Okta OIDC.

If IDP-initiated logins are malfunctioning, you may see an error message: "IdP-Initiated login is not enabled". In this case, refer to the chiclet setup docs for Okta/OIDC, Okta/SAML, or Microsoft Entra ID/SAML.

Troubleshooting Resources

Cribl University offers an SSO Integration – Cribl.Cloud – Okta Troubleshooting Criblet. To follow the direct course link, first log into your Cribl University account.

To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses. Cribl's training is always free of charge.

Once logged in, check out other useful Troubleshooting Criblets and Advanced Troubleshooting short courses.

10.6.2. On-Prem SSO

10.6.2.1. SSO With Okta And OIDC (On-Prem)

Cribl Stream supports setting up SSO using OIDC to provide user authentication (login/password) and authorization (by mapping SSO users to Cribl Roles).

This page presents a walkthrough of setting up an OIDC SSO, using Okta as the example.

If you'd prefer to learn this information in the form of a video course, take a look at Cribl University's Troubleshooting Criblet on SSO Integration for Stream On-Prem - Okta. The course walks you through a configuration flow of SSO wth Okta and OIDC. (To follow the direct course link, first log into your Cribl University account - it's free!)

This page is a guide for configuring SSO for an on-prem installation. For Cribl.Cloud, see SSO with Okta and OIDC (Cribl.Cloud).

Create OIDC App Integration

To create your app integration:

1. In Okta, navigate to the **Applications** section and select **Create App Integration**.
2. Configure the app integration with the options below:
    - **Sign-in method**: `OIDC - OpenID Connect`
    - **Application type**: `Web Application`
3. Proceed with **Next**.

General Settings

4. Configure the app integration's **General Settings** with the options below:

Setting	Description
App integration name	You application name.
Logo	(Optional) Upload the Cribl logo. You can use a logo from the Cribl Press Kit.

Setting	Description
Sign-in redirect URIs	Your Leader base URL, and with `/api/v1/auth/authorization-code/callback` as the path.
Sign-out redirect URIs	(Optional) Append `/login` to the pre-filled path.

Assignments

5. In the **Assignments** pane, configure the access granted to Okta users:
    - To grant access to Cribl Stream to all Okta users, select **Allow everyone in your organization to access**.
    - To grant access to Cribl Stream to specific Okta groups, select **Limit access to selected groups**. Then, in the field below, add the groups you want to include.
      After you finish creating the app, if you need to add or remove groups, do that in the **Applications** > **Assignments** tab.
6. **Save** your application.

In the **Client Credentials** panel, note down **Client ID** and **Client Secret**. You will need them in the next step.

Submit Your App Info to Cribl

Next, provide Cribl with essential details about your application to implement the SSO setup on the Cribl side.

1. In Cribl Stream, in the sidebar, select **Settings**, then **Global**.
2. In **Access Management**, select **Authentication**.
3. From the **Type** dropdown, choose `OpenID Connect`.
4. In the **Provider name** dropdown, select `Okta`.
5. In the **Audience (Relying Party ID)** field, enter your Cribl Stream UI base URL.

If you have a Distributed deployment with a fallback Leader configured, modify the **Audience (Relying Party ID)** field to point to the load balancer instead of the Leader Node.

6. In the **Client ID** and **Client secret** fields, enter the respective values that you copied from the Okta **Client Credentials** in the previous step.
7. If your Cribl Stream is in Enterprise Distributed mode:
   In the **Scope** field, add the scope `groups` to the default space-separated list of scopes, so that it reads: `openid profile email groups`.

Get Okta App URLs

Next, get the `authentication`, `token`, `userinfo`, and `logout` URLs for your Okta app.

You can get them in JSON format from the `/.well-known/openid-configuration` endpoint: `https://<tenant>.okta.com/.well-known/openid-configuration` (`<tenant>` is your Okta tenant name). For example: `https://dev-12345678.okta.com/.well-known/openid-configuration`.

You can use a tool like jq to automatically extract the URLs from the endpoint's response with the following `curl` command:

```
curl -s https://<tenant>.okta.com/.well-known/openid-configuration | jq '. | {"a
```

Once you have the values, enter them in the respective fields in your Cribl Stream SSO configuration:

Cribl Stream field	Okta URL
Authentication URL	`authentication`
Token URL	`token`
User info URL	`userinfo`. Fill it in if you configured Okta to use groups.
Logout URL	`logout`. Fill it in if you want **Account** > **Log out** in Cribl Stream to log the user out globally. This means that when a user selects the **Accounts** > **Log out** link in Cribl Stream, they are logged out of both Cribl Stream and Okta.

Configure Response to Okta `/userinfo` Endpoint

An Okta tenant's user groups can be mastered either inside Okta, outside Okta, or both.

When Cribl Stream queries the `/userinfo` endpoint, Okta returns the appropriate groups membership of the user.

See the Okta documentation on dynamic allow lists and using Okta together with Active Directory.

To configure this behavior, you need to set **Groups claim type** correctly, depending on where user groups are mastered.

1. In Okta, go to your app and open the **Sign On** tab.
2. In the **OpenID Connect ID Token** panel, select **Edit**

Inside Okta | Outside Okta

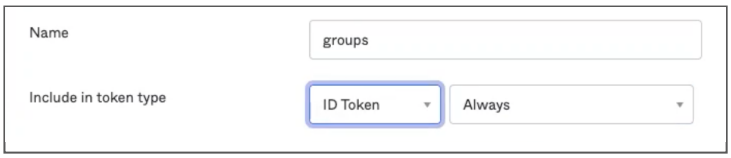
3. Set **Groups claim type** to `Filter`.
4. Choose **Matches regex** from the dropdown, and enter `.*` as the regex.

5. Click **Save**.

Configure ID Token to Include Groups Claim

For Okta to recognize your groups, you must configure the ID token to include your groups claim:

1. In Okta, open the **Security** > **API** page.
2. In the **Authorization Servers** tab, click the edit (pencil) button for the desired Authorization Server.
3. In the resulting page, select the **Claims** tab.
4. If your groups claim already exists, click the edit (pencil) button. Otherwise, click **Add Claim**.
5. In the **Include in token type** drop-downs, choose `ID Token` and `Always`, respectively.



Including the groups claim in the token ID

6. Configure the remaining settings in the way that suits your groups claim.
7. Click **Save** (or **Create** if you're adding the claim for the first time).

Map Okta Groups to Cribl Stream Roles

Mapping groups to Roles is possible only for Cribl Stream deployments that are in Distributed mode, with an Enterprise license. With a Standard license, all your external users will be imported to Cribl Stream in the `admin` role.

If you are running Cribl Stream in Single-instance mode, you cannot map Okta groups to Cribl Stream Roles, although you can still set up SSO with Okta.

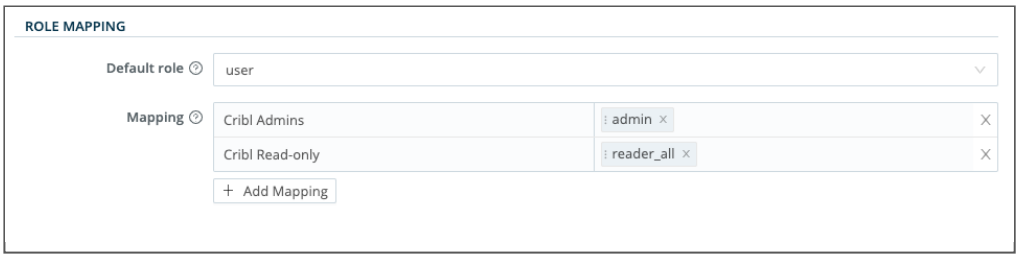
As you think through how best to map your Okta groups to Cribl Stream Roles, keep these principles in mind:

- An Okta group can map to more than one Cribl Stream Role.
- A Cribl Stream Role can map to more than one Okta group.
- If a user has multiple Roles, Cribl Stream applies the union of the most permissive levels of access.
- Cribl Stream automatically assigns the `default` Role to any user who has no mapped Roles.

For details on mapping your external identity provider's configured groups to corresponding Cribl Stream user access Roles, see External Groups and Roles.

You can assign a Cribl Stream Role to each Okta group name, and you can specify a `default` Role for users who are not in any groups.

1. In Cribl Stream, in the sidebar, select **Settings**, go to **Access Management** and then select **Authentication**.
2. Scroll down to **Role Mapping**.
   Cribl recommends that you set the `default` Role to `user`, meaning that this Role will be assigned to users who are not in any groups.
3. Add mappings as needed.
   The Okta group names in the left column are case-sensitive, and must match the values returned by Okta (those you saw earlier when configuring Okta and OIDC).



Example Role mapping

Verify that SSO with Okta Is Working

1. Log out of Cribl Stream, and verify that Okta is now an option on the login page.
2. Select **Log in with Okta**.
3. You should be redirected to Okta to authenticate yourself.
4. The OpenID connect flow should complete the authentication process.

Getting Temporary Access Credentials for AWS S3 Buckets

You can use your SSO/OIDC IDP to issue temporary access credentials so your on-prem Worker Node can access AWS S3 buckets.

Set the `AWS_WEB_IDENTITY_TOKEN_FILE` environment variable. This variable defines a path to a file that contains the OAuth/OIDC provided by the SSO IDP. You'll also need to define `AWS_ROLE_ARN` and `AWS_ROLE_SESSION_NAME`.

You can use curl/Postman to make the required API calls.

Ensure Fallback Access

To ensure fallback access for local users if SSO authentication fails, enable local authentication.

1. In the sidebar, select **Settings**, then **Global**.
2. In **Access Management**, select **Authentication**.
3. Toggle **Allow local auth** to **Yes** to allow users to log in using Cribl local authentication. This enables an extra button called `Log in with local user` on the login page.

To prevent lockout, Cribl strongly recommends enabling **Allow local auth** until you're certain that external auth is working as intended. If you do get locked out, see Manual Password Replacement.

OIDC/Okta Chiclet Setup (Optional)

If you want to initiate login from an Okta instance on which you have configured OIDC authentication, an Okta admin can configure an app integration as follows:

1. From Okta's left nav, select the **Applications** page.
2. Find the OIDC application created earlier in the OIDC/Okta Setup Example.
3. Select that application, and in the **General** tab's **General Settings** section, select **Edit**.
4. In the **Initiate login URI** field, enter the `<host>:<port>` of your Cribl Leader Node.
5. Confirm with **Save** to complete the chiclet.

10.6.2.2. SSO With Okta And SAML (On-Prem)

Cribl Stream supports setting up SSO using SAML to provide user authentication (login/password) and authorization (by mapping SSO users to Cribl Roles).

This page presents a walkthrough of setting up a SAML SSO, using Okta as the example.

This page is a guide for configuring SSO for an on-prem installation. For Cribl.Cloud, see SSO with Okta and SAML (Cribl.Cloud).

Create SAML 2.0 App Integration

To create your app integration:

1. In Okta, navigate to the **Applications** section and select **Create App Integration**.
2. In **Sign-in method**, select `SAML 2.0`.
3. Proceed with **Next**.

General Settings

4. Configure the app integration's **General Settings** with the options below:

Setting	Description
App integration name	You application name.
Logo	(Optional) Upload the Cribl logo. You can use a logo from the Cribl Press Kit.

SAML Settings

5. In the **Configure SAML** tab configure the following options:

Setting	Description
Single sign-on URL	Cribl Stream **Sign-on callback URL**.
Audience URI (SP Entity ID)	Cribl Stream **Audience (SP entity ID)**.

Setting	Description
Application username	A plain username, an email, or a custom username. In the SAML assertion's `subject` statement, this is the value for `NameID`. By default, this value will be the username in Cribl Stream. Alternatively, you can set a custom attribute statement in Okta, then set the **Username field** in Cribl Stream to use that instead.

6. Define custom **Attribute Statements** that Okta will insert in the SAML assertions shared with Cribl Stream. This applies only when creating a custom **Application username**, as described in the previous step.
7. Configure **Group Attribute Statements**. Similar to the previous step, except that here, Cribl Stream supports creating a custom attribute whose value is one or more Okta groups that will populate Cribl Stream's **Group name field**.
8. To check the SAML assertion in XML form, click **Preview the SAML Assertion**.
9. Skip thought the **Feedback** pane and **Save** your application.

Submit Your App Info to Cribl

Next, provide Cribl with essential details about your application to implement the SSO setup on the Cribl side.

1. In Cribl Stream, in the sidebar, select **Settings**, then **Global**.
2. In **Access Management**, select **Authentication**.
3. From the **Type** dropdown, choose `SAML 2.0`.
4. In the **Audience (SP entity ID)** field, enter the base URL of your Cribl Stream instance, for example, `https://yourDomain.com:9000`. Do **not** append a trailing slash.

If you have a Distributed deployment with a fallback Leader configured, modify the **Audience (SP entity ID)** field to point to the load balancer instead of the Leader Node.

5. Return to your Okta environment to the **Sign On** tab and in the right pane, select **View SAML setup instructions**. Use the provided fields to fill in the information in Cribl Stream:

Cribl Stream field	Okta field
Single sign-on (SSO) URL	Identity Provider Single Sign-On URL
Single logout (SLO) URL	Identity Provider Single Logout URL
Issuer (IDP entity ID)	Identity Provider Issuer
Response validation certificate	X.509 Certificate

Map Okta Groups to Cribl Stream Roles

Mapping groups to Roles is possible only for Cribl Stream deployments that are in Distributed mode, with an Enterprise license. With a Standard license, all your external users will be imported to Cribl Stream in the `admin` role.

If you are running Cribl Stream in Single-instance mode, you cannot map Okta groups to Cribl Stream Roles, although you can still set up SSO with Okta.

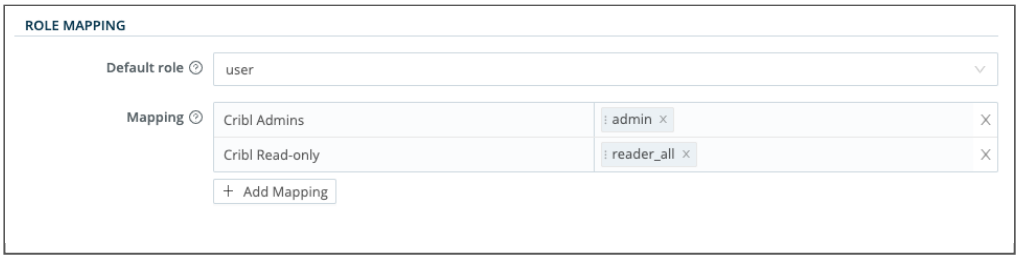
As you think through how best to map your Okta groups to Cribl Stream Roles, keep these principles in mind:

- An Okta group can map to more than one Cribl Stream Role.
- A Cribl Stream Role can map to more than one Okta group.
- If a user has multiple Roles, Cribl Stream applies the union of the most permissive levels of access.
- Cribl Stream automatically assigns the `default` Role to any user who has no mapped Roles.

For details on mapping your external identity provider's configured groups to corresponding Cribl Stream user access Roles, see External Groups and Roles.

You can assign a Cribl Stream Role to each Okta group name, and you can specify a `default` Role for users who are not in any groups.

1. In Cribl Stream, in the sidebar, select **Settings**, go to **Access Management** and then select **Authentication**.
2. Scroll down to **Role Mapping**.
   Cribl recommends that you set the `default` Role to `user`, meaning that this Role will be assigned to users who are not in any groups.
3. Add mappings as needed.
   The Okta group names in the left column are case-sensitive, and must match the values returned by Okta (those you saw earlier when configuring Okta and SAML).



Example Role mapping

Verify that SSO with Okta Is Working

1. Log out of Cribl Stream, and verify that Okta is now an option on the login page.
2. Select **Log in with Okta**.
3. You should be redirected to Okta to authenticate yourself.
4. The SAML connect flow should complete the authentication process.

Getting Temporary Access Credentials for AWS S3 Buckets

You can use your SSO/SAML IDP to issue temporary access credentials so your on-prem Worker Node can access AWS S3 buckets.

Call the `AssumeRoleWithSAML` API endpoint. It will return the STS access, secret, and session tokens. These can be written into the `~/.aws/` credentials file, which Cribl Stream will pick up because it uses the native AWS SDK.

You can set up multiple S3 Sources with different credentials. Cribl Stream relies on the AWS SDK for authentication support, and the SDK evaluates credentials in the following order:

1. Loaded from AWS Identity and Access Management (IAM) roles for Amazon EC2.
2. Loaded from the shared credentials file (~/.aws/credentials).
3. Loaded from environment variables.
4. Loaded from a JSON file on disk.
5. Other credential-provider classes provided by the JavaScript SDK.

To enable the use of multiple Sources, set the S3 Source **Authentication method** to **Auto**.

See the AWS SDK documentation and AWS CLI documentation for further information on setting credentials.

Ensure Fallback Access

To ensure fallback access for local users if SSO authentication fails, enable local authentication.

1. In the sidebar, select **Settings**, then **Global**.
2. In **Access Management**, select **Authentication**.

3. Toggle **Allow local auth** to **Yes** to allow users to log in using Cribl local authentication. This enables an extra button called `Log in with local user` on the login page.

To prevent lockout, Cribl strongly recommends enabling **Allow local auth** until you're certain that external auth is working as intended. If you do get locked out, see Manual Password Replacement.

SAML/Okta Chiclet Setup (Optional)

If you want to initiate login from an Okta instance on which you have configured SAML authentication, an Okta admin can configure an app integration as follows:

1. From Okta's left nav, select the **Applications** page.
2. Select **Browse App Catalog**.
3. From the resulting catalog, use the search bar to find and select the `Bookmark App` application.
4. From that application's page, select **Add Integration**.
5. On the **General settings** page, enter an **Application label** that will identify this app as supporting Cribl login. (`Cribl` is a good choice, but the label is arbitrary.)
6. In the **URL** field, enter the `<host>:<port>` of your Cribl Leader Node.
7. Confirm with **Done**.
8. Select **Assign** and assign all of the Cribl groups to the application.
9. The `Cribl` chiclet should now be available for all users in the Cribl groups you've assigned.

10.6.2.3. SSO With Microsoft Entra ID And SAML (On-Prem)

Cribl Stream supports setting up SSO using SAML to provide user authentication (login/password) and authorization (by mapping SSO users to Cribl Roles).

This page presents a walkthrough of setting up a SAML SSO, using Microsoft Entra ID (formerly Azure AD) as the example.

This page is a guide for configuring SSO for an on-prem installation. For Cribl.Cloud, see SSO with Microsoft Entra ID and SAML (Cribl.Cloud).

Create an Enterprise Application

To create your app integration:

1. In Microsoft Entra ID's top nav, select **Add**, then **Enterprise application**, then **Create your own application**.
2. Name your new app `Cribl` (or any name you prefer).
3. Select **Integrate any other application you don't find in the gallery (Non-gallery)**.
4. Confirm with **Create**.

Submit Your App Info to Cribl

Next, provide Cribl with essential details about your application to implement the SSO setup on the Cribl side.

1. In Cribl Stream, in the sidebar, select **Settings**, then **Global**.
2. In **Access Management**, select **Authentication**.
3. From the **Type** dropdown, choose `SAML 2.0`.
4. In the **Audience (SP entity ID)** field, enter the base URL of your Cribl Stream instance, for example, `https://yourDomain.com:9000`. Do **not** append a trailing slash.

If you have a Distributed deployment with a fallback Leader configured, modify the **Audience (SP entity ID)** field to point to the load balancer instead of the Leader Node.

5. Then fill in remaining information from the Entra ID's **SAML-based Sign-on** page:

Cribl Stream field	Entra ID field
Issuer (IDP entity ID)	Microsoft Entra Identifier
Single sign-on (SSO) URL	Login URL
Single logout (SLO) URL	Logout URL
Response validation certificate	Certificate (Base64) under **SAML Certificates**
Group name field	`http://schemas.microsoft.com/ws/2008/06/identity/claims/groups`

5. Select **Save** to complete your submission.

Configure Single Sign-On

From Microsoft Entra ID's left nav, under **Manage**, select **Single sign-on**, then **SAML**, to open the **SAML-based Sign-on** page. Then, edit the fields below with the information from the Cribl **Authentication** page:

1. In **Identifier (Entity ID)**, select **Add identifier** and enter the **Audience URI** value from the Cribl **Authentication** page.
2. In **Reply URL (Assertion Consumer Service URL)**, select **Add reply URL** and enter the **Sign-on callback URL** value from the Cribl **Authentication** page.
3. In **Logout Url (Optional)**, enter the **Logout callback URL** value from the Cribl **Authentication** page.

Map Entra ID Groups to Cribl Stream Roles

Mapping groups to Roles is possible only for Cribl Stream deployments that are in Distributed mode, with an Enterprise license. With a Standard license, all your external users will be imported to Cribl Stream in the `admin` role.

If you are running Cribl Stream in Single-instance mode, you cannot map Entra ID groups to Cribl Stream Roles, although you can still set up SSO with Entra ID.

As you think through how best to map your Entra ID groups to Cribl Stream Roles, keep these principles in mind:

- An Entra ID group can map to more than one Cribl Stream Role.
- A Cribl Stream Role can map to more than one Entra ID group.
- If a user has multiple Roles, Cribl Stream applies the union of the most permissive levels of access.

- Cribl Stream automatically assigns the `default` Role to any user who has no mapped Roles.

For details on mapping your external identity provider's configured groups to corresponding Cribl Stream user access Roles, see External Groups and Roles.

You can assign a Cribl Stream Role to each Entra ID group name, and you can specify a `default` Role for users who are not in any groups.

1. In Cribl Stream, in the sidebar, select **Settings**, go to **Access Management** and then select **Authentication**.
2. Scroll down to **Role Mapping**.
   Cribl recommends that you set the `default` Role to `user`, meaning that this Role will be assigned to users who are not in any groups.
3. Add mappings as needed.
   The Entra ID group names in the left column are case-sensitive, and must match the values returned by Entra ID .

Assign Groups

Now, map your Cribl groups to your Entra ID groups. From Microsoft Entra ID's left nav:

1. Select **Manage**, then **Users and groups**, then select **Add user/group**.
2. Add the Cribl groups you created above

You need to synchronize Microsoft Entra ID with your on-premises Active Directory to be able to configure returning `sAMAccountName` for group names. Otherwise, Entra ID will return only GUIDs.

For the groups claim configuration, select `Groups assigned to the application` for association and set **Source attribute** to `sAMAccountName`. Enable **Emit group name for cloud-only groups** to also return the `sAMAccountName` attribute for cloud-only groups.

Verify that SSO with Entra ID Is Working

1. Log out of Cribl Stream, and verify that Entra ID is now an option on the login page.
2. Select **Log in with Saml 2.0**.
3. You should be redirected to Entra ID to authenticate yourself.
4. The SAML connect flow should complete the authentication process.

Ensure Fallback Access

To ensure fallback access for local users if SSO authentication fails, enable local authentication.

1. In the sidebar, select **Settings**, then **Global**.
2. In **Access Management**, select **Authentication**.
3. Toggle **Allow local auth** to **Yes** to allow users to log in using Cribl local authentication. This enables an extra button called `Log in with local user` on the login page.

To prevent lockout, Cribl strongly recommends enabling **Allow local auth** until you're certain that external auth is working as intended. If you do get locked out, see Manual Password Replacement.

10.6.2.4. SSO With Microsoft Entra ID And OIDC (On-Prem)

Cribl Stream supports setting up SSO using OIDC to provide user authentication (login/password) and authorization (by mapping SSO users to Cribl Roles).

This page presents a walkthrough of setting up an OIDC SSO, using Microsoft Entra ID (formerly Azure AD) as the example.

Register Your Microsoft Entra ID App

1. Open the Microsoft Entra ID portal and log in.
2. In the left nav's **Manage** section, select **App registrations**.
3. Select **New registration** and provide a name for your app.
4. In **Supported account types**, select **Accounts in this organizational directory only (Default Directory only - Single tenant)**.
5. In **Redirect URI (optional)**, select **Web** and provide the appropriate callback URL for your own Cribl Stream Leader instance, for example:
   `https://yourDomain.com:9000/api/v1/auth/authorization-code/callback`

Create and Copy a Client Secret

Next, create a client secret:

1. From your app's left nav, select **Manage** > **Certificate & secrets**. Then select **New client secret**.
2. Add a new client secret with a descriptive name, and an expiration timeframe.
3. Confirm with **Add**.
4. Immediately copy the **Value** and **Secret ID** from the resulting page. You'll need to paste the **Value** into Cribl Stream's **Authentication** > **Client secret** field below.

This is the only time the secret is shown! Make sure you copy it while it's visible. (If you missed your chance, you can start over by creating a new secret.)

Configure Token and Claims

Here, you'll add the groups claim to the OIDC ID token.

1. From your app's left nav, select **Manage** > **Token configuration**, then select **Add groups claim**.

2. Under **Select group types to include in Access, ID, and SAML tokens**, select **Groups assigned to the application**.
3. Confirm with **Add**.

You need to synchronize Microsoft Entra ID with your on-premises Active Directory to be able to configure returning `sAMAccountName` for group names. Otherwise, Entra ID will return only GUIDs.

In the **Group claims** modal check **Emit group name for cloud-only groups** to ensure that `sAMAccountName` is added to the **Group** attribute.

Submit Your App Info to Cribl

Next, provide Cribl with essential details about your application to implement the SSO setup on the Cribl side.

1. In Cribl Stream, navigate to **Settings** > **Global**.
2. In **Access Management**, select **Authentication**.
3. From the **Type** dropdown, choose `OpenID Connect`.
4. In **Provider name**, enter an arbitrary identifier for this integration.
5. In the **Audience (Relying Party ID)** field, enter your Cribl Stream Leader's base URL. Do **not** append a trailing slash.

If you have a Distributed deployment with a fallback Leader configured, modify the **Audience (Relying Party ID)** field to point to the load balancer instead of the Leader Node.

6. Fill in the remaining fields:

Cribl Stream field	Entra ID field
Client ID	**Application (client) ID** from Entra ID app overview.
Client secret	The secret value your copied earlier.
Authentication URL	**OAuth 2.0 authorization endpoint (v2)** from Entra ID app overview > **Endpoints**.
Token URL	**OAuth 2.0 token endpoint (v2)** from Entra ID app overview > **Endpoints**.

7. If your Cribl Stream is in Enterprise Distributed mode:
   In the **Scope** field, add the scope `groups` to the default space-separated list of scopes, so that it reads: `openid profile email groups`.
8. Change the **Filter type** to `User info filter`.

v1 Endpoints

You can alternatively use v1 endpoints instead of v2. In that case, replace the values for **Authentication URL** and **Token URL** with their v1 equivalents from Entra ID. When using v1 endpoints, you also need to modify the default value for **User identifier**.

In v1 only the `name` field is included in the token by default, so an acceptable entry here might be: `` `${unique_name || upn || username || name}` ``. You can check the token fields returned by enabling debug-level logging on Cribl Stream's `auth:sso` channel.

Map Microsoft Entra ID Groups to Cribl Stream Roles

Next, map your Microsoft Entra ID groups to Cribl Stream Roles.

Unless you synchronize Entra ID with your on-premises Active Directory, the group names will appear as GUIDs. You can view the groups and their GUIDs on the Entra ID **Groups** page.

To map the groups:

1. In Entra ID, in the left nav's **Manage** section, select **Groups**.
2. Find the group you want to configure and copy its **Object Id**.
3. In Cribl Stream, go to **Global Settings**.
4. Under **Access Management**, select **Authentication**.
5. Under **Role Mapping**, under **Mapping**, paste the group's object ID.
6. In the right column, select the Cribl Role you want to assign to this group.
7. Repeat this for all groups you want to configure.
8. Confirm with **Save**.

Ensure Fallback Access

To ensure fallback access for local users if SSO authentication fails, enable local authentication.

1. In the sidebar, select **Settings**, then **Global**.
2. In **Access Management**, select **Authentication**.
3. Toggle **Allow local auth** to **Yes** to allow users to log in using Cribl local authentication. This enables an extra button called `Log in with local user` on the login page.

To prevent lockout, Cribl strongly recommends enabling **Allow local auth** until you're certain that external auth is working as intended. If you do get locked out, see Manual Password Replacement.

11. Securing

11.1. Secure Your Cribl.Cloud Deployment

Cribl.Cloud is SOC 2 Type II–certified and GDPR-compliant, simplifying compliance with industry standards and regulatory requirements. To secure your Cribl.Cloud deployment, consider implementing the following.

Secure Your Cribl.Cloud Account

Create a strong password during your initial setup.

To create a secure password, ensure it is at least 12 characters long and includes a combination of lowercase letters, uppercase letters, numbers, and special characters (!@#$%^&*). Follow the on-screen instructions carefully to meet these requirements.

(For Cribl.Cloud setup instructions, see Initial Cribl.Cloud Setup).

Review Your Network Settings

When you log into your Cribl.Cloud Organization, navigate to the **Workspace** link. Here you can check and manage connectivity details – Data Sources, Access Control, and Trust relationships – for your Cribl-managed Workers in Cribl.Cloud.

On the **Data Sources** tab, you can review the available ports and TLS configurations.

Note that TLS encryption is pre-enabled for you on some, but not all Sources. For more information, see TLS in Cribl.Cloud.

Configure TLS Mutual Authentication on Cribl.Cloud

Within Cribl.Cloud, enabling mutual TLS authentication for individual data sources requires a trusted Certificate Authority (CA) certificate chain. This CA certificate verifies the legitimacy of the client certificate presented by the source during connection. For details, see TLS Mutual Authentication in Cribl.Cloud.

Set Up Role-Based Access Control for Members

Cribl.Cloud offers detailed role-based access control (RBAC) to ensure appropriate permissions and security. For details on how to invite and manage the roles for Members of your Organization, see Managing

Cribl.Cloud.

Set Up Your Preferred Authentication Method

Cribl.Cloud with certain plan tiers offers a range of secure and convenient login options to fit your organization's needs. Options include:

- Local Accounts – Create traditional usernames and passwords for direct login. For details, see Local Authentication.
- Federated Authentication (OIDC and SAML): Integrate with existing identity providers (IdPs) like Okta or Entra ID for centralized user management and single sign-on (SSO). For details, see Cribl.Cloud SSO Setup.

Secure Data in Motion

Cribl.Cloud provides built-in encryption for data at rest, ensuring that your information remains secure within its infrastructure. For an extra layer of protection, you can enrypt individual fields within events. For details, see Data Encryption.

Currently, Cribl Stream supports decryption only when Splunk is the end system. For details, see Data Decryption.

For a comprehensive solution, we recommend configuring TLS. TLS encrypts the entire data stream, including all event fields, regardless of Source or Destination type. This provides a more robust security posture for your data in motion. For details, see Secure Cribl Stream Sources and Destinations with Certificates.

Configure a Key Management Service (KMS)

Cribl.Cloud with certain plan tiers offers a Key Management Service (KMS) that strengthens the security of your data. KMS securely manages the encryption keys used to protect sensitive information on Worker Groups and Nodes within Cribl. For details on how to activate and configure KMS, see KMS Configuration.

(Optional) Segment Your Organization with Workspaces

Segment your organization's data and user access using Workspaces. This multi-tenancy feature allows you to create isolated instances within your Cribl.Cloud Organization, addressing critical security, compliance, and data isolation requirements tailored for diverse business units.

Each Workspace boasts a dedicated virtual private cloud (VPC). This essentially creates a separate environment within your Organization for each Workspace, ensuring the complete isolation of data and users in different Workspaces.

For details, see Configuring Workspaces.

(Optional) Create Isolated Data Environments Using Stream Projects

Within Cribl Stream, Projects offer a more granular level of isolation allowing teams and users to manage and share data flows without impacting others. Projects enable you to define the data that the Project's users can consume, where that data can be sent, and who has access to the Project.

Projects are ideal for teams and users who need to share and manage specific data, with accelerated access to relevant data and minimal configuration requirements. Data can be forked into full-fidelity versus redacted views to match the authorzation requirements and needs of different teams or users.

For details, see Configuring Projects.

11.2. Secure Your On-Prem/Hybrid Deployment

This document outlines essential security considerations to safeguard your on-premises/hybrid Cribl deployment.

Secure Your Installation

Secure your Cribl Stream deployment by ensuring the following during installation.

Choose a Secure Environment

Protect your Cribl deployment by:

- **Isolating your deployment** – deploy Cribl Stream on a dedicated network segment to minimize exposure.
- **Restricting physical access** – control who can physically access the deployment hardware.

Configure a System Proxy

Enhance the security and reliability of your Cribl deployment by leveraging proxy servers.

- To configure a system proxy for outbound HTTP/S traffic: Set the HTTP_PROXY and HTTPS_PROXY environment variables before starting Cribl Stream, specifying the proxy's IP address or FQDN and optionally the port number. For details, see System Proxy Configuration.
- To configure a SOCKS proxy for secure communication between Leader and managed Nodes: Follow the steps in Configure a SOCKS proxy. This will allow you to bypass network restrictions and ensure uninterrupted data flow.

Create a Dedicated User

To enhance security, avoid running Cribl Stream with root privileges. Instead, create a dedicated user account with limited permissions.

For details, see Setting Capabilities for Cribl Stream or Running Edge as an Unprivileged User.

Change Default Admin Password

After your initial login, immediately create a strong, unique password for the administrator account. This will help prevent unauthorized access.

Note: Worker Node passwords are managed by the Leader Node.

Locate and Access Your Cribl Secrets

When you install Cribl Stream, the following security files are created:

- `cribl.secret` – This file stores a unique cryptographic key used for authentication, password encryption, and key encryption. It's essential for securing your Cribl Stream deployment when authenticating with integrated services.
- `keys.json` – This file contains cryptographic keys used for internal operations within Cribl Stream.

These files are stored in:

Single-instance deployment – both files are located in `$CRIBL_HOME/local/cribl/auth/`.

Distributed deployment – both files reside on the Leader Node, in `$CRIBL_HOME/groups/<group-name>/local/cribl/auth/`.

You can use the **Settings** > **Security** > **Secrets** section to create and update authorization tokens, username/password combinations, and API-key/secret-key combinations for reuse across the application. For details, see Secrets.

Set Your Remote Git Repo to Private

Cribl uses Git for efficient configuration management. In Distributed deployments, a local Git repository tracks configuration changes. For added security and disaster recovery, you can also connect to a remote Git repository. Here are some key considerations.

- **Private repositories** – Always ensure that your remote Git repository is private, to prevent unauthorized access to your configuration files.
- **Disaster recovery** – Remote repositories provide a valuable backup for your Cribl configuration in case of system failures or data loss.

FIPS Mode (Cribl Stream only)

Do not start Cribl Stream without FIPS mode enabled, or else you will be unable to run it in FIPS mode later. You must enable FIPS mode as described in the FIPS Mode document, after installing **but before starting** Cribl Stream.

Secure the Leader Auth Token

Cribl Stream generates a strong, random authentication token for new installations and when transitioning from Single-instance to Distributed mode.

If you need to change the default token:

- Create a unique, secure value.
- Update the token in the UI or Docker Compose file.

For details, see How to Secure the Auth Token for the Leader Node.

Set up Role-Based Access Control for Members

Cribl offers detailed role-based access control (RBAC) to ensure appropriate permissions and security. For details on how to define and manage fine-grained access control across Cribl products and resources, see Members and Permissions.

Enhance Security with an Identity Provider (IDP)

We strongly recommend using an external Identity Provider (IDP) to implement single sign-on (SSO) for Cribl. This enhances your organization's security, by centralizing user authentication and authorization.

For details, see:

- SSO with Okta and OIDC (on-prem)
- SSO with Okta and SAML
- SSO with Microsoft Entra ID and SAML (On-Prem)
- SSO with Microsoft Entra ID and OIDC (On-Prem)

Secure Your Communication

Secure your Cribl communication channels by using the following options.

- **SSL/TLS** – Encrypt Cribl access and traffic with SSL or TLS.
- **Custom headers** – Enhance security with custom HTTP headers.
- **Encryption** – Create and manage your own keys to encrypt events in real time.
- **Secrets** – Centrally manage secrets that your instances use to authenticate on integrated services.
- **KMS** – Use internal or external key management service for advanced key management.

Choose a combination that best aligns with your organization's security policies.

Secure Access to the Leader and Worker Nodes

You can secure access to the Cribl Edge API and UI by configuring Secure Sockets Layer (SSL) or Transport Layer Security (TLS). Do this on the Leader, to secure inbound communications to the Edge Nodes. You can use your own certs and private keys, or you can generate a pair with OpenSSL. For details, see Configure TLS for API and UI Access.

For TLS details, see the following:

- TLS version support and defaults
- TLS settings and Traffic Types
- System-wide TLS Settings Including Ciphers

Import an Existing Certificate and Key

You can secure Leader-to-Worker Node communications by using an existing TLS/SSL certificate and key, in `\.pem\` format. For details, see Import Certificate and Key.

Create a Self-signed Certificate

You also have the option to create a self-signed certificate and key by following the steps outlined in Configure SSL.

Connect to the Leader Securely

Configure secure communication between your Leader and Edge Nodes using either the user interface, the `instance.yml` configuration file, or environment variables. For details, see Secure Leader/Worker Nodes Communications.

Secure Access to the Worker/Edge Nodes UI

Cribl recommends that in Enterprise Distributed deployments, you prevent direct browser access to the UI for all Worker Nodes. For details, see Secure Access to Worker Node UIs.

Configure TLS Mutual Authentication (optional)

Implement client certificate exchange to enhance security by allowing only authorized clients with valid certificates to connect to the Leader. Configure this feature after setting up encrypted TLS communication. For details, see Configuring TLS Mutual Authentication.

Secure Communication Between Sources and Destinations

To authenticate Cribl Stream with external data senders and receivers, configure certificates at the Worker Group level. For details, see Secure Cribl Stream Sources and Destinations with Certificates.

Configure Custom HTTP Headers

Custom HTTP headers are metadata that can be sent along with HTTP requests and responses. They provide a way to convey extra data that is not part of the standard HTTP protocol. You can customize Cribl's security settings with custom HTTP headers. For details, see Custom HTTP Headers.

Create Encryption Keys

You can create and manage keys that Cribl Stream will use for real-time encryption of fields and patterns within events. For details, see:

- Accessing Keys
- Add New Key
- Get Key Bundle
- Safeguarding Unencrypted Private Key Files for Rollback.
- Restoring Unencrypted Private Keys

Configure a Key Management Service (KMS)

Cribl offers a built-in Key Management Service (KMS) that strengthens the security of your data. With certain license tiers, you have the option to integrate an external KMS. A KMS securely manages the encryption keys used to protect sensitive information on Worker Groups and Worker Nodes within Cribl Stream.

For details, see Configure KMS.

Create Secrets

Use the Cribl secrets store to isolate and simplify the management of authentication tokens, usernames/passwords, and API keys.

- To find out more about secrets, see The cribl.secret File.
- To access secrets, see Accessing Secrets.

- To add a new secret, see Add New Secret..
- For secret types, see Secret Type.

Secure Data in Motion

For an extra layer of protection, consider encrypting your data while it travels between Cribl Stream and your data Sources and Destinations. For details, see Data Encryption.

Currently, Cribl Stream supports decryption only when Splunk is the end system. For details, see Data Decryption.

For a comprehensive solution, we recommend configuring TLS. TLS encrypts the entire data stream, including all event fields, regardless of Source or Destination type. This provides a more robust security posture for your data in motion. For details, see Secure Cribl Stream Sources and Destinations with Certificates.

Disable the Exec Source

The Exec Source, while powerful, can pose security risks if not configured and used carefully. To mitigate these risks, you can disable the Exec source by setting the `CRIBL_NOEXEC` environment variable. This prevents the execution of arbitrary commands, reducing the attack surface. For details, see Disable the Exec Source.

11.3. Secure Leader/Worker Nodes Communication

You can configure secure communication between your Leader and Worker Nodes. As an additional security measure, we recommend you prevent direct browser access to the UI for all Worker Nodes.

Secure Browser Access to Worker Node

Cribl recommends that in enterprise distributed deployments, you prevent direct browser access to the UI for all Worker Nodes.

On the Leader Node, start by enabling UI access to Worker Nodes (Stream, Edge). This way, admins will still be able to tunnel through from the Leader to the UI on any Worker Node. This is also a prerequisite for Connect to the Leader Securely described below.

1. Select a Worker Group.
2. Open **Group Settings** (top right).
3. Under **General Settings** > **API Server Settings**, select **Advanced**.
4. Toggle **Local UI access** to `No`.
5. Select **Save**.

Connect to the Leader Securely

You can configure secure communication between your Leader and Worker Nodes using the UI, the `instance.yml` config file, or environment variables.

Secure via the UI

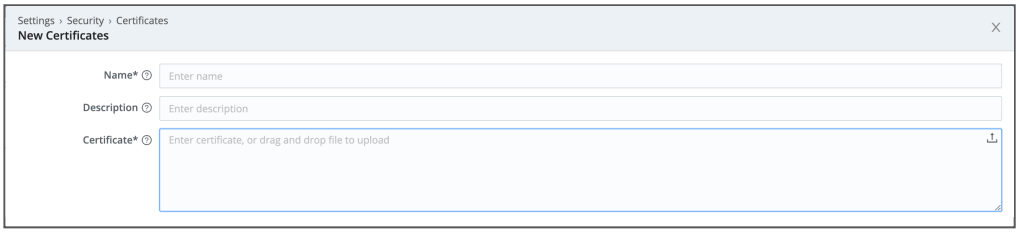
To set up secure communication via the UI, you configure first the Worker Group, then the Worker Node, then the Leader.

Worker Group Setup

For each Worker Group whose Worker Nodes you want to secure:

1. Open your TLS/SSL certificate file, and copy its contents to your clipboard. (This can be the same certificate you uploaded to the Leader, or a different certificate.)
2. In the sidebar, select **Worker Groups**, and then select the Worker Group you want to configure.

3. Select **Group Settings** or **Fleet Settings** (upper right).
4. Select **Security** > **Certificates** > **TLS**.
5. Click **Add Certificate**.
6. In the **New Certificates** modal, add the certificate's contents to the **Certificate** field.
   (You can paste the file's contents, or you can drag/drop or upload the `.pem` file.)
7. As you did on the Leader, also insert your **Private key**, and (as needed) your **Passphrase** and **CA certificate**.
8. Click **Save**.
9. Commit and Deploy the Worker Group's new configuration, including the new certificate.
10. Repeat the preceding steps on each Worker Group.

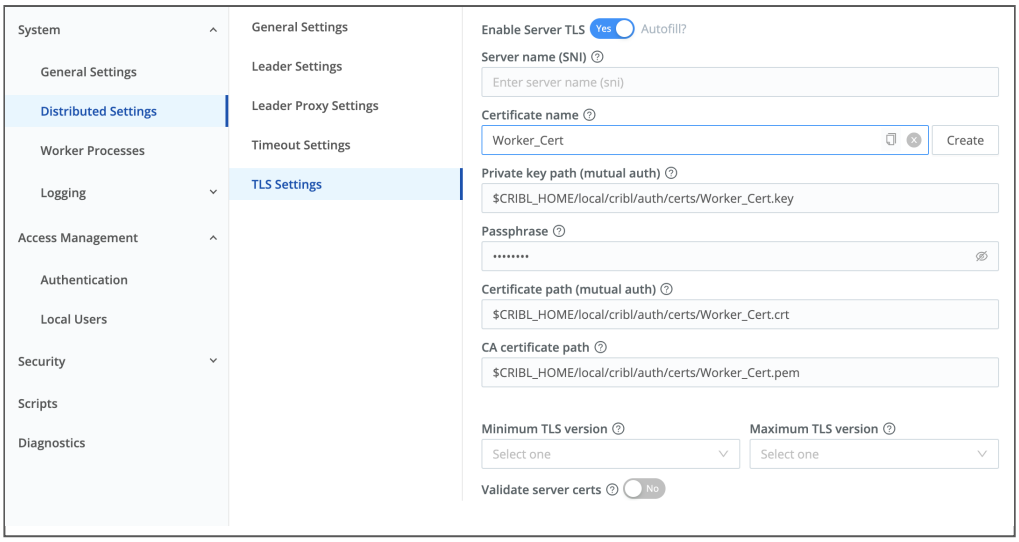


Worker Group-level certificates are configured like the Leader's certificate

Worker Node Setup

For each Worker Node that you want to secure:

1. Enable the Leader's UI access to each desired Worker Node (Stream, Edge).
2. Tunnel through from the Leader to the Worker Node's UI.
3. Navigate to this Worker Node's **Worker Settings** (upper right) > **System** > **Distributed Settings** > **TLS Settings**.
4. Toggle **Enable Server TLS** to `Yes`.
   This will expose the remaining TLS settings.
5. From the **Certificate name** drop-down, select the certificate you uploaded to the parent Worker Group.
   This will prefill all the required fields. (See all deployed certificates at the left nav's **Security** > **Certificates** link.)
6. Click **Save**.
   The Worker will be unavailable during a short lag, while it restarts with the new configuration.
7. Repeat the preceding steps on each Worker Node.



Configuring TLS on Worker Node's UI, from the Leader

Leader Setup

Next, return to the Leader's UI:

1. Select **Settings** > **Global** > **System** > **Distributed Settings** > **TLS Settings**.
2. Toggle **Enable server TLS** to `Yes`.
3. In the **Certificate name** drop-down, select an existing certificate. This will auto-populate the corresponding certificate fields.
4. Click **Save**.

After you've enabled TLS on the Leader, generating bootstrap scripts to add or update Worker Nodes will automatically prepend `https://` to the Leader's URL.

Secure via the YAML Config File

You can also configure the Leader's `$CRIBL_HOME/local/_system/instance.yml` file to ensure that TLS is enabled. Here's the relevant section:

```
distributed:
  mode: managed-edge
  master:
    host: <hostname>
    port: 4200
    authToken: <token>
    tls:
      disabled: false
      rejectUnauthorized: false
      requestCert: false
    resiliency: none
  group: default_fleet
```

After you've enabled TLS on the Leader, generating bootstrap scripts to add or update Worker Nodes will automatically prepend `https://` to the Leader's URL.

Secure via Environment Variables

Another way to set up secure communications between Worker Nodes and the Leader is via environment variables (Stream, Edge).

If you deploy your Worker Nodes in a container, you can enable encrypted TLS communications with the Leader by configuring the `CRIBL_DIST_MASTER_URL` with the `tls:` protocol. This will override the default setting in `instance.yml`. Here's the format:

```
CRIBL_DIST_LEADER_URL=tls://<authToken>@leader:4200
```

Secure the Leader Node

This is a best practice that enables the Leader to validate itself to clients. We can secure it using the self-signed certificate we created in Configure SSL Certificates:

1. Navigate to **Settings** > **Global** > **General Settings** > **API Server Settings** > **TLS**.
2. Slide the toggle to **Enabled**.
3. From the **Certificate Name** drop-down, select a cert you've previously imported. This will populate the corresponding fields here.
4. Click **Save**.

After this save, you must prepend `https://` to all Cribl Stream URLs on the Leader Node. E.g., to get back to the Settings page you just configured, you'll now need to use `https://<hostname>:<port>/settings/system)`.

11.3.1. How To Secure The Auth Token For The Leader Node

For new installations, the Cribl Stream Leader generates its own secure, random auth token. The Leader also creates a new token when you switch from Single-instance to the Distributed mode by configuring a Node to be a Leader Node.

In versions before v4.5.0, the default token was `criblmaster`. This default auth token does not change automatically if you upgrade your deployment to v4.5.0 or later.

If you need to change your auth token (for example, you prefer to use your own token or you are still using the older default of `criblmaster`), change the token value to a unique secure value.

This applies whether you configure your Leader via the UI, or via a Docker Compose file.

High Availability (Failover) Mode

Beginning in Cribl Stream 4.7, the auth token information that is stored in the `leader.yml` file on the failover volume will take precedence over the auth token stored in the local `instance.yml` file. This way, a single token is shared between primary and any standby Leaders.

Before 4.7, there is no `leader.yml` file; instead, the auth token is in the `instance.yml` file only. Whenever you change an auth token, you must update it to be identical on all Leaders. See Configuring Additional Leader Nodes in the failover topic.

Change the Auth Token Value

Changing the auth token once you have Worker Nodes deployed will break communication between the Nodes and the Leader. If you do change the auth token value, make sure that you update the auth tokens for the Leader and the Worker Nodes to the same value.

Create a unique token value with strong security. We recommend creating a string that contains at least 14 characters and includes uppercase letters, lowercase letters, and numbers.

Allowed Characters in the Leader Auth Token

Starting in version 4.6.1, these are the only allowed characters you can use in the auth token for your Cribl Stream Leader:

- a-z: Lowercase letters from a to z.
- A-Z: Uppercase letters from A to Z.
- 0-9: Digits from 0 to 9.
- _: Underscore.
- !: Exclamation mark.
- -: Hyphen (dash).

In version 4.5.1 and newer, you *can't* use these special characters in the Leader auth token:

- <: Open angle bracket.
- >: Close angle bracket.
- ": Double quotation mark.
- {: Open brace.
- }: Close brace.
- |: Pipe.
- \: Backslash.
- ^: Caret.
- ': Single quotation mark.
- `: Backtick.
- Whitespace

One option is to generate a token value with a shell command. For example, on Linux or Mac OS, the following command generates a 32-character value:

```
head /dev/urandom | LC_ALL=C tr -dc A-Za-z0-9 | head -c32 | cut -c 1-
```

Once you have created a secure auth token value, you can change it:

- In the **Auth token** field in the UI.
- In the appropriate place in your Docker Compose file (if applicable).
- For the Leader via command line: `./cribl mode-master -u <token>`. If your Cribl Stream deployment uses High Availability (HA), you must use the command line (not the UI) with the command listed above.
- For the Worker Nodes via command line:
  - `./cribl mode-managed-edge -u <token>` for Cribl Edge.
  - `./cribl mode-worker -u <token>` for Cribl Stream.

Running either of the commands resets all the related options. This means that, in addition to the token, you must provide the command with the current values of all the other arguments.

You can find the **Auth token** setting by navigating to **Settings** > **Global** > **System** > **Distributed Settings** > **Leader Settings**.

11.3.2. TLS Defaults And System-Wide Settings

Cribl Stream prioritizes secure communication by default. This ensures the integrity and confidentiality of data transmitted between your Cribl Stream instance and various Sources and Destinations.

TLS Version Support and Defaults

The minimum supported TLS version in Cribl Stream is `TLS 1.2` by default. This default applies to all secure connections, including supported Sources and Destinations, Worker/Leader communications, and Cribl.Cloud.

Cribl.Cloud and on-prem deployments use the same TLS settings, with `TLS 1.2` being the default minimum version.

You can check whether a Source or Destination supports TLS by reviewing the information box at the beginning of its corresponding documentation page.

TLS Settings and Traffic Types

This table shows TLS client/server pairs, and encryption defaults, per traffic type.

Traffic Type	TLS Client	TLS Server	Encryption	Cert Auth	CN* Check
UI	Browser	Cribl Stream	Default disabled	Default disabled	Default disabled
API	Worker/Edge Node	Leader	Default disabled	Default disabled	Default disabled
Worker-to-Leader	Worker/Edge Node	Leader	Default disabled	Default disabled	Default disabled
Data	Any data sender	Cribl Stream (Source)	Default disabled	Default disabled	Default disabled
Data	Cribl Stream (Destination)	Any data receiver	Default disabled	Default disabled	Default disabled
Authentication	—————	—————	—————	—————	—————
Local*	Browser	Cribl Stream	Default Disabled	N/A	N/A

Traffic Type	TLS Client	TLS Server	Encryption	Cert Auth	CN* Check
LDAP*	Cribl Stream	LDAP Provider	Custom	N/A	Default Disabled
Splunk*	Cribl Stream	Splunk Search Head	Default Enabled	N/A	Default Disabled
OIDC†/Okta*	Browser and Cribl Stream	Okta	Default Enabled	N/A	Enabled (Browser)
OIDC†/Google*	Browser and Cribl Stream	Google	Default Enabled	N/A	Enabled (Browser)

** Common name*
† OpenID Connect

System-wide TLS Settings Including Ciphers

You can configure advanced, system-wide TLS settings – minimum and maximum TLS versions, default cipher lists, and ECDH curve names. Select **Settings** > **Global** > **System > General Settings > Default TLS Settings**.

In the **Default cipher list** field, you can specify one or more ciphers from the following list:

- `ECDHE-RSA-AES128-GCM-SHA256`
- `ECDHE-ECDSA-AES128-GCM-SHA256`
- `ECDHE-RSA-AES256-GCM-SHA384`
- `ECDHE-ECDSA-AES256-GCM-SHA384`
- `DHE-RSA-AES128-GCM-SHA256`
- `ECDHE-RSA-AES128-SHA256`
- `DHE-RSA-AES128-SHA256`
- `ECDHE-RSA-AES256-SHA384`
- `DHE-RSA-AES256-SHA384`
- `ECDHE-RSA-AES256-SHA256`
- `DHE-RSA-AES256-SHA256`
- `HIGH`
- `!aNULL`
- `!eNULL`
- `!EXPORT`

- `!DES`
- `!RC4`
- `!MD5`
- `!PSK`
- `!SRP`
- `!CAMELLIA`

CA Certificates and Environment Variables

For any Cribl Stream Source or Destination that supports TLS, you can configure a **CA Certificate Path** field that points to a Certificate Authority (CA) `.pem` file(s). However, you can also use environment variables to manage CAs globally. Here are some common scenarios:

- **Add a set of trusted root CAs to the list of trusted CAs that Cribl Stream trusts**
  Set this environment variable for each Worker Node (for example, in its systemd unit file): `NODE_EXTRA_CA_CERTS=/path/to/file_with_certs.pem`. For details, see the nodejs docs.
- **Configure Cribl Stream to accept all TLS certificates, regardless of their validity**
  Set this environment variable: `NODE_TLS_REJECT_UNAUTHORIZED=0` – for details, see the nodejs docs.

Global CA Certificates and Sources

While Cribl Stream supports using environment variables like `NODE_EXTRA_CA_CERTS` to add trusted root CAs globally, this approach is not applicable to all Sources. Some Sources, such as the Windows Events Fowarder (WEF), require a specific CA certificate configured at the Source level to function correctly.

Additionally, OS certificate stores accessed through Node.js boot flags (such as `--use-bundled-ca`, `--use-openssl-ca`) are not supported by Cribl Stream. These flags are stripped during application startup.

In summary, certain Sources, like the WEF, exclusively rely on the specific CA certificate configured within the Source itself.

11.3.3. Securing Cribl.Cloud With TLS And Mutual TLS

Cribl.Cloud prioritizes secure data transfer with pre-enabled TLS on many sources. This guide details configuring TLS and enabling mutual TLS (mTLS) for additional sources.

For detailed instructions on configuring certificates to send Palo Alto logs to Cribl.Cloud via Syslog, refer to the guide: Palo Alto Syslog to Cribl.Cloud.

TLS in Cribl.Cloud

TLS encryption is pre-enabled on several Sources in Cribl.Cloud, as indicated on the **Data Sources** tab of the Cribl.Cloud portal. All TLS is terminated by individual Nodes.

If you enable TLS for additional Sources, the UI will autofill these configuration settings:

- **Private key path:** `<path-to-certificates>/$CRIBL_CLOUD_KEY`
- **Certificate path**: `<path-to-certificates>/$CRIBL_CLOUD_CRT`
- **Minimum TLS version**: `TLSv1.2` – the default; you can select a different version from the drop-down

The Cribl.Cloud Leader connections on port `4200/tcp` do not currently support mutual TLS (mTLS).

Enable mTLS Authentication on Cribl.Cloud

In Cribl.Cloud, you configure mTLS authentication separately for each Source.

This requires a CA certificate chain that can validate the client certificate used for authentication. You add your CA certificate by creating a new certificate entry in Cribl.Cloud.

1. Prepare the CA certificate chain PEM file.
2. Go to the Worker Node: **Settings** > **Global** > **Security** > **Certificates** and select **Add Certificate**.
3. Populate the **Certificate** field with any valid PEM-formatted content:

```
-----BEGIN CERTIFICATE-----
CERTIFICATE CONTENT
-----END CERTIFICATE-----
```

The certificate and key are required only for UI validation and are not used otherwise.

4. Populate the **Private key** with the key in PEM format:

```
-----BEGIN RSA PRIVATE KEY-----
HIDDEN PRIVATE KEY
-----END RSA PRIVATE KEY-----
```

5. In the **CA certificate** field, enter your PEM-formatted certificate and save. This will generate the CA certificate path.
6. Edit the certificate again to view the certificate path and copy it.
7. Go to the Source where you want to enable mTLS and paste the path in the **CA certificate path** field.
8. Save, commit, and deploy to finish the process.

11.3.4. Configure MTLS Authentication On-Prem

Once you have configured the Leader for encrypted TLS communication, you can implement client certificate exchange to enable mutual authentication (mTLS). This allows Cribl Stream to permit only explicitly authorized clients, which hold valid certificates, to connect to the Leader.

When a client certificate is presented to a Leader, two things happen:

1. The Leader validates the client certificate presented to Cribl Stream. The `Validate Client Certs` setting is optional, but highly recommended. When enabled, the Leader checks the certificate against the trust store, to see if it has been signed by a valid certificate authority (CA).

The Leader checks the list of certificates in the `CA Certificates Path` box first (if populated), then against the list of built-in system certificates.

2. The Leader checks whether the `Common Name` (CN) matches the regular expression in the configuration. Cribl Stream's default is to accept any value in the `Common Name` field. You can customize this as needed.

Within the `Common Name`, we validate against the value after the `CN=string`. If your `Common Name` is `CN=logstream.worker`, you would enter `logstream\.worker` in the `Common Name` field – including the backslash, because the value entered is a regular expression.

The Cribl.Cloud Leader connections on port `4200/tcp` do not currently support mutual TLS (mTLS).

Limitations on mTLS Authentication

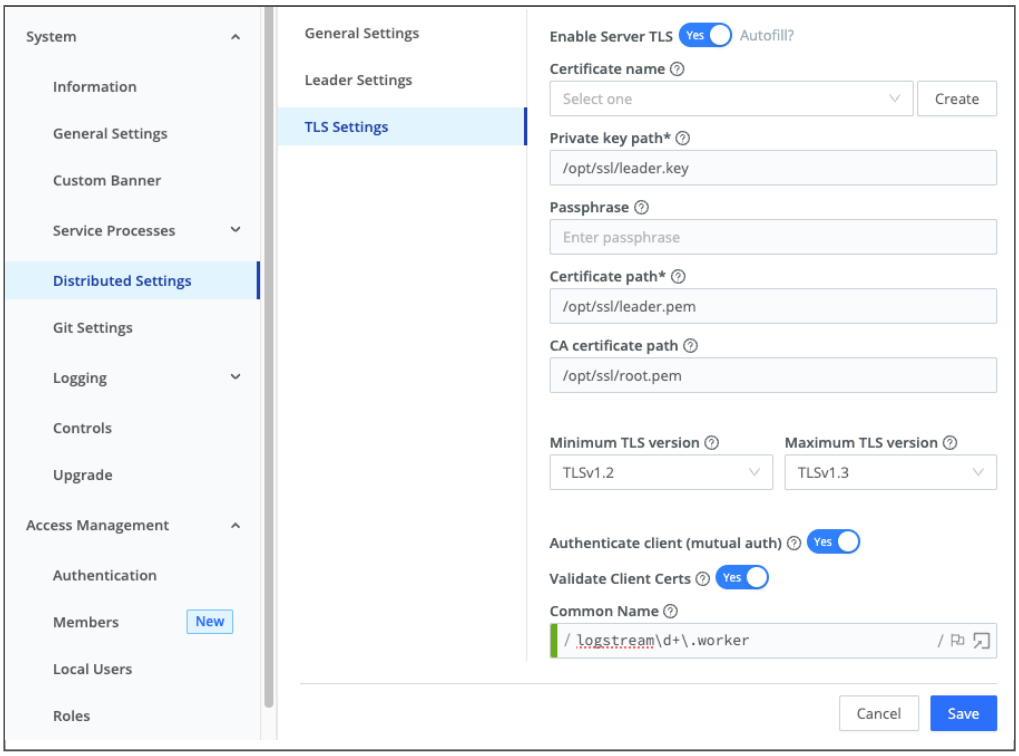
When configuring mTLS authentication on Worker Nodes, make sure you place your certificates into a separate directory outside of `$CRIBL_HOME`. If you place the certificates inside `$CRIBL_HOME`, they'll be removed when the next config bundle is deployed from the Leader.

Similarly, you can't bootstrap Worker Nodes with mutual authentication already populated. To bootstrap Worker Nodes, you supply only the shared authentication token. Certificates should be viewed as two-factor authentication; so placing the certificates in the config bundle defeats the purpose of two-factor authentication.

Configure via the UI

mTLS authentication in Cribl.Cloud is configured separately for each Source.

Below is a sample configuration on the Leader:



Configuring mutual authentication

In the above configuration, note:

- You can set both the **Minimum TLS version** and **Maximum TLS version**.
- The `Common Name` regex contains an additional check for `\d+`. This allows checking for the format: `logstream1.worker`, `logstream2.worker`, `logstream3.worker`, etc.

Using YAML Config File

To set up mTLS authentication via the Worker Node's `instance.yml` config file, you need to change some values and also add a few keys, as shown in this example:

```
distributed:
  mode: managed-edge
  master:
    host: <hostname>
    port: 4200
    authToken: <token>
    tls:
      disabled: false
      rejectUnauthorized: true # false if ignoring untrusted certs
      requestCert: true
      privKeyPath: /path/to/certs/worker.key
      certPath: /path/to/certs/worker.pem
      caPath: /path/to/certs/root.pem
    resiliency: none
  group: default_fleet
```

Using Environment Variables

You can set up mTLS authentication by configuring this environment variable, using the format shown in this example:

```
CRIBL_DIST_Master_URL="tls://<authToken>@leader.cribl:4200?tls.privKeyPath=/path/to/
```

Once you've set this variable, restart the Worker Node. You should see the Worker Node successfully reconnect to the Leader.

If the Worker Node doesn't connect, check `cribl.log` on both the Worker Node and Leader for more context about the problem. You should see errors related to `dist leader communications`.

To build your own Certificate Authority (a self-signed CA), see our blog post on How to Secure Cribl Stream Worker-to-Leader Communications.

11.3.5. Secure Leader Using An Existing TLS/SSL Certificate And Key

This page outlines how to protect Cribl Stream Leader to Worker Nodes communications, using an existing TLS/SSL certificate and key.

Cribl Stream expects certificates and keys to be formatted in privacy-enhanced mail (`.pem`) format.
To generate a self-signed certificate and corresponding key, see Securing Cribl Stream.

Import Certificate and Key

To use your certificate and key to prepare secure communications between Workers/Edge Nodes and the Leader:

1. Navigate to the Leader's **Settings** > **Globals** > **Security** > **Certificates** > **New Certificates** modal.
2. Open your TLS/SSL certificate file. (The self-signed certificate example in Configure TLS for API and UI Access used the placeholder name `myCert.pem`.)
3. Copy the file's contents to your clipboard.
4. Paste the file's contents into the modal's **Certificate** field.

You can skip the preceding three steps: Just drag/drop your `.pem` file from your filesystem into the **Certificate** field, or upload it using the button at the field's upper right.

5. Open your private key file. (The self-signed certificate example in Configure TLS for API and UI Access used the placeholder name `myKey.pem`.)
6. Copy the file's contents to your clipboard.
7. Paste the clipboard contents into the same Leader modal's **Private key** field.

Here again, you can skip the preceding three steps by dragging/dropping or uploading the `.pem` file from your filesystem.

8. Fill in the **Name** and **Description** fields.
9. If you've uploaded a self-signed certificate, just **Save** it now.
10. If your private key is encrypted, fill in the modal's **Passphrase** with the corresponding key. (You can paste the key's contents, or you can drag/drop or upload the key file.)
11. If you're uploading a certificate signed by an external certificate authority – For example, a downloaded Splunk Cloud certificate – import the chain into the **CA certificate** field before saving the certifcate. For

details, see Obtain the Certificate Chain (TLS/SSL).

11.3.6. Configure TLS For API And UI Access

To safeguard inbound communications to your Worker Nodes, configure Transport Layer Security (TLS) on the Leader. This will enable secure access to the Cribl Stream API and UI.

In Cribl Stream v.4.1 and newer, for enhanced security, Cribl encrypts TLS certificate private keys in configuration files when you add or modify them. Before upgrading to v.4.1.0 (or newer), back up your existing unencrypted key files – see Safeguarding Unencrypted Private Keys for Rollback. If you need to roll back to a pre-4.1 version, see Restore Unencrypted Private Keys below.

You can use your own certificates and private keys, or you can generate a pair with OpenSSL, as shown here:

```
openssl req -nodes -new -x509 -newkey rsa:2048 -keyout myKey.pem -out myCert.pem -days 420
```

This example command will generate both a self-signed cert `myCert.pem` (certified for 420 days), and an unencrypted, 2048-bit RSA private key `myKey.pem`. (Change the filename arguments to modify these placeholder names.)

As indicated by these examples, Cribl Stream expects certificates and keys to be formatted in privacy-enhanced mail (`.pem`) format.

In the Cribl Stream UI, you configure the certificate and its associated private key differently depending on your deployment type:

- For Single-instance deployments, navigate to **Settings** > **Globals** > **Security** > **Certificates** (Edge, Stream).
- For Distributed deployments, navigate to a Worker Group and select **Worker Group Settings** > **Security** > **Certificates** (Edge, Stream).

Alternatively, in the `local/cribl.yml` file, you can edit the `api` section to directly set the `privKeyPath` and `certPath` attributes. For example:

cribl.yml

```
api:
  host: 0.0.0.0
  port: 9000
  disabled : false
  ssl:
    disabled: false
    privKeyPath: /path/to/myKey.pem
    certPath: /path/to/myCert.pem
...
```

See Secure Leader/Worker Nodes Communication for details about using this certificate and key to secure communications on, and among, your Cribl Stream Leader and Worker Nodes.

Restore Unencrypted Private Keys

If you need to roll back from Cribl Stream v.4.1 or later to an earlier version, follow this procedure to restore the unencrypted private key files that you backed up earlier.

1. Stop Cribl Stream v.4.1 (or later) on hosts – the Leader and all Worker Nodes.
2. Untar the older Cribl Stream version (v.4.0.4, for example) onto the Leader and all Worker Nodes.
3. Manually edit each Cribl Stream config file that contains an encrypted private key. Replace each key with its prior unencrypted version.
4. Start up Cribl Stream, commit and deploy, and resume normal operations.

11.3.7. Secure Cribl Stream Sources And Destinations With Certificates

You can use certificates and custom HTTP headers to authenticate Cribl Stream with external Sources and Destinations, enhancing the security of your data pipelines.

Setting Authentication on Sources/Destinations

You can use certificates to authenticate Cribl Stream to external data senders and receivers. In the Cribl Stream UI, you configure the certificate and its associated private key differently depending on your deployment type:

- For Single-instance deployments, navigate to **Settings** > **Security** > **Certificates** (Edge, Stream). Next, select **Add Certificate**.
- For Distributed deployments, navigate to a Worker Group and select **Worker Group Settings** > **Security** > **Certificates** (Edge, Stream). Next, select **Add Certificate**.
- On Cribl.Cloud, navigate to **Settings** > **Global** > **Security** > **Certificates**.

As an alternative to the preconfiguration in steps 1–4 below, you can import a certificate on the fly, using the Source's or Destination's **Create** button.

In the **New Cerfificates** modal:

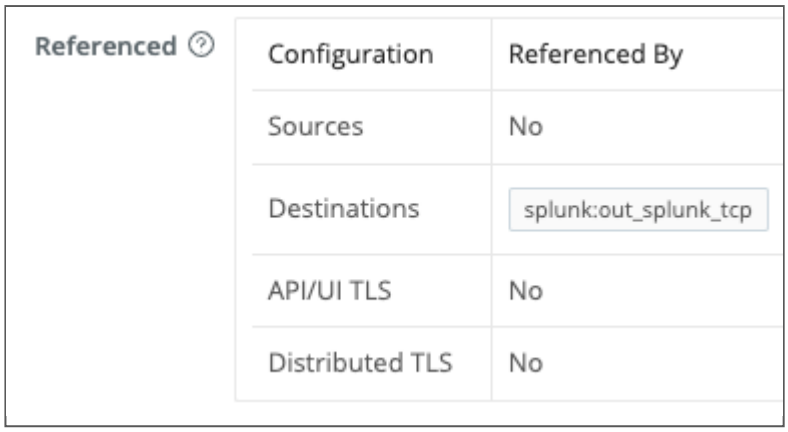
1. Paste or upload `.pem` files, according to the instructions in Import Certificate and Key.
2. Supply a **Passphrase** and/or **CA certificate**, if required by your integration partner's certificate.
3. Click **Save**.
4. Open your relevant Source's or Destination's config modal.
5. Select **TLS Settings (Client Side)** or **TLS Settings (Server Side)**, depending on the integration.
6. Toggle **Enabled** on.
7. In the **Certificate name** drop-down, select a certificate that you've preconfigured for this integration. (This will auto-populate the corresponding fields here.)

   Or, if you're creating a new certificate, instead click the adjacent **Create** button.

1. Click **Save**.

Cribl Stream will create new certificates at the same Worker Group level that you're configuring. You can verify this at the bottom of the **Create new certificate** modal, by making sure that the **Referenced** table

includes rows for poulated for the appropriate **Sources** and **Destinations**.



Group-level certificate modal

Certificate revocation can lead to unexpected service interruptions. To mitigate risks:

- To minimize impact, regularly review and renew certificates.
- Implement robust monitoring and alerting systems to detect potential issues.
- Ensure secure storage of certificates and private keys.
- In case of emergency, have a well-defined recovery plan to restore service quickly.

Custom HTTP Headers

You can also encode custom, security-related HTTP headers as needed. In a Distributed deployment, navigate to Worker Group Settings, then **API Server Settings** > **Advanced** > **HTTP Headers**. (In a Single-instance deployment, the **API Server Settings** are within **Global Settings** > **General Settings**.) Define HTTP headers as key-value pairs, clicking **Add Header** as needed.

11.3.8. Configure System Proxy

This document outlines how to configure Cribl Stream to use a proxy server for outbound HTTP/S requests.

There are two ways to define proxy variables in Cribl Stream:

- **Using environment variables**: This method is independent of the systemd service manager and can be used regardless of how Cribl Stream is installed or started.
- **Using systemd override files**: This method is specific to systemd and requires that Cribl Stream is started as a systemd service. Choose the method that best suits your deployment environment and preferences.

Prevent Proxy, Config, and Case Conflicts

Before you deploy Cribl Stream and configure proxies, Cribl recommends running the `printenv` shell command to check for any existing proxies in your environment. If you find existing proxies, be sure to include their environment variables in the systemd override file.

If Cribl Stream is already running on any Nodes you are proxying, restart the Cribl server after you initially configure – or make any changes to – the variables outlined on this page.

The environment variables' names can be either uppercase or lowercase. However, if you set duplicate versions of the same name, the lowercase version takes precedence. For example, if you've set both `HTTPS_PROXY` and `https_proxy`, the IP address specified in `https_proxy` will take effect.

Set Up Proxy Environment Variables (Using Environment Variables)

You can direct all outbound HTTP/S requests to go through proxy servers. You do so by setting a few environment variables before starting Cribl Stream, as follows:

Configure the `HTTP_PROXY` and `HTTPS_PROXY` environment variables, either with your proxy's IP address, or with an FQDN that resolves to that IP address.

Optionally, follow either convention with a colon and the port number to which you want to send queries. Some `HTTP_PROXY` examples:

```
$ export HTTP_PROXY=http://10.15.20.25:1234
$ export HTTP_PROXY=http://proxy.example.com:1234
```

`HTTPS_PROXY` examples:

```
$ export HTTPS_PROXY=http://10.15.20.25:5678
$ export HTTPS_PROXY=http://proxy.example.com:5678
```

In the above examples, note that an `HTTPS_PROXY` environment variable's referenced URL should generally be in `http://` format.

To set up Leader/Worker communication, use the CRIBL_DIST_WORKER_PROXY environment variable.

HTTP and/or HTTPS?

Several Cribl Stream endpoints rely on the HTTPS protocol. These include the Cribl telemetry endpoint (which must be accessed under some license types and all Cribl.Cloud plans), and the CDN used to propagate application updates and certain documentation features (API Reference and docs PDFs).

You might configure certain other Cribl Stream features (such as REST API Collectors) that require access to HTTP endpoints. For maximum flexibility, consider setting environment variables to handle both the HTTPS and HTTP protocols.

Set Up Proxy Configuration with systemd

If you are proxying outbound traffic and starting Cribl Stream using systemd, add your proxy environment variables to the systemd override file (see Persisting Overrides). Add statements of this form:

Installed systemd File

```
[Service]
Environment=http_proxy=<yourproxy>
Environment=https_proxy=<yourproxy>
Environment=no_proxy=<no_proxy_list>
```

This will prevent Cribl Stream from throwing "failed to send anonymized telemetry metadata" errors.

Authenticating on Proxies

You can use HTTP Basic authentication on HTTP or HTTPS proxies. Specify the username and password in the proxy URL. For example:

```
$ export HTTP_PROXY=http://username:password@proxy.example.com:1234
$ export HTTPS_PROXY=http://username:password@proxy.example.com:5678
```

If your `username` or `password` contains special characters, Cribl Stream will try to use these fields as the proxy address. As a workaround, URL-encode these fields.

Bypassing Proxies with `NO_PROXY`

If you've set the above environment variables, you can negate them for specified (or all) hosts. Set the `NO_PROXY` environment variable to identify URLs that should bypass the proxy server, to instead be sent as direct requests. Use the following format:

```
$ export NO_PROXY="<list of hosts/domains>"
```

Cribl recommends including the Leader Node's host name in the `NO_PROXY` list.

Client Configuration and Leader Reference

The way a client references the Leader Node depends on its configuration, which originates from the Distributed Settings for that particular Node. These settings reside in the `$CRIBL_HOME/local/_system/instance.yml` file.

When deploying a configuration update, the Leader Node informs all connected clients (Workers and Edge Nodes) within its Group or Fleet that a new configuration bundle is available. The Leader will reference itself using the same method (IP address or FQDN) that clients already use to connect to it in the distributed environment. This ensures a seamless download process for the clients, regardless of their initial connection method.

If a Worker is configured to use the Leader's IP for communication, the URL will also contain that specific IP. Consequently, the `NO_PROXY` variable on the client must match the IP address used in the client configuration and Leader URL for optimal operation.

Cribl v.4.6.0 introduces direct S3 downloads for configuration bundles, bypassing the Leader Node and scaling deployments with many Worker Nodes. However, if your S3 bucket is firewalled or requires access controls, a proxy might be needed. In such scenarios, you need to exclude the S3 bucket address from the "NO_PROXY" list for successful downloads.

`NO_PROXY` Usage

Within the `NO_PROXY` list, separate the host/domain names with commas or spaces.

Optionally, you can follow each host/domain entry with a port. If not specified, the protocol's default port is assumed.

To match subdomains, you must either list them all in full (for example, `NO_PROXY="foo.example.com,bar.example.com"`), or apply a wildcard by prefixing the domain name with a period or `*.`: `No_Proxy=".example.com"` or `No_Proxy="*.example.com"`.

To match the whole domain including its subdomains, add it both with and without wildcard to the list: `No_Proxy="example.com,.example.com"`.

To disable all proxies, use the `*` wildcard: `NO_PROXY="*"`. `NO_PROXY` with an empty list disables no proxies.

Cloud `NO_PROXY` Usage

You must include any cloud metadata endpoints (such as the AWS Instance Metadata Service) in the `NO_PROXY` list:

- AWS EC2 and Azure VM instances must include `169.254.169.254` in the list. If using IPv6 on AWS EC2, add `fd00:ec2::254` to the list.
- AWS ECS Fargate tasks must include `169.254.170.2`.
- GCP (Google Cloud Platform) VM instances must include `metadata.google.internal` and `169.254.169.254`.

Where Proxies Apply

Proxy configuration is relevant to the following Cribl Stream components that make outbound HTTP/S requests:

Destinations

- Amazon CloudWatch Logs
- Amazon Kinesis Data Streams
- Amazon S3 Compatible Stores
- Amazon SQS
- Azure Blob Storage

- Azure Monitor Logs
- Cribl HTTP
- CrowdStrike Falcon LogScale
- Datadog
- Data Lake > S3
- Elasticsearch
- Google Chronicle
- Google Pub/Sub
- Grafana Cloud
- Honeycomb
- Loki
- New Relic Ingest: Logs & Metrics
- New Relic Ingest: Events
- OpenTelemetry
- Prometheus
- SentinelOne DataSet
- SignalFX
- Splunk HEC
- Sumo Logic
- Wavefront
- Webhook

Sources

- Amazon SQS
- Amazon S3
- Azure Blob Storage
- CrowdStrike FDR
- Office 365 Services
- Office 365 Activity
- Office 365 Message Trace
- Prometheus Scraper
- Prometheus Edge Scraper
- Wiz

Collectors

- Amazon S3 Collector
- Azure Blob Storage Collector
- Google Cloud Storage Collector
- Health Check Collector
- REST/API Collector

Notification Targets

- PagerDuty
- Webhook

Testing Proxies

To initially test your proxy configuration, consider setting up a simple, free proxy server like mitmproxy (https://mitmproxy.org), and then monitoring traffic through that server. Verify that you can trace proxied requests from your Cribl Stream instance, and can validate that outgoing requests (to Destinations) are working properly.

Proxying Multiple Cribl Stream Instances in One Browser

Cribl Stream stores authentication tokens based on each http header's URI scheme, host, and port information. Within a given browser, Cribl Stream enforces a same-origin policy to isolate instances.

This means that if you want to run multiple proxied Cribl Stream instances in one browser session, you must assign them different URI schemes, hosts, and/or ports. Otherwise, logging into an extra Cribl Stream instance will expire the prior instance's session and log it out.

For example, assume that you've set up this pair of Apache proxy forward rules:

- https://web/cribla forwards to `cribl_hosta:8001/cribla`.
- https://web/criblb forwards to `cribl_hostb:8001/criblb`.

These two proxied addresses cannot be run simultaneously in the same browser session. However, this pair – which lead with separate URI schemes – could:

- https://web/cribla forwards to `cribl_hosta:8001/cribla`.
- https://web2/criblb forwards to `cribl_hostb:8001/criblb`.

Where separate instances **must** share URI formats, a workaround is to open the second instance in an incognito/private browsing window, or in a completely different browser.

11.3.9. Configure SOCKS Proxy

This document outlines how to configure Cribl Stream to use a SOCKS proxy server for outbound communication.

By using a SOCKS proxy, you can enhance security, bypass network restrictions, and route specific traffic through a controlled intermediary server. This document will guide you through the necessary steps to set up a SOCKS proxy for your Cribl Stream deployment.

There are two ways to define proxy variables in Cribl Stream.

- **Environment Variables**: Ideal for most scenarios, especially when automating deployments or managing a large number of Worker Nodes.
- **UI Configuration**: Suitable for smaller deployments or when manual configuration is preferred. However, be aware of the additional steps and potential complexities involved.

Configure via Environment Variables

This is the most straightforward and flexible method.

`CRIBL_DIST_WORKER_PROXY` lets you configure a SOCKS proxy for communication between the Leader Node and Worker Nodes.

The default protocol is SOCKS5, which uses the format: `socks5://<username>:<password>@<host>:<port>`. Specify the SOCKS proxy host, port, and optional authentication credentials in the variable.

You can alternatively specify SOCKS4 as the protocol with the format: `socks4://<proxyhost>:<port>.` To authenticate on a SOCKS4 proxy with username and password, use this format: `socks4://<username>:<password>@<proxyhost>:<port>`. The `<proxyhost>` can be a `hostname`, `IPv4`, or `IPv6`.

Configure via the UI

Configuring a SOCKS proxy for Cribl Stream using the UI is more complex than using environment variables due to the multi-step process involved. It requires enabling direct access to the Leader, setting up the proxy on the Worker Nodes, and then configuring the SOCKS proxy settings. Additionally, using the UI might not be suitable for all deployment scenarios, especially those with large numbers of Worker Nodes or complex network configurations.

To configure a SOCKS proxy for Cribl Stream, follow these steps.

1. **Enable direct access**: Allow Worker Nodes to access the Leader Node directly.

    - Cribl Edge: Set up Leaders and Edge Nodes.
    - Cribl Stream: Set up Leaders and Worker Nodes.
    - Remember to enable UI Access (and teleport) to Workers or Edge Nodes as applicable.
2. **Set up Worker Nodes and SOCKS proxy**: Configure the Worker Nodes and ensure the SOCKS proxy server is running and accessible.
3. **Configure proxy details**: You can access the Worker Node via teleporting. To configure without teleporting, log in to each Worker Node directly using a local user account.
4. Select **Worker Node Settings** from the Worker Node submenu. Navigate to **Distributed Settings** > **Leader Proxy Settings** and configure the following fields:
    - **Username**: Enter the username for the SOCKS Proxy authentication.
    - **Password**
    - **Proxy host**: Enter the proxy server host. Can be a `hostname`, `IPv4`, or `IPv6`.
    - **Proxy port**
    - **Protocol version**: Version of the SOCKS protocol. Defaults to `5` for `socks5`.
5. **Save the settings**: The Worker Nodes will automatically reconnect to the Leader node using the configured SOCKS proxy.
6. **Disable direct access**: Verify the SOCKS proxy configuration is verified. To ensure all traffic between Worker Nodes and Leader is routed through the SOCKS proxy, disable the direct network connections between them. This includes removing any firewall rules or network configurations that allow direct communication.

11.4. Manage Secrets And Keys

11.4.1. Create And Manage Encryption Keys

You can create and manage keys that Cribl Stream will use for real-time encryption of fields and patterns within events. For details on applying the keys that you define here, see Encryption Keys.

Access Keys

- In a Single-instance deployment, select **Settings** > **Security** > **Encryption Keys**.
- In a Distributed deployment with one Worker Group, select **Settings** > **Security** > **Encryption Keys**.
- In a Distributed deployment with multiple Worker Groups, keys are managed per Worker Group. Select **Manage** > **Groups** > `<group-name>` **Group Settings** > **Security** > **Encryption Keys**.

On the resulting **Manage Encryption Keys** page, you can configure existing keys, and/or use the following options to add new keys.

Get Key Bundle

To import existing keys, click **Get Key Bundle**. You'll be prompted to supply a login and password to proceed.

Add New Key

To define a new key, click **New Key**. The resulting **New Key** modal provides the following controls:

Key ID: Cribl Stream will automatically generate this unique identifier.

Description: Optionally, enter a description summarizing the purpose of the key.

Encryption algorithm: Currently, Cribl Stream supports the `aes-256-cbc` (default) and `aes-256-gcm` algorithms.

KMS for this key: Currently, the only option supported here is `local` (the Key Management Service built into Cribl Stream).

Key class: Classes are arbitrary collections of keys that you can map to different levels of access control. For details, see Key Classes. This value defaults to `0`; you can assign more classes, as needed.

Expiration time: Optionally, assign the key an expiration date. Directly enter the date or select it from the date picker.

Use initialization vector: If enabled, Cribl Stream will seed encryption with a nonce to make the key more random and unique. Optional (and defaults to disabled) with the `aes-256-cbc` algorithm; automatically enabled (and cannot be disabled) with the `aes-256-gcm` algorithm.

Initialization vector size: Length of the initialization vector (IV), in bytes. This option is displayed only with the `aes-256-gcm` algorithm. Defaults to `12` bytes to optimize interoperability, but you can use the drop-down to set this anywhere between `12` to `16` bytes.

11.4.2. Create And Manage Secrets In Cribl Stream

The Cribl Stream secrets store enables you to centrally manage secrets that Cribl Stream instances use to authenticate on integrated services. Use the **Manage Secrets** page to create and update authorization tokens, username/password combinations, and API-key/secret-key combinations for reuse across the application.

To ensure they can be decoded correctly, all secrets in Cribl Stream must use `latin1` encryption.

Access Secrets

- In a Single-instance deployment, select **Settings** > **Security** > **Secrets**.
- In a Distributed deployment with one Worker Group, select **Configure** > **Settings** > **Security** > **Secrets**.
- In a Distributed deployment with multiple Worker Groups, secrets are managed on each Worker Group. Select **Groups** > `<group-name>` **Settings** > **Security** > **Secrets**.

On the **Manage Secrets** page, you can configure existing secrets, and/or click **New Secret** to define new secrets.

Add New Secret

The **New Secret** modal provides the following controls:

- **Secret name**: Enter an arbitrary, unique name for this secret.
- **Secret type**: Some options for this field expose additional controls, as described below.
- **Description**: Optionally, enter a description summarizing the purpose of the secret.
- **Tags**: Optionally, enter one or multiple tags related to this secret.

Secret Type

This drop-down offers the following types:

- **Text**: This default type exposes a **Value** field where you directly enter the secret.
- **API key and secret key**: Exposes **API key** and **Secret key** fields, used to retrieve the secret from a secure endpoint. This is the only secret type that Cribl Stream supports for its AWS-based Sources, Collectors, and Destinations, and its Google Cloud Storage Destination.
- **Username with password**: Exposes **Username** and **Password** fields, which you fill to retrieve the secret using Basic Authentication.

Encrypt Secrets Using the Command Line

You also have the option to create and encrypt sensitive values using the same mechanism Cribl Stream employs internally for all sensitive fields. This ensures consistency and leverages the built-in encryption capabilities within Cribl Stream.

This approach allows you to store all your secrets securely in a password store, keeping them out of your Git repository, and adheres to strict organizational security standards that prohibit storing secrets in version control.

Modifying credentials directly through the Cribl Stream UI won't be possible, even in development environments. This approach prioritizes security by keeping secrets out of the UI altogether.

For details, see Encrypt in the CLI Reference doc.

11.4.3. Configure KMS

Cribl Stream's Key Management Service (KMS) maintains the keys that Cribl Stream uses to encrypt secrets on Worker Groups and Worker Nodes. The internal KMS is always available, but integrating an external KMS provider is available on certain plan/license tiers. For details, see Pricing..

To configure KMS for Cribl Stream in Cribl.Cloud, see the Launch Guide.

In an on-prem Single-instance deployment, you configure the KMS at **Settings** > **Global** > **Security** > **KMS** > **Configure**. In a Distributed deployment, you configure the Leader's KMS at the same global location, while additional KMS configs for each Worker Group are available at the Worker Group's **Group Settings** > **Security** > **KMS** > **Configure** page.

The resulting **KMS Provider** drop-down currently provides these options:

- Stream Internal: The **only** option available without an Enterprise license/plan. With this option, the secrets themselves are configured and maintained in Cribl Stream Settings' parallel Secrets section.
- HashiCorp Vault
- AWS KMS

External KMS Providers and Worker Groups

To integrate an external KMS provider into an on-prem Distributed deployment, Cribl Stream's Leader Node must have internet access.

When you initially install a license in Distributed mode, a known bug prevents immediate use of KMS features within Worker Groups. Here is the workaround:

1. Open **Settings** > **Global** > **Service Processes** > **Processes**.
2. In the list of processes, locate any process with a Role of `CONFIG_HELPER`.
3. Select that process' **Restart** button.

Upon restarting, KMS will be available for use in the corresponding Worker Group.

Internal KMS

The **KMS provider** field defaults to `Stream Internal`. With this option, no further configuration here is required (or possible). See Secrets to configure individual secrets.

HashiCorp Vault

Cribl Stream's integration with HashiCorp Vault uses a Vault policy to define the capabilities granted to tokens used for KMS access. This policy ensures tokens have the necessary permissions to interact with Vault paths relevant to KMS functionality.

Vault Policy Permissions

This table outlines the required Vault policy permissions for different access scenarios.

Path	Capabilities	Description
`<path to vault secret>`	Create, Update, Read	Grants access to create, update, and read secrets at the specified path.
`auth/token/create`	Update	Grants permission to update authentication tokens (only required for Token authentication).
`sys/health`	Read	Allows reading system health information (only needed if enabling health checks).

`<path to vault secret>` represents the actual path to the secret within your Vault hierarchy.

Keep these capabilities in mind as you proceed with the configuration.

Setting the **KMS provider** drop-down to `HashiCorp Vault` exposes the following configuration options:

KMS Settings

Vault URL: Enter the Vault server's URL (for example, `http://localhost:8200`).

Namespace: If you are using HashiCorp Vault Enterprise namespaces, enter the desired namespace.

Authentication

Auth Provider: The method for authenticating requests to HashiCorp Vault server. Select one of `Token`, `AWS IAM`, or `AWS EC2`. Your selection determines the remaining **Authentication** options displayed.

Token-based Authentication

Token: Enter the authentication token. This token will be used only to generate child tokens for further authentication actions.

AWS IAM Authentication

In HashiCorp Vault, the term "method" can refer to `userpass`, `token`, or `aws`, among others, but the `aws` method supports two authentication types: `iam` and `ec2`. Meanwhile, in Cribl Stream, you'll see "method" used differently, for example in the **Authentication method** setting described below.

Use the **Authentication method** buttons to select one of the following:

- **Auto**: Uses the AWS instance's metadata service to automatically obtain short-lived credentials from the IAM role attached to an EC2 instance, local credentials, sidecar, or other source. The attached IAM role grants Cribl Stream Worker Nodes access to authorized AWS resources. Can also use the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. Works only when running on AWS.
- **Manual**: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials directly or by reference. This is useful for Worker Nodes not in an AWS VPC, for example, those running in a private cloud. It prompts you to provide an **Access key** and a **Secret key**.

Vault AWS IAM Server ID: Value to use for the `Vault-AWS-IAM-Server-ID` header value. This should match the value configured with IAM authentication on Vault.

Vault Role: Authentication role to use in Vault.

Custom Auth Path: If you enabled authentication in HashiCorp Vault with a custom path, enter that path again here.

For example:

- If you enabled authentication with the HashiCorp Vault command `vault auth enable -path /my-auth aws` instead of `vault auth enable aws` you would set a custom path of `my-auth`. Subsequently, when you perform actions using the `vault write` command, you'd specify an auth type with the `auth_type=ec2` or `auth_type=iam` options.

Assume Role

This section is displayed for all AWS IAM authentication methods.

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for Vault Auth: Toggle to `Yes` if you want to use your Assume Role credentials to access Vault authentication.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming the role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

AWS EC2 Authentication

Vault Role: Enter the authentication role to use in Vault.

Custom auth path: If you enabled authentication in HashiCorp Vault with a custom path, enter that path again here. For example:

- You could have used the HashiCorp Vault command `vault auth enable -path /my-auth aws` to enable authentication with a custom path of `my-auth`. Subsequently, when you perform actions using the `vault write` command, you'd specify an auth type with the `auth_type=ec2` or `auth_type=iam` options.

Secret Engine

Mount: Mount point of the Vault secrets engine to use. (Currently, only the KVv2 engine is supported.) Defaults to `secret`.

Secret Path: Enter the path on which the Cribl Stream secret should be stored. For example, `<somePath>/cribl-secret`.

In a Distributed deployment, the Leader, and each Worker Group, require a distinct secret. This location cannot be shared between them.

Advanced

Enable Health Check: Whether to perform a health check before migrating secrets data. Defaults to `Yes`.

Health check endpoint: Configurable endpoint to use for validating system health. Defaults to `/v1/sys/health`.

AWS KMS

Setting the **KMS provider** drop-down to `AWS KMS` exposes the following configuration options:

Authentication

Authentication method: Select an AWS authentication method.

- **Auto**: This default option uses the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`, or the attached IAM role. Works only when running on AWS.
- **Manual**: You must select this option when not running on AWS.

The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to `env.AWS_ACCESS_KEY_ID`, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to `env.AWS_SECRET_ACCESS_KEY`, or to the metadata endpoint for IAM credentials.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for KMS: Toggle to `Yes` if you want to use Assume Role credentials to access the AWS KMS.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID in order to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Service Configuration

KMS Key ARN: Enter the Amazon Resource Name (ARN) of the AWS KMS Key to use for encryption. This entry is required.

When you configure your IAM account/role in AWS, grant access to the following permissions on the KMS key that will be used:

- `kms:Encrypt`
- `kms:Decrypt`

Then use that account for authentication.

11.5. Compliance

11.5.1. FIPS Mode

Federal Information Processing Standards FIPS represent a set of US government standards and guidelines for information security. You can deploy Cribl Stream in **FIPS mode**. This mainly restricts the cryptographic algorithms used within Cribl Stream and also enforces FIPS compliant password requirements.

Do not start Cribl Stream without FIPS mode enabled, or else you will be unable to run it in FIPS mode later. You must enable FIPS mode as described in this section, after installing **but before starting** Cribl Stream.

Requirements

This section describes the system and password requirements for FIPS mode.

FIPS Mode System Requirements

To run Cribl Stream in FIPS mode, your environment must satisfy the following requirements.

Operating Systems

Must support FIPS 140-2. Several Linux distributions meet this standard. See NIST's list of tested configurations here.

OpenSSL

The operating system environment must have a FIPS validated version of OpenSSL installed.

- **For Cribl Stream versions 4.5.0 through 4.8.1**: The FIPS provider version must be 3.0.8 or 3.0.9, and the system-wide OpenSSL version must also be version 3.0.9 or 3.0.8, with its associated certificate.
- **For Cribl Stream starting with version 4.8.2**: The FIPS provider version requirement must be >= 3.0.5, and the system-wide OpenSSL version is no longer a factor. Cribl Stream now verifies the OpenSSL version bundled within the binary.

Enterprise Linux 9 is the only version of Enterprise Linux that includes OpenSSL version 3.0.9 out of the box. While it's possible to manually install compatible versions of OpenSSL on older Enterprise Linux versions, this process is complex and generally not recommended. Therefore, the minimum recommended Enterprise Linux version for running Cribl Stream in FIPS mode is 9.

FIPS Mode Restrictions on Cryptographic Algorithms

When running in FIPS mode, Cribl Stream uses only those cryptographic algorithms that satisfy the FIPS standards. This means that Cribl Stream operates exclusively with FIPS-compliant cryptographic algorithms, disallowing the use of non-compliant algorithms like MD5 (message-digest) or CRC-32 (Cyclic Redundancy Check 32) algorithms.

To ensure proper functionality in FIPS mode, the FIPS provider version must be at least `3.0.5`.

Therefore, in FIPS mode:

Cribl expressions that rely on MD5 or CRC-32 will fail silently. This includes expressions that use the `C.Mask.md5()` method and can in turn affect the behavior of parent Functions and their existing parent Pipelines.

The UI will hide certain options normally made available by the typeahead feature.

No Source, Destination, or Email Notification target that uses the Amazon AWS SDK v2 will perform checksums. This is because that SDK uses MD5 to verify checksums, and it applies to both incoming or outgoing payloads. Specifically:

- The Amazon Kinesis Data Streams Source will not perform checksums and the **Verify KPL checksums** setting will not be available.
- The Amazon SNS Notification target will not perform checksums.
- The following Destinations will not perform checksums:
    - Amazon CloudWatch Logs
    - Amazon Kinesis Data Streams
    - Amazon SQS
    - Google Cloud Storage
    - MinIO
    - Prometheus

Role-Based Access Control (RBAC) Controls

Cribl Stream's FIPS mode requires RBAC to be enabled for enhanced security. This ensures proper access management within FIPS-compliant environments. To enable RBAC, the Cribl Stream instance has to be running in Distributed mode. FIPS mode is available on certain license tiers. For details, see Pricing.

If FIPS mode is already enabled and RBAC is subsequently disabled, Cribl Stream will automatically disable FIPS mode and log a message stating:

```
"Disabling FIPS due to Role-based Access Control (RBAC) being disabled."
```

FIPS Mode Password Rules

When Cribl Stream is in FIPS mode, all passwords must:

- Contain eight or more characters.
- Use characters from three or more of the following categories:
  - Lowercase letters.
  - Uppercase letters located after the first character in the password.
  - Digits located before the last character in the password.
  - Non-alphanumeric ASCII characters such as `#`, `!`, or `?`.
  - Non-ASCII characters such as `ñ`, `€`, or emoji.

As of Cribl Stream version 4.5.0, these rules apply for all passwords, whether or not Cribl Stream is running in FIPS mode, with one exception:

- For Cribl Stream not running in FIPS mode, local users whose passwords existed before Cribl Stream 4.4.4 was released can continue to use their passwords, even if those passwords do not satisfy the rules.
- When these users change to new passwords, the new passwords must satisfy the rules.
- New users must create passwords that satisfy the rules.

If you get locked out of your account, you need to reset your password manually.

Running Cribl Stream in FIPS Mode

To begin using Stream with FIPS enabled, complete either the non-systemd or the systemd procedure below, **before you start Cribl Stream for the first time after installing**.

Enabling FIPS Mode on a Non-systemd Distribution

If the Linux distribution on which you run Cribl Stream **does not** use systemd:

1. Complete **either** of the two following steps:
   - Set the `CRIBL_FIPS` environment variable to `1` (true), **or**,
   - Edit `cribl.yml`, adding this top-level element:

```
fips: true
```

Note that `fips: true` is the entire top-level element. For this element, the following "stanza" syntax would be incorrect – **do not** use it:

```
# stanza syntax is incorrect for the fips element
# even if other elements use it
fips
  fips: true
```

2. If you have installed a non-default OpenSSL binary (otherwise, skip this step):
   - Run the following command, and in the output, note the values of `MODULESDIR` and `OPENSSLDIR`.

     ```
     <binary_of_non-default_OpenSSL> version -a
     ```

   - Set `OPENSSL_MODULES` to the value of `MODULESDIR`.
   - Set `CRIBL_OPENSSL_DIR` to the value of `OPENSSLDIR`.
3. Ensure RBAC is Configured in Cribl Stream.
4. Start Cribl Stream.

Finally, verify that you are in FIPS mode as explained below.

Enabling FIPS Mode on a systemd Distribution

If the Linux distribution on which you run Cribl Stream **does** use systemd:

1. Run the following command, and in the output, note the values of `MODULESDIR` and `OPENSSLDIR`. (As shown, the command will run the default OpenSSL binary. If you have installed a different OpenSSL binary, you can modify the command to run that one instead.)

   ```
   openssl version -a
   ```

2. Run the following command, replacing the placeholders with the relevant paths from your environment. (This assumes that you do not already have a `nodejs.cnf` file. If you **do** have one, complete the workaround below instead of this step.)

   ```
   <path_to_Cribl_binary> generateFipsConf -d <path_to_OpenSSL_root_directory>
   ```

For example, you might run this and get the output shown:

```
useralice@123456791234:/# /opt/cribl/bin/cribl generateFipsConf -d /lib/usr/ssl
/opt/cribl/state/nodejs.cnf
```

This command creates `nodejs.cnf` – the configuration file that NodeJS uses to run in FIPS mode as Cribl Stream starts.

3. Run the following command to open an empty temporary file in an editor:

```
systemctl edit cribl
```

4. Add the following content to the file, replacing the first placeholder with the value of `MODULESDIR` that you noted in Step 1, and the second with the path to your `nodejs.cnf` file:

```
[Service]
Environment="OPENSSL_MODULES=<value_of_MODULESDIR>"
Environment="OPENSSL_CONF=<path_to_nodejs.cnf_file>"
```

5. Save and exit the editor.
6. Run the following commands to reload the systemctl overrides and start Cribl:

```
systemctl daemon-reload
systemctl start cribl
```

7. Finally, verify that you are in FIPS mode as explained below.

When a `nodejs.cnf` File Already Exists

If you already have a `nodejs.cnf` file, replace Step 2 above with the following workaround:

1. Create a file with the following content, replacing `<placeholder>` with the value of `OPENSSLDIR`. Name the file something other than `nodejs.cnf`.

```
nodejs_conf = nodejs_init
openssl_conf = nodejs_init

.include /<placeholder>/fipsmodule.cnf

[nodejs_init]
providers = provider_sect

[provider_sect]
default = default_sect
# The fips section name should match the section name inside the
# included fipsmodule.cnf.
fips = fips_sect
[default_sect]
activate = 1
```

2. Resume the main procedure above, starting with Step 3.

Verifying that you are in FIPS mode

- On the Leader, search `cribl.log` for this message:

```
"level":"info","message":"running with FIPS enabled", "OpenSSLVersion":"3.0.13+c
```

- The presence of the above message confirms that Cribl Stream is in FIPS mode.

Log in as `admin` – you will be prompted to enter a FIPS compliant password.

11.5.2. Running Cribl Stream On A Hardened OS

When deploying Cribl Stream in environments with stringent security requirements, such as those adhering to the Department of Defense Security Technical Implementation Guides (STIGs), additional configuration steps are necessary to ensure the application can operate without interference.

Understanding STIG Compliance

Operating any system on a network, especially in restricted environments like the DoD, requires obtaining an Authority to Operate (ATO). This involves compliance with STIGs, which cover various aspects of system security, including the operating system, database, and application.

For Cribl Stream, the most relevant STIGs are those governing the operating system deployment. By adhering to these STIGs, you ensure a hardened environment with configured tools to safeguard your system. However, certain actions within these STIGs may be blocked by default, requiring explicit configuration to allow Cribl Stream to execute.

Security Tools and Configurations

To ensure Cribl Stream operates securely in a hardened environment, consider implementing the following essential configurations for your relevant security tools.

SELinux (Security Enhanced Linux)

When running Cribl Stream on a system with SELinux, it's crucial to download the `tgz` file directly to the `/opt/` directory. Additionally, ensure that the `.tgz` file is uncompressed within the `/opt/` directory. Moving files on a system with SELinux might lead to complications.

For details, see the SELinux Configuration topic.

firewalld

firewalld is a dynamic firewall management tool that offers support for network/firewall zones, allowing you to define the trust level of network connections or interfaces. It encompasses features for managing IPv4 and IPv6 firewall settings, Ethernet bridges, and IP sets. According to the DOD STIG, firewalld should enforce a deny-all rule and should selectively open ports.

In a Cribl Stream environment, the Leader Node requires ports `4200` and `9000` over TCP to be open. Additionally, Worker Nodes should have port `9000` over TCP open if Worker UI access is enabled, along with any necessary Source ports.

Refer to your specific firewall configuration guidelines for details.

fapolicy

fapolicy is a software framework that regulates application execution through a user-defined policy, adhering to an allow-list approach. In this case, you should explicitly permit or trust applications to execute within a deny-all catch-all policy. This framework serves as an efficient method to prevent the execution of untrusted and potentially malicious applications on the system.

Cribl Stream operates seamlessly in secure environments, but additional configuration steps are needed for systems using fapolicy (File Access Policy). To ensure Cribl Stream can execute without interference, we'll use trust files to explicitly authorize Cribl Stream binaries.

There are two main ways to achieve this:

Trust Files (Recommended): Trust files offer a more efficient and streamlined approach compared to writing custom fapolicyd rules. Trust files allow you to define authorized applications and their locations, enabling fapolicy to recognize Cribl Stream as a trusted application without the need for extensive rule configurations.

You define trusted applications and their locations in a trust file. fapolicy then recognizes Cribl Stream as trusted and allows it to run.

Custom Rules (Advanced): This method offers more granular control but requires writing custom fapolicy rules. While less performant, you can write custom fapolicyd rules to allow Cribl Stream execution. However, this approach is recommended for advanced users familiar with fapolicy rule syntax.

For most users, using trust files is the recommended approach due to its simplicity and performance benefits. However, if you require more granular control or have specific fapolicy configurations, custom rules might be a suitable alternative.

Upgrading Cribl Stream with fapolicy

When using fapolicy, UI-based upgrades might fail due to its tracking of individual binaries. To successfully upgrade, you must manually update the fapolicy trust file to recognize the new Cribl Stream binaries. This ensures fapolicy allows the upgraded components to execute properly.

Common Challenges and Solutions

- **Access Denied Errors:** If you encounter errors related to file access or execution permissions, ensure SELinux and fapolicy are configured correctly.
- **Network Connectivity Issues:** Verify that firewall rules allow necessary network traffic for Cribl Stream to communicate with other components.

- **Configuration Errors:** Double-check your configuration settings for SELinux, fapolicyd, and firewall rules to ensure they align with your security requirements.

For details and configuration templates, refer to the Guides section in the Cribl Curious Knowledge Base.

11.5.3. SELinux (Enforcing Mode) Configuration

SELinux (Security-Enhanced Linux) is a mandatory access control system for Linux that provides a granular level of security by defining access controls for applications, processes, and files. When SELinux is in enforcing mode, it strictly enforces security policies, which can sometimes cause conflicts with applications that aren't explicitly allowed to perform certain actions.

If you're unsure about SELinux and its modes, here's some background:

- Security-Enhanced Linux (SELinux) is a mandatory access control (MAC) security mechanism implemented in the kernel. (Source: CentOS Wiki.)
- SELinux defines access controls for the applications, processes, and files on a system. It uses security policies, which are a set of rules that tell SELinux what can or can't be accessed, to enforce the access allowed by a policy. (Source: Red Hat.)
- Processes and files are labeled with an **SELinux context** that contains additional information, such as an SELinux user, role, type, and, optionally, a level. When running SELinux, all of this information is used to make access control decisions. (Source: Red Hat.)
- SELinux has two modes, **enforcing** and **permissive**. When running in enforcing mode, SELinux enforces the SELinux policy and denies access based on SELinux policy rules. (Source: Red Hat.)

Cribl Stream and SELinux

To effectively integrate Cribl Stream with SELinux, consider the different policy requirements for in-stream processing and network ports.

- Cribl Stream's in-stream processing often involves predefined processes and files, allowing for a relatively restrictive SELinux policy.
- Network ports might require a more permissive policy because users configure them within the UI.

Key Steps for SELinux Configuration

To ensure optimal integration of Cribl Stream with SELinux, begin by verifying the current SELinux status and the context of the Cribl Stream binary.

Check SELinux Status

Use the `getenforce` command to determine the current status of Security-Enhanced Linux (SELinux) on a Linux system.

```
getenforce
```

The output will be one of the following:

- `Enforcing`
- `Permissive`
- `Disabled`

If the output is `Enforcing`, SELinux is enabled and enforcing policies.

Verify Cribl Stream's SELinux Context

Use the command `ls -Z /opt/cribl/bin/cribl` to list the contents of the directory `/opt/cribl/bin` while displaying their SELinux security contexts.

```
ls -Z /opt/cribl/bin/cribl
```

The output should show the SELinux context for the Cribl Stream binary.

Example output:

```
-rwxr-xr-x. cribl cribl cribl unconfined /opt/cribl/bin/cribl
```

Deploy Cribl Stream directly to `/opt` to avoid context issues. Do not deploy Cribl Stream to a user's home directory, or to root (/), and then move it to `/opt`.

Revert labels on files and directories

You can also use `restorecon` (if needed) to revert labels on files and directories to their default SELinux security context:

```
restorecon -R -v /opt/cribl
```

Check for SELinux Denials

Use `auditd` to log SELinux denials. Look for messages related to Cribl Stream in the `/var/log/audit/audit.log` file.

Modify SELinux Policy

If you encounter SELinux denials, you might need to modify the SELinux policy. There are three options ranging from least secure to most secure.

Use semanage (Less Secure):

This is the simplest but least secure method. It grants permissive access to the `cribl_t type`, allowing all operations.

Command: `semanage permissive -a cribl_t`

Use audit2allow (slightly more secure)

This method creates SELinux policy rules to permit actions that were previously denied.

To identify and address SELinux denials related to Cribl Stream, follow these steps:

1. Find denied operations: `sudo grep cribl /var/log/audit/audit.log | audit2allow -M cribl`
2. Install the generated policy: `sudo semodule -i cribl.pp`

Create a Custom Policy (Most Secure)

Use tools like `secil` or `policycoreutils` to create a custom policy tailored to Cribl Stream's needs. This provides the highest level of security but requires more technical expertise.

Reload SELinux Policy

Once you've altered the SELinux policy using tools like `semanage`, `audit2allow`, or through custom policy creation, use this command to ensure that the new rules take effect immediately.

```
sudo semanage reload -a
```

Specific Cribl Stream Considerations

In addition to the general SELinux guidelines, pay close attention to these Cribl Stream–specific factors:

- **Cribl Stream Configuration**: Review Cribl Stream configuration files for any settings that might conflict with SELinux restrictions.
- **Integration with Other Applications**: Ensure that Cribl Stream's interactions with other applications are compatible with their SELinux contexts and permissions.

Additional Considerations

In addition to the basic configuration, these factors are also important for optimal performance:

- **SELinux Booleans**: Check the SELinux documentation for relevant booleans that might affect Cribl Stream's behavior.
- **SELinux Context Labeling**: Ensure files and directories used by Cribl Stream have the correct SELinux context. Use tools like `restorecon` to relabel files.
- **SELinux Troubleshooting Tools**: Use tools like `audiscan` and `audit2why` to analyze SELinux audit logs.

SELinux Troubleshooting

SELinux problems usually surface when you try to start the Cribl Stream service. Users immediately receive an error like the following:

Cribl Stream fails to start

```
Job for cribl.service failed because the control process exited with error code.
See "systemctl status cribl.service" and "journalctl -xe" for details.
```

One indication that the problem is in SELinux configuration, not in the Cribl Stream service itself, is when (1) nothing has been logged in `$CRIBL_HOME/log/cribl.log`, and (2), when you run `journalctl -xe` you see errors like the following:

Errors from journalctl -xe

```
cribl.service: Failed to execute command: Permission denied
cribl.service: Failed at step EXEC spawning /opt/cribl/bin/cribl: Permission denied

cribl.service: Control process exited, code=exited status=203
cribl.service: Failed to execute command: No such file or directory
cribl.service: Failed at step EXEC spawning /bin/rm -f /opt/cribl/pid/cribl.pid: Perr
```

You can confirm that SELinux configuration is the issue by verifying that the Cribl Stream service is able to start up on its own. To do this, run the `cribl start` command.

Here are three commands that you can think of as a basic SELinux troubleshooting toolkit:

- `getenforce` verifies that SELinux is enabled and enforcing policy.

- `sestatus -v` shows details of the SELinux policy that's in effect.
- `ls` with the `-Z` or `--context` option shows the SELinux tags on files and/or folders. In the output, the fifth column reports the SELinux context in the form `user:role:type:level`.

Example Problem

Suppose you run `ls -lZ /opt/cribl` to see the SElinux context for `/opt/cribl`.

If the output looks like the following, there is a problem: the presence of "home" among the `type` part of the Linux context. In this case, `user_home_t` is the offending type. When the type is `user_home_t` or `admin_home_t`, SELinux will not permit the service to read, write, or execute files.

Problematic SELinux context output

```
$ ls -laZ /opt/cribl
total 0
drwxr-xr-x. 6 cribl cribl unconfined_u:object_r:user_home_t:s0  62 Feb 16 08:31 .
drwxr-xr-x. 3 root  root  system_u:object_r:usr_t:s0            19 Feb 16 19:54 ..
drwxr-xr-x. 2 cribl cribl unconfined_u:object_r:user_home_t:s0 202 Feb 16 08:31 bin
drwxr-xr-x. 5 cribl cribl unconfined_u:object_r:user_home_t:s0  49 Feb 16 08:20 data
drwxr-xr-x. 6 cribl cribl unconfined_u:object_r:user_home_t:s0  59 Feb 16 08:31 defa
drwxr-xr-x. 3 cribl cribl unconfined_u:object_r:user_home_t:s0  22 Feb 16 08:31 thir
```

Example Solution

To fix the labeling, download Cribl Stream again directly to `/opt`. **Do not** download Cribl Stream to a user's home directory, or to root (`/`), and then move it to `/opt` - that was what caused our example problem.

Downloading Cribl Stream to /opt

```
curl -Lso - $(curl -s https://cdn.cribl.io/dl/latest) | sudo tar zxvf - -C /opt
```

A simpler option is to revert the labels using restorecon, an SELinux policy utility that's in the `policycoreutils-python-utils` package.

Reverting labels with restorecon

```
restorecon -R -v /opt/cribl
systemctl restart cribl
```

Once you correct the problem, the output will look like the following. Instead of `*home_t` listings in the `type` field, this SELinux context has `usr_t`, a type that will satisfy SELinux's criteria for allowing the service to read, write, and execute files.

Corrected SELinux context output

```
# ls -laZ /opt/cribl
total 0
drwxr-xr-x. 6 cribl cribl unconfined_u:object_r:usr_t:s0  62 Feb 16 08:31 .
drwxr-xr-x. 3 root  root  system_u:object_r:usr_t:s0      19 Feb 16 20:05 ..
drwxr-xr-x. 2 cribl cribl unconfined_u:object_r:usr_t:s0 202 Feb 16 08:31 bin
drwxr-xr-x. 5 cribl cribl unconfined_u:object_r:usr_t:s0  49 Feb 16 08:20 data
drwxr-xr-x. 6 cribl cribl unconfined_u:object_r:usr_t:s0  59 Feb 16 08:31 default
drwxr-xr-x. 3 cribl cribl unconfined_u:object_r:usr_t:s0  22 Feb 16 08:31 thirdparty
```

12. Monitoring

The Monitoring section of Cribl Stream provides insights into the performance, health, and operational status of your Cribl Stream deployment and data pipelines. Use Monitoring for:

- **Real-time Pipeline monitoring** - Monitor the real-time status of Pipelines, including metrics such as data throughput. See Data Monitoring for more information.
- **Performance tuning and resource utilization tracking** - Get visibility into the utilization of system resources, such as CPU, memory, and network bandwidth for your nodes. Use this information to predict future resource needs and plan for capacity expansion or infrastructure upgrades as needed. Identify areas for optimization, such as tweaking Pipeline configurations or adjusting resource allocations. See Overview and System Monitoring for more information.
- **Alerting and notification** - View Notifications that are triggered when certain thresholds or conditions are met, such as a node going offline, data processing delays, or high error rates. Detect errors or anomalies in data processing, such as failed processing tasks, dropped events, or unexpected data patterns. See Notifications for more information.

Monitoring Page

From Cribl Stream's sidebar, select **Monitoring** to access the Monitoring section of Cribl Stream. The Monitoring section has these submenus:

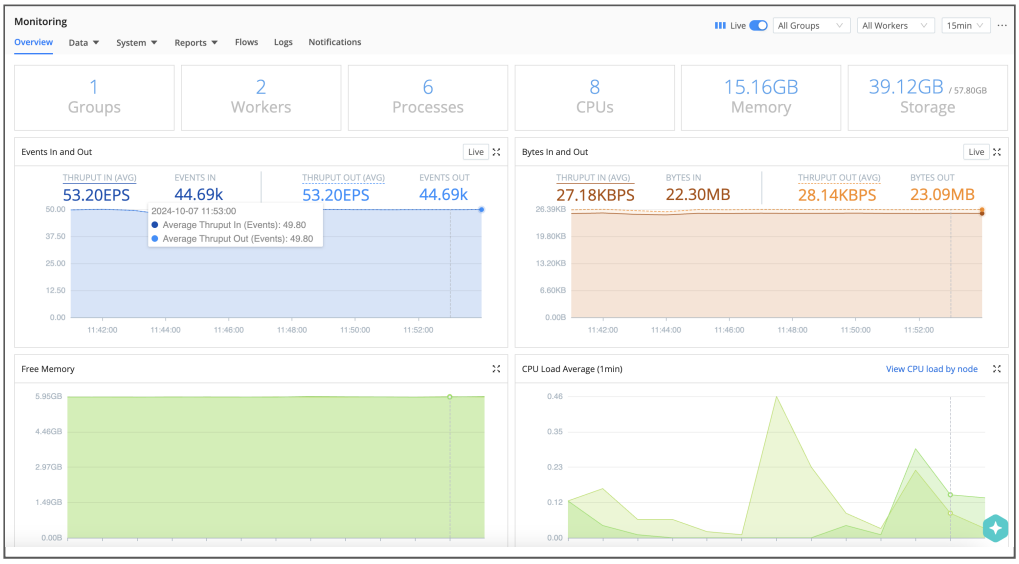
Submenu	Description
Overview	Displays information about traffic in and out of the system, as well as collection jobs and tasks. It tracks events, bytes, splits by data fields over time, and broader system metrics.
Data	View isolated throughput data for: • Data Fields • Destinations • Packs • Pipelines • Projects • Routes • Sources • Subscriptions
System	View isolated throughput data for: • Job Inspector

Submenu	Description
	• Jobs (and tasks in-flights; see Collector Sources) • Leaders (available only with High Availability enabled; see Second Leader) • Licensing • Queues (Destinations) • Queues (Sources)
Reports	Examine the Top Talkers report to see your five highest-volume Sources, Destinations, Pipelines, Routes, and Packs.
Flows	A graphical, left-to-right visualization of data flow through your deployment.
Logs	Comprehensive information about an instance's status/health, inputs, outputs, Pipelines, Routes, Functions, and traffic.
Notifications	Notifications alert Cribl Stream admins about issues that require their immediate attention.

Overview

The Overview page is the default page of the Monitoring section. It displays multiple dashboards with information about traffic in and out of the system, as well as collection jobs and tasks. It tracks events, bytes, splits by data fields over time, and broader system metrics.

The initial view shows aggregate data for all Worker Groups and all Workers. You can use the drop-downs at the upper right to isolate individual Groups, or individual Workers.



Monitoring page

Also at the upper right, you can change the display's granularity from the default `15 min`, selecting from a variety of time ranges from `1 min` up to `1 day`. (The latter covers the preceding 24 hours, and this maximum window is not configurable.)

Vertical lines across each chart display configuration changes. Click anywhere on the line to view summary information including time, data, and configuration versions.

Except for these configuration change markers, Monitoring data does not persist across Cribl Stream restarts. Keep this in mind before you restart the server.

Storage and Memory Calculations

The displayed **Storage** tile (upper right) represents the amount of free storage remaining on the partition that hosts Cribl Stream. (This quantity might not represent the maximum storage available for the selected Worker or Group. Also, it does not calculate the system free space.)

Similarly, the **Free Memory** graph reflects only the operating system's `free` statistic, matching Linux's strict `free` definition by excluding `buff/cache` memory. So this graph indicates a lower value than the OS' `available` memory statistic – and it does not necessarily indicate that the OS is running out of memory to allocate.

The Cribl Stream user interface displays metrics in units of KB, MB, GB, and TB. At each level, these are multiples of `1024`.

Byte Calculations

Byte-related charts show the uncompressed amounts and rates of data processed over the selected time range:

- Events (total) in and out
- Events per second in and out
- Bytes (total) in and out
- Bytes per second in and out

When Cribl Stream receives data from a Source:

- Bytes in gets counted after deserializing and event breaking.

- Most Sources generate a `_raw` string. For these sources, bytes are counted as the length of the `_raw` string.
- For Sources that do not generate a `_raw` string, bytes are counted as the size of the `__bytes` field, such as for metrics and network flows. In this case, `__bytes` will represent the size of the raw bytes read in, before being parsed into event fields.
- Byte count does not include the size of any fields other than `_raw`.

When Cribl Stream sends data to a Destination:

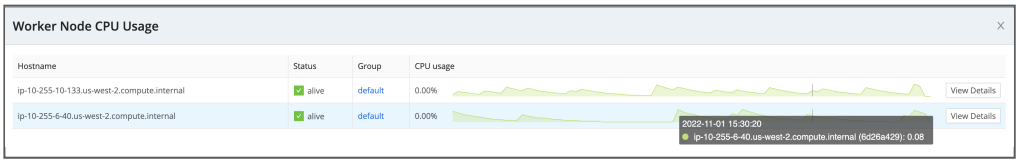
- For most typical Destinations, Cribl Stream calculates the bytes out based on the outgoing payload (typically a JSON string) prior to compression. A JSON-based destination will count the length of the JSON string post-serialization. This string would not include any internal fields or any fields that the Destination does not serialize, even if they are present on the event.
- For these typical Destinations, what is actually serialized may still differ. For example, protobuf-based Destinations will count the protobuf-encoded bytes, but a JSON-based Destination will count the length of the JSON string post-serialization. The result is that the same event may have two different reported bytes counts, depending on which Destination the event is sent through.
- However, some Destinations are exceptions to the typical bytes out calculation. These are the possible alternative calculation scenarios. For some Destinations, Cribl Stream calculates the byte count in one of the following ways:
    - The length of `_raw`, when sent as plain text instead of JSON.
    - A static number of bytes per event. For example, when sending metrics to Splunk using S2S.
    - The length of the stringified JSON, including all internal (__*) fields.

See the documentation for a specific Destination for more information on the bytes out calculation.

CPU Load Calculations

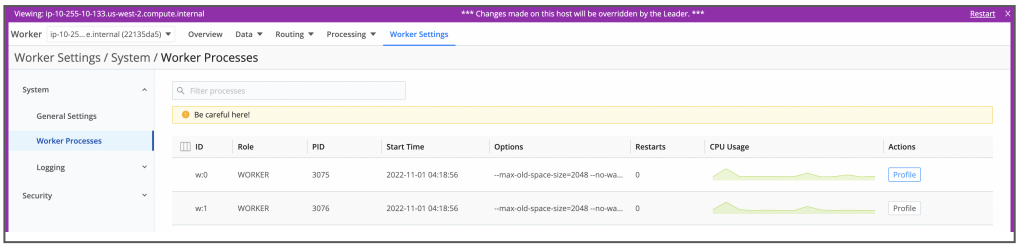
The displayed **CPU Load Average** is an average per Worker Process, updated at 1-minute granularity. (It is not an average for the Worker Node as a whole.)

Select **View CPU load by node** to open a modal showing CPU usage per Worker.



Monitoring page

Select a **View Details** button to access a Worker Node's **Worker Settings**, with details per Worker Process. (To enable this button, you must first enable the parent Group's Remote UI Access.)

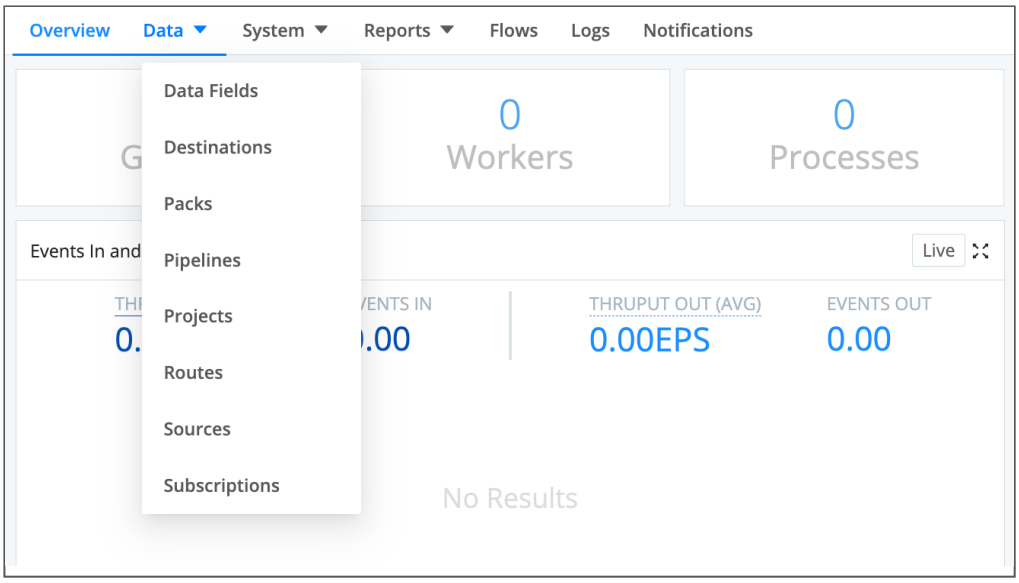


Monitoring page

Data Monitoring

From the **Monitoring** page, open the **Data** submenu to isolate throughput for any of the following:

- Data Fields
- Destinations
- Packs
- Pipelines
- Projects
- Routes
- Sources
- Subscriptions



Monitoring > Data submenu

Sparklines

Dense displays are condensed to sparklines for legibility. Hover over the right edge to display Maximize buttons that you can select to zoom these up to detailed graphs.

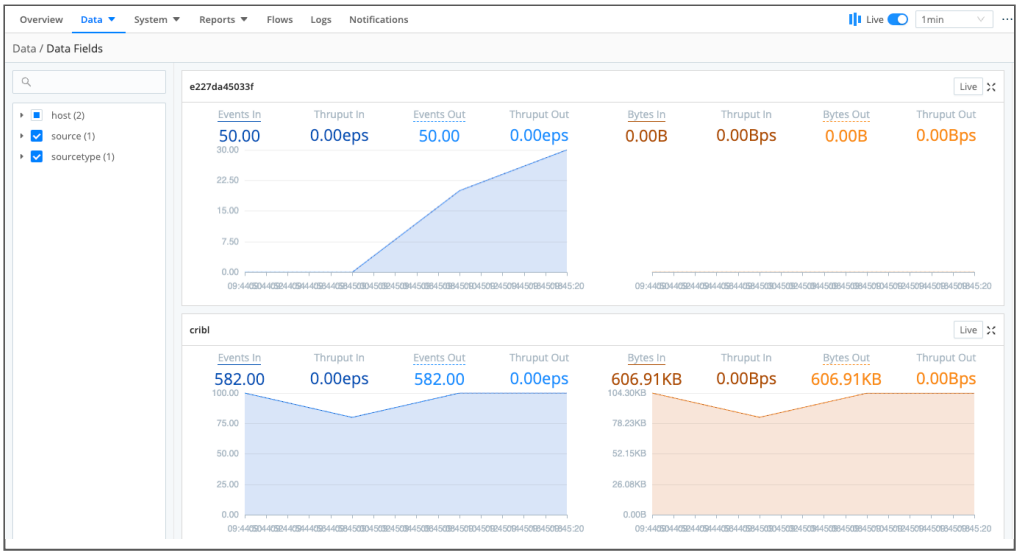
Sparklines and fly-out

Data Fields

The **Data Fields** page lets you preview the flow of events that contain a specific data field. The left (blue) side summarizes events in/out. The right (orange) side summarizes bytes in/out.

To control which data fields get included in these graphs, use the Disable field metrics setting.

To add data fields to this setting, navigate to **Settings**, then select **Global Settings**. From here, select **General Settings**, then **Metrics** (under **Limits**).



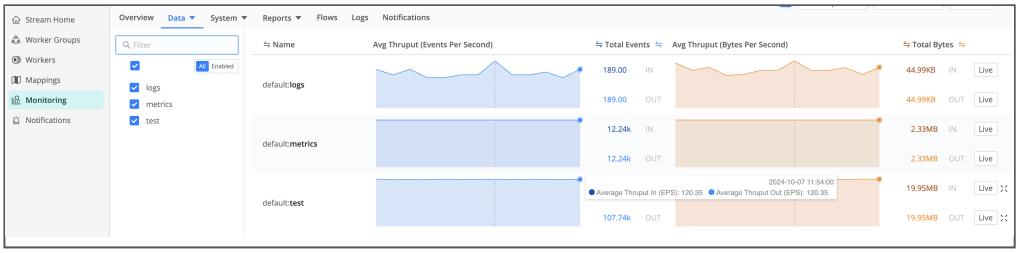
Data Fields graph in Monitoring

Disable field metrics settings are not available on Cribl.Cloud-managed Worker Nodes.

Routes

The **Routes** page condenses multiple details and options:

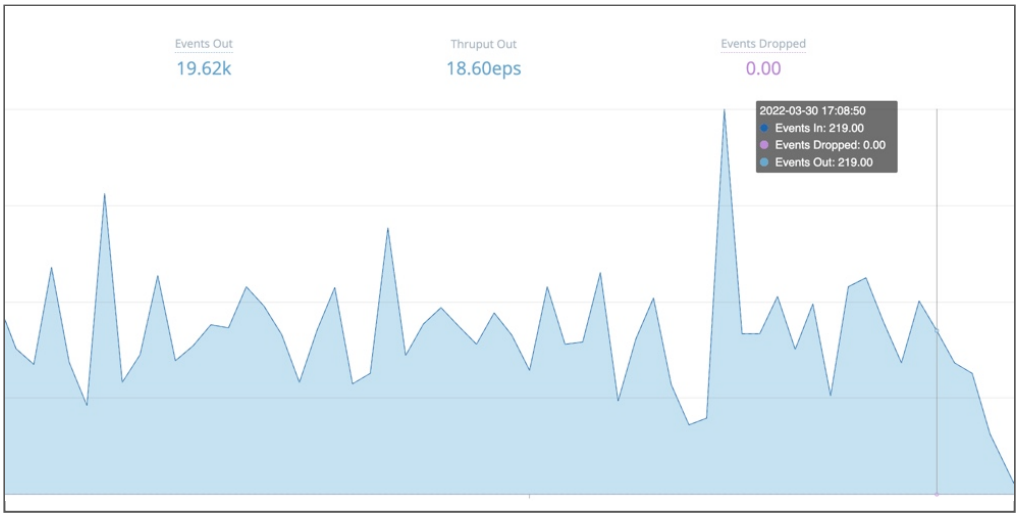
- Each row independently summarizes throughput for a separate Route.
- The left (blue) side summarizes events in/out. The right (orange) side summarizes bytes in/out.
- On each row, the top number summarizes average events/bytes into the Route, and the bottom number summarizes events/bytes out. Both are averaged over your selected time granularity.
- On each row, the upper Maximize button zooms up the left (events) graph, and the lower Maximize button zooms up the right (bytes) graph.



Routes page's multiple rows and controls

Fly-Out Details

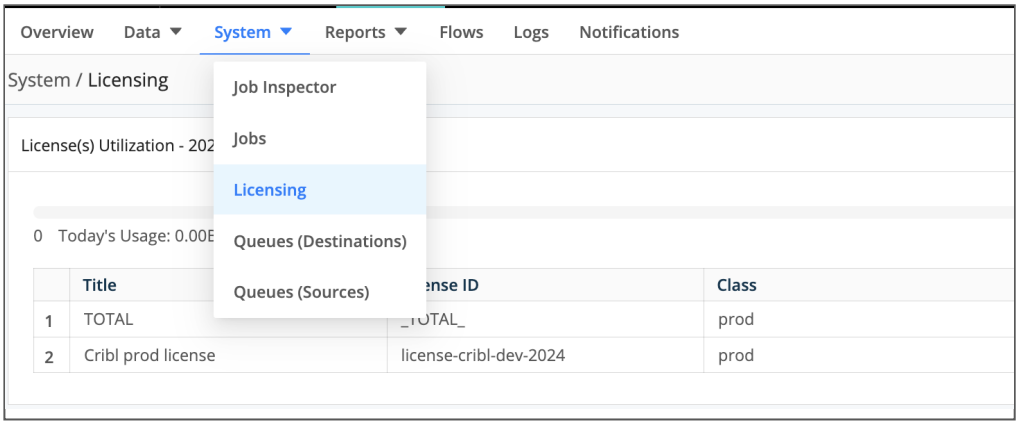
You can hover over graphs to display a fly-out with details. The **Free Memory** and **CPU Load Average** graphs only display fly-outs for up to 10 Worker Nodes, even when more Nodes are active. These fly-outs will occasionally show transient `0` metrics for some Workers, because Cribl Stream prioritizes reporting current throughput over memory/load metrics.



System Monitoring

From the **Monitoring** page, open the **System** submenu to isolate throughput for any of the following:

- Job Inspector
- Jobs (and tasks in-flight, see Collector Sources)
- Leaders (available only with High Availability enabled; see Second Leader)
- Licensing
- Queues (Destinations)
- Queues (Sources)



Monitoring > System submenu

Job Inspector

Select **System** then **Job Inspector** from the Monitoring page to view and manage pending, in-flight, and completed collection jobs and their tasks. For details about the resulting page, see Monitoring and Inspecting Collection Jobs.

Leaders

This menu item is available only in Distributed Deployments with High Availability (HA) enabled.

Select **Monitoring**, then **System** and **Leaders** to view the status of your Leader Nodes. For more information on how to configure a second Leader Node for failover/durability, see Second Leader).

Licensing

Select **System**, then **Licensing** from the Monitoring page to check the expiration dates of your licenses, daily data throughput, and events quotas. You can also compare your daily Stream and Edge data throughput against your license quota – and against granular and average throughput over the last 30 to 365 days.

In this graph, you'll see the following:

- A horizontal bar that indicates your quota limit.
- Combined legacy data represented by blue bars that show licensing usage prior to v4.6.0, when the system separated Edge data and Stream data.
- Tooltips display details about data usage, data amount over/under license quota, Edge dropped bytes, and data percentage over/under license quota.
- Dots on the daily usage bar graph represent configuration changes in the system.
- The **Daily Events In** chart only shows events that count towards your license, broken out by product (Stream and Edge). It filters out `datagen`, `cribl_http`, and `cribl_tcp` events.

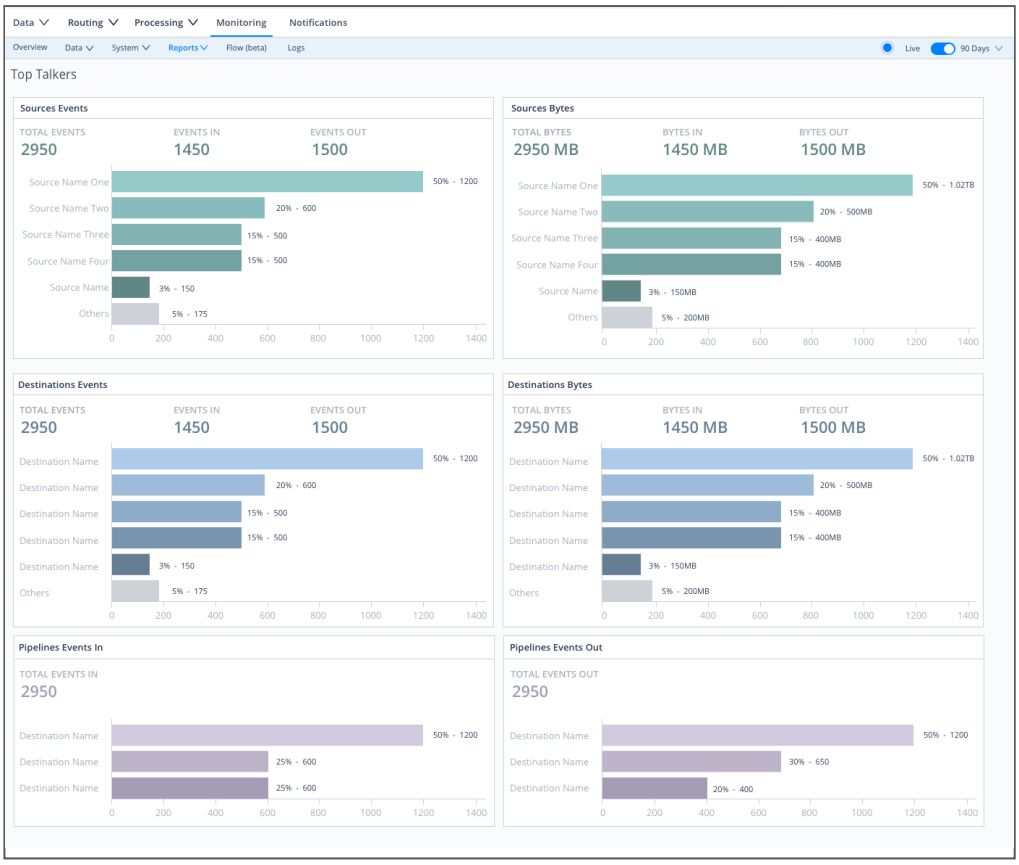
Licensing breakdown from the Monitoring page

Even on single-instance deployments, you must have `git` installed in order for the Monitoring > **Licensing** page to display configuration change markers.

For the most current and accurate throughput data, enable the Cribl Internal Source's CriblMetrics option. Forward metrics to your metrics Destination of choice, and run a report on `cribl.total.in_bytes`. CriblMetrics aggregates metrics at the Worker Process level, every 2 seconds.

Reports/Top Talkers

Select **Monitoring** > **Reports / Top Talkers** > **Top Talkers**, where you can examine your five highest-volume Sources, Destinations, Pipelines, Routes, and Packs. Cribl Stream ranks all components by events throughput. Sources and Destinations get separate rankings by bytes in and out, respectively.



Monitoring > Reports/Top Talkers

Flows

Select **Flows** from the Monitoring page's submenu or ••• overflow menu to see a graphical, left-to-right visualization of data flow through your Cribl Stream deployment.

Internal Logs and Metrics

Select **Logs** from the Monitoring page's submenu. Cribl Stream's internal logs and internal metrics provide comprehensive information about an instance's status/health, inputs, outputs, Pipelines, Routes, Functions, and traffic.

Types of Logs

Cribl Stream provides the following log types, by originating process:

- API Server Logs – The `API/main` process is the primary source for these logs. They correspond to the top-level `cribl.log` that shows up on the Diag page. These include telemetry/license-validation logs.

Filesystem location: `$CRIBL_HOME/log/cribl.log`

- Worker Process(es) Logs – These logs are emitted by all the Worker Processes, and are common on single-instance deployments and Workers. Filesystem location: `$CRIBL_HOME/log/worker/N/cribl.log`
- Worker Group/Fleet Logs – These logs are emitted by all processes that help a Leader Node configure Worker Groups/Fleets. Filesystem location: `$CRIBL_HOME/log/group/GROUPNAME/cribl.log`

In a distributed deployment (Stream), all Workers forward their metrics to the Leader Node, which then consolidates them to provide a deployment-wide view.

For details about generated log files, see Internal Logs. To work with logs in Cribl Stream's UI, see Search Internal Logs.

Log Rotation and Retention

Cribl Stream rotates logs every 5 MB, keeping the most recent 5 logs. Logs will reach the 5 MB threshold more quickly with verbose logging levels (such as `debug`) and with high volumes of system activity.

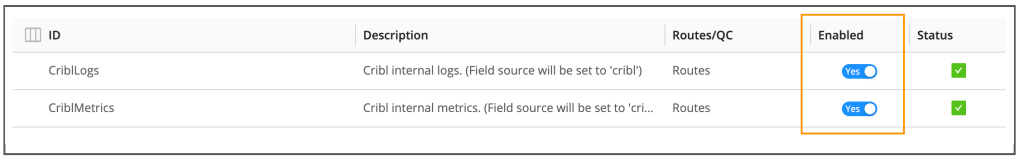
For long-term retention, Cribl recommends sending logs from the Leader, and from Workers' Cribl Internal > CriblLogs Sources, to a downstream service of your choice. See the next section for details.

Forward Logs and Metrics Externally

Cribl Stream supports forwarding internal logs and metrics to your preferred external monitoring solution. The Cribl Internal Source captures internal logs and metrics to send to Destinations.

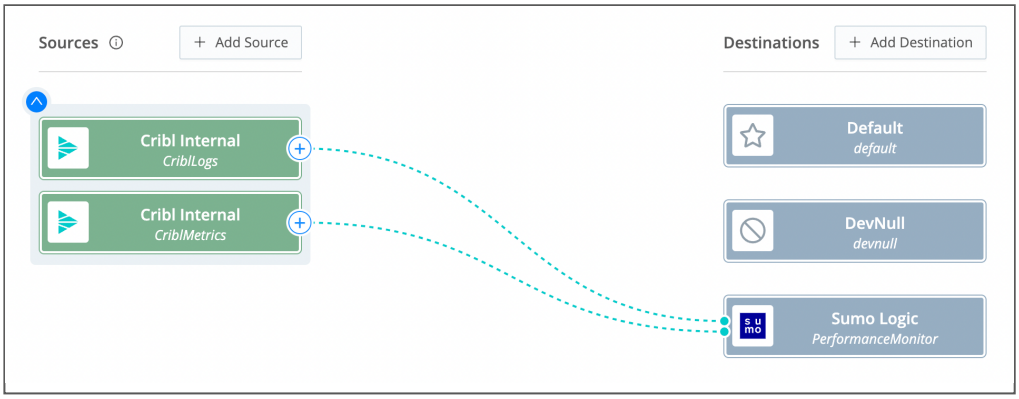
In the following steps, we'll use the graphical QuickConnect UI to set up the **Cribl Internal** Source and how data is sent to your Destination. See Cribl Internal for details on how to instead configure the **Cribl Internal** Source via the **Data** > **Sources** (Stream) or **More** > **Sources** (Edge) submenus.

1. On the top bar, select Products, and then select **Cribl Stream**. Then select a **Worker Group** to configure.
2. To open **QuickConnect**: Stream – select the **QuickConnect** tile on the **Overview** page. Edge – select the **Collect** submenu.
3. Select **Add Source**.
4. From the resulting drawer's tiles, select **System and Internal**, then hover over the **Cribl Internal** tile.
5. Select **Select Existing**.
6. On the **CriblLogs** and/or the **CriblMetrics** row, toggle **Enabled** to `Yes`. Confirm your choice in the resulting message box.



Cribl Internal Sources – Select to configure

7. Notice how the **Routes/QC** column still says **Routes**. We want to use QuickConnect, so we'll change this by clicking on the **CriblLogs** and/or the **CriblMetrics** row again. Once clicked, you'll confirm **Yes** to the message box asking to switch the Source to send to QuickConnect instead of Routes.
8. Select and drag the **+** button on the right side of the Source to your desired Destination.
   A **Connection Configuration** modal will prompt you to select a **Passthru**, **Pipeline**, or **Pack connection**. See QuickConnect for details.



Cribl Internal forwarding to Sumo Logic

9. This will send internal logs and metrics to your Destination, just like another data Source. Both logs and metrics will have a field called `source`, set to the value `cribl`, which you can use in Routes' filters.

Note that the only logs supported here are Worker Process logs (see Types of Logs above). You can, however, use a Script Collector to listen for API Server or Worker Group events.

For recommendations about useful Cribl metrics to monitor, see Internal Metrics.

Controlling Metrics Volume

To reduce the volume of metrics sent through Cribl Stream, see options on the Cribl Internal Source.

Disable Field Metrics

To send fewer metrics to the Leader Node, you can specify these metrics types in the blocklist at **Settings** > (**Global Settings**) > **System** > **General Settings** > **Limits** > **Metrics** > **Disable field metrics**.

The default fields to ignore are `host`, `source`, `sourcetype`, `index`, and `project`. You can remove any of the defaults, or add other fields you do not want to send as metrics.

However, when you enable the **Cribl Internal** Source, Cribl Stream ignores this **Disable field metrics** setting, and full-fidelity data will flow down the Routes.

Dropping Metrics

When the number of in-flight requests for sending metrics from Worker to Leader exceeds a limit (1,000 requests), Workers will stop sending metrics. Check `channel="clustercomm"` for a log of dropped metrics if needed.

You can exclude certain metrics from being dropped due to exceeding limits. Specify these metrics at **Settings** > **System** > **General Settings** > **Limits** > **Metrics** > **Metrics never-drop list**.

This setting is available only on Worker Nodes.

Metrics Garbage Collection

Metrics garbage collection (GC) runs when the total number of stored metrics exceeds the max metrics limit (default 1,000,000). Metrics are then removed, starting with the oldest ones. This happens both on Workers and Leaders.

You can define how often to run garbage collection on each Worker Group. Select **Group Settings** > **System** > **General Settings** > **Limits** > **Metrics** > **Metrics GC period**. The default is 60 seconds.

Metrics Tracking by Worker ID

Typically, Cribl Stream assigns all metrics their own Worker Node ID dimensions so they can be split by Worker if needed.

You can define which metrics are **not** assigned a Worker Node ID dimension by adding them to the list at **Group Settings** > **System** > **General Settings** > **Limits** > **Metrics** > **Metrics worker tracking**.

Control Metrics Lag and Disk Usage

If one or more Worker Groups has a large number of enabled Sources, and clicking into these Sources does not promptly display their status, a workaround is to prevent Cribl Stream from writing metrics to disk. On the Leader (versions 4.1.2 and later), navigate to **Settings** > **Global Settings** > **System** > **General Settings** > **Limits** > **Storage**, and disable the **Persist metrics** toggle. Then restart the Leader.

If you keep **Persist metrics** enabled, you can use the adjacent **Metrics max disk space** field to control the written metrics' footprint. This threshold defaults to `64 GB`.

Cardinality Limit

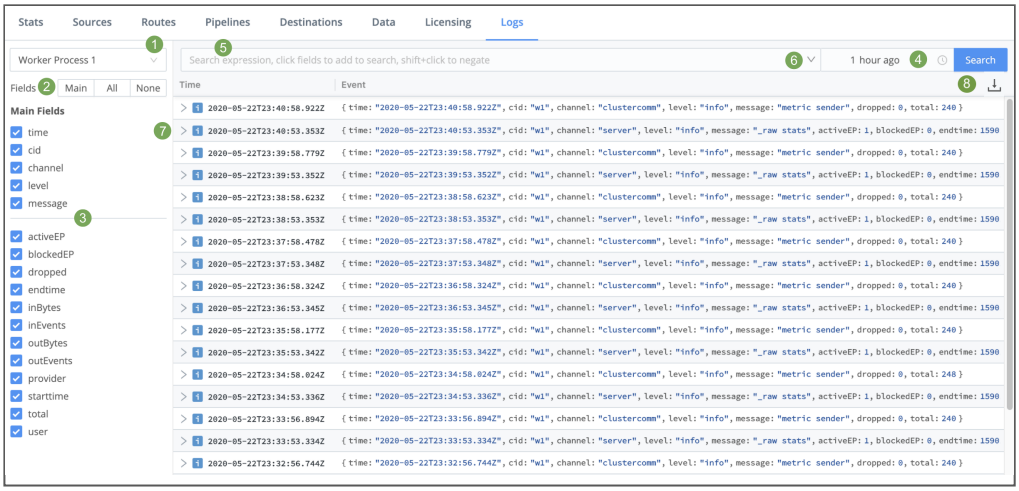
You can define the cardinality limit or metrics on each Worker Group. Select **Group Settings** > **System** > **General Settings** > **Limits** > **Metrics** > **Metrics cardinality limit** The default is 1,000.

Refer to **Monitoring** > **Data** > **Data Fields** to identify the fields that have the highest cardinality.

Search Internal Logs

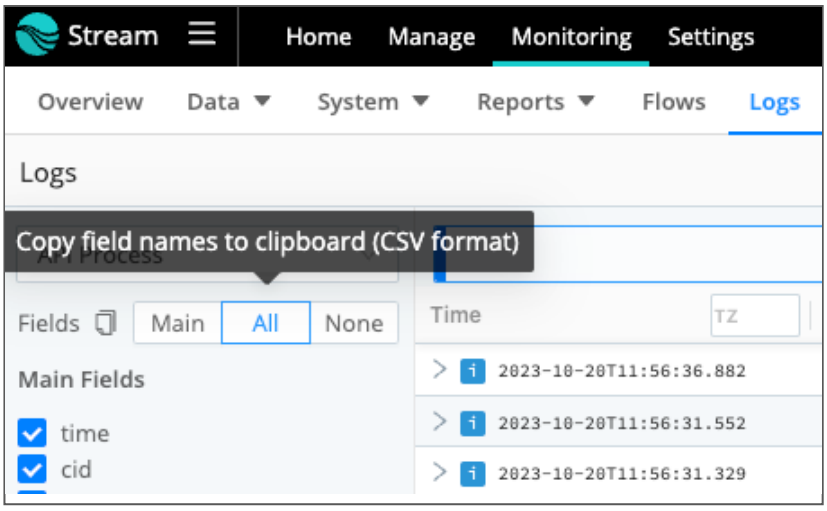
Cribl Stream exists because logs are great and wonderful things! Using Cribl Stream's **Monitoring > Logs** page, you can search all Cribl Stream's internal logs at once – from a single location, for both Leader and Worker. This enables you to query across all internal logs for strings of interest.

The labels on this screenshot highlight the key controls you can use (see the descriptions below):



Logs page (controls highlighted)

1. **Log file selector**: Choose the Node to view. In a distributed deployment (Stream), this list will be hierarchical, with Workers displayed inside their Leader.
2. **Fields selector**: Click the **Main** | **All** | **None** toggles to quickly select or deselect multiple check boxes below. Beside these toggles, a Copy button enables you to copy field names to the clipboard in CSV format.



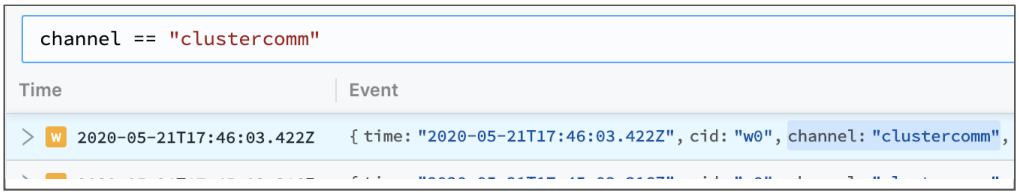
Monitoring - Copy Fields Icon

3. **Fields**: Select or deselect these check boxes to change the columns displayed in the Results pane at right. (The upper **Main Fields** group will contain data for *every* event; other fields might not display data for all events.)
4. **Time range selector**: Select a standard or custom range of log data to display. (The **Custom Time Range** pickers use your local time, even though the logs' timestamps are in UTC.)
5. **Search box**: To limit the displayed results, enter a JavaScript expression here. An expression must evaluate to `truthy` to return results. You can press **Shift+Enter** to insert a newline.

Typeahead assist is available for expression completion:

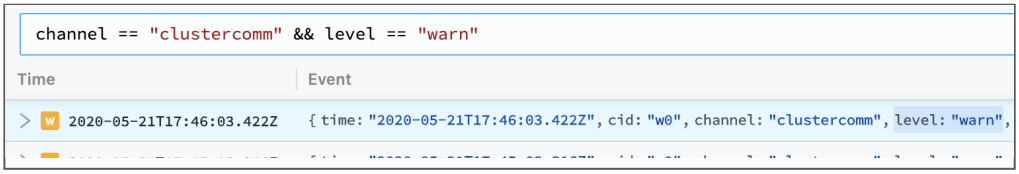
Expression autocompletion

Click a field in any event to add it to a query:



Click to add a field

Click other fields to append them to a query:



Click to append a field

Shift+click to *negate* a field:

Shift-click to negate a field

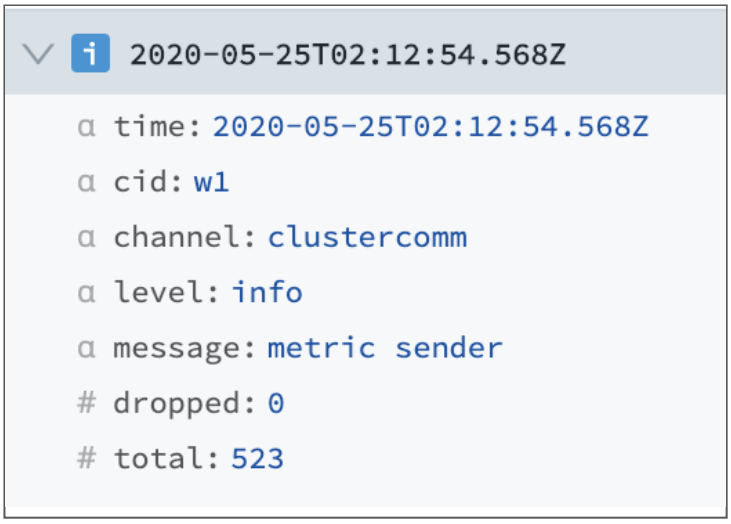
To modify the depth of information that is originally input to the Logs page, see Logging Settings.

6. Click the Search box's history arrow (right side) to retrieve recent queries:

Retrieve recent searches

7. The Results pane displays most-recent events first. Each event's icon is color-coded to match the event's severity level.

Click individual log events to unwrap an expanded view of their fields:



Log event details

8. **Export Logs as JSON** button: Exports logs as a file initially named `CriblMonitoringLogs.json`. (You can edit this name upon export.) The logs' scope will be filtered both by your Time range selector setting, and by how fully you've scrolled down to lazy-load that time range into the displayed UI.

Logging Settings

On Cribl Stream's Settings pages, you can adjust the level (verbosity) of internal logging data processed, per logging channel. You can also redact fields in customized ways. In a Distributed Deployment, you manage each of these settings per Worker Group.

The logging levels help to categorize the detail and severity of logged information. Choosing the right level ensures you get the information you need for troubleshooting without getting overwhelmed by a flood of data.

Here's a breakdown of each logging level:

Code	Description
`error`	Logs only critical issues that have occurred, which need immediate attention to ensure the system's integrity.
`warn`	Logs warnings about potential issues that might not be critical but warrant attention to prevent future problems.
`info`	Logs general information about the system's operation, providing insights into standard processes and procedures.
`debug`	Logs detailed information for diagnosing and troubleshooting potential problems, providing deep insights into the system's behavior.
`silly`	Logs extremely detailed information and metrics, primarily used for in-depth troubleshooting of inputs and other operations.Use it sparingly and only for short debugging bursts, treating it as "use at your own risk." Enable temporarily, then disable promptly.

Notes:

- By default, all integration logging levels are set to `info`. This default setting displays the means logs of level `info` and above (including `error` and `warn`). Manually adjust this setting to see `debug` and `silly` logs.
- Cribl.Cloud users cannot adjust logging levels for Worker Groups or specific integrations.

Change Logging Levels

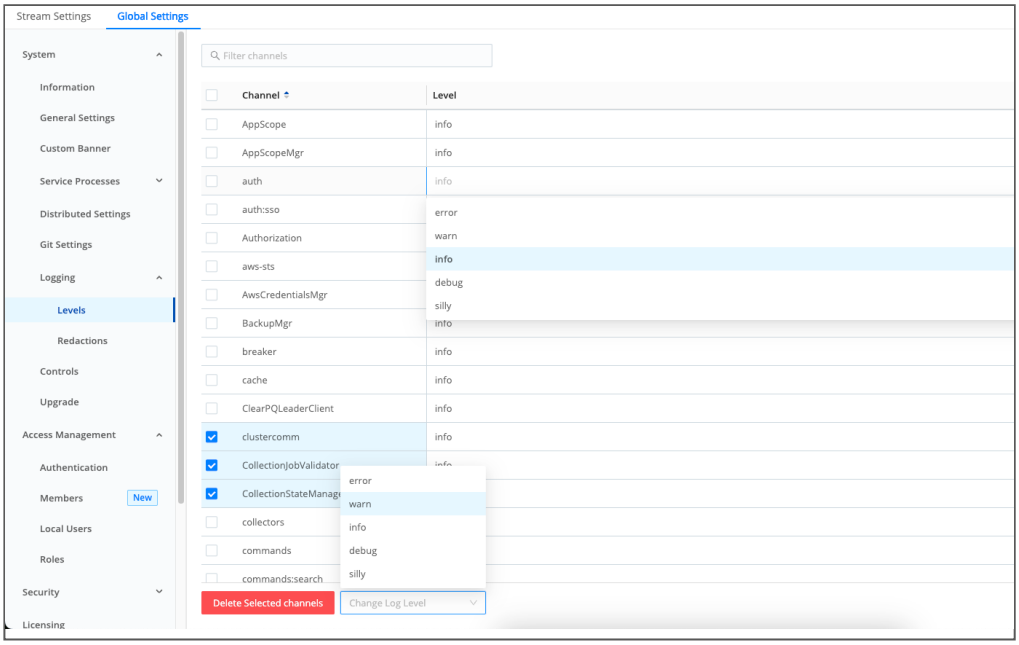
To adjust logging levels:

- In a single-instance deployment, select **Settings** > **System** > **Logging** > **Levels**.
- For the Leader Node's own logs, select **Settings** > **Global Settings** > **System** > **Logging** > **Levels**.

- In a distributed deployment, select the group you want to configure. Next, select **Group Settings** (or **Fleet Settings**) > **System** > **Logging** > **Levels**.

On the resulting **Manage Logging Levels** page, you can:

- Modify one channel by clicking its **Level** column. In the resulting drop-down, you can set a verbosity level ranging from **error** up to **debug**. (Top of composite screenshot below.)
- Modify multiple channels by selecting their check boxes, then clicking the **Change log level** drop-down at the bottom of the page. (Bottom of composite screenshot below.) You can select all channels at once by clicking the top check box. You can search for channels at top right.

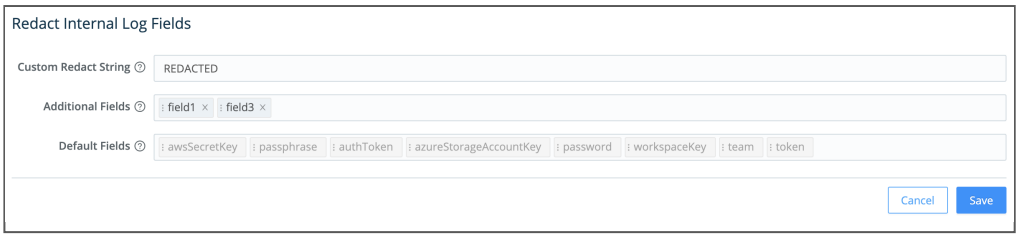


Manage Logging Levels page

Change Logging Redactions

On the **Redact Internal Log Fields** page, you can customize the redaction of sensitive, verbose, or just ugly data within Cribl Stream's internal logs. To access these settings:

- In a single-instance deployment, select **Settings** > **System** > **Logging** > **Redactions**.
- In a single-instance deployment, or for the Leader Node's own logs, select **Settings** > **Global Settings** > **System** > **Logging** > **Redactions**.
- In a distributed deployment, select the group you want to configure. Next, select that group's **Group Settings** > **System** > **Logging** > **Redactions**.



Redact Internal Log Fields page

It's easiest to understand the resulting **Redact Internal Log Fields** page's fields from bottom to top:

- **Default fields**: Cribl Stream always redacts these fields, and you can't modify this list to allow any of them through. However, you can use the two adjacent fields to define stricter redaction:
- **Additional fields**: Type or paste in the names of extra fields you want to redact. Use a tab or hard return to confirm each entry.
- **Custom redact string**: Unless this field is empty, it defines a literal string that will override Cribl Stream's default redaction pattern (explained below) on the affected fields.

Default Redact String

By default, Cribl Stream transforms this page's selected fields by applying the following redaction pattern:

- Echo the field value's first two characters.
- Replace all intermediate characters with a literal `...` ellipsis.
- Echo the value's last two characters.

Anything you enter in the **Custom redact string** field will override this default `??...??` pattern.

Health Endpoint

Each Cribl Stream instance exposes a `health` endpoint – typically used in conjunction with a Load Balancer – that you can use to make operational decisions.

A healthy response (`200 – Healthy` response code) indicates only that the server is running. It does not mean that all the instance's configured Sources are functioning correctly.

Health Check Endpoint	Healthy Response
`curl http(s)://<host>:<port>/api/v1/health`	`{"status":"healthy","startTime":1617814717110}`

Specifically, the `health` endpoint can return one of the following response codes:

- 200 – Healthy.
- 420 – Shutting down.
- 503 – HTTP engine reports server busy: too many concurrent connections (configurable).

In the above curl example, `<port>` stands for the API port (by default, `9000`).

Several HTTP-based Sources provide the option to enable a Source-level health check endpoint. Enable this option in the **Advanced Settings** for the Source. This option uses `http(s)://<host>:<port>/cribl_health`.

12.1. Internal Metrics

When sending Cribl Stream metrics to a metric system of analysis – such as InfluxDB, Splunk, or Elasticsearch – some metrics are particularly valuable. You can use these metrics to set up alerts when Worker Nodes are having problems, a Node is down, a Destination is down, a Source stops providing incoming data, and so on.

Cribl Stream reports its internal metrics within the Cribl Stream UI, in the same way that it reports internal logs. Navigate to **Monitoring** > **Logs** (Cribl Stream), or to a Fleet's **Health** > **Sources** tab (Cribl Edge).

To expose metrics for capture or routing, enable the Cribl Internal Source in the Fleet, then enable **CriblMetrics**.

You can also export metrics (and logs) to JSON files.

By default, Cribl Stream generates internal metrics every 2 seconds. To consume metrics at longer intervals, you can use or adapt the `cribl-metrics_rollup` Pipeline that ships with Cribl Stream. Attach it to your **Cribl Internal** Source as a pre-processing Pipeline. The Pipeline's **Rollup Metrics** Function has a default **Time Window** of 30 seconds, which you can adjust to a different granularity as needed.

You can also use our public endpoints to automate monitoring using your own external tools.

Counter-type metrics in Cribl Stream do not monotonically increase or decrease. They are reset at the end of each reporting period. Cribl Stream does not report counters when their value is 0. For example, if there aren't any Destinations reporting dropped events then the `total.dropped_events` metric won't be reported because its value would be 0.

Breaking Changes

- The `ci` and `co` dimensions are deprecated as of Cribl Stream 4.1.2. See Dimensions for their replacements.
- Disabled Sources no longer generate Cribl internal metrics as of Cribl Stream 4.2.

Total Throughput Metrics

Five important metrics below are prefixed with `total.` These power the top of Cribl Stream's **Monitoring** dashboard. The first two report on Sources, the remainder on Destinations.

- `total.in_bytes`
- `total.in_events`
- `total.out_events`

- `total.out_bytes`
- `total.dropped_events` – helpful for discovering situations such as: you've disabled a Destination without noticing.

Interpreting Total Metrics

These `total.` metrics' values could reflect Cribl Stream's health, but could also report low activity simply due to the Source system. For example, logs from a store site will be low at low buying periods.

Also, despite the `total.` prefix, these metrics are each specific to the Worker/Edge Node Process that's generating them.

You can distinguish **unique** metrics by their `#input=<id>` dimension. For example, `total.in_events|#input=foo` would be one unique metric, while `total.in_events|#input=bar` would be another.

System Health Metrics

Five specific metrics are most valuable for monitoring system health. The first two are Cribl Stream composite metrics; the remaining three report on your hardware or VM infrastructure. Because the Cribl Internal Source does not export these metrics to Routes or Pipelines, you can obtain them only by using the REST endpoints listed on this page.

- `health.inputs`
- `health.outputs` – see the JSON Examples below for both `health.` metrics.
- `system.load_avg`
- `system.free_mem`
- `system.disk_used` – valuable if you know your disk size, especially for monitoring Persistent Queues. Here, a `0` value typically indicates that the disk-usage data provider has not yet provided the metric with data. (Getting the first value should take about one minute.)

All of the above metrics take these three values:

- `0` = green = healthy.
- `1` = yellow = warning.
- `2` = red = trouble.

Health Inputs/Outputs JSON Examples

The `health.inputs` metrics are reported per Source, and the `health.outputs` metrics per Destination. The `health.inputs` example below has two configured Sources, and two Cribl Stream-internal inputs. The `health.outputs` example includes the built-in `devnull` Destination, and six user-configured Destinations.

Given all the `0` values here, everything is in good shape!

```
"health.inputs": [
  { "model": { "input": "http:http" }}, "val": 0},
  { "model": { "input": "cribl:CriblLogs" }}, "val": 0},
  { "model": { "input": "cribl:CriblMetrics" }}, "val": 0},
  { "model": { "input": "datagen:DatagenWeblog" }}, "val": 0 }
  ],
"health.outputs": [
  { "model": { "output": "devnull:devnull" }}, "val": 0},
  { "model": { "output": "router:MyOut1" }}, "val": 0},
  { "model": { "output": "tcpjson:MyTcpOut1" }}, "val": 0},
  { "model": { "output": "router:MyOut2" }}, "val": 0},
  { "model": { "output": "tcpjson:MyTcpOut2" }}, "val": 0},
  { "model": { "output": "router:MyOut3" }}, "val": 0},
  { "model": { "output": "router:MyOut4" }}, "val": 0 }
  ],
```

Worker Node Resource Metrics

The Cribl Internal Source reports two useful metrics on the resource usage of individual Worker Node Processes:

- `system.cpu_perc` – CPU percentage usage.
- `system.mem_rss` – RAM usage in bytes.

Worker Node Shutdown Metric

This metric tracks events lost during Worker Process shutdown:

- `shutdown.lost_events` – Number of events lost because they were not flushed before the **Drain timeout** elapsed during Worker Process shutdown, as explained on the Shutdown and Restart Sequence docs.

Persistent Queue Metrics

These metrics are valuable for monitoring Persistent Queues' behavior:

- `pq.queue_size` – Total bytes in the queue.
- `pq.in_bytes` – Total bytes in the queue for the given **Time Window**.
- `pq.in_events` – Number of events in the queue for the given **Time Window**.
- `pq.out_bytes` – Total bytes flushed from the queue for the given **Time Window**.
- `pq.out_events` – Number of events flushed from the queue for the given **Time Window**.

These are aggregate metrics, but you can distinguish unique metrics per queue. On the Destination side, use the `#output=<id>` dimension. For example, `pq.out_events|#output=kafka` would be one unique metric; `pq.out_events|#output=camus` would be another.

Other Internal Metrics

The Cribl Internal Source emits other metrics that, when displayed in downstream dashboards, can be useful for understanding Cribl Stream's behavior and health. These include:

- `cribl.logstream.total.activeCxn` – Total active inbound TCP connections.
- `cribl.logstream.pipe.in_events` – Inbound events per Pipeline.
- `cribl.logstream.pipe.out_events` – Outbound events per Pipeline.
- `cribl.logstream.pipe.dropped_events` – Dropped events per Pipeline.
- `cribl.logstream.metrics_pool.num_metrics` – The total number of unique metrics that have been allocated into memory.
- `cribl.logstream.collector_cache.size` – Each Collector function (`default/cribl/collectors/<collector>/index.js`) is loaded/initialized only once per job, and then cached. This metric represents the current size of this cache.
- `cribl.logstream.cluster.metrics.sender.inflight` – Number of metric packets currently being sent from a Worker/Edge Node Process to the API Process, via IPC (interprocess communication).
- `cribl.logstream.backpressure.outputs` – Destinations experiencing backpressure, causing events to be either blocked or dropped.
- `cribl.logstream.blocked.outputs` – Blocked Destinations. (This metric is more restrictive than the one listed just above.)
- `cribl.logstream.pq.queue_size` – Current queue size, in bytes, per Worker Process.
- `cribl.logstream.host.in_bytes` – Inbound bytes from a given host (host is a characteristic of the data).
- `cribl.logstream.host.in_events` – Inbound events from a given host (host is a characteristic of the data).

- `cribl.logstream.host.out_bytes` – Outbound bytes from a given host (host is a characteristic of the data).
- `cribl.logstream.host.out_events` – Outbound events from a given host (host is a characteristic of the data).
- `cribl.logstream.index.in_bytes` – Inbound bytes per index.
- `cribl.logstream.index.in_events` – Inbound events per index.
- `cribl.logstream.index.out_bytes` – Outbound bytes per index.
- `cribl.logstream.index.out_events` – Outbound events per index.
- `cribl.logstream.route.in_bytes` – Inbound bytes per Route.
- `cribl.logstream.route.in_events` – Inbound events per Route.
- `cribl.logstream.route.out_bytes` – Outbound bytes per Route.
- `cribl.logstream.route.out_events` – Outbound events per Route.
- `cribl.logstream.source.in_bytes` – Inbound bytes per Source.
- `cribl.logstream.source.in_events` – Inbound events per Source.
- `cribl.logstream.source.out_bytes` – Outbound bytes per Source.
- `cribl.logstream.source.out_events` – Outbound events per Source.
- `cribl.logstream.sourcetype.in_bytes` – Inbound bytes per sourcetype.
- `cribl.logstream.sourcetype.in_events` – Inbound events per sourcetype.
- `cribl.logstream.sourcetype.out_bytes` – Outbound bytes per sourcetype.
- `cribl.logstream.sourcetype.out_events` – Outbound events per sourcetype.
- `nodecluster.primary.messages` – Number of IPC (interprocess communication) calls made by a Worker/Edge Node Process to the API Process.

Dimensions

Cribl Stream internal metrics have extra dimensions. These include:

- `cribl_wp` – Identifies the Worker/Edge Node Process that processed the event.
- `event_host` – Machine's hostname from which the event was made.
- `event_source` – Set as `cribl`.
- `group` – Name of Cribl Worker Group from which the event was made.
- `input` – Entire **Input ID**, including the prefix, from which the event was made.
- `output` – Entire **Output ID**, including the prefix, from which the event was made.
- `ci` – Deprecated; use `input` instead. Cribl plans to drop support for this dimension after version 4.x.

- `co` – Deprecated; use `output` instead. Cribl plans to drop support for this dimension after version 4.x.

The `ci` and `co` (duplicate) dimensions are deprecated as of Cribl Stream 4.1.2, and will be removed in a future version. Where any of your code relies on these dimensions, Cribl recommends that you promptly substitute their respective replacements, `input` and `output`. This applies to relevant Cribl Functions and Pipelines, dashboards in downstream services, etc.

Control Metrics

You can control the volume of internal metrics that Cribl Stream emits, by adjusting Metrics Limits. You access these as follows, per deployment type:

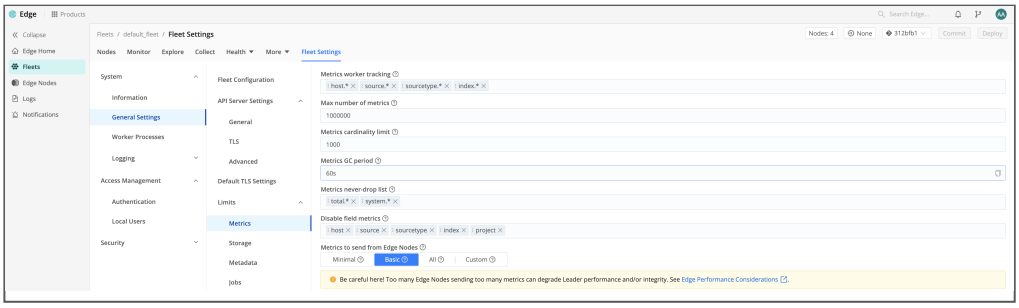
- Single-instance: **Settings** > **System** > **General Settings** > **Limits** > **Metrics**.
- Distributed Leader: **Settings** > **Global Settings** > **System** > **General Settings** > **Limits** > **Metrics**.
- Distributed Worker Groups: [Select a Worker Group] > **Group Settings** > **System** > **General Settings** > **Limits** > **Metrics**.

Here, you can adjust the maximum number of metric series allowed, metrics' cardinality, metrics to always include (**Metrics never-drop list**), metrics to always exclude in order to optimize performance (**Disable field metrics**), and other options.

Here's how these controls look in Cribl Stream:

Metrics settings for Cribl Stream Worker Groups

They're somewhat different in Cribl Edge – see the next section for an explanation:



Metrics settings for Cribl Edge Fleets

Control Metrics in Cribl Edge

Cribl Edge lets you choose what metrics each Fleet sends to its Leader Node. Your goal should be to collect the metrics most important to you, within the limits of the Leader's capacity to process them. This is a matter of balancing Fleet cardinality and Leader performance, as explained in the Deployment Planning topic.

Use the **Metrics to send from Edge Nodes** buttons to select one of the metrics sets listed in the table below.

Set	Purpose	List of Metrics Sent
Minimal	Sends metrics for events and bytes in and out. Recommended for high-cardinality deployments.	Sent as aggregate totals per Fleet: `total.in_events`, `total.out_events`, `total.in_bytes`, `total.out_bytes` excluding metrics that are coming directly from Sources or Destinations.

Basic (default)	Contains all the metrics in the minimal set, and more. Sends metrics required to display all monitoring data available in the Edge UI.	Sent as aggregate totals per Source/Destination:
		
		`total.in_events`, `total.out_events`, `total.in_bytes`, `total.out_bytes`.
		
		Also, Sent as aggregate totals per Source:
		
		`health.inputs`
		
		Sent as aggregate totals per Destination:
		
		`health.outputs`
		
		Sent as aggregate totals per Route:
		
		`route.in_events`, `route.in_bytes`, `route.out_events`, `route.out_bytes`, `route.dropped_events`
		
		Sent as aggregate totals per Pipeline:
		
		`pipe.in_events`, `pipe.out_events`, `pipe.dropped_events`
		
		Sent as aggregate totals per Pack:
		
		`pack.in_events`, `pack.out_events`, `pack.err_events`, `pack.dropped_events`

All	Send all metrics with no filtering.	All metrics without filtering, including **Basic**, plus Worker/Edge Node Resource Metrics,

Set	Purpose	List of Metrics Sent
		Persistent Queue Metrics, and Other Internal Metrics.
Custom	Send a customized set of metrics.	All metrics that match a JavaScript expression that you define, plus the metrics in the **Minimal** set.

Basic is the default selection, and includes the **Minimal** set of metrics. Every Edge Fleet always sends at least **Minimal** metrics, and selecting one of the other options adds more metrics.

Choosing the **Minimal** metrics set has the following effects in the Edge UI:

- Only one UI page, **Edge Home** > **Monitor**, will be fully populated. For the metrics that the **Minimal** set excludes, other pages will show zero values. This applies to the **[Select a Fleet]** > **Health** pages for **Sources**, **Destinations**, **Routes**, **Pipelines**, and **Packs**.
- In the **[Select a Fleet]** > **More** pages for **Sources** and **Destinations**, the health indicators in the tile and list views do not function when you select the **Minimal** set. Rather than red, green, or gray, they'll always show white, because the relevant metrics, `health.inputs` and `health.outputs`, will not be sent to the Leader.

The simplest form of a **Custom** set just specifies additional desired metrics by name, using an expression of the form: `name === "metric.name"`. Among the most useful metrics to consider adding are `system.load_avg`, `system.free_mem`, `system.disk_used`, `system.cpu_perc`, and `system.mem_rss`.

Custom Metrics and Their Impact on Monitoring

Enabling custom metrics switches monitoring from **Basic** to **Minimal**. This hides monitoring data for Fleets and Edge Nodes, giving the impression that data flow has stopped. To ensure system monitoring features work as expected with custom metrics, include the **Basic** metrics set within the custom configuration.

Other Metrics Endpoints

Below is basic information on using the `/system/metrics` endpoint, the `/system/info` endpoint, and the `cribl_wp` dimension.

`/system/metrics` Endpoint

`/system/metrics` is Cribl Stream's primary public metrics endpoint, which returns most internal metrics. Note that many of these retrieved metrics report configuration only, not runtime behavior. For details, see our API Docs.

`/system/info` Endpoint

`/system/info` generates the JSON displayed in the Cribl Stream UI at **Settings** > **Global Settings** > **Diagnostics** > **System Info**. Its two most useful properties are `loadavg` and `memory`.

`loadavg` Example

```
"loadavg": [1.39599609375, 1.22265625, 1.31494140625],
```

This property is an array containing the 1-, 5-, and 15-minute load averages at the UNIX OS level. (On Windows, the return value is always `[0, 0, 0]`.) For details, see the Node.js os.loadavg() documentation.

`memory` Example

```
"memory": { "free": 936206336, "total": 16672968704 },
```

Divide `total / free` to monitor memory pressure. If the result exceeds 90%, this indicates a risky situation: you're running out of memory.

`cpus` Alternative

The `cpus` metric returns an array of CPU/memory key-value pairs. This provides an alternative way to understand CPU utilization, but it requires you to query all your CPUs individually.

12.2. Internal Logs

Cribl Stream generates internal application logs that monitor its own operations and health. They provide valuable insights into the system's behavior, performance, and potential issues.

Distributed deployments emit a larger set of logs than single-instance deployments. We'll describe the distributed set first.

You can display and export all internal logs by selecting **Monitoring** in the sidebar, then selecting **Logs** (Stream) or selecting **Logs** in the sidebar (Edge). Logs' persistence depends on event volume, not time – for details, see Log Rotation and Retention.

Currently, most logs listed on this page are available only in on-prem deployments. Cribl.Cloud currently supports only Worker Node logs, and only on customer-managed hybrid Workers.

Leader Node Logs (Distributed)

The `API/main` process emits the following logs into the Leader Node's `$CRIBL_HOME/log/` directory.

Logfile Name	Description	Equivalent on Logs page
`cribl.log`	Principal log in Cribl Stream. Includes telemetry/license-validation logs. Corresponds to top-level `cribl.log` on Diag page.	**Leader** > **API Process**
`access.log`	API calls, e.g., `GET /api/v1/version/info`.	**Leader** > **Access**
`audit.log`	Actions pertaining to files, e.g., `create`, `update`, `commit`, `deploy`, `delete`.	**Leader** > **Audit**
`notifications.log`	Messages that appear in the Notification list in the UI.	**Leader** > **Notifications**
`ui-access.log`	Interactions with different UI components described as URLs, e.g., `/settings/apidocs`, `/dashboard/logs`.	**Leader** > **UI Access**

The `API/main` process emits the following service logs into the Leader Node's `$CRIBL_HOME/log/service/` directory. Each service includes a `cribl.log` file that logs the service's internal telemetry and an `access.log` file that logs which API calls the service has handled.

SERVICE NAME	DESCRIPTION	EQUIVALENT ON Logs PAGE
Connections Service	Handles all worker connections and communication, including heartbeats, bundle deploys, teleporting, restarting, etc. Workers are assigned to connection processes using a round-robin algorithm.	**Leader** > **Connections Service**
Lease Renewal Service	Handles lease renewal for the primary Leader Node.	**Leader** > **Lease Renewal Service**
Metrics Service	Handles in-memory metrics, merging of incoming packets, metrics persistence and rehydration, and UI queries for metrics.	**Leader** > **Metrics Service**
Notifications Service	Triggers Notifications based on its configuration.	**Leader** > **Notifications Service**

The Config Helper process for each Worker Group/Fleet emits the following log in `$CRIBL_HOME/log/group/GROUPNAME`.

Logfile Name	Description	Equivalent on Logs page
`cribl.log`	Messages about config maintenance, previews, etc.	**GROUPNAME** > **Config helper**

Worker Node Logs (Distributed)

The API Process emits the following log in `$CRIBL_HOME/log/`.

Logfile Name	Description	Equivalent on Logs page
`cribl.log`	Messages about the Worker/Edge Node communicating with the Leader Node (i.e., with its API Process) and other API requests, e.g., sending metrics, reaping job artifacts.	**GROUPNAME** > **Worker:HOSTNAME** > **API Process**

Each Worker Process emits the following logs in `$CRIBL_HOME/log/worker/N/`, where `N` is the Worker/Edge Node Process ID. (The `metrics.log` file is written only when HTTP-based Destinations exist.)

Logfile Name	Description	Equivalent on Logs page
`cribl.log`	Messages about the Worker/Edge Node processing data.	**GROUPNAME** > **Worker:HOSTNAME** > **Worker Process N**

Logfile Name	Description	Equivalent on Logs page
`metrics.log`	Messages about the Worker/Edge Node's outbound HTTP request statistics.	**GROUPNAME** > **Worker:HOSTNAME** > **Worker Process N**

For convenience, the UI aggregates the Worker/Edge Node Process logs as follows.

Logfile Name	Description	Equivalent on Logs page
N/A	Aggregation of all the `Worker Process N` logs and the API Process log.	**GROUPNAME** > **WORKER_NAME**

The Worker Node logs listed above are currently available only on customer-managed hybrid Workers. The single-instance logs listed below are not relevant to Cribl.Cloud.

Single-Instance Logs

The `API/main` process emits the same logs as it does for a Distributed deployment, in `$CRIBL_HOME/log/`:

- `cribl.log`
- `access.log`
- `audit.log`
- `notifications.log`
- `ui-access.log`

Each Worker/Edge Node Process emits the following logs in `$CRIBL_HOME/log/worker/N/`, where `N` is the Worker/Edge Node Process ID. (The `metrics.log` file is written only when HTTP-based Destinations exist.)

Logfile Name	Description	Equivalent on Logs page
`cribl.log`	Messages about the Worker/Edge Node processing data.	**GROUPNAME** > **Worker:HOSTNAME** > **Worker Process N**
`metrics.log`	Messages about the Worker/Edge Node's outbound HTTP request statistics.	**GROUPNAME** > **Worker:HOSTNAME** > **Worker Process N**

`_raw stats` Event Fields

Each Worker/Edge Node Process logs this information at a 1-minute frequency. So each event's scope covers only that Worker/Edge Node Process, over a 1-minute time span defined by the `startTime` and `endTime` fields.

Sample Event

```
{"time":"2022-11-17T16:54:05.349Z","cid":"w0","channel":"server","level":"info","mes
```

Field Descriptions

Field	Description
`abortCxn`	Number of TCP connections that were aborted.
`activeCxn`	Number of TCP connections newly opened at the time the `_raw` stats are logged. (This is a gauge when exported in internal metrics, and can otherwise be ignored as an instantaneous measurement. Only some application protocols count toward this; e.g., any HTTP-based Source does not count.)
`activeEP`	Number of currently active event processors (EPs). EPs are used to process events through Breakers and Pipelines as the events are received from Sources and sent to destinations. EPs are typically created per TCP connection (such as for HTTP).
`blockedEP`	Number of currently blocked event processors (caused by blocking Destinations).
`closeCxn`	Number of TCP connections that were closed.
`cpuPerc`	CPU utilization from the combined user and system activity over the last 60 seconds.
`droppedEvents`	This is equivalent to the `total.dropped_events` metric. Drops can occur from Pipeline Functions, from Destination Backpressure, or from other errors. Any event not sent to a Destination is considered dropped.
`eluPerc`	Event loop utilization. Represents the percentage of time over the last 60 seconds that the NodeJS runtime spent processing events within its event loop.
`endTime`	The end of the timespan represented by these metrics. (Will always be 60 seconds after `startTime`.)
`inBytes`	Number of bytes received from all Sources (based only off `_raw`).
`inEvents`	Number of events received from all inputs after Event Breakers are applied. This can be larger than `outEvents` if events are dropped via Drop, Aggregation, Suppression, Sampling, or similar Functions.
`mem.buffers`	Memory allocated for ArrayBuffers and SharedArrayBuffers.

Field	Description
`mem.ext`	External section of process memory, in MB.
`mem.heap`	Used heap section of process memory, in MB.
`mem.heapTotal`	Total heap section of process memory, in MB.
`mem.rss`	Resident set size section of process memory, in MB.
`openCxn`	Same as `activeCxn`, but tracked as a counter rather than a gauge. So `openCxn` will show all connections newly opened each minute, and is more accurate than using `activeCxn`.
`outBytes`	Number of bytes sent to all Destinations (based only off `_raw`).
`outEvents`	Number of events sent out to all Destinations. This can be larger than `inEvents` due to creating event clones or entirely new unique events (such as when using the Aggregation Function).
`pqInBytes`	Number of bytes that were written to persistent queues, across all Destinations.
`pqInEvents`	Number of events that were written to persistent queues, across all Destinations.
`pqOutBytes`	Number of bytes that were flushed from persistent queues, across all Destinations.
`pqOutEvents`	Number of events that were flushed from persistent queues, across all Destinations.
`pqTotalBytes`	Amount of data currently stored in persistent queues, across all Destinations.
`rejectCxn`	Number of TCP connections that were rejected.
`startTime`	The beginning of the timespan represented by these metrics.
`tasksCompleted`	The number of tasks the process has started and completed for all collection jobs for which it was executing tasks.
`tasksStarted`	The number of tasks the process started for all collection jobs for which it was executing tasks.

Troubleshooting With the `cribl_stderr` Log

In rare instances, Cribl Stream's Node.js backend may encounter an OOM or fatal error, preventing logging to its usual location. To aid in troubleshooting, a special `cribl_stderr.log` file is created, containing timestamped error details in UTC. This file is intended for Cribl Support and is not accessible through the UI.

To prevent excessive disk usage, Cribl Stream implements log rotation for `cribl_stderr.log`, limiting files to 5MB each with a maximum of 5 rotated copies. This addresses an issue where the log file could rapidly expand

due to logged errors, impacting system performance.

13. Working With Data

13.1. Event Model

Cribl Stream bases all data processing on discrete data entities commonly known as **events**. An event is a collection of key-value pairs (fields). Some Sources deliver events directly, while others might deliver bytestreams that need to be broken up by Event Breakers. Events travel from a Source through Pipelines' Functions, and on to Destinations.

The internal representation of a Cribl Stream event is as follows:

Event Model

```
{
  "_raw": "<body of non-JSON parse-able event>",
  "_time": "<timestamp in UNIX epoch format>",
  "__inputId": "<Id/Name of Source that delivered the event>",
  "__other1": "<Internal field1>",
  "__other2": "<Internal field2>",
  "__otherN": "<Internal fieldN>",
  "key1": "<value1>",
  "key2": "<value2>",
  "keyN": "<valueN>",
  "...": "..."
}
```

Internal Fields

Cribl Stream adds internal fields before Pipeline data processing. They serialize only to Cribl internal Destinations.

A few notes about internal fields:

- Internal fields start with a double-underscore.
- Each Source can add one or many internal fields to each event. For example, Syslog adds both a `__inputId` and a `__srcIpPort` field.
- Treat internal fields as read-only. Modifying them can result in unintended consequences to your data flows.
- Upon arrival from a Source, if an event cannot be JSON-parsed, Cribl assigns all of its content to `_raw`.

- If you do not configure a timestamp for extraction, the Pipeline process assigns the current time (in UNIX epoch format) to the `_time` field. (Note that when Cribl Stream emits events based on incoming Kafka messages, it handles the `_time` field a bit differently. See Kafka Source for more information.)
- Cribl reserves the right to change all internal fields that are not documented under Sources or Destinations.

System Fields

Cribl Stream automatically can add system fields to events during post-processing. By default, this includes `cribl_pipe`, a field that identifies the Cribl Stream Pipeline that processed the event. Other additional system fields include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

A few notes about system fields:

- System fields start with the string `cribl_`.
- Treat system fields as read-only. Like internal fields, modifying system fields can result in unintended consequences to your data flows. Adding a Pipeline function to trim system fields will not successfully remove system fields since Cribl Stream adds these fields during post-processing.
- Cribl reserves the right to change all system fields that are not documented under Sources or Destinations.

Use Capture

Use the Capture tool to:

- Troubleshoot events.
- Observe what an event looks like as it travels through the system.

While in Preview (right pane):

1. Select **Capture Data**.
2. In the resulting modal, enter a **Filter expression** to narrow down the events of interest.
3. Select **Capture...** and (optionally) change the default Time and/or Event limits.

4. Select the desired **Where to capture** option. There are four options:

	Option	Description
1	**Before the pre-processing Pipeline**	Capture events right after they're delivered by the respective Input (and after PQ, if enabled).
2	**Before the Routes**	Capture events right after the pre-processing Pipeline. before they go down any Routes (QuickConnect bypasses Routes, and can bypass processing Pipelines.)
3	**Before the post-processing Pipeline**	Capture events right after any Processing Pipeline that handled them, before any post-processing Pipeline.
4	**Before the Destination**	Capture events right after any post-processing Pipeline, before they go out to the configured Destination.

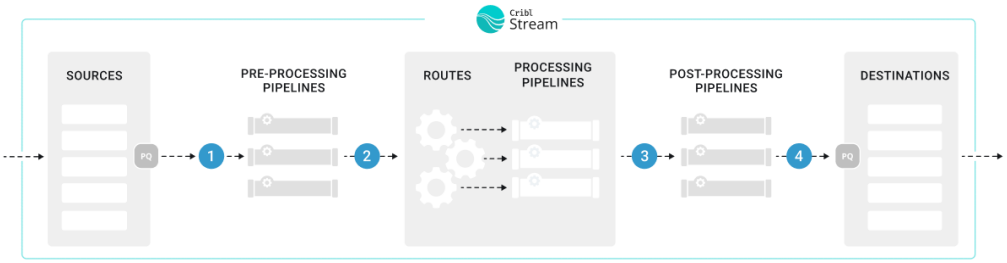


Illustration of the Capture options in the Pipeline

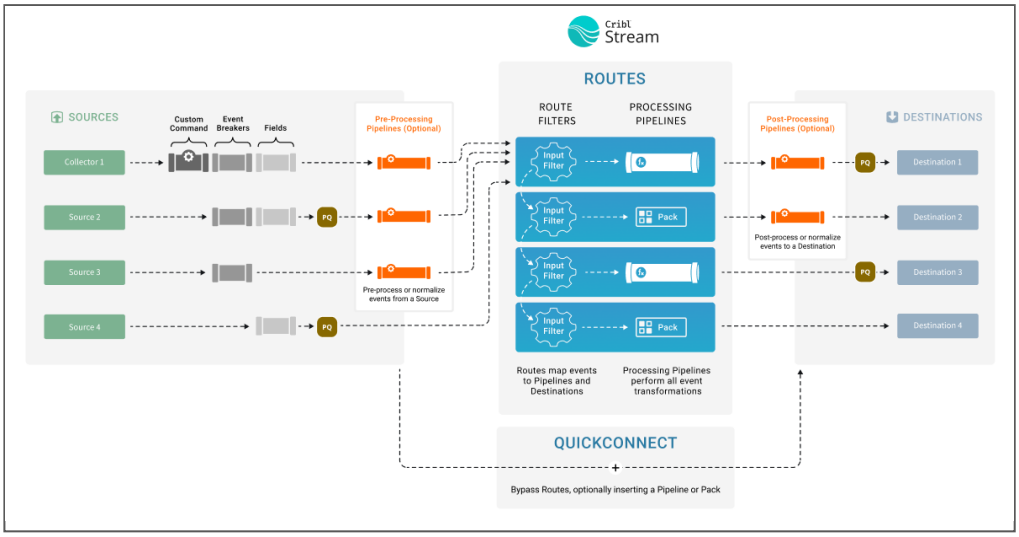
13.2. Event Processing Order

The expanded schematic below shows how all events in the Cribl Stream ecosystem are processed linearly, from left to right.



Cribl Stream in great detail

Here are the stages of event processing:

1. Sources: Data arrives from your choice of external providers. (Cribl Stream supports Splunk, HTTP/S, Elastic Beats, Amazon Kinesis/S3/SQS, Kafka, TCP raw or JSON, and many others.) Many internal fields are added during the event parsing within the Source.
2. Custom command: Optionally, you can pass this input's data to an external command before the data continues downstream. This external command will consume the data via `stdin`, will process it and send its output via `stdout`.
3. Event Breakers can, optionally, break up incoming bytestreams into discrete events. (Note that because Event Breakers precede tokens, Breakers cannot see or act on tokens.)
4. Auth tokens are applied at this point on Splunk HEC Sources. (Details here.)
5. Fields/Metadata: Optionally, you can add these enrichments to each incoming event. You add fields by specifying key-value pairs, per Source, in a format similar to Cribl Stream's Eval Function. Each key defines a field name, and each value is a JavaScript expression (or constant) used to compute the field's value.
6. Auth tokens are applied at this point on HTTP-based Sources other than Splunk HEC (e.g., Elasticsearch API Sources).
7. Persistent queue (Source-side): Optionally, you can enable PQ per Source instance, to disk-buffer and maximize data delivery despite downstream backpressure. Events will be written to a disk queue at this point.
8. The internal field `__inputId` is added at this stage, after the event exits the Source.

9. Pre-processing Pipeline: Optionally, you can use a single Pipeline to condition (normalize) data from this input before the data proceeds further.
10. Routes map incoming events to Processing Pipelines and Destinations. A Route can accept data from multiple Sources, but each Route can be associated with only one Pipeline and one Destination. (QuickConnect bypasses Routes.)
11. Processing Pipelines perform most event transformations. Within a Pipeline, you define these transformations as a linear series of Functions. A Function is an atomic piece of JavaScript code invoked on each event. (QuickConnect optionally bypasses processing Pipelines.)
12. Post-processing Pipeline: Optionally, you can append a Pipeline to condition (normalize) data on its way into its Destination.
13. Persistent queue (Destination-side): Optionally, you can enable PQ per Destination instance, to disk-buffer and maximize data delivery during imbalances between inbound and outbound data rates. Events will be written to a disk queue at this point.
14. Destinations: Each Route/Pipeline combination forwards processed data to your choice of streaming or storage Destination. (Cribl Stream supports Splunk, Syslog, Elastic, Kafka/Confluent, Amazon S3, Filesystem/NFS, and many other options.)

Pipelines Everywhere

All Pipelines have the same basic internal structure – they're a series of Functions. The three Pipeline types identified above differ only in their position in the system.

13.3. Routes

Before incoming events are transformed by a processing Pipeline, Cribl Stream uses a set of filters to first select a **subset** of events to deliver to the correct Pipeline. This selection is normally made via Routes.

Don't Need Routes?

Routes are designed to filter, clone, and cascade incoming data across a related set of Pipelines and Destinations. If all you need are independent connections that link parallel Source/Destination pairs, you can use Cribl Stream's QuickConnect rapid visual configuration tool as an alternative to Routes.

Accessing Routes

To access Routes:

1. In the sidebar, select **Worker Groups**, then select a Worker Group.
2. On the **Worker Groups** submenu, select **Routing**, then **Data Routes**.

   On a Single-instance deployment, select **Routing** straight from the **Home** submenu.

3. To configure a new Route, select **Add Route**.

How Do Routes Work

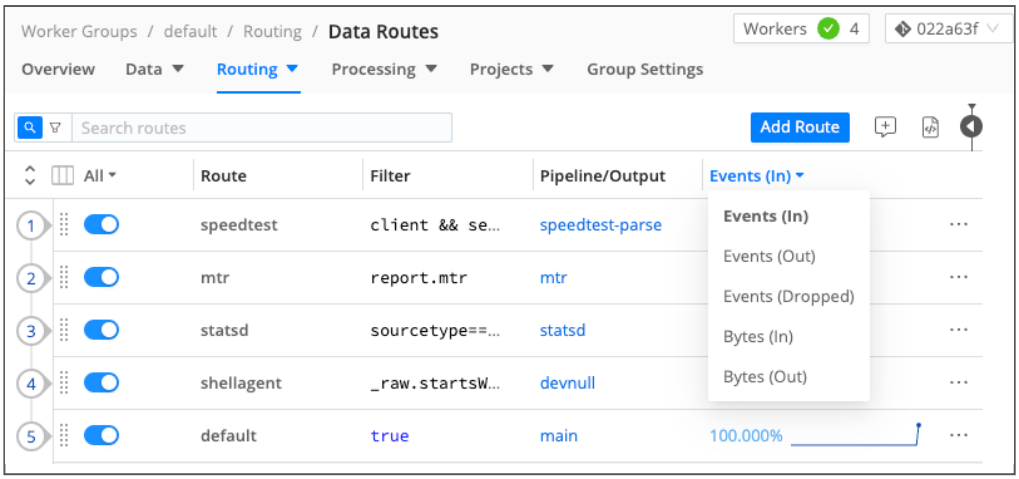
Routes apply filter expressions on incoming events to send matching results to the appropriate Pipeline. Filters are JavaScript-syntax–compatible expressions that are configured with each Route. Examples are:

- `true`
- `source=='foo.log' && fieldA=='bar'`

There can be multiple Routes in a Cribl Stream deployment, but each Route can be associated with only **one processing** Pipeline. (Sources and Destinations can also have their own attached pre-/post-processing Pipelines.)

Each Route must have a unique name. The **Route Name** field is case-sensitive, so entering the same characters with different capitalization will create a Route with a separate name.

Routes are evaluated in their display order, top->down. The stats shown in the **Bytes/Events** (toggle) column are for the most-recent 15 minutes.



Routes and bytes

In the example above, incoming events will be evaluated first against the Route named **speedtest**, then against **mtr**, then against **statsd**, and so on. At the end, the **default** Route serves as a catch-all for any event that does not match any of the other Routes.

Above, note the **Events In** drop-down menu to toggle between displaying Events versus Bytes, and to display In, Out, or Dropped.

Displayed percentages of Events and Bytes In and Out are by comparison to throughput or filtering across all Routes. For example, if you have four Routes that share an identical filter, each Route's Events In might show approximately `25%` of the total inbound traffic across all Routes.

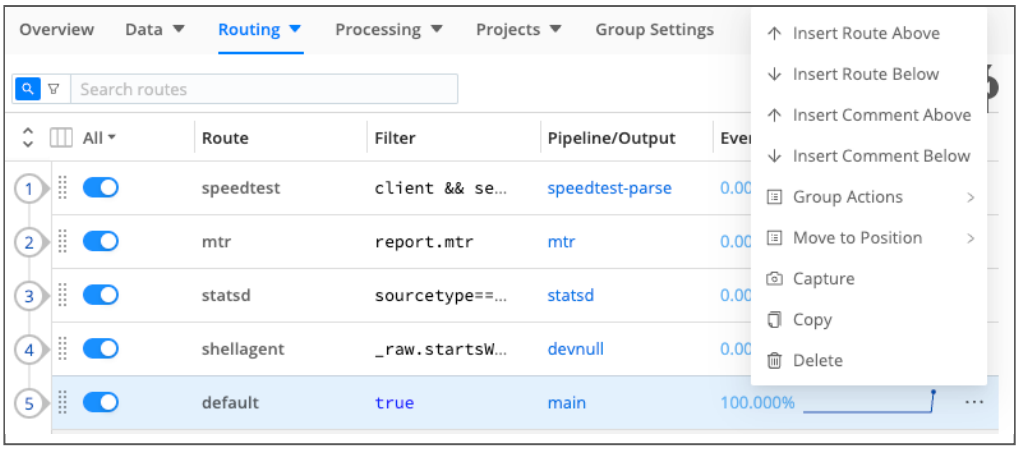
Managing the Routes Page

To apply a Route before another, simply drag it vertically. Use the toggles to turn Routes `On/Off` inline, as necessary, to facilitate development and debugging.

You can press the `]` (right-bracket) shortcut key to toggle between the Preview pane and the expanded Routes display shown above. (This works when no field has focus.)

Click a Route's Options (•••) menu to display multiple options:

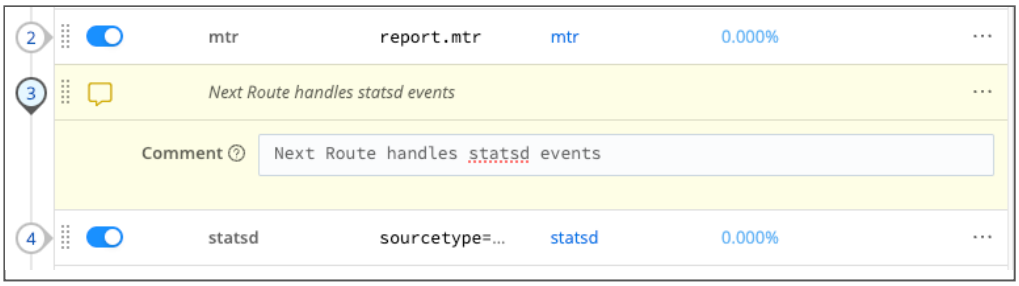
- Insert, group, move, copy, or delete Routes.
- Insert comments above or below Routes.
- Capture sample data through a selected Route.



Route > Options menu

Copying a Route displays a confirmation message and adds a Paste button next to **Add Route**. Pasting creates an exact duplicate of the Route, with a warning indicator to change its duplicate name.

You can use comments to describe Routes' purposes and/or interactions.

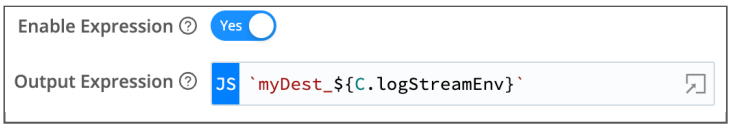


Comments make the Routing table self-documenting

Output Destination

You can configure each Route with an **Output** that defines a Destination to send events to, after they're processed by the Pipeline.

If you toggle **Enable expression** to `Yes`, the **Output** field changes to an **Output expression** field. Here, you can enter a JavaScript expression that Cribl Stream will evaluate as the name of the Destination. Sample expression format: `` `myDest_${C.logStreamEnv}` ``. (This evaluation happens at Route construction time, not per event.)



Output expression enabled

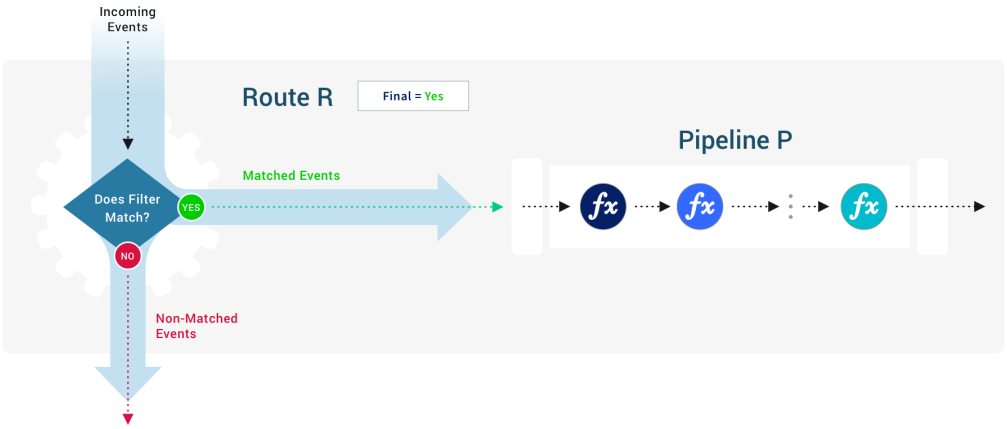
Expressions that match no Destination name will silently fail.

> On Routes within Packs, neither **Output** control is available, because Packs cannot specify Destinations.

The `Final` Toggle

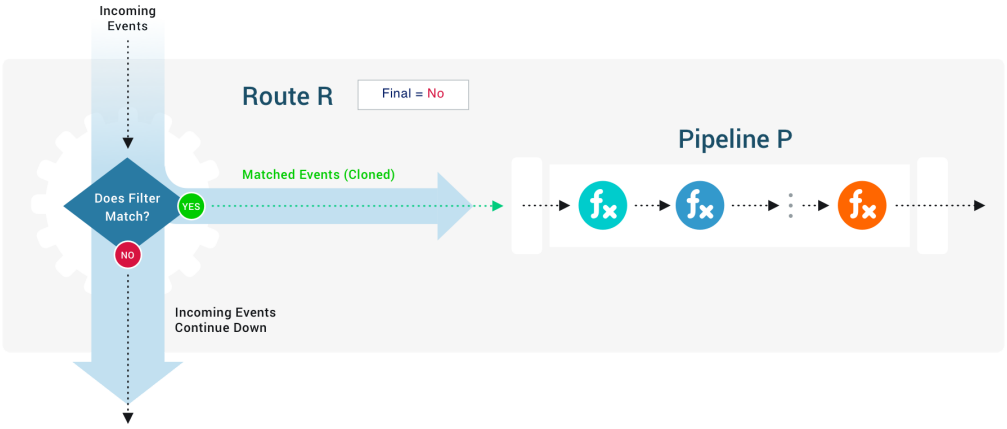
The `Final` toggle in Route settings controls what happens to an event after a Route-Pipeline pair matches it.

When `Final` is toggled to `Yes` (default), the Route "consumes" an event, meaning the event will not pass down to any other Route below.



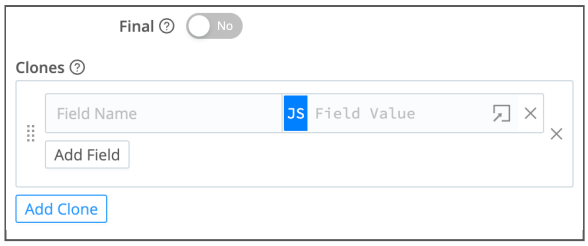
The Route is Final and non-matched events stop here

When `Final` is toggled to `No`, the event will be processed by this Route, **and** then passed on to the next Route below.



The Route isn't Final and all events pass further on

When you toggle `Final` to `No`, the event sent to the current Route technically becomes a *clone* of the original event. The **Add Clone** button lets you add a fields – names and values – to the cloned events sent to this Route's Pipeline.



Non-final Route: add clone fields

Event Cloning Strategy

Depending on your cloning needs, you might want to follow a **most-specific first** or a **most-general first** processing strategy. The general goal is to minimize the number of filters/Routes an event gets evaluated against. For example:

If you don't need to clone any events (that is, `Final` is toggled to `Yes` everywhere), then it makes sense to start with the broadest expression at the top. This will consume as many events as early as possible.

If you need to clone a narrow set of events, then it might make sense to do that upfront. Then, follow it with a Route that consumes those clones immediately after.

The `endRoute` Bumper

The `endRoute` bumper appears at the bottom of the Routing table. This is a reminder that, if **no** Route in the table has the `Final` flag enabled, events will continue to Cribl Stream's configured Default Destination.

endRoute warning and link

This is a backstop to ensure data flow. However, if that configured default is also configured as the **Output** of a Route higher in the table, duplicate events will reach that Destination.

You can correct this either by setting a Route to `Final`, or by changing the Default Destination. The bumper provides a link to the Default Destination's config, and identifies the currently configured default in parentheses.

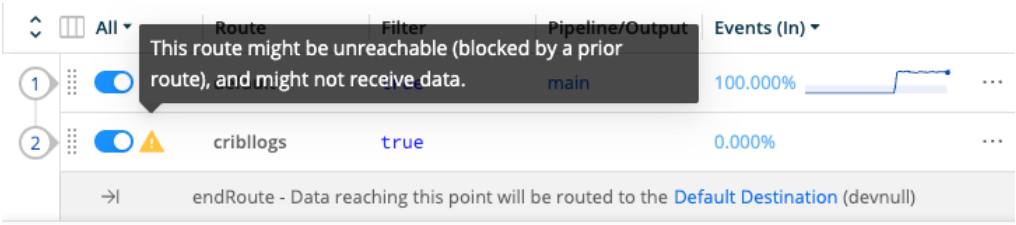
Route Groups

A Route Group is a collection of consecutive Routes that can be moved up and down the Route stack together. Groups help with managing long lists of Routes. They are a UI visualization only: While Routes are in a group, those Routes maintain their global position order.

Route groups work much like Function groups, offering similar UI controls and drag-and-drop options.

Unreachable Routes

Routes display an "unreachable" warning indicator (orange triangle) when data can't reach them.



Unreachable Route warning, on hover

This condition will occur when, with your current configuration, any Route higher in the stack matches **all** three of these conditions:

- Previous Route is enabled.
- Previous Route is final (**Final** toggle is set to `Yes`).
- Previous Route's **Filter** expression evaluates to true, (e.g., `true`, `1 === 1`, etc.).

Note that the third condition above can be triggered intermittently by a randomizing method like `Math.random()`. This might be included in a previous Route's own Filter expression, or in a Pipeline Function (such as one configured for random data sampling).

Routing with Output Router

Output Router Destinations offer another way to route data. These function as meta-Destinations, in that they allow you to send data to multiple peer Destinations based on rules. Rules are evaluated in order, top->down, with the first match being the winner.

13.4. Pipelines

Data matched by a given Route is delivered to a Pipeline. Pipelines are the heart of Cribl Stream processing. Each Pipeline is a list of Functions that work on the data.

As with Routes, the order in which the Functions are listed matters. A Pipeline's Functions are evaluated in order, top->down.

Access Pipelines

To access Routes:

1. In the sidebar, select **Worker Groups**, then select a Worker Group.
2. On the **Worker Groups** submenu, select **Processing**, then **Pipelines**.

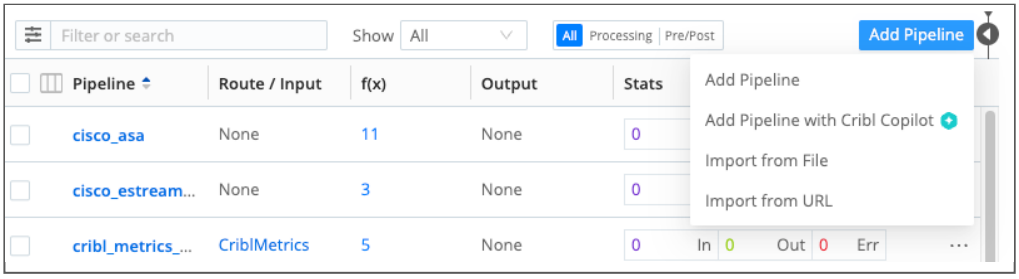
On a Single-instance deployment, select **Processing** straight from the **Home** submenu.

After you've opened a Pipeline, the right Preview pane adds a Pipeline Status tab, which you can select to see the Pipeline's events throughput.

Add Pipelines

To create a new Pipeline, or to import an existing Pipeline to a different Cribl Stream instance, select **Add Pipeline** at the upper right. The resulting menu offers three options:

- **Add Pipeline**: Configure a new Pipeline from scratch, by adding Functions in Cribl Stream's graphical UI.
- **Add Pipeline with Cribl Copilot**: Use the Cribl Copilot Pipeline assistant to create a Pipeline using AI. See Create Pipelines Using Cribl Copilot to learn more.
- **Import from File**: Import an existing Pipeline from a `.json` file on your local filesystem.
- **Import from URL**: Import an existing Pipeline from `.json` file at a remote URL. (This must be a public URL ending in `.json` – the import option doesn't pass credentials to private URLs – and the target file must be formatted as a valid Pipeline configuration.)

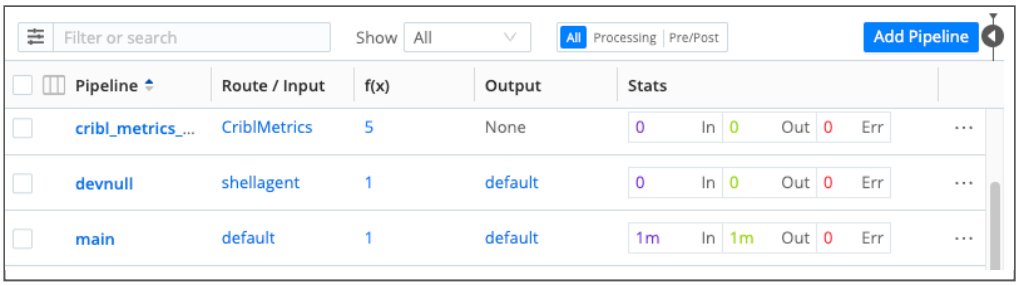


To export a Pipeline, see Advanced Mode (JSON Editor).

To import or export a Pipeline along with broader infrastructure (like Knowledge Objects and/or sample data files), see Packs.

How Pipelines Work

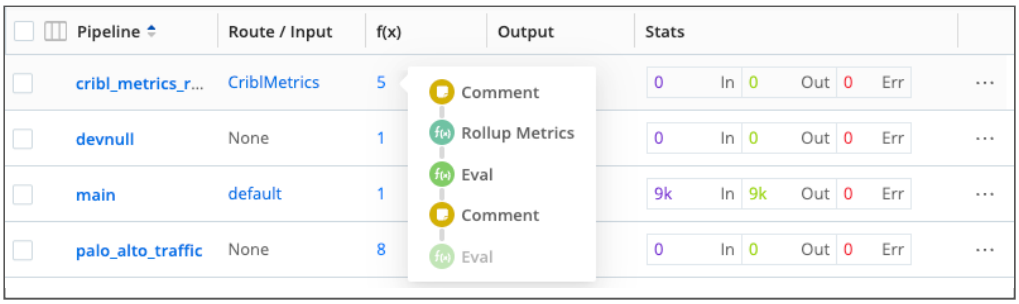
Events are always delivered to the beginning of a Pipeline via a Route. The data in the **Stats** column shown below are for the last 15 minutes.



Pipelines and Route inputs

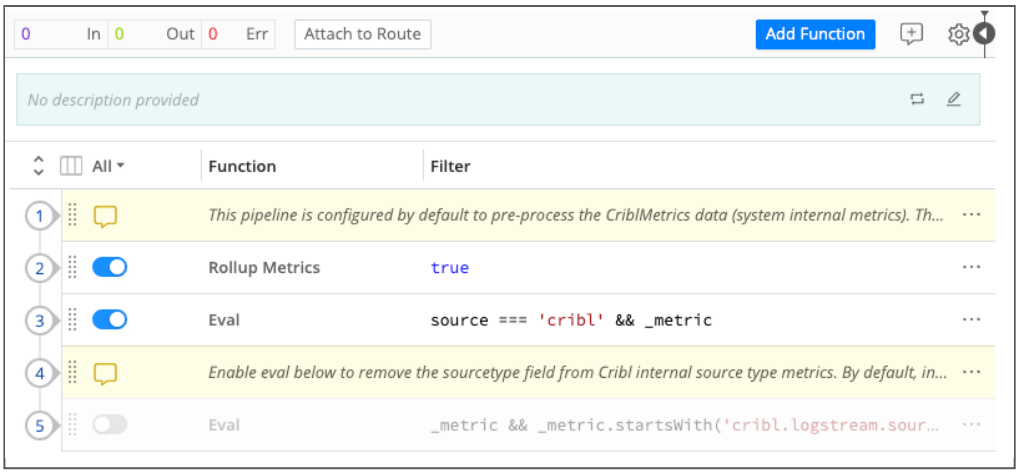
You can press the] (right-bracket) shortcut key to toggle between the Preview pane and an expanded Pipelines display. (This shortcut works when no field has focus.)

In the condensed Pipelines display above, you can also hover over any Pipeline's **Functions** column to see a vertical preview of the stack of Functions contained in the Pipeline:



Preview on hovering over the top Pipeline (highlighted in gray)

Within the Pipeline, events are processed by each Function, in order. A Pipeline will always move events in the direction that points outside of the system. This is on purpose, to keep the design simple and avoid potential loops.



Pipeline Functions

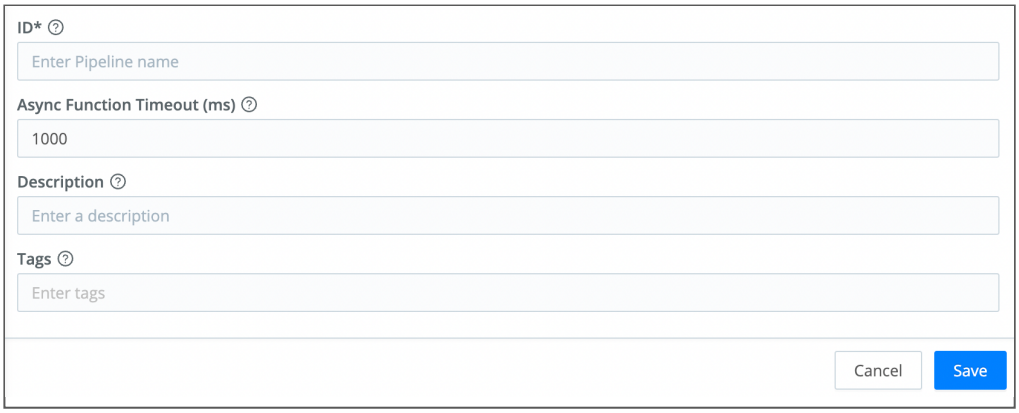
Use the **Attach to Route** link at the top to associate a new Pipeline with a Route.

You can streamline a complex Pipeline's display by organizing related Functions into Function groups.

Pipeline Settings

Select the gear button at the top right to open the Pipeline's Settings. Here, you can:

- Use the **Async function timeout (ms)** to set the maximum amount of processing time, in milliseconds, that a Function is allowed to take before it is terminated. This prevents a Function from causing undesirable delays in your Pipeline (for example, a Lookup Function taking too long to process a large lookup file).
- Use the **Tags** field to attach arbitrary labels to the Pipeline. Once attached, you can use these tags to filter/search and group Pipelines.



Pipeline Settings

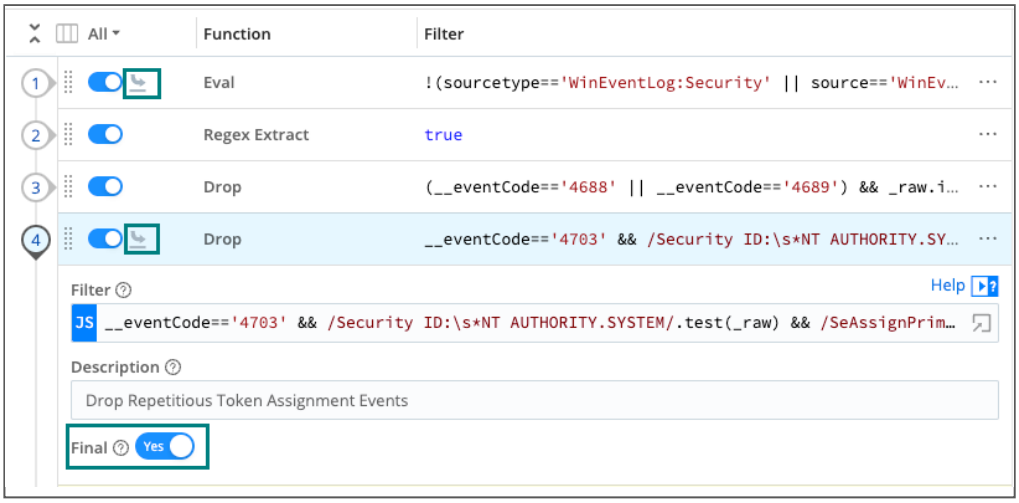
The `Final` Toggle

The `Final` toggle in Function settings controls what happens to the results of a Function.

When `Final` is toggled to `No` (default), events will be processed by this Function, **and** then passed on to the next Function below.

When `Final` is toggled to `Yes`, the Function "consumes" the results, meaning they will not pass down to any other Function below.

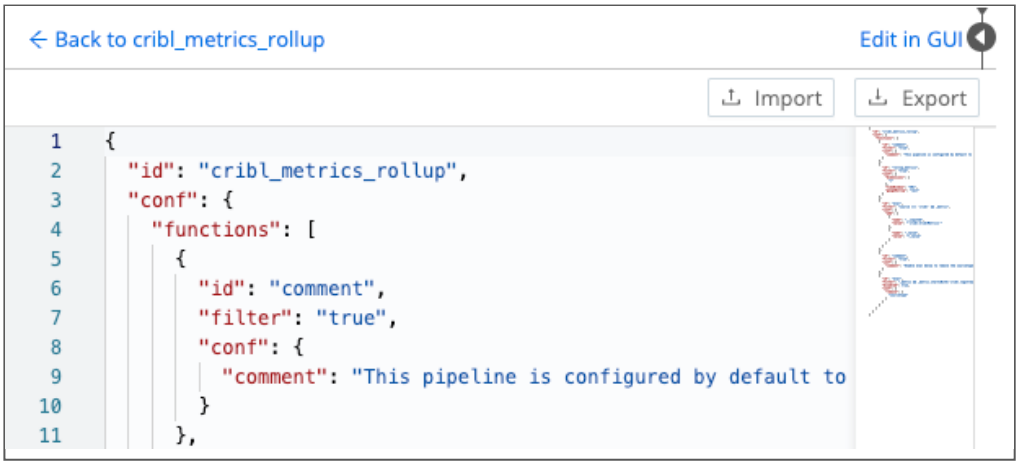
An icon in Pipeline view indicates that a Function is `Final`.



The Eval and first Drop Functions bearing the Final icons

Advanced Mode (JSON Editor)

Once you've selected the gear button to enter Pipeline Settings, you can select **Manage as JSON** at the upper right to edit the Pipeline's definition in a JSON text editor. In this mode's editor, you can directly edit multiple values. You can also use the **Import** and **Export** buttons here to copy and modify existing Pipeline configurations, as `.json` files.



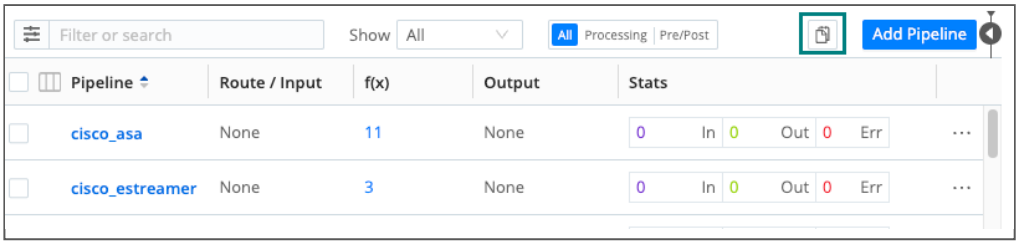
Advanced Pipeline Editing

Select **Edit in GUI** at upper right to return to the graphical Pipeline Settings page; then select **Back to <pipeline-name>** to restore the graphical Pipeline editor.

Pipeline Actions

Select a Pipeline's Actions (...) menu to display options for copying or deleting the Pipeline.

Copying a Pipeline displays a confirmation message and the (highlighted) Paste button shown below.



Paste button for copied Pipeline

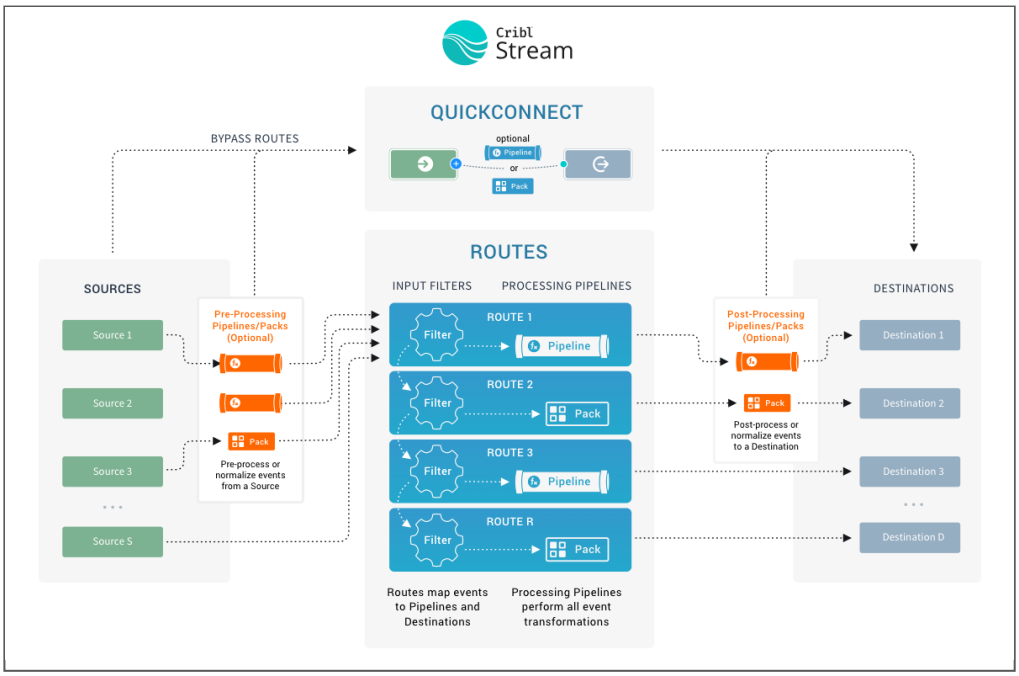
Pasting prompts you to confirm, or change, a modified name for the new Pipeline. The result will be an exact duplicate of the original Pipeline in all but name.

Chain Pipelines

You can use the Chain Function to send the output of a Pipeline to another Pipeline or Pack. There are scope restrictions within Packs, and general guardrails against circular references.

Types of Pipelines

You can apply various Pipeline types at different stages of data flow. All Pipelines have the same basic internal structure (a series of Functions) – the types below differ only in their position in the system.



Pre-Processing Pipelines

These are Pipelines that are attached to a Source to condition (normalize) the events **before** they're delivered to a processing Pipeline. They're optional.

Typical use cases are event formatting, or applying Functions to **all** events of an input. (For example, to extract a `message` field before pushing events to various processing Pipelines.)

You configure these Pipelines just like any other Pipeline, by selecting **Processing** > **Pipelines** from the **Worker Group** submenu. You then attach your configured Pipeline to individual Sources, using the Source's **Pre-Processing** > **Pipeline** drop-down.

Fields extracted using pre-processing Pipelines are made available to Routes.

Processing Pipelines

These are "normal" event processing Pipelines, attached directly to Routes.

Post-Processing Pipelines

These Pipelines are attached to a Destination to normalize the events before they're sent out. A post-processing Pipeline's Functions apply to **all** events exiting to the attached Destination.

Typical use cases are applying Functions that transform or shape events per receiver requirements. (For example, to ensure that a `_time` field exists for all events bound to a Splunk receiver.)

You configure these Pipelines as normal, by selecting **Processing** > **Pipelines** from the **Worker Group** submenu. You then attach your configured Pipeline to individual Destinations, using the Destination's **Post-Processing** > **Pipeline** drop-down.

You can also use a Destination's **Post-Processing** options to add **System Fields** like `cribl_input`, identifying the Cribl Stream Source that processed the events.

Best Practices for Pipelines

Functions in a Pipeline are equipped with their own filters. Even though filters are not required, we recommend using them as often as possible.

As with Routes, the general goal is to minimize extra work that a Function will do. The fewer events a Function has to operate on, the better the overall performance.

For example, if a Pipeline has two Functions, **f1** and **f2**, and if **f1** operates on `source 'foo'` and **f2** operates on `source 'bar'`, it might make sense to apply `source=='foo'` versus `source=='bar'` filters on these two Functions, respectively.

13.4.1. Create Pipelines Using Cribl Copilot

The Cribl Copilot Pipeline assistant in Cribl Stream uses AI to help you create and edit data transformation Pipelines. Simply describe what you want the Pipeline to do using natural language, and Cribl Copilot will create the Pipeline for you. You'll usually get results in about 10 seconds.

The Cribl Copilot Pipeline assistant is available in Cribl.Cloud, and in on-prem installations of Cribl Stream v4.8 and newer. Cribl Copilot always requires internet access.

The Cribl Copilot Pipeline assistant can generate Pipelines of any length using the following Functions:

- CEF Serlializer
- Code
- Comment
- DNS Lookup
- Drop
- Eval
- Flatten
- Mask
- Numerify
- Regex Extract
- Regex Filter
- Rename
- Serialize
- Suppress

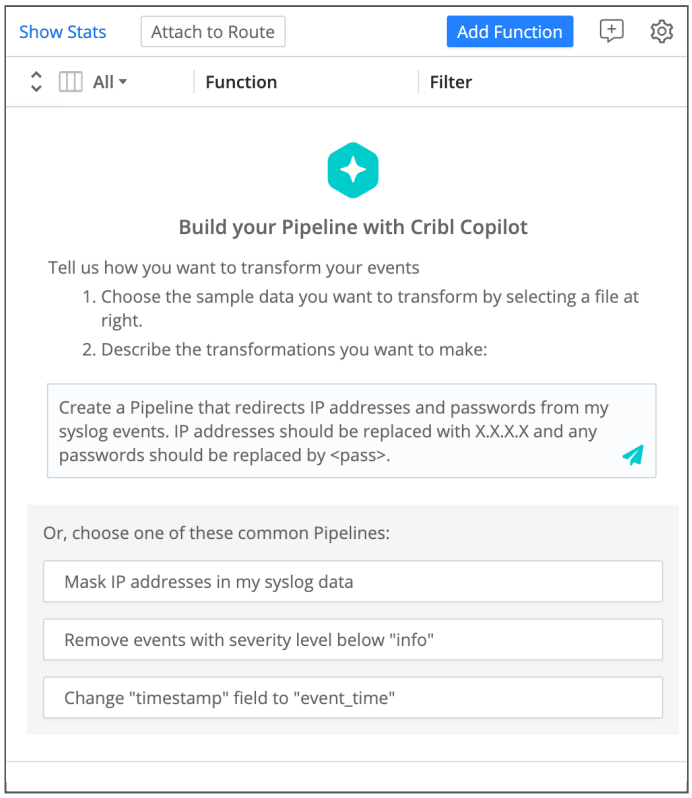
Cribl does not make any warranty regarding the availability, uptime, performance, or accuracy of Cribl Copilot, including PII Detection and Prevention. Please read the Supplemental Terms for Cribl Copilot for more information.

To create a Pipeline:

1. In a Cribl Stream Worker Group, on the Worker Group top menu, select **Processing** and select **Pipelines**.
2. Select **Add Pipeline**, and select **Add Pipeline with Cribl Copilot**. Enter a name for your Pipeline in the **ID** field. The ID can contain only letters (A-Z, a-z), numbers (0-9), and the characters "_" and "-".

Optionally, change the async function timeout, and add a description or tags.
Select **Save**.

3. On the right, select an input event that your Pipeline will apply transformations to.
4. On the left, in the text box under **Build your Pipeline with Cribl Copilot**, type a prompt that describes what you want your Pipeline to do.



Sample Pipeline prompt

Make sure you have an input event selected on the right before trying to send a Pipeline creation prompt. You will know an event is selected when it is outlined in blue.

5. Select Send .
6. Confirm that the Pipeline performs the action you expected. If not, you can make edits manually, or cancel and try entering a new Pipeline description.
7. Save the Pipeline.

Example Prompts

The following are sample prompts you can try to better understand how Cribl Copilot uses information about Cribl Stream, Pipelines, your query, and the sample input event, and combines this information to generate a new Pipeline.

- **Redact PII (personally identifiable information).** Try a prompt like, “Redact any log data that may fall under GDPR compliance restriction”

- **Reduce data storage costs by dropping unnecessary events.** Try a prompt like, “Filter out any logs that have a 200 status code or a null ‘error’ field”
- **Enrich incoming data.** Try a prompt like, “Parse any IP addresses from my logs and then perform a DNS lookup on them. Place the IP and DNS hostname from the results in a separate top-level field.”

How to Use Prompts Successfully

To ensure the best results from the Pipeline assistant:

- **Be specific.** To receive high-quality results, be clear and explicit with your requests. Provide exact names of fields that you want to reference or create.
- **Provide examples.** For instance, if you want to mask a specific piece of text, describe the target text in detail and explain what it should be masked to (for example, `Mask all IPv4 IP addresses to X.X.X.X`).
- **Ask questions.** Use the Cribl Copilot chatbot to answer general questions about Pipelines. For example, you could ask the chatbot, `What Pipeline Functions can I use to redact sensitive information like IP addresses?`

What the Pipeline Assistant Doesn’t Do

You can’t edit an existing Pipeline Function; Cribl Copilot will always create new Functions and append them to the existing Pipelines. Also, this feature, like any AI, is still learning. It may not always work exactly as expected, so be sure to check the generated output events and logic carefully. Please provide feedback to help Cribl Copilot learn!

What Data the Pipeline Assistant Can Access

The Cribl Copilot Pipeline assistant has access to:

- The natural language query, written by the user.
- The sample input event selected by the user.

Cribl Copilot has access to no other user or Organization data.

13.5. Packs

Packs enable Cribl Stream administrators and developers to pack up and share complex configurations and workflows across multiple Worker Groups, or across organizations.

Packs = Portability

With a Cribl Stream deployment of any size, using Packs can simplify and accelerate your work. Packs can also accelerate internal troubleshooting, and can accelerate working with Cribl Support, because they facilitate quickly replicating your Cribl Stream environment.

For example, where a Pipeline configuration references Lookup file(s), Cribl Stream will import the Pipeline only if the Lookups are available in their configured locations. A Pack can consolidate this dependency, making the Pipeline portable across Cribl Stream instances. If you import the Lookups into the Pack, you can develop and test a configuration, and then port it from development to production instances, or readily deploy it to multiple Worker Groups.

What Is a Pack?

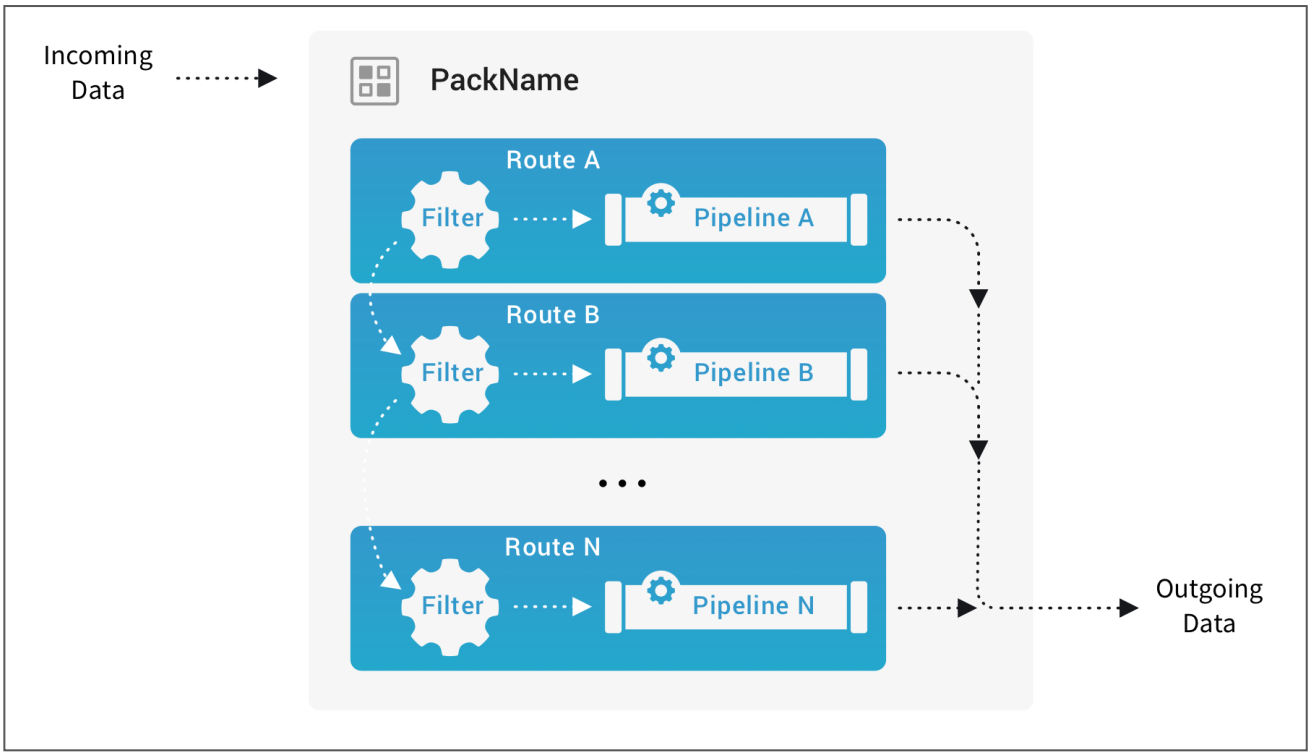
Each Pack provides you with a microcosm of a Cribl Stream deployment. (See the next section for what's included and excluded). A Pack also includes a restricted version of Cribl Stream's user interface (outlined in the first half of the Use Packs section below). You can import and export each Pack as a file, in `.crbl` format.

What's in a Pack?

Currently, a Pack can pack up everything between a Source and a Destination:

- Routes (Pack-level).
- Pipelines (Pack-level).
- Functions (built-in and custom).
- Sample data files.
- Knowledge objects (Lookups, Parsers, Global Variables, Grok Patterns, Schemas, and more).

As the above list suggests, a Pack can encapsulate a whole set of infrastructure for a given use case.



A Pack with internal Routes & Pipelines; no Knowledge or samples

Packs don't have access to Knowledge objects (Lookups, Global Variables, and so forth) that are defined outside the Pack. Knowledge objects defined **within** a Pack are not available to Cribl Stream resources outside the Pack. In either scenario, you must explicitly duplicate the Knowledge objects in the opposite scope.

What's Not in a Pack?

Sources, Collectors, and Destinations are external to Packs, so you can't specify them within a Pack. This excludes a few other things:

- Routes configured within a Pack can't specify a Destination.
- Packs can't include Event Breakers, which are associated with Sources. (However, you can instead use the Event Breaker Function in Pipelines that you include in your Pack.)

You connect a Pack with a Source and Destination by attaching it to a Route, just as you'd attach a Pipeline. For details, ssee Where Can I Use Packs? below.

Where Can I Get Some Packs?

See The Cribl Packs Dispensary below.

Use Packs

These instructions cover using predefined Packs, as well as creating and modifying Pack configurations.

Version Compatibility

Packs created or modified in Cribl Stream 4.0.x cannot be used in any pre-4.0 version of Cribl Stream. (If you try, you'll see a `should NOT have additional properties` error.) To avoid this problem, Cribl recommends that you upgrade to Cribl Stream 4.0.x or later.

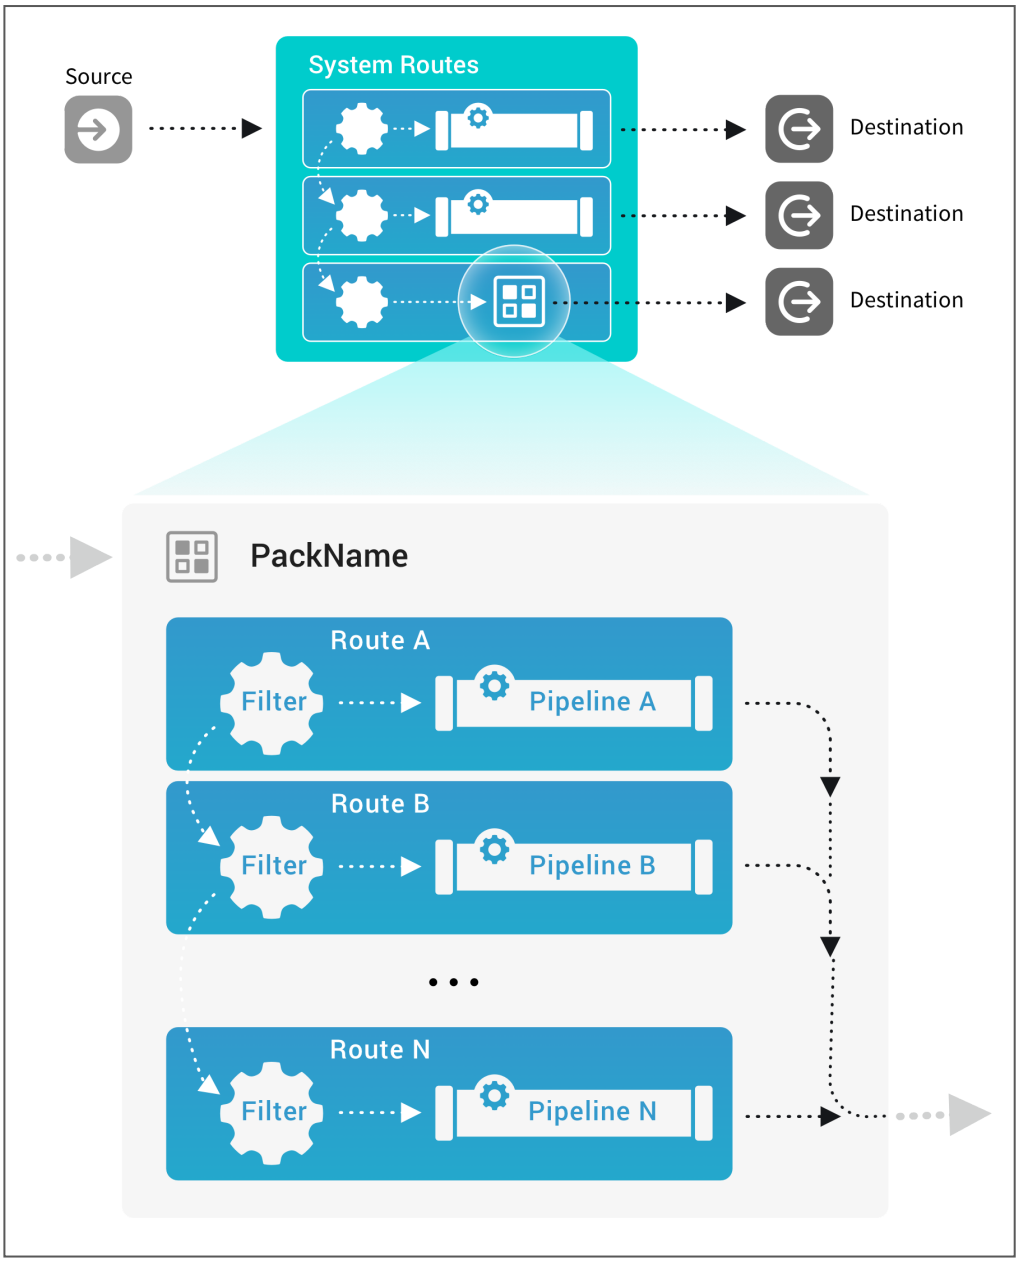
For compatibility questions about any individual Packs, please contact us in the Cribl Community Slack `#packs` channel.

Where Can I Use Packs?

Wherever you can reference a Pipeline, you can specify a Pack:

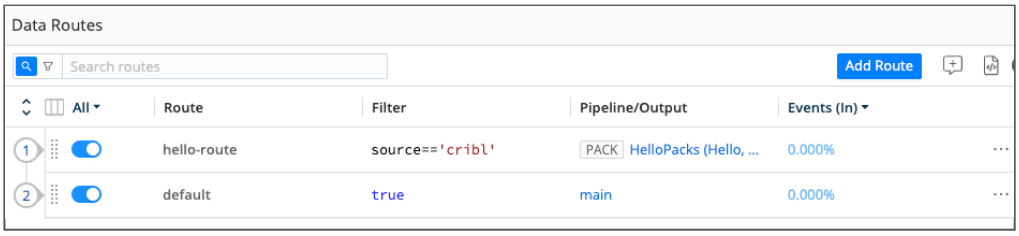
- In Sources, where you attach pre-processing Pipelines.
- In Destinations, where you attach post-processing Pipelines.
- In Routes, in the Routing table's **Pipeline/Output** column.

This expanded view shows how a Pack can replace a Pipeline in a Route:



A Pack snaps into Cribl Stream like an enhanced Pipeline

Packs are distinguished in the display with a **PACK** badge, as you can see here in the Routing table:



PACKs badged in Routing table's Pipeline column

The **PACK** badge is also displayed when you click into a resource – shown here on one of the Routes from the above table:

PACK badge on a Pack connected to a Route

Cribl Stream's **Monitoring** page includes a **Packs** link where you can monitor the throughput of a Pack.

Access Packs

You access Packs differently, depending on your deployment type.

Single-Instance Deployment

In a single-instance deployment, Packs are global. On the top bar, select **Processing** > **Packs**. On the filesystem, Packs (including those that you add) are stored at `$CRIBL_HOME/default/`.

Distributed Deployment

In a Distributed deployment, Packs are associated with (and installed within) Worker Groups. In the sidebar, select **Worker Groups**, and then select the Worker Group you want to manage. Next, from that Worker Group' submenu, select **Processing** > **Packs** (Stream) or **More** > **Packs** (Edge).

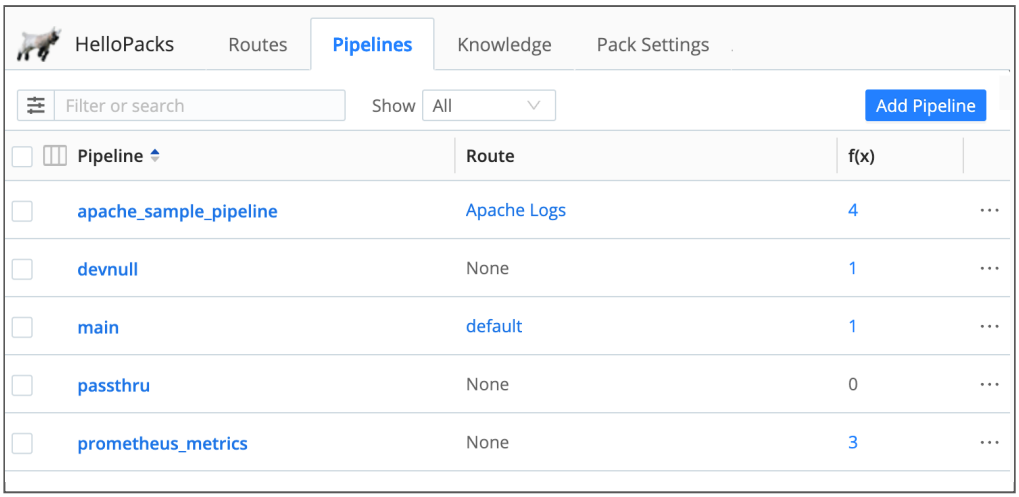
Each Group's Packs are stored at `$CRIBL_HOME/groups/<group-name>/default/`. (In a typical installation, you'll find the starter `HelloPacks` Pack at `/opt/cribl/groups/default/default/`.)

By design, you can readily share Packs **across** Worker Groups by copying them between Groups.

Get Started with Packs

To unpack Packs, use the above instructions (per deployment type) to navigate to the **Packs** page. Select `HelloPacks` to see its configuration.

Select **Pipelines**, and you'll see that the Pack includes `devnull`, `main`, and `passthru` Pipelines, corresponding to the default Pipelines provided at Cribl Stream's global level. This Pack also includes an Apache-specific sample Pipeline – select it to unpack that, too.

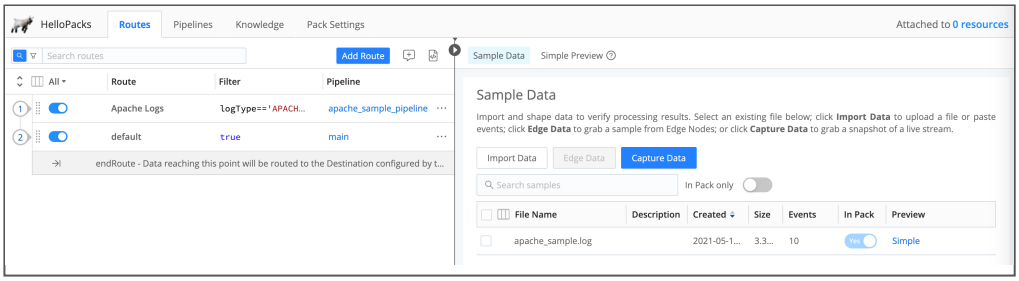


Pipelines within example Pack

Select **Routes**, and you'll see that this Pack also provides both a `default` and an Apache-specific Route.

Configure a Pack

Once loaded, each Pack displays tabs labeled with familiar links: **Routes**, **Pipelines**, **Knowledge**, and **Pack Settings** in the left pane, along with **Sample Data**, and **Simple Preview** on the right.



Configuring a Pack

The left pane tabs give you access to configuration objects specific to this Pack.

Cribl imposes a limit of 200 maximum Pipelines per Pack. This limit helps ensure optimal performance, and prevents potential errors. It helps maintain stability and avoids issues that can arise from managing very large Packs.

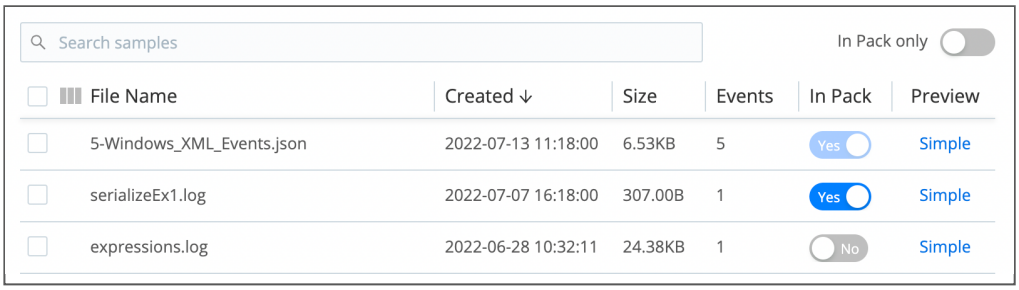
Sample Data

Within a Pack, the right pane defaults to displaying all sample data files available on your Cribl Stream instance. If you prefer to filter only sample files internal to the Pack, select the **In Pack only** option.

If you add sample data files via a Pack UI, they will be internal to that Pack. Each sample file here displays its own **In Pack** toggle on its row, which works as follows:

A light-blue toggle is locked, meaning that this sample file is internal to the Pack. It will export with the Pack. If you want to make this sample available across Cribl Stream, you'll need to also add it via the global right preview pane (accessed from **Routing** > **Data Routes** or **Processing** > **Pipelines**).

A grayed-out or dark-blue toggle means that this sample file is global to Cribl Stream. It is available to this Pack. Toggle this to `Yes` (dark blue) if you want the sample file to export along with the Pack.



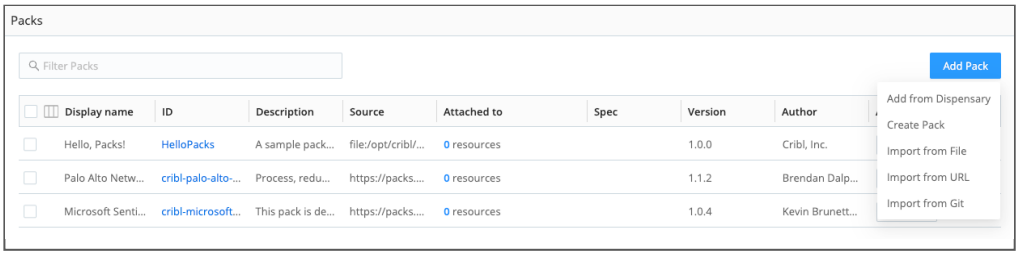
Sample file in Pack

Basically, you can manipulate all the options here as you would work with the equivalent options in the global navigation.

Import or Upgrade a Pack

To import a new Pack, or an updated version of an existing Pack, from your filesystem:

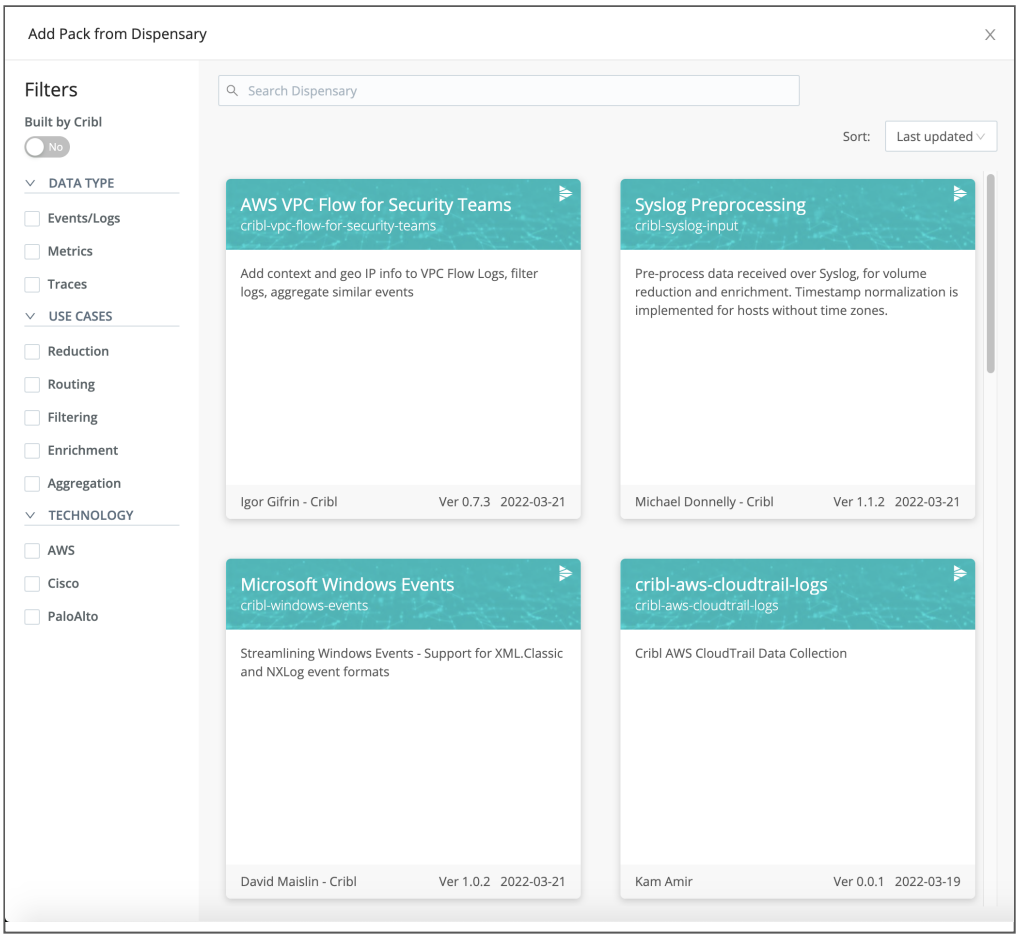
1. Navigate to the **Packs** page.
2. Select **Add Pack** at the upper right.
3. Select your desired **Add/Import** source: Dispensary, File, URL, or Git repo. When you import Packs that were exported in `merge` mode, make sure to re-enter any required secrets to restore full functionality. This is necessary because Cribl Stream deletes all encrypted fields during the export process to ensure security and prevent the accidental sharing of sensitive information.
4. Follow the above links to details on each of these options.



The Cribl Packs Dispensary

The Cribl Packs Dispensary is a Cribl-hosted resource for you to find and share Packs. Cribl, our partners, and community users develop Packs and submit them to the Dispensary for easy sharing. Cribl tests submissions before publication, to ensure each Pack's quality, security guardrails, and stability.

You can install Dispensary Packs directly through Cribl Stream's user interface, as outlined in Add from Packs Dispensary below.



Cribl Packs Dispensary (as displayed in Cribl Stream's **Add** drawer)

Interested in publishing your own Packs on the Cribl Packs Dispensary? See Publishing a Pack.

Add from the Packs Dispensary

To add a Pack from the Cribl Packs Dispensary sharing site:

1. Navigate to the **Packs** page.

2. Select **Add Pack** at the upper right and select **Add from Dispensary**.
3. The Packs Dispensary will open in a drawer, as shown in the screenshot above.
4. Using the drawer controls, browse or search for the Pack(s) you want. (You can use the check boxes at the left to filter by data type, use case, and technology.)
5. Select any Pack tile to display its details page with its README. This will typically outline the Pack's purpose, compatibility, requirements, and installation.
6. To proceed, select **Add Pack** on this page.
7. That's it! You'll see a banner confirming that the Pack is now installed.

Import from a File

To import a Pack (`.crbl` file) from your local filesystem:

1. Navigate to the **Packs** page.
2. Select **Add Pack** at the upper right and select **Import from File**.
3. Select the file to import.
4. Optionally, give the Pack an explicit, unique **New Pack ID**. (For details about this option, see Upgrade an Existing Pack below.)
5. Select **Import** to confirm the import.

Import from a URL

To import a Pack from a known, public or internal, URL:

1. Navigate to the **Packs** page.
2. Select **Add Pack** at the upper right and select **Import from URL**.
3. Enter a valid URL for the Pack's source. (This field's input is validated for URL format, but not for accuracy, before you submit the modal.)
4. Optionally, give the Pack an explicit, unique **New Pack ID**. (See Upgrade an Existing Pack.)
5. Select **Import** to confirm the import.

To import a Pack from a public URL, the Leader Node (or single instance) requires Internet access. A Distributed deployment Leader can then deploy the Pack to Workers even if the Workers lack Internet access.

Import from Git Repos

To import a Pack from a known public or private Git repo:

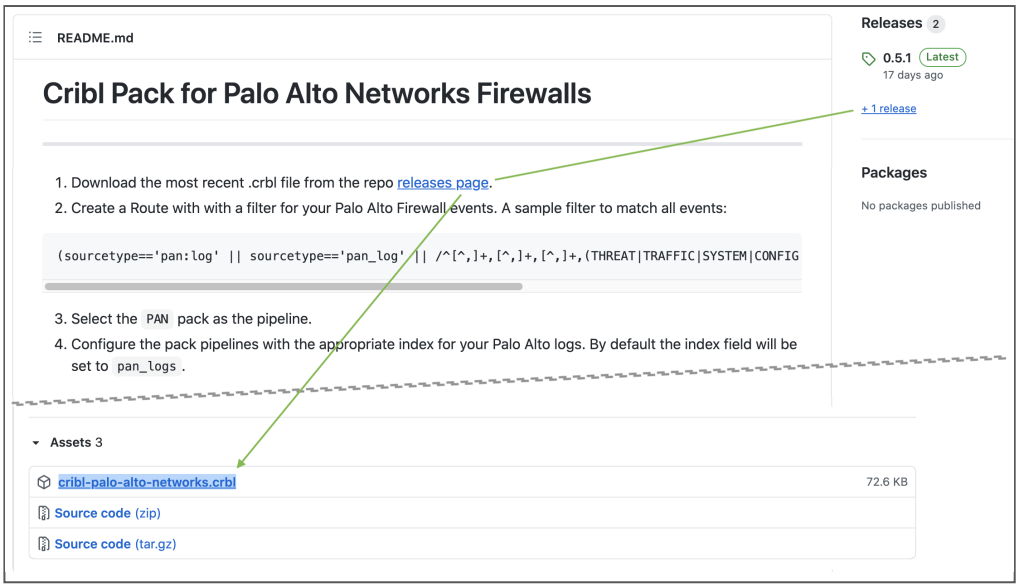
1. Navigate to the **Packs** page.
2. Select **Add Pack** at the upper right and select **Import from Git**.
3. Enter the source repo's valid URL.
   This field's input is validated for URL format, but not for completeness or accuracy, before you submit the modal. When targeting a private repo, use the format: `https://<username>:<token/password>@<repo-address>`. Public repos need only `https://<repo-address>`, as shown in the example below.
4. Optionally, give the Pack an explicit, unique **New Pack ID**. (See Upgrade an Existing Pack.)
5. Optionally, enter a **Branch or tag** to filter the import source using the repo's metadata. You can specify a branch (such as `master`) or a tag (such as a release number: `0.5.1`, and so forth).
6. Select **Import** to confirm the import.

To import a Pack from a public repo, the Leader Node (or single instance) requires Internet access. A Leader in a Distributed deployment can then deploy the Pack to Workers even if the Workers lack Internet access.

Dispensary GitHub Repo

A particularly useful public repo is the Cribl Pack Dispensary on GitHub. This repo was established prior to the Cribl-hosted Cribl Packs Dispensary site described above, and it is a place to collaborate on developing Packs prior to submitting them to the newer site.

You can install this repo's Packs directly through Cribl Stream's user interface, as outlined in Import from Git Repos above. However, if you prefer, you can click through to any Dispensary repo release page, download the corresponding `.crbl` file, and then upload the file into Cribl Stream.



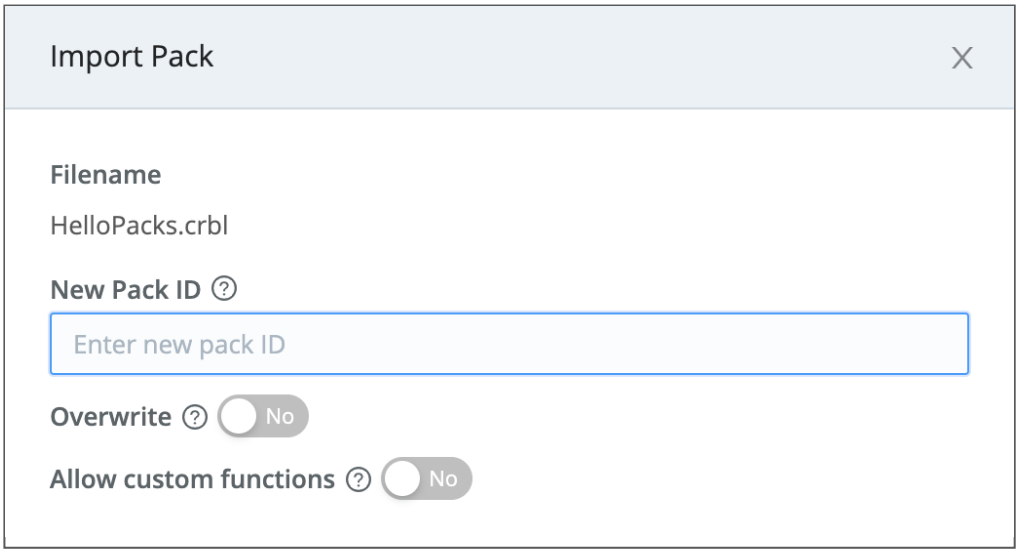
Downloading a `.crbl` file from the Cribl Pack Dispensary's Web UI

If you've posted completed Packs to our GitHub repo, we encourage you to also submit them to the Cribl Packs Dispensary site. See Publishing a Pack.

Upgrade an Existing Pack

Each Pack that you install within a given Worker Group (or single-instance deployment) must have a unique ID. The ID is based on the internal configuration of the Pack – not its container file name, nor on its Display name.

If you import a Pack whose internal ID matches an installed Pack – whether an update, or just a duplicate – you'll be prompted to assign a unique **New Pack ID** to import it as a separate Pack.



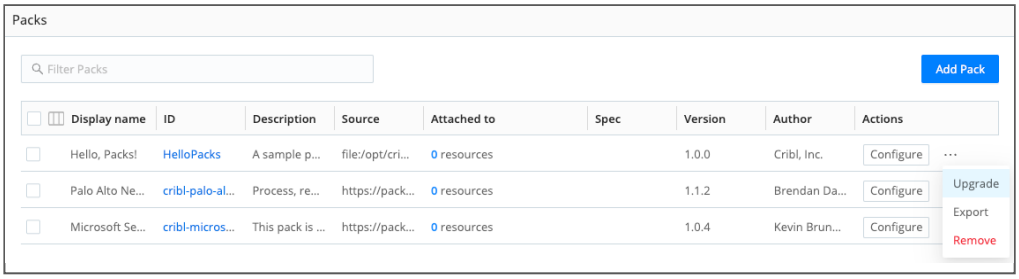
Renaming a Pack on import

You'll also have the option to **Overwrite** the installed Pack, reusing the same ID.

Be careful about enabling the **Overwrite** option. Doing so will cause the imported Pack to completely overwrite your existing Pack configuration.

Each Pack within a Cribl Stream instance must have a unique **Pack ID**, so you cannot share an ID between two (or more) installed Packs.

To explicitly upgrade an **existing** Pack, you can instead open the Options ••• menu on its row, and then select **Upgrade**.



Upgrading an existing Pack

If you've modified an installed Pack, Cribl Stream will block the overwrite of the Pack, to prevent deletion of your locally created resources.

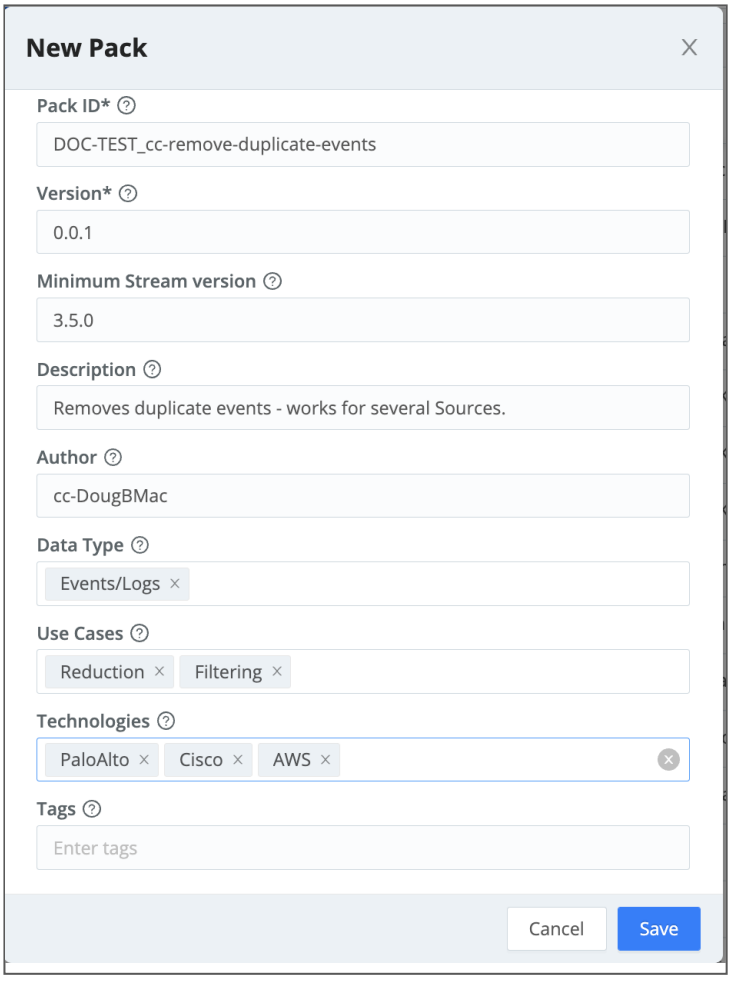
When upgrading a Pack, Cribl recommends that you:

- Import the updated Pack under a new name that includes the version number (for example, `cribl-syslog-input-120`). This allows you to review and adjust new functionality against currently–deployed configurations.
- Do a side–by–side comparison of the previous and new versions of the Pack – remember to review all comments in the new Pack. Doing this side-by-side comparison allows you to copy Function expressions and other settings from the current version into the same fields in the new version.
- Enable or disable any Functions in the new Pack as necessary.
- Update any Routes, Pipelines, Sources, or Destinations that use the previous Pack version to reference the new Pack.
- If the Pack includes any user–modified versions of default Cribl Stream Knowledge objects (for example, Lookup files): Be sure to copy the modified files locally for safekeeping, before upgrading the Pack. After you install the upgrade, copy those files back to the upgraded Pack, overwriting the default versions in the Pack.
- Test, test, and test!
- Commit and Deploy.

Create a Pack

You can create a new Pack from scratch, to consolidate and export multiple Cribl Stream configuration objects:

1. Navigate to the **Packs** page and select **Add Pack**.
2. From the submenu, select **Create Pack**.
3. Enter a unique **Pack ID** and other details:
    - Each Pack within a Cribl Stream instance must have a separate **Pack ID**, but you can assign arbitrary **Display names**.
    - **Version** is a required field identifying the Pack's own versioning.
    - **Minimum Stream version** is an optional field specifying the lowest compatible version of Cribl Stream software.
    - **Description** and **Author** are optional identifiers.
    - **Data type**, **Use cases**, and **Technologies** are optional combo boxes. You can insert one or multiple keywords to help users filter Packs that you post publicly on the Cribl Packs Dispensary.
    - **Tags** are optional, arbitrary labels that you can use to filter/search and organize Packs.
4. Select **Save**.



5. On the **Packs** page, select the new Pack's row to open the Pack.

Manage Packs page

6. Use the standard Cribl Stream controls to configure and save the infrastructure you want to pack up. As you save changes in the UI, they're saved to the Pack.

Publish a Pack

If you'd like to share your Pack with the community of Cribl users, you can publish it on the Cribl Packs Dispensary.

The Cribl Packs Dispensary site is designed for sharing completed Packs. If you want to collaborate with others on iteratively developing a Pack, Cribl recommends relying on our Dispensary GitHub Repo for the development phase.

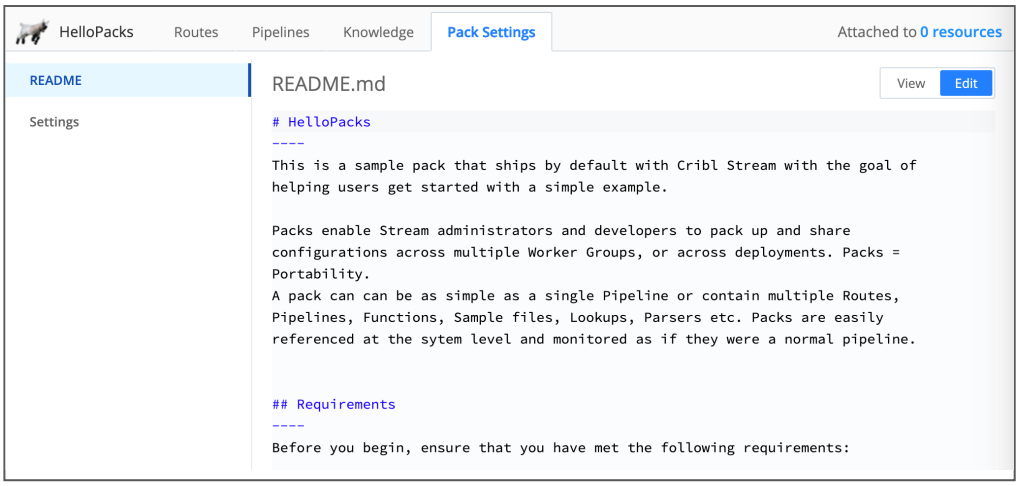
If you have a Cribl.Cloud account, you can also collaborate there by inviting team members to your Cribl.Cloud Organization. See Inviting and Managing Other Users.

Once your Pack is ready to share, we encourage you to submit it to the Cribl Packs Dispensary site. If you already have completed Packs on our GitHub repo, bring them over here!

Modify Pack Settings

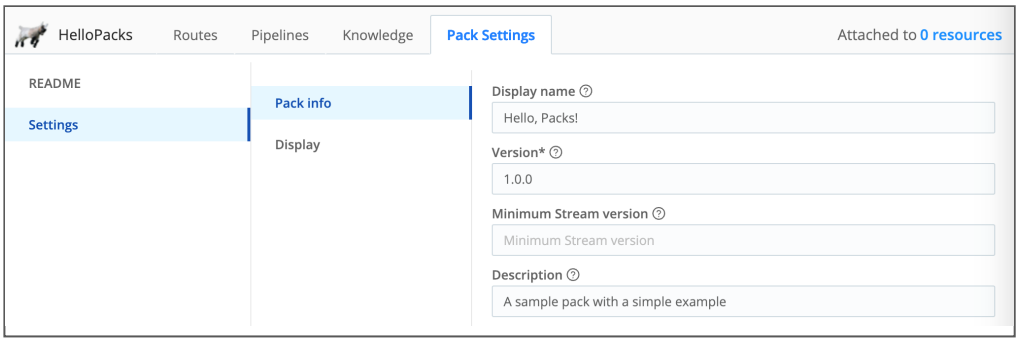
You can update Pack metadata (such as Version, Description and Author) and the Pack's display settings. If you're developing a new Pack to share, you'll want to use this interface to populate the README and display logo within the Pack:

1. Open a Pack and select **Pack Settings**. The left **README** tab will gain focus.
2. To populate the Pack README file, toggle **View** to **Edit**, replace the placeholder markdown content with your actual Pack description, and **Save**.



Editing a Pack's README

3. To update other metadata, select the left **Settings** tab.



Editing a Pack's metadata

4. You can add a Pack logo on the **Settings** tab.
   Cribl recommends adding a logo to each custom Pack, to visually distinguish the Pack UI from the surrounding Cribl Stream UI (as well as from other Packs). You can upload a `.png` or `.jpg`/`.jpeg` file, up to a maximum size of 2 MB and 350x350 px. Cribl recommends a transparent image, sized approximately 280x50 px.

Copy a Pack

You can share Packs in a Distributed deployment by copying the Packs between Worker Groups. You can copy one or more Packs from the **Packs** page, as follows.

To copy a single Pack, your first step is to open its Options ••• menu, then select **Copy to another Worker Group**.

To copy multiple Packs in one operation, your first step is to select their check boxes on the **Packs** page. Then, Options ••• menu, select **Copy selected Packs to another Worker Group**.

Next;

1. Select the Worker Groups to which you want to copy the Pack.
2. Optionally, select the **Overwrite** option to replace existing Packs that have the same **Pack ID**. (Use this option with caution, because it is destructive.)
3. Select **Copy**.

A status modal will either display a success message, or list any Packs that failed to copy.

Export a Pack

To export a newly created or modified Pack from the **Packs** page, open its Options ••• menu and select **Export**.

The **Export Pack** modal provides the following options.

Export Mode

Select one of these three buttons to determine the export mode:

- **Merge safe**: Attempt to safely merge local modifications into the Pack's default layer (original configuration), then export.
- **Merge**: Force-merge local modifications into the Pack's original configuration, then export. When you export Packs in `merge` mode, Cribl Stream deletes all encrypted fields from Pipelines. Upon importing these packs, you will need to re-enter the secrets to make them functional again.
- **Default only**: Export only the Pack's original configuration, without local modifications.

The **Merge safe** option is conservative, and will block the export where Cribl Stream can't readily merge modified contents with the Pack's original contents, due to conflicts. If you encounter an error like the example shown below, use the **Merge** or **Default only** export mode instead.

Merge safe error

Exported Pack ID

Defaults to the Pack's current ID, with the version number appended. This field provides an opportunity to change the Pack's ID, if you're exporting a new version of the Pack.

Manage Packs via API

You can perform Pack operations by running Cribl Stream API calls on the command line or in a script. The API option is required if you plan to automate Pack operations, such as in a CI/CD pipeline.

In this section, we'll walk through one scenario where running API calls on the command line works well: exporting a Pack from one Worker Group and installing it into another. The two Worker Groups/Fleets do **not** need to have the same Leader Node.

About the Following Examples

- The API calls here include Worker Group names as path parameters.
- The `curl` commands assume that you have set the `$token` environment variable to match the value of a bearer token. Of course, this is just one option for authentication. See the Authentication topic for others; adapt the example commands to suit your chosen approach.

Export via API

Adapt and run this **Export pack** API call, using the export mode of your choice:

```
GET /api/v1/m/<worker_group_name>/packs/<pack_name>/export?mode=merge
```

Export Example

Let's export a Pack named `goat-herd` from the `default` Worker Group, and use the `>` redirect to write the exported Pack to a file named `goat-herd.crbl`:

```
curl -X GET -H "Authorization: Bearer $token" 'https://stream:9000/api/v1/m/default/
```

This request returns an octet-stream attachment which is downloaded as a `.crbl` file. And there you are, you have exported your Pack.

Install via API

Installing the exported Pack in a different Worker Group is a two-step process: First upload, then actually install.

Install via API – Step 1

Adapt and run this **Upload pack** API call, referencing the exported Pack file:

```
PUT /api/v1/m/<new_worker_group>/packs?filename=<pack_name>.crbl
```

Install Example – Step 1

We'll use our target Worker Group name (in this example, it's `group420`). Then we need to specify the exported Pack contents as a file payload, using the `--data-binary` option to upload the binary data without modification. The `@` prefix tells `curl` that `goat-herd.crbl` is the path to the file, not the data itself.

```
curl -X PUT 'https://stream:9000/api/v1/m/group420/packs?filename=goat-herd.crbl' \
-H 'Authorization: Bearer $token' \
-H 'Accept-Encoding: gzip, deflate, br, zst' \
-H 'Connection: keep-alive' \
-H 'Content-Type: application/octet-stream' \
--data-binary '@goat-herd.crbl'
```

This request returns a JSON object of the following form:

```
{"source":"pack_name.random_id.crbl"}
```

Install via API – Step 2

Adapt and run this **Install pack** API call:

```
POST /api/v1/m/<new_worker_group>/packs
```

Meanwhile, remember that this API call will need a payload – the JSON object returned by the previous API call.

Install Example – Step 2

We'll use the `curl -d` option to specify the JSON object payload. We'll add a new element to the object, whose key is `id`, and whose value is the Pack's new name in the new Worker Group.

Here, we rename the `goat-herd` Pack as `billys_pack`. (If you do not wish to rename the Pack, just omit the `id` element – but keep the `source` element.)

```
curl -X POST 'https://stream:9000/api/v1/m/group420/packs' \
-H 'Authorization: Bearer $token' \
-H 'Content-Type: application/json' \
-d '{
  "source": "goat-herd.987654321.crbl",
  "id": "billys_pack"
}'
```

Copy via API

To bulk-copy Packs between @{groups}s, adapt and run this **Clone pack** API call, referencing a source Worker Group, destination Worker Group(s), and Pack(s).

```
POST /api/v1/packs/__clone__

{
  "srcGroup": "copy_from_this_worker_group_id",
  "dstGroups": [
    "destination_group_1",
    "destination_group_2",
    ...
  ],
  "packs": [
    "pack_id_1",
    "pack_id_2",
    ...
  ]
}
```

Copy Example

For example, to copy the Palo Alto Networks and Cisco ASA Packs from the default to `dc1-logs` and `dc2-logs` Worker Groups:

```
curl -X POST -H "Authorization: Bearer $token" -H "Content-Type: application/json" '{
```

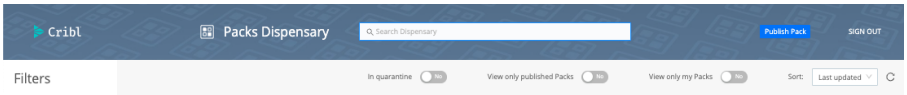
13.5.1. Packs Publication Standards

This page outlines the process for Cribl Community members to publish Cribl Stream Packs to the Cribl Packs Dispensary. It also lists standards that apply to all publicly available Community Packs.

Publication Overview

Publishing your Pack is a five-stage process:

1. **Prepare**
    - Prior to starting development, read the Pack Review Summary and Pack Review Checklist below. This will help you create a Pack that can easily pass the review process. Decide on the problems you're trying to solve, and determine the dataset(s), Sources, and Destinations you're going to work with.
2. **Develop your Pack**
    - Development is generally done in your own Cribl environment, using saved samples to build out pipelines. During this stage, you might consider working collaboratively within Cribl's Community Slack `#packs` channel. When the Pack is ready for review, export the `.crbl` file using the Cribl UI.
3. **Test your Pack**
    - Cribl strongly recommends that you test the Pack yourself, in your own environment. To test that all content was exported correctly, import your Pack into a fresh Cribl environment, such as a newly created Docker instance, or to a newly created Worker Group in your Cribl environment. Upload the Pack, then use the Pack Review Checklist to verify that the Pack will pass review.
4. **Submit your Pack for review**
    - Sign into, or create an account on, the Cribl Packs Dispensary site. You can use your Cribl.Cloud account's email address to create the Cribl Packs Dispensary account.
    - If you don't have a Cribl.Cloud account, Cribl automatically creates a new one for you when you create your Cribl Packs Dispensary account.
    - Once you sign in, you'll see the Dispensary page with the **Publish Pack** button.



Packs Dispensary controls

    - Click **Publish Pack**, and then click **Upload Pack**.
    - Select the `.crbl` Pack file you want to publish, and click **Submit**. You will be prompted to agree to the terms of Cribl's Pack Developer Agreement. As a Pack author, you must electronically acknowledge that you have read the Agreement, and that you intend to adhere to its requirements.

Once the Pack has been uploaded, Cribl will review your Pack. The review process typically takes a week or more. Once your Pack is reviewed, you'll receive an email from `packs@cribl.io` either informing you that it was accepted, or providing the reason(s) why it was rejected.

5. **Once your accepted Pack is published to the Cribl Packs Dispensary, it's time to celebrate!**

Pack Review Summary

To ensure consistency across published Packs, Cribl evaluates all submitted Packs against the checklist below. Any Pack that fails to satisfy the checklist's requirements will be rejected.

Cribl recommends:

- Check your Pack against the checklist **before** trying to submit the Pack. This way you can avoid having your Pack rejected for something easily fixed.
- Install the **Syslog Pre-processing** (`cribl-syslog-input`) Pack as a reference – it includes clear examples of each item on the checklist.

Pack Review Checklist

1. Naming

Every Pack must have both a Pack ID and a Display Name.

When you view Packs in the Dispensary, the Display Name appears above the Pack ID. For example, **Syslog Pre-processing** is a Display name while `cribl-syslog-input` is a Pack ID:

Display Name and Pack ID

Pack ID

The Pack ID:

- Must start with either `cc-` (community-contributed) or `cribl-` (Cribl-contributed). Packs not satisfying this requirement will be immediately rejected.
- Should (by convention) be all lowercase, using the hyphen (`-`) as a delimiter.
- Should **not** include the word "pack."

For Packs normalizing to or from Elastic's Common Schema, the Pack ID (but not the Display Name) should include `-source` or `-dest`.

Display Name

The Display Name is a human-friendly version of the Pack name that:

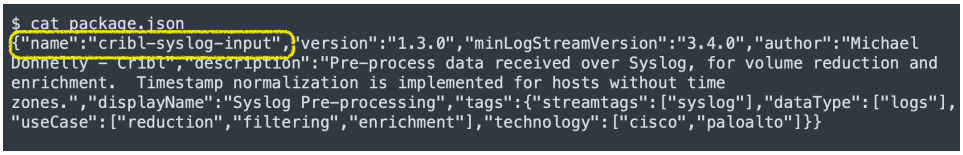
- Omits `cc-` and `cribl-`.
- Uses spaces where appropriate, and proper capitalization.
- If it includes a company or product name, matches the company's preferred spelling, spaces, and capitalization.

You can view or edit the Display Name on the **Pack Settings** tab.

How to Review the Pack ID

This is the same procedure that the Cribl will perform when reviewing your Pack.

1. Extract the `.crbl` tarball that was submitted to the Dispensary:
   `tar zxvf <your_filename>.crbl`
2. View the `package.json` file:
   `cat package.json`
3. Check the value of the `name` field: this should be the Pack ID that you want.



Verifying the Pack ID

2. Pack Settings

You must review your **Pack Settings** to verify that the Pack satisfies all of the following criteria.

Display Name

A human-friendly version of the Pack name as defined above.

Version

The version number in the submitted Pack must have a corresponding entry in the README Release Notes.

- The minimum version for initial publication is `0.1.0`. A Pack with a lower version **will be rejected**.
- A release that is considered "beta quality" should be designated as version `0.9.0`.

Description

Use this as a brief "hook" of one to two sentences. Example: `This pack for Syslog inputs will reduce volume, and address timestamp normalization for Syslog senders that omit timezones.`

Author

Community-contributed Packs may include the author's name, a company name, or both.

All three of the following examples are valid:

1. `Jon Smith`
2. `Bazookatron`
3. `Jon Smith - Bazookatron`

Cribl-published Packs must use author's full name, plus `- Cribl`. Example: `Michael Donnelly - Cribl`.

Data Type, Use Cases, Technologies

Select all that apply.

Tags

Tags are optional but recommended, especially where multiple Packs are intended to work together. Tag examples include: `OCSF`, `AWS`.

Logo

The logo is optional, but recommended. You can include a logo associated with the technology addressed by the Pack. For example, a Windows logo for Windows events, an AWS Cloudwatch logo for AWS Cloudwatch data, and so on.

You can set the logo via **Pack Settings** > **Settings** > **Display**.

3. Routes

A Pack submitted must include at least one Route in addition to the default Route.

- A Pack's Routes page must have a Route, with an appropriate filter, routing to a Pipeline.
- The filter should match **only** the set of data that the Pipeline is designed to process. The filter must **not** be set to `true`.
- If the Pack deals with multiple datasets, each dataset should have its own Route/Pipeline pair. (For a good example, look at the PAN Pack.)
- The Pack must not use the `default` Route to send events to a Pack-specific custom Pipeline. The `default` Route may have a Pipeline set to `main`, `devnull`, or `passthru` to handle events that do not match the Pack filter(s).
- Each Route must include a short description of the dataset being matched.
- Pairs of Routes and Pipelines should have matching names.

4. Pipelines

A Pack submitted must include at least one Pipeline in addition to the stock Pipelines (`devnull`, `main`, `passthru`, `prometheus_metrics`, etc.).

- If the Pack deals with multiple datasets, there must be one Pipeline (and one Route) for each dataset. (For a good example, look at the PAN Pack.)
- The Pack must not use the stock Pipelines. Leave these Pipelines unmodified.
- Every Pipeline must begin with a Comment Function that gives an overview of the Pipeline's operation as a whole. This Comment is a synopsis of what the entire Pipeline will be doing. Refer to the **Syslog Pre-processing** (`cribl-syslog-input`) Pack for an example of the expected level of detail.
- If Function Groups are used within the Pipeline, each Function Group must begin with a Comment Function that gives an overview of what will happen within that Function Group.
- Every Function must have a Description that briefly explains exactly what is happening in that particular Function. During review, change the Pipeline view option to display the Description for each Function.
- Using the sample files provided with the Pack, validate that the Functions work as detailed in the Comment at the top of the Pipeline.

5. Sample Files

The Pack must include at least one sample file for each of its Pipelines.

Sample files:

- Must **not** have an expiration date.
- Must **never** include PII, customer data, or customer hostnames.
- Must be named in such a way that it's obvious which sample file(s) apply to each Pipeline.
- Must contain samples that are adequate for a customer to use to review the operation of a Pipeline. To allow performance analysis of the corresponding Pipeline, a sample should include 20 or more events, with 100 or more recommended.
- May be reused across Pipelines, but it is preferable to include multiple data samples, each specific to a Pipeline's Route and filter.
- Must work as expected on a clean installation of the Pack. This applies to all samples listed in the Pack – Pack developers should test this before submitting the Pack.

6. README

The `README` is the documentation others will use in selecting and deploying the Pack. The `README` requirements ensure that others will be able to deploy the Pack successfully.

The default sections for README, as created when you click **Create Pack**, do not match the required and optional sections in the checklist. You will need to delete or replace certain sections.

On the Pack's **Pack Settings** > **README** tab, validate that the README text is correct. The following rules apply to all sections of the README:

- Proper grammar will help the users of your Pack. Use a grammar and spelling checker to make sure the README is clear and readable.
- If the README includes any text that looks like a placeholder, the Pack will be rejected.
- Trademark or product names must be spelled and capitalized exactly as the company that owns them would dictate. This requirement also applies to Pack settings, inline comments, and other uses. Examples: Amazon (not amazon), GCP (not Gcp), CrowdStrike (not Crowdstrike).
- The README must include all of the sections listed below (sections **6a** through **6f**). The README may include additional sections as necessary.

6a. About This Pack

Think of this initial section as the first paragraph of an essay, or as the only paragraph a person will read when deciding to use the Pack. It must clearly state what the Pack does. Start with the benefits of using the Pack. In sum, this section should answer the question, **Why should anyone use this Pack?**

If the Pack is tied to a specific data source, dataset, or destination, spell that out clearly here – even if that source or destination is in the Pack name.

6b. Deployment

This **required** section must include all instructions necessary to get the Pack up and running. If the Pack requires any configuration after initial installation - but before it's put it into production - you must specify the configuration steps here.

Filters: If applicable, say what filter must be used to route data to the Pack, or explain how to configure the filter. A filter based on `__inputId` is much more efficient than a match against `_raw`.

Sources: If the Pack requires a specific Source, include information on how to configure that Source. At a minimum, this needs to cover setting up the Source within Cribl. In some cases, this might include information on how to set up an external environment for collection by Cribl as well.

Destinations: If the Pack requires a specific Destination, include information on how to configure that Destination. Does it need a post-processing Pipeline tied to the Pack?

Pipelines: If the Pack includes Functions (within a Pipeline) that need to tailored, enabled, or disabled, include a full explanation and instructions.

Lookups: If the Pack includes Lookup files that need to be tailored, you must specify the configuration steps here.

6c. Upgrades

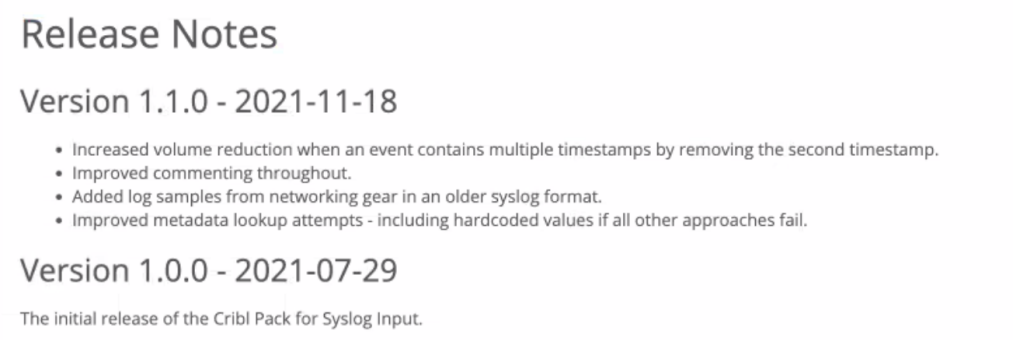
This **optional** section is strongly recommended if you expect others to customize their copy of the Pack and later upgrade the modified Pack.

- If included, this section should cover the usual set of problems with Pack upgrades as described in Upgrading an Existing Pack, and should explain the specifics of upgrading this particular Pack.

6d. Release Notes

This **required** section is a list of release notes where each release note:

- Starts with the version number and date of release, separated by a space, a hyphen, and a space. For example: `Version 1.2.0 - 2022-07-11`.
- Continues with bullet points that describe what has changed and/or is new in the release.



Release notes

Release notes must adhere to the following rules:

- Designate the initial release version `Initial release`.
- The most current version listed must exactly match the Pack version in **Pack Settings** > **Settings**.
- Release notes versions must be listed starting with the most recent (in descending chronological order).

6e. Contributing to the Pack

This **required** section explains how to contribute to the Pack.

- The information provided must be **actionable**. A section reading `[Contributor instructions go here.]` would be rejected.
- Cribl recommends that you refer potential contributors to Cribl's Community Slack. For example, Cribl-created Packs read as follows:

```
To contribute to the Pack, please connect with us on [Cribl Community Slack](htt
```

6f. License

This **required** section must include text that designates **and links to** a legitimate license.

- Community-contributed Packs must include a license that allows for use by the general public, such as Apache 2.0, MIT, or GNU.
- Built-by-Cribl Packs must use the following snippet:

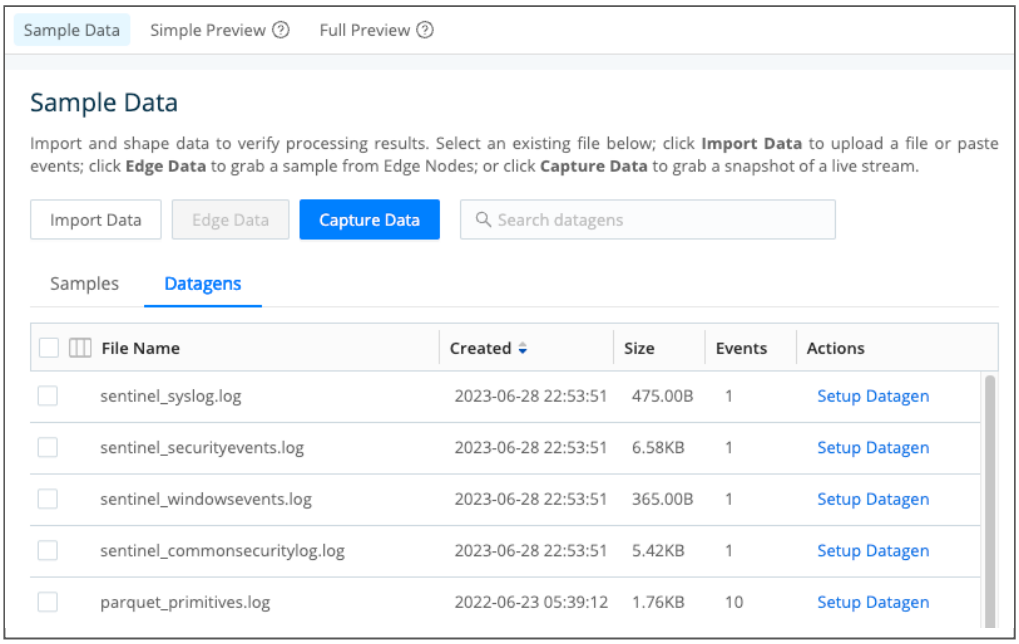
```
This Pack uses the following license: [Apache 2.0](https://github.com/criblio/ap
```

13.6. Use Datagens

Data generators for testing and troubleshooting

Cribl Stream's datagens feature enables you to generate sample data for the purposes of troubleshooting Routes, Pipelines, Functions, and general connectivity.

Several datagen template files ship with the product, out of the box. You can create others from sample files or live captures.



Preview pane – add samples via paste, attach/upload file, or live capture

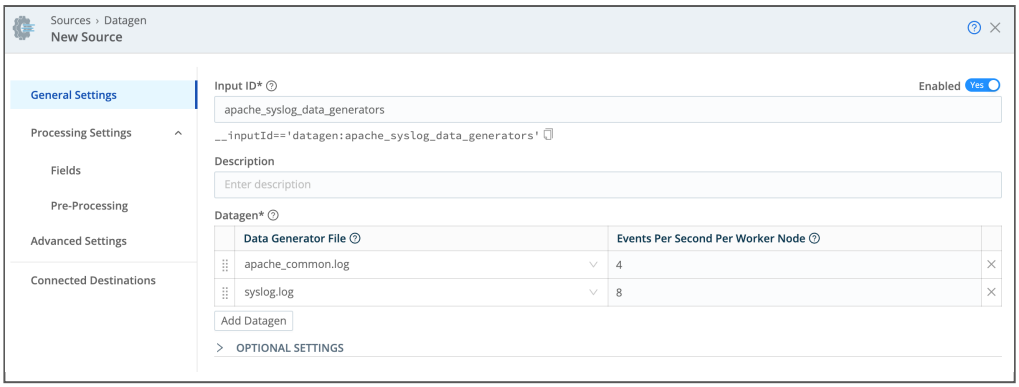
As outlined in the following tutorial: Once you've created a template, you can configure a Datagen Source to use the template to generate real-time data at a given EPS (events per second) rate.

Enable a Datagen

To see how datagens work, start by enabling a pair of Cribl Stream's out-of-the-box generators:

Navigate to **Sources** > **Datagens** and select **Add Source**.

After entering a unique ID and an optional description, select a data generator file (such as `apache_common.log`) and set it at `4` **Events Per Second Per Worker Node**. Select **Add Datagen** to select another data generator file (such as `syslog.log`) and set it at `8` **Events Per Second Per Worker Node**. Select **Save**.



Selecting datagen files and event rates

In the sidebar, select **Monitoring**, select **Data** > **Sources**, and search for `datagen` to confirm that the Source is generating data.

Create a Datagen Template from a Sample File

To convert a sample into a template:

From the **Data Routes** or **Pipelines** page, select **Import Data** in the right preview pane, and paste a sample like the AWS VPC Flow logs below:

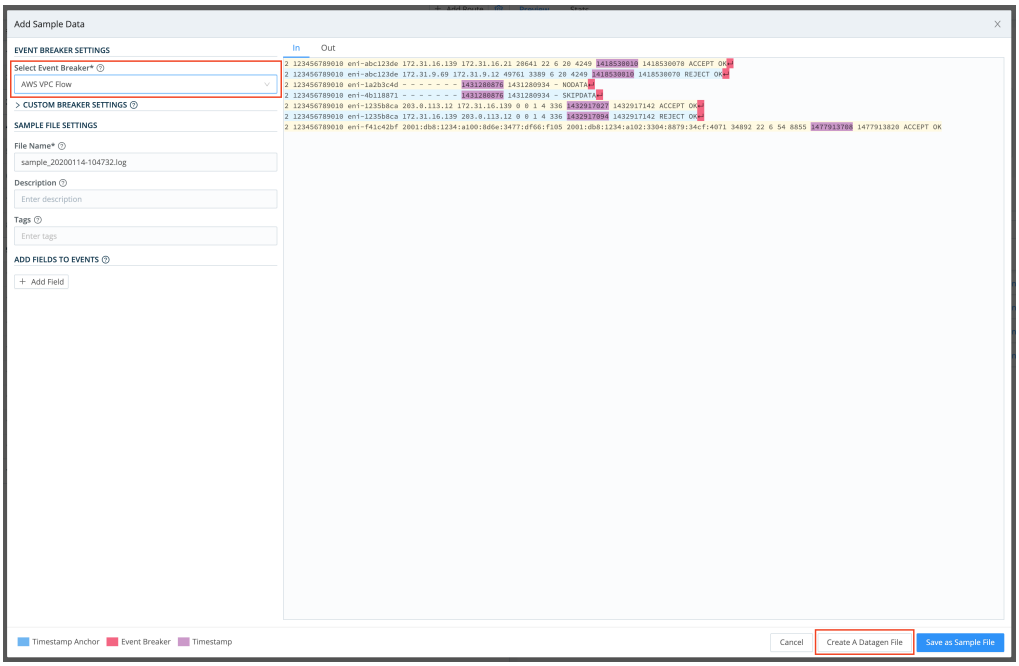
Sample VPC Flow Logs

```
2 123456789010 eni-abc123de 172.31.16.139 172.31.16.21 20641 22 6 20 4249 1418530010
2 123456789010 eni-abc123de 172.31.9.69 172.31.9.12 49761 3389 6 20 4249 1418530010 1
2 123456789010 eni-1a2b3c4d - - - - - - - 1431280876 1431280934 - NODATA
2 123456789010 eni-4b118871 - - - - - - - 1431280876 1431280934 - SKIPDATA
2 123456789010 eni-1235b8ca 203.0.113.12 172.31.16.139 0 0 1 4 336 1432917027 143291
2 123456789010 eni-1235b8ca 172.31.16.139 203.0.113.12 0 0 1 4 336 1432917094 143291
2 123456789010 eni-f41c42bf 2001:db8:1234:a100:8d6e:3477:df66:f105 2001:db8:1234:a10
```

From the **Select Event Breaker** drop-down, select **AWS VPC Flow** to ensure that:

- The pasted text gets broken properly into individual events (notice the Event Breaker on newlines).
- Timestamps are extracted correctly (text highlighted purple below).

Once you've verified these results, select **Create a Datagen File**.

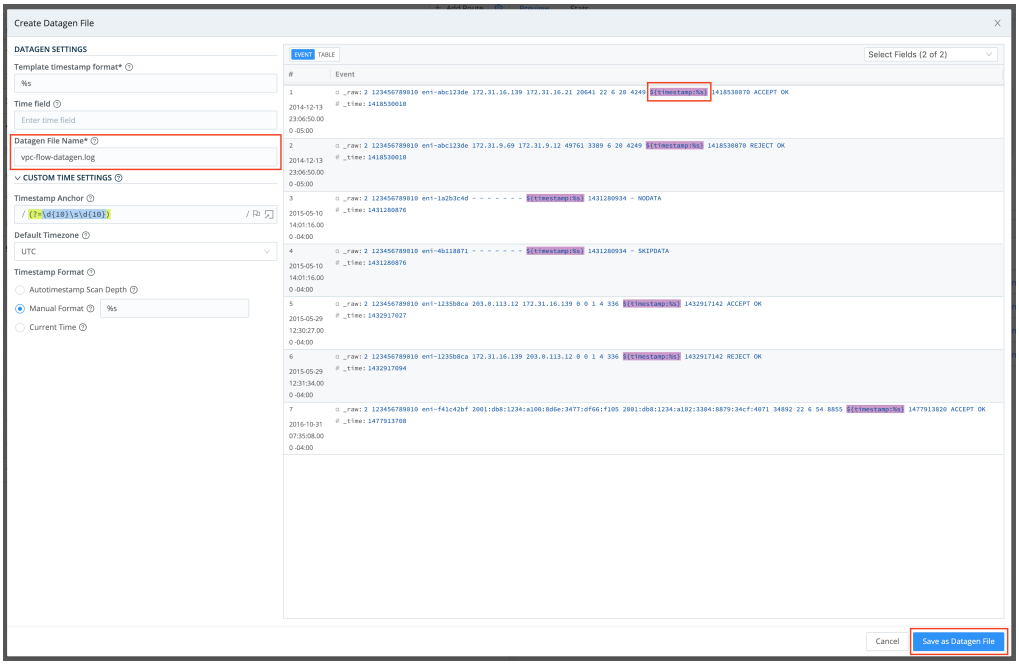


Creating a datagen template

On the resulting **Create Datagen File** screen:

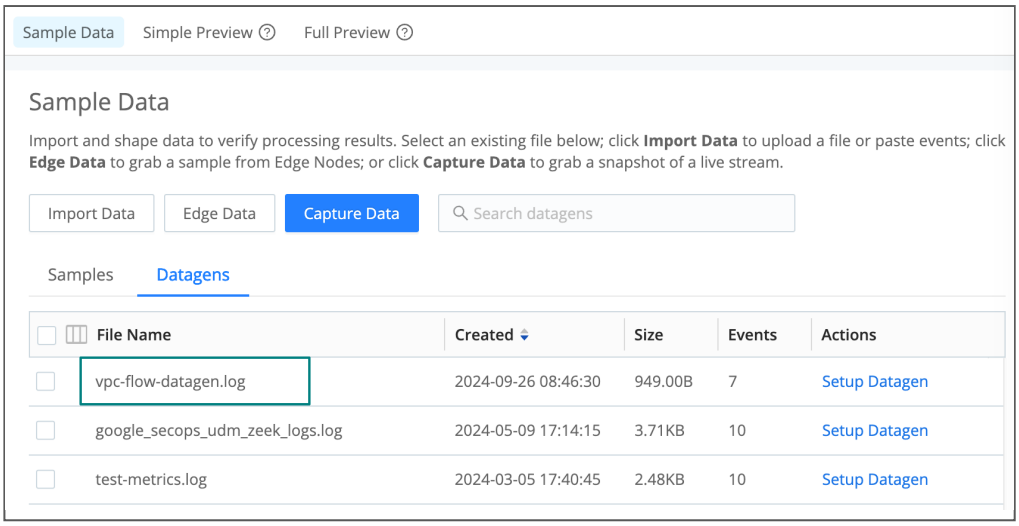
- Enter a file name, such as `vpc-flow-datagen.log`
- Ensure that the timestamp template format is correct: `${timestamp: %s}`
  `${timestamp: <format>}` is a template that the datagen engine uses to insert the current time – in each newly generated event – using the given format. In this case, `%s` is the desired `strftime` format for the timestamp (the epoch).

Once you've verified these results, click **Save as Datagen File**.



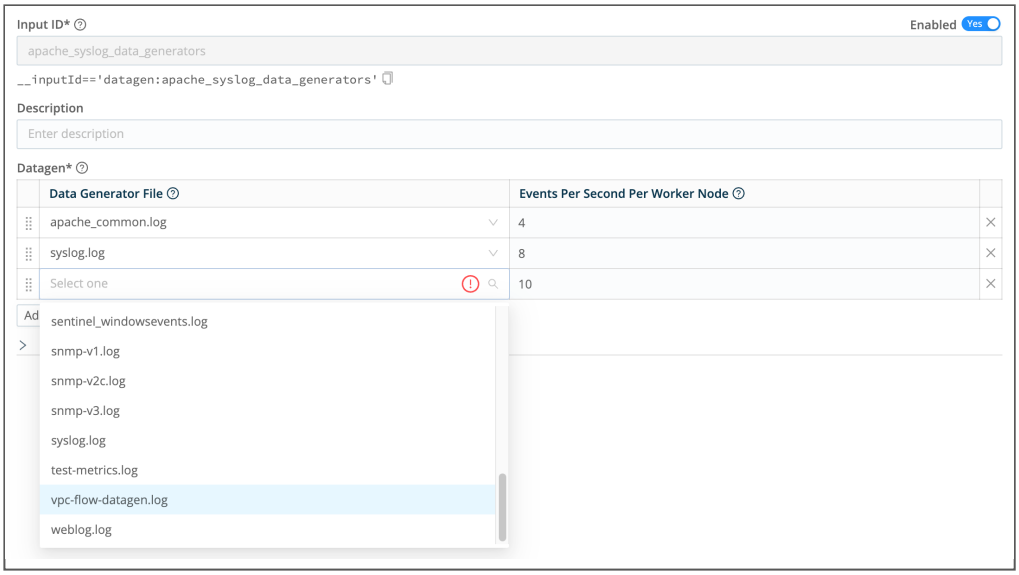
Saving a named datagen template

To confirm that the datagen file has been created, select the **Datagens** tab in the preview pane.



Verifying datagen file creation

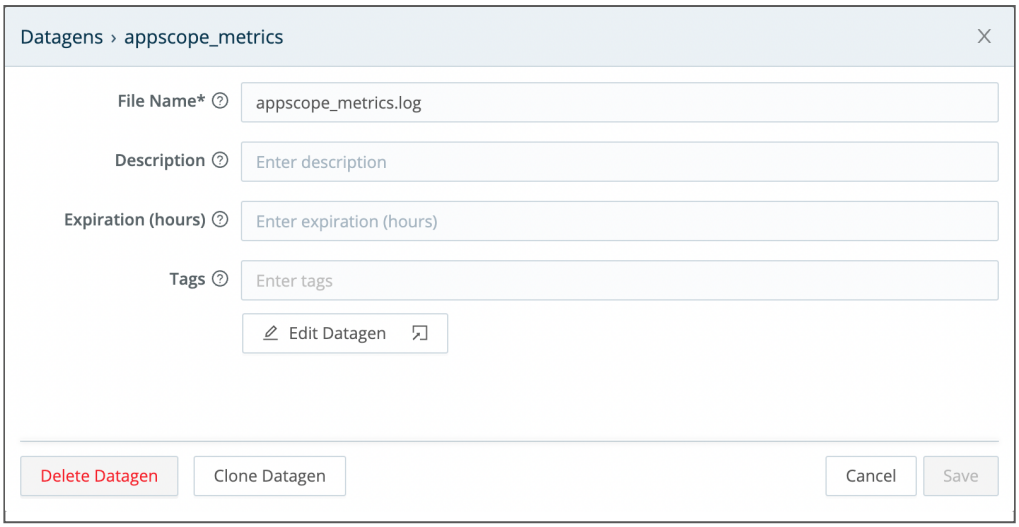
Now, to start using your newly created datagen file, go back to **Sources** > **Datagens**. Add it using the drop-down shown below.



Adding new template file to datagens Source

Modify a Datagen

1. In the right Preview pane, select the **Datagens** tab.
2. Hover over the file name you want to modify. This displays an edit (pencil) button to its left.
3. Select that button to open the modal shown below. It provides options to edit the datagen, clone it, delete it, or modify its metadata (**File name**, **Description**, **Expiration time**, and **Tags**).



Options for modifying a datagen

4. To make changes to the datagen, select the modal's **Edit Datagen** button. This opens the **Edit Datagen** modal shown below, exposing the raw data that this datagen uses to generate events.
5. Edit the raw data as desired.
6. Select **Update Datagen** to resave the modified datagen, or select **Save as New Datagen** to give the modified version a new name.

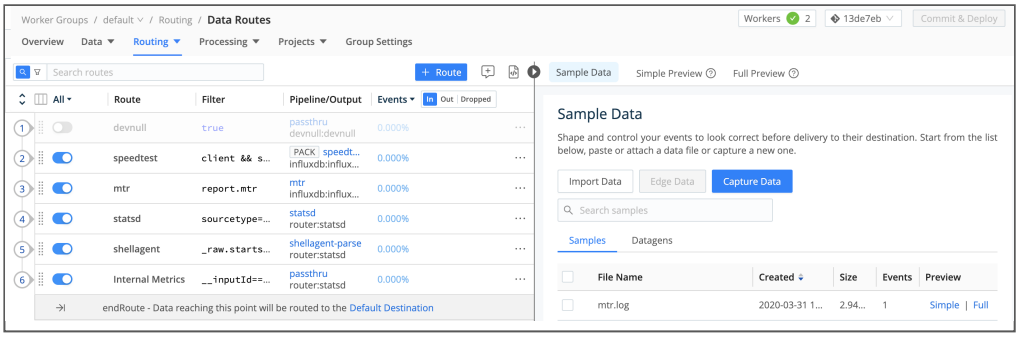
Editing a datagen

13.7. Data Preview

Cribl Stream's Sample Data Preview features enable you to visually inspect events as they flow into and out of a Pipeline. Preview helps you shape and control events before they're delivered to a Destination, and helps you troubleshoot Pipeline Functions.

Preview works by taking a set of sample events and passing them through the Pipeline, while displaying the inbound and outbound results in a separate pane. Any time a Function is modified, added, or removed, the Pipeline changes, and so does its displayed output.

The Preview pane is shown below, to the right of the Pipelines pane.

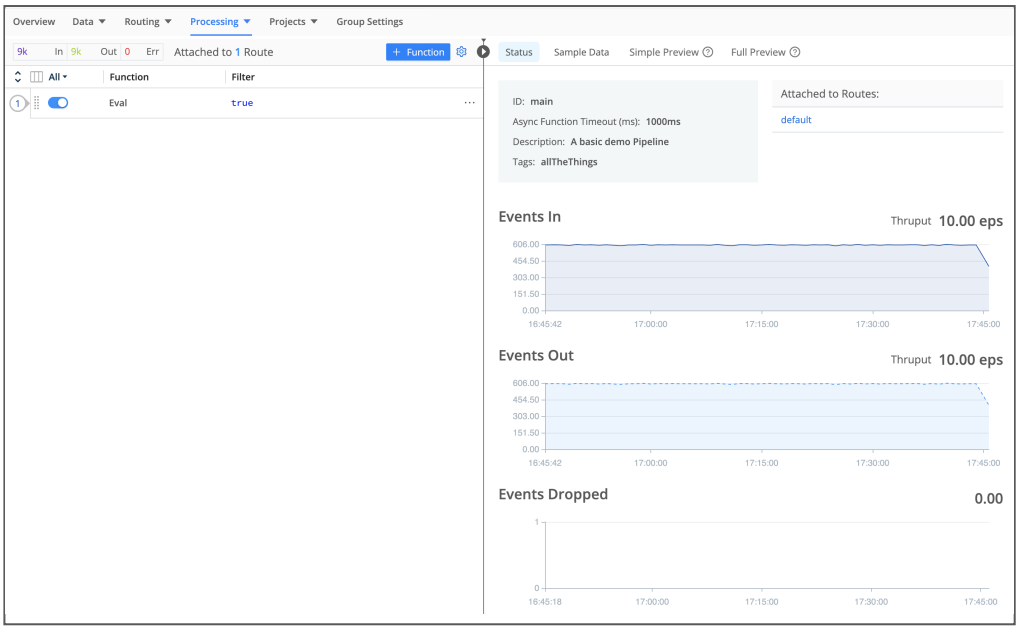


Preview options

You can press the] (right-bracket) shortcut key to toggle the visibility of the Preview pane. (This shortcut works when no field has focus.)

Check Pipeline Status

From the Pipelines page, select any Pipeline at left to display a **Status** tab in the right Preview pane. Select this tab to reveal graphs of the Pipeline's **Events In**, **Events Out**, and **Events Dropped** over time, along with summary throughput statistics (in events per second).



Pipeline status tab

Add Sample Data

When you're on the Pipelines or Routes page, you can add samples through any of the Preview pane's supported options:

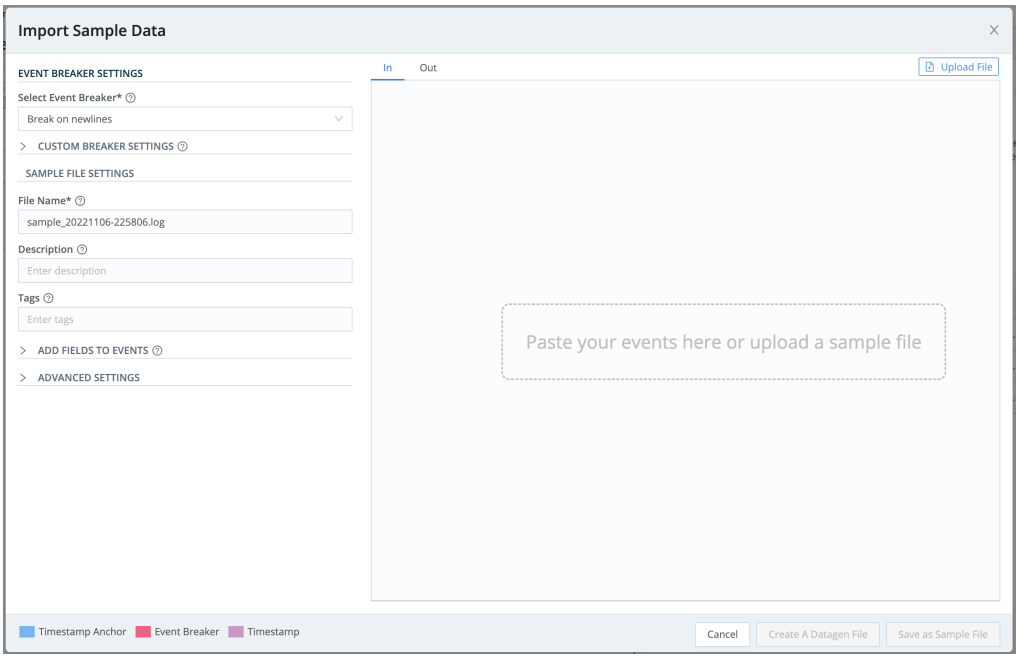
- **Import Data**: Opens a modal where you can paste data from your clipboard or use the **Upload File** button
- **Edge Data**: Lets you import data from any Edge Nodes deployed on your account
- **Capture New**

The **Import Data** options work with content that needs to be broken into events, while the **Capture New** option works with events only.

The **Edge Nodes** option requires at least one working Edge Node, and is not available when you've teleported to the Node.

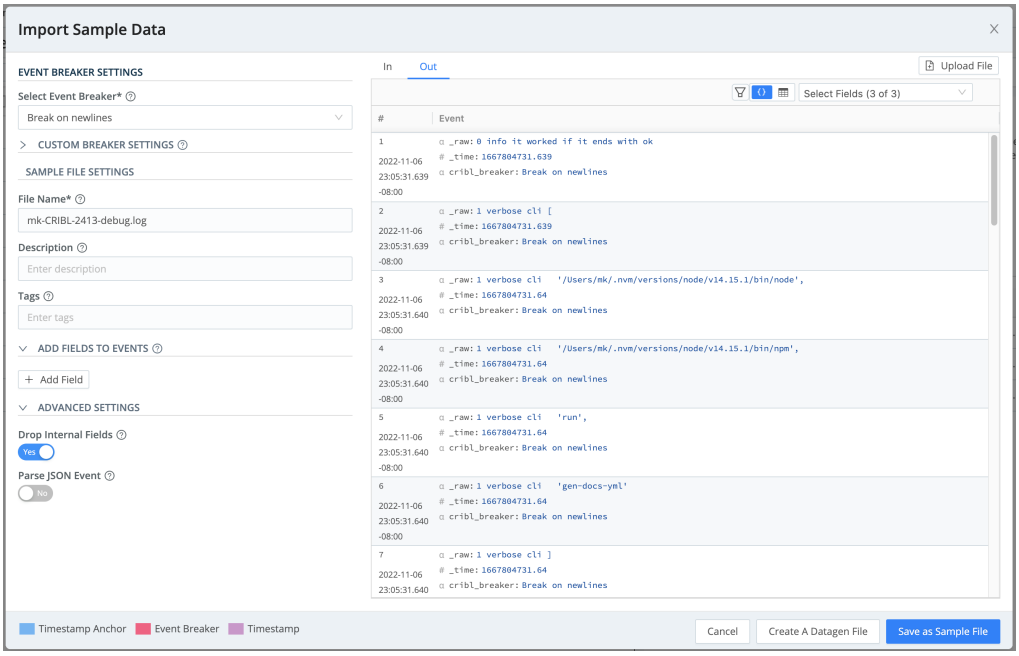
Paste Area

Once you've selected **Import Data** or imported Edge data, you'll see an **Import Sample Data** modal, where you can paste data or upload a file.



Import Sample Data modal

Once your data is onboard, you have options to modify it using Event Breakers, to add and drop fields, and to save it to a file.



Working with imported data

Edge Data

To upload data from a file on an Edge node:

1. Select **Edge Data** and navigate to the Edge node where the file is stored.
   Selecting the Edge Node opens the **Select a file** modal.

2. In **Manual** mode, use the available filters to narrow the results:
    - **Path**: Sets the location from which to discover files.
    - **Allowlist**: This filter supports wildcard syntax (as shown in the screenshot above), and supports the exclamation mark (`!`) for negation.
    - **Max depth**: Sets which layers of files to return highlighted in bold typeface. By default, this field is empty, which implicitly specifies `0`. This default will boldface only the top-level files within the **Path**.
3. Once you find the file you want, select its name to add its contents to the **Add Sample Data** modal, where you'll finish configuring the data sample.

Event Breaker Settings

Cribl Event Breakers are regular expressions that tell Cribl Stream how to break the file or pasted content into events. Breaking will occur at the **start** of the match. Cribl Stream ships with several common breaker patterns out of the box, but you can also configure custom breakers. The UI here is interactive, and you can iterate until you find the exact pattern.

Troubleshoot Event Breakers

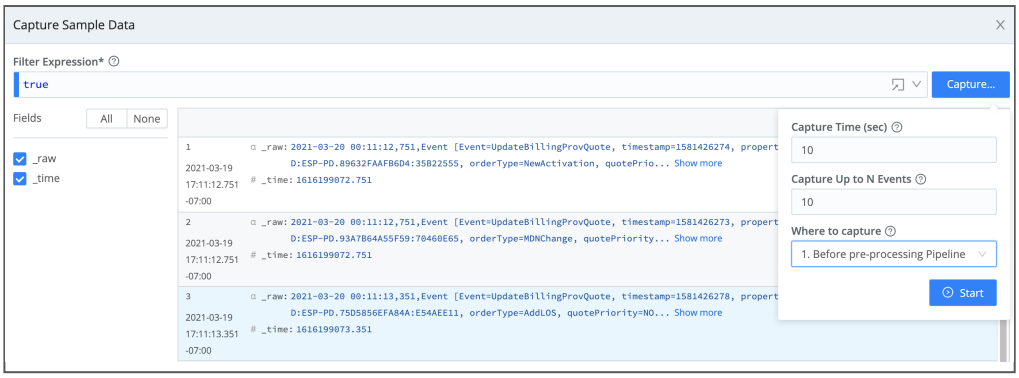
If you notice fragmented events, check whether Cribl Stream has added a `__timeoutFlush` internal field to them. This diagnostic field's presence indicates that the events were flushed because the Event Breaker buffer timed out while processing them. These timeouts can be due to large incoming events, backpressure, or other causes.

Capture Sample Data

The **Capture Data** button opens a slightly different modal – it does not require event breaking.

In order to capture live data, you must have Worker Nodes registered to the Worker Group for which you're viewing events. You can view registered Worker Nodes from the **Status** tab in the Source.

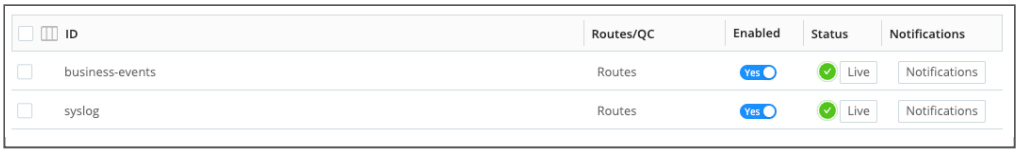
In the composite screenshot below, we've already captured some events using the **Capture** drop-down.



Capture Data > Capture Sample Data modal

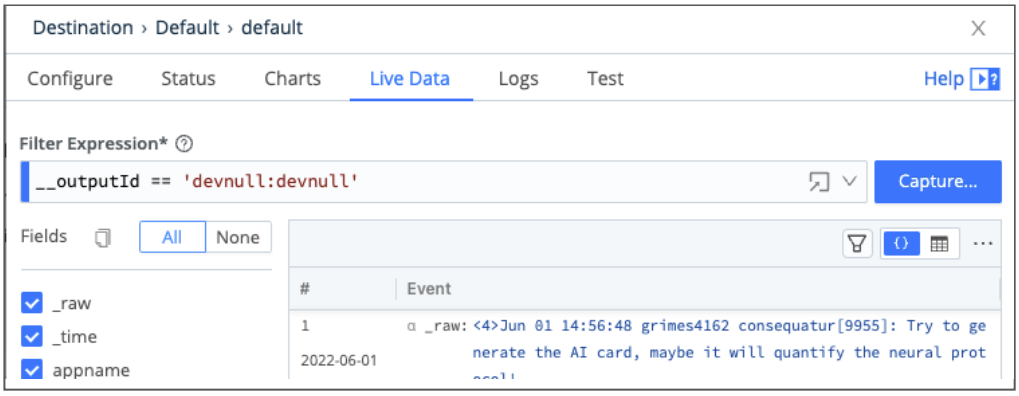
Capture from a Single Source or Destination

To capture data from a single enabled Source or Destination, it's fastest to use the Sources or Destinations UI instead of the Preview pane. You can initiate an immediate capture by selecting **Live** on the Source's or Destination's configuration row.



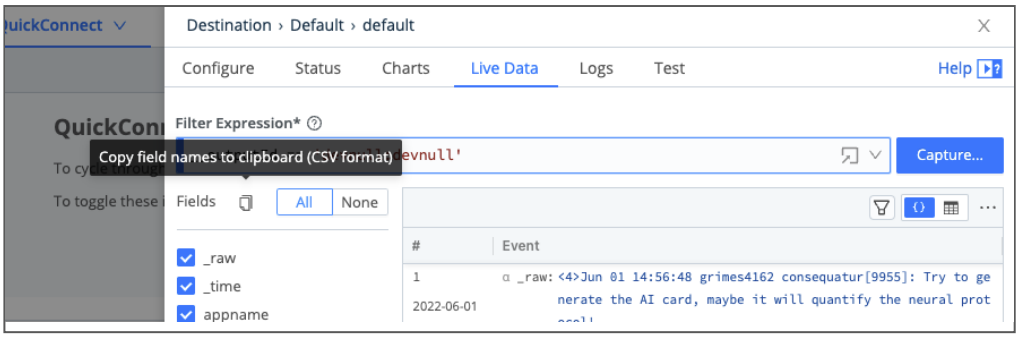
Source > Live button

You can similarly start an immediate capture from within an enabled Source's or Destination's configuration modal, by selecting the modal's **Live Data** tab.



Destination modal > Live Data tab

Beside the **Live Data** tab's **Fields** selectors is a Copy button, which enables you to copy the field names to the clipboard in CSV format. The **Logs** tab also provides this copy button.



Destination modal > Live Data - Copy Fields Icon

Control Sample Size

To prevent in-memory samples from getting unreasonably large, samples that you input by any means (Import Data, Edge Data, or Capture Data) are constrained by a limit set as follows:

- On a single instance at **Settings** > **General Settings** > **Limits** > **Storage** > **Max sample size**.
- On distributed Worker Groups (both Cribl-managed and customer-managed) at **Group Settings** > **General Settings** > **Limits** > **Storage** > **Max sample size**.

In each location, the default limit is `256 KB`. You can adjust this upward (to a maximum of `3 MB`) or downward.

Very Large Integer Values

Cribl Stream's JavaScript implementation can safely represent integers only up to the Number.MAX_SAFE_INTEGER constant of about 9 quadrillion (precisely, {2^53}-1). Data Preview will round down any integer larger than this, and trailing 0's might indicate such rounding.

Fields

In the **Capture Data** and **Live Data** modals, use the **Fields** sidebar (at left) to streamline how events are displayed. You can toggle among **All** fields, **None** (to reset the display), and check boxes that enable/disable individual fields by name.

Field Type Symbols

Within the right Preview pane, each field's type is indicated by one of these leading symbols:

Symbol	Meaning
α	string

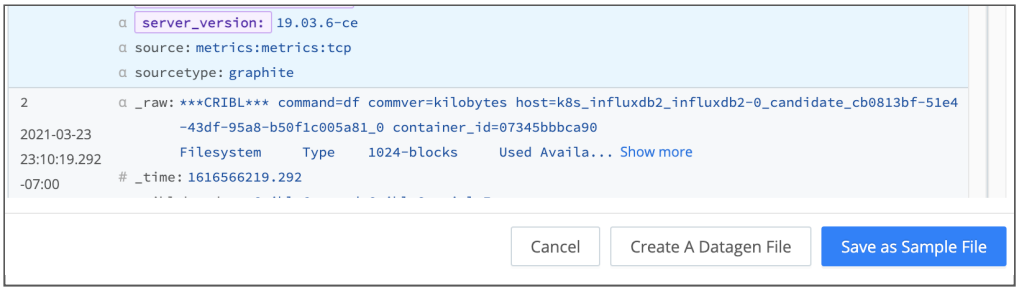
Symbol	Meaning
#	numeric
b	boolean
m	metric
{}	JSON object
[]	array

On JSON objects and arrays, you'll also see:

Symbol	Meaning
+	expandable
-	collapsible

Save Sample Data

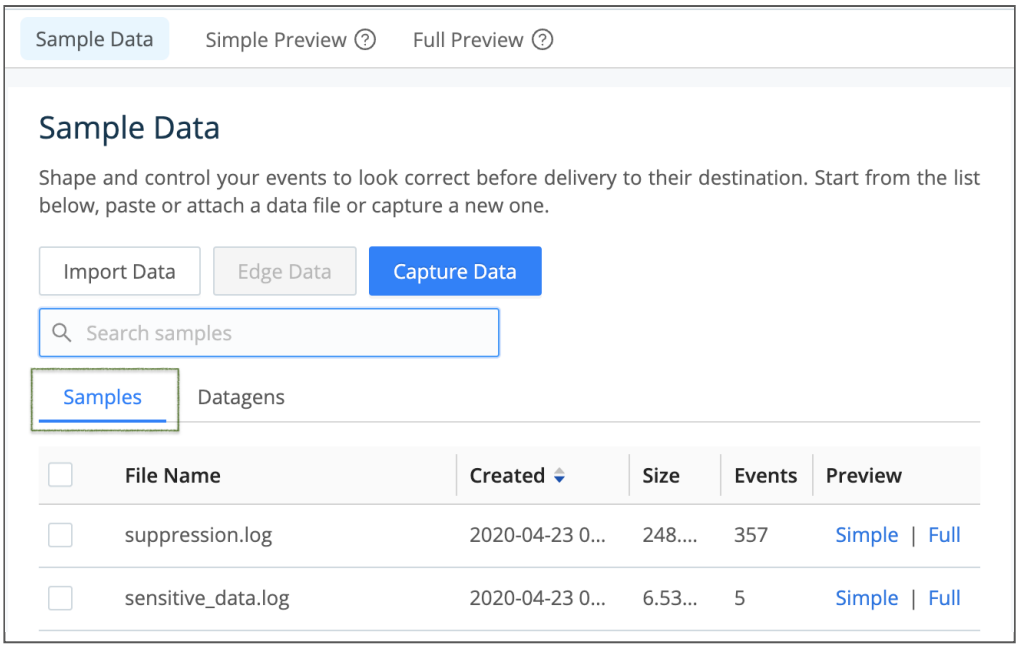
The Preview pane's **Import Data** or **Capture Data** modal, once you've successfully populated it with data, provides options to save the data as a sample and/or datagen file. Select the appropriate button, accept or modify the default/generated file name and other options, and confirm the save.



Saving sample data

Access and Manage Data Files

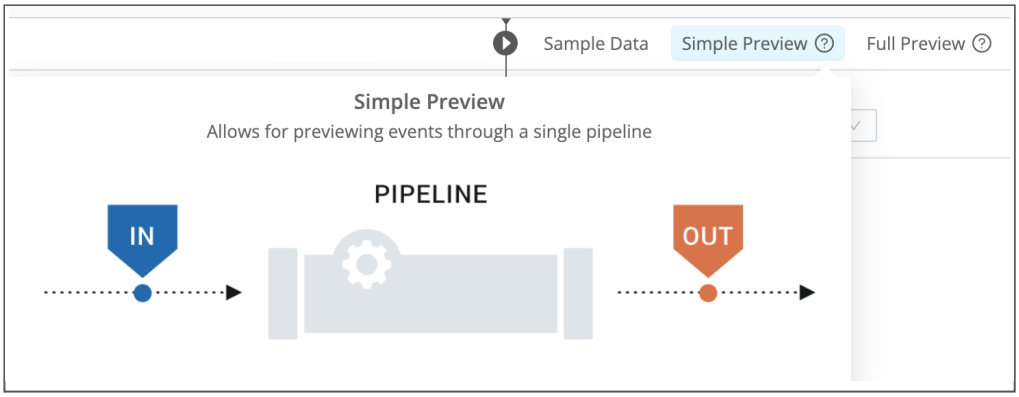
As you add more samples to your system, you can easily access them via the **Sample data file** drop-down. You can also manage and modify sample files via the **Samples** tab highlighted below.



Managing sample files

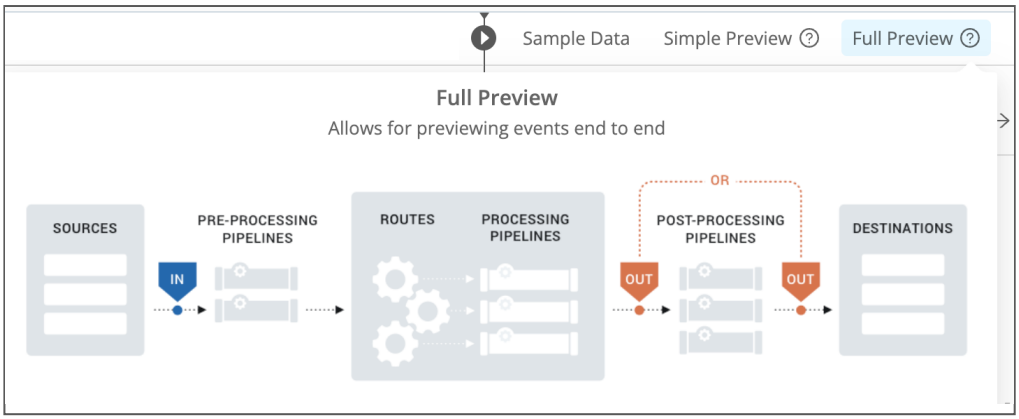
Simple Versus Full Preview

Select **Simple** or **Full** beside a file name to display its events in the Preview pane. The **Simple Preview** option enables you to view events on either the **IN** or the **OUT** (processed) side of a single Pipeline.



Simple Preview schematic

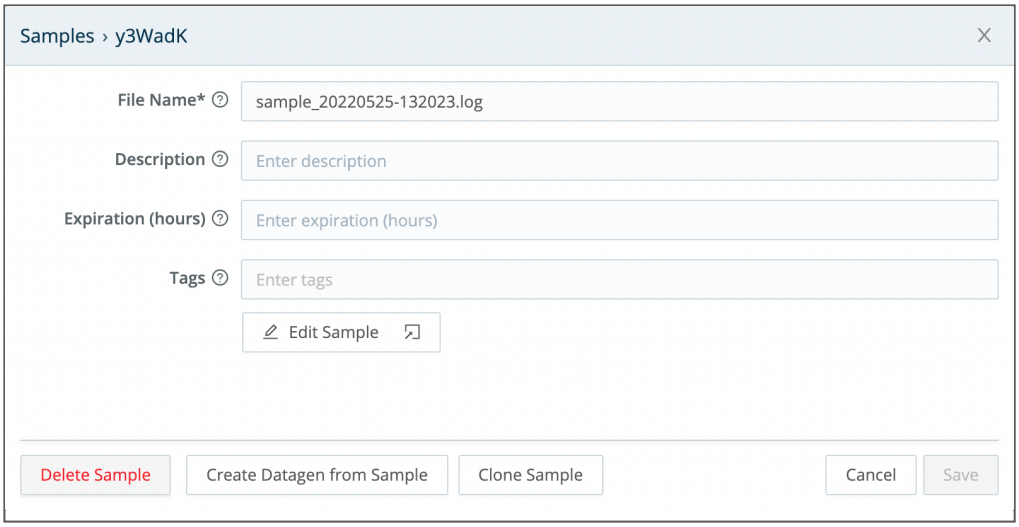
The **Full Preview** option gives you a choice of viewing events on the **OUT** side of either the processing or post-processing Pipeline. Selecting this option expands the Preview pane's upper controls to include an **Exit Point** drop-down, where you make this choice.



Full Preview schematic

Modify Sample Files

1. In the right Preview pane, select the **Samples** tab.
2. Hover over the file name you want to modify. This displays an edit (pencil) button to its left.
3. Select that button to open the modal shown below. It provides options to edit, clone, or delete the sample, save it as a datagen Source, or modify its metadata (**File name**, **Description**, **Expiration time**, and **Tags**).



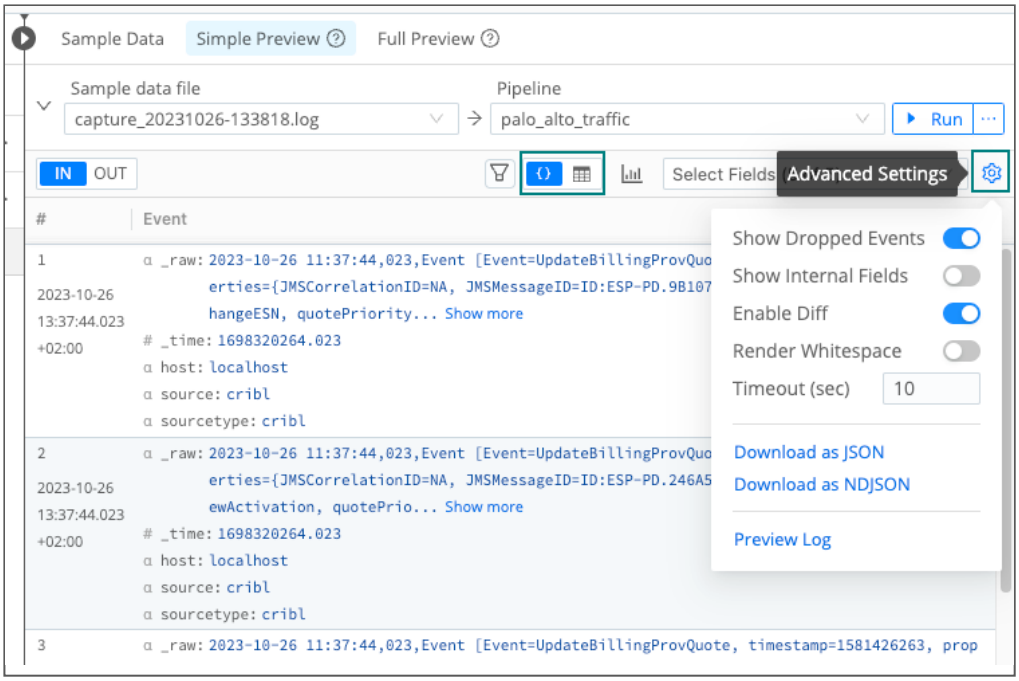
Options for modifying a sample

4. To make changes to the sample, select the modal's **Edit Sample** button. This opens the **Edit Sample** modal shown below, exposing the sample's raw data.
5. Edit the raw data as desired.
6. Select **Update Sample** to resave the modified sample, or select **Save as New Sample** to give the modified version a new name.

Editing a sample file

IN Tab: Display Samples on the Way IN to the Pipeline

The Preview pane offers two display options for events: Event and Table. Each format can be useful, depending on the type of data you are previewing. This screenshot shows Event view:



Event, Table, and Advanced options (composite screenshot)

On the **Advanced Settings** menu at the upper right, the first few toggles are self-explanatory, and are used primarily to filter the OUT tab's display of processed data. The following subsections cover the less-obvious controls at the menu's bottom.

Render Whitespace

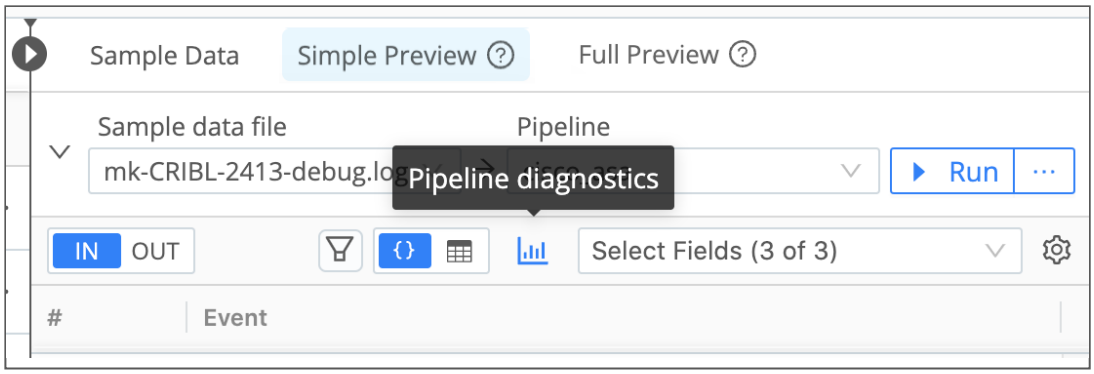
This toggles between displaying carriage returns, newlines, tabs, and spaces as white space, versus as(respectively) the symbols □, □, →, and ·.

Timeout (Sec)

If large sample files time out before they fully load, increase this field's default value of `10` seconds. A blank field is interpreted as the minimum allowed timeout value of `1` second.

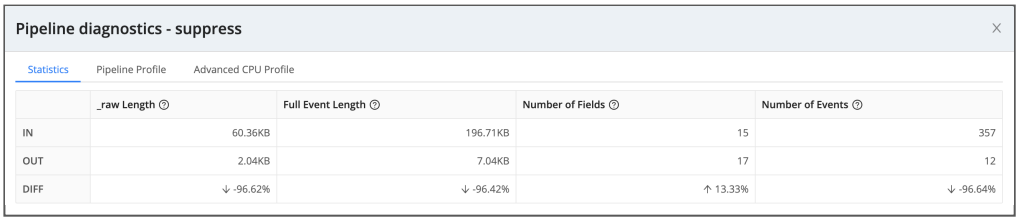
Pipeline Profiling

At the Preview pane's top, you can select a sample data file and Pipeline, then select the Pipeline diagnostics (bar-graph) button to access statistics on the selected Pipeline's performance. (The same button is available on Pipelines within a Pack.)



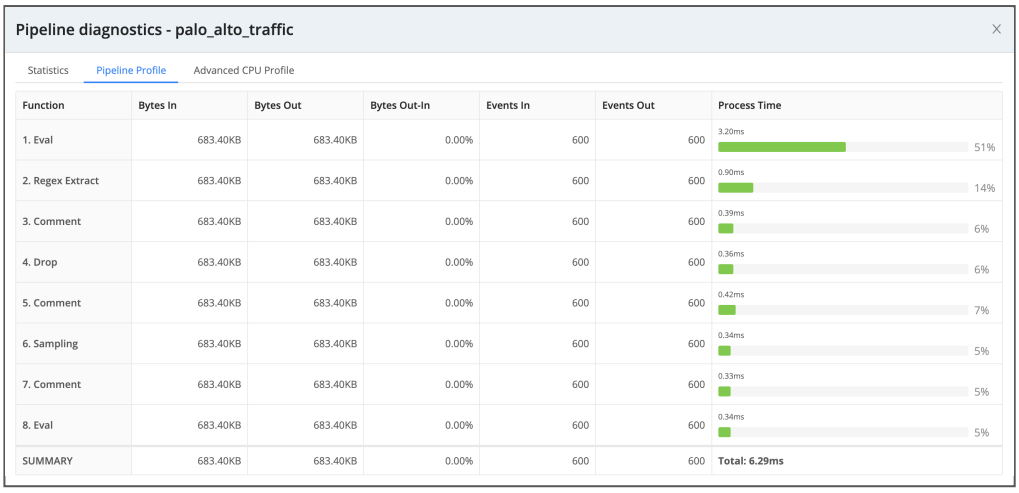
Pipeline diagnostics

The resulting modal's **Statistics** tab displays basic stats about the Pipeline's processing impact on field and event length and counts.



Pipeline diagnostics > Statistics tab

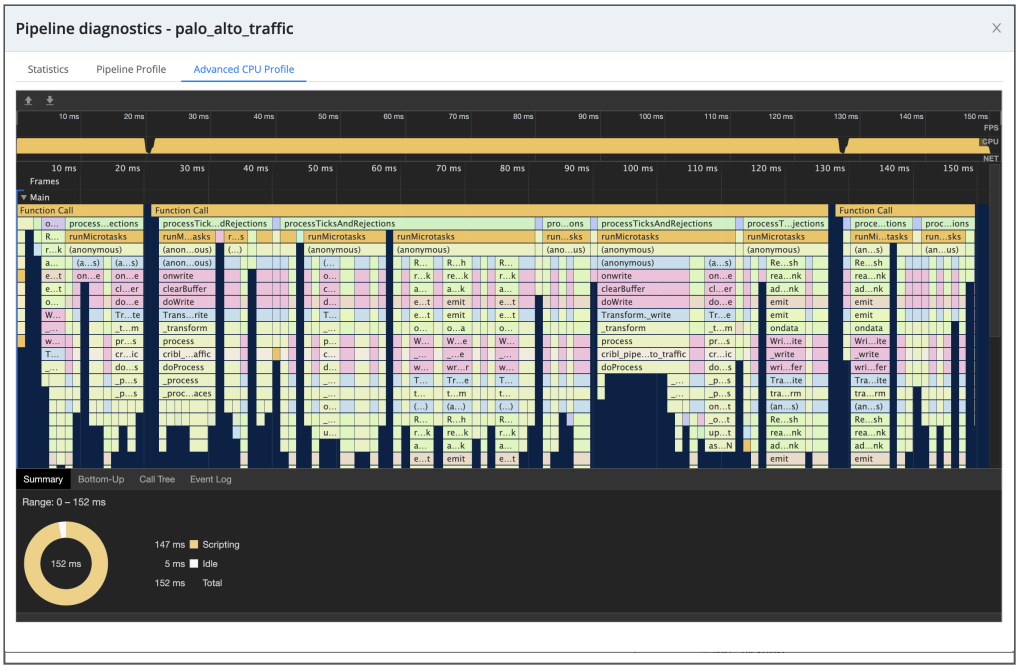
The **Pipeline Profile** tab, available from the **Simple Preview** tab, helps you debug your Pipeline by showing individual Functions' contributions to data volume, events count, and the Pipeline's processing time. Every Function has a minimum processing time, including Functions that make no changes to event data, such as the Comment Function.



Pipeline diagnostics > Pipeline Profile tab

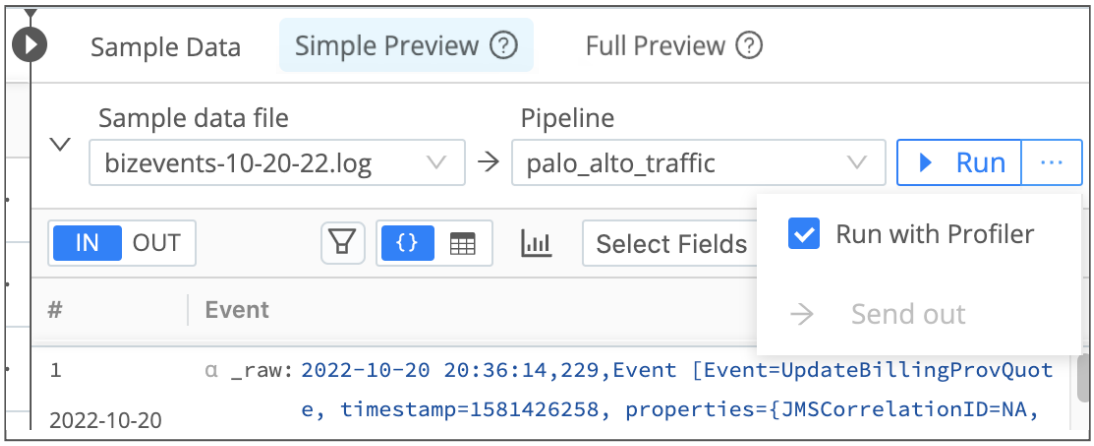
When you profile a Chain Function, this tab condenses all of the chained Pipeline's processing into a single **Chain** row. To see individual statistics on the aggregated Functions, profile the chained Pipeline separately.

The **Advanced CPU Profile** tab, available from the **Simple Preview** tab, displays richer details on individual Function stacks.



Pipeline diagnostics > Advanced CPU Profile tab

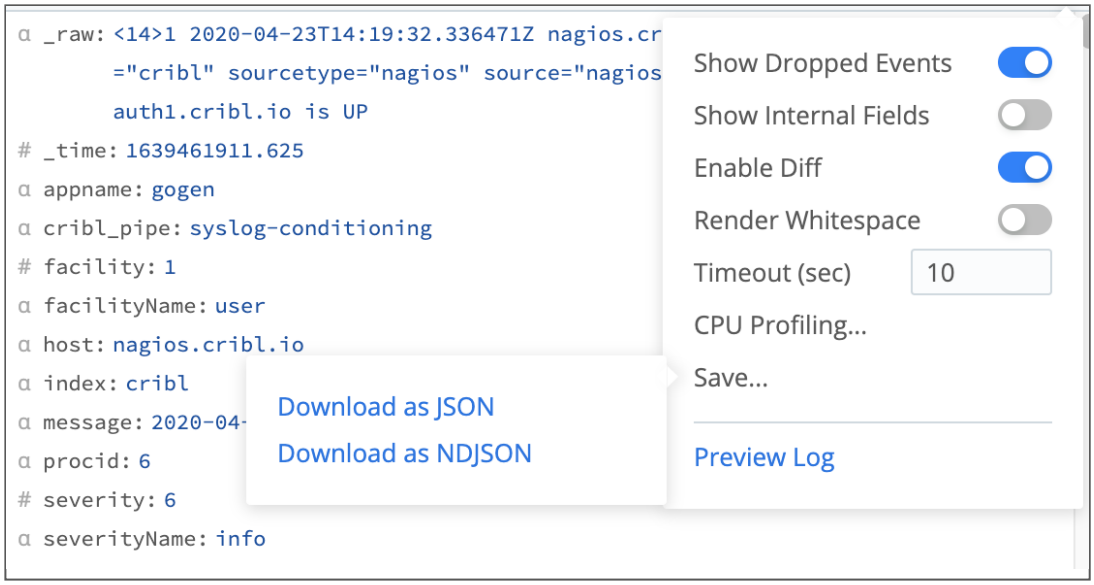
You can disable the profiling features – and regain their own (minimal) resources – by selecting the drop-down list beside the **Run** button and clearing the **Run with Profiler** check box.



Disabling Pipeline profiling

Save

The **Save** submenu enables you to save your captured data to a file, using either the **Download as JSON** or the **Download as NDJSON** (Newline-Delimited JSON) option.



Saving sample data as JSON

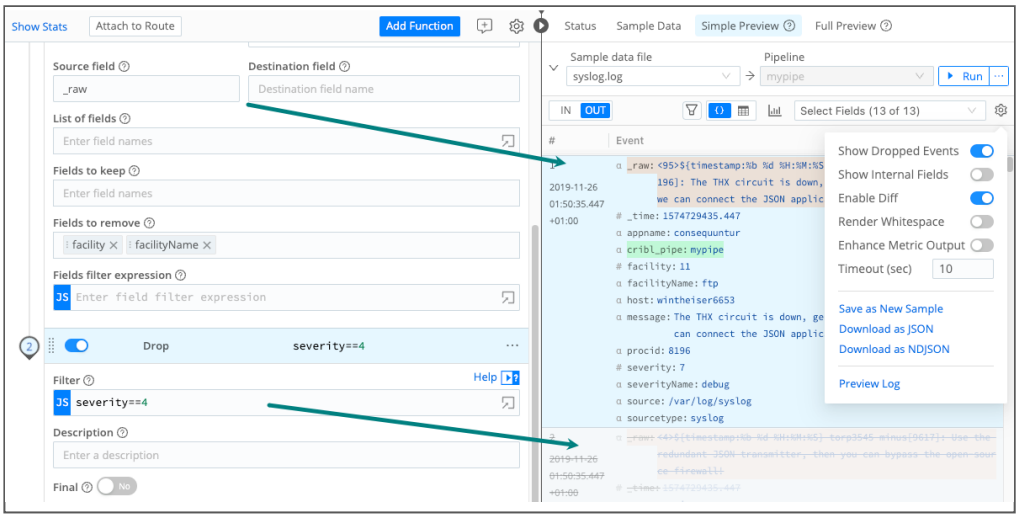
Preview Log

The final option on the **Advanced Settings** menu opens a modal where you can preview Cribl Stream's internal logs summarizing how this data sample was processed and captured.

OUT Tab: Display Samples on the Way OUT of the Pipeline

As data traverses through a Pipeline's Functions, events can be modified, and some might be dropped altogether. The **OUT** tab indicates changes using this color coding:

- **Dropped events**: When events are dropped, the **OUT** tab displays them as grayed-out text, with strikethrough. You can control their display using the **Advanced Settings** menu's **Show Dropped Events** toggle.
- **Added fields**: When Cribl Stream's processing adds new fields, these fields are highlighted green. You can control these fields' display using the **Select Fields** drop-down.
- **Redacted fields**: These fields are highlighted amber.
- **Deleted fields**: These fields are highlighted red.



Dropped and added fields in a Pipeline's output

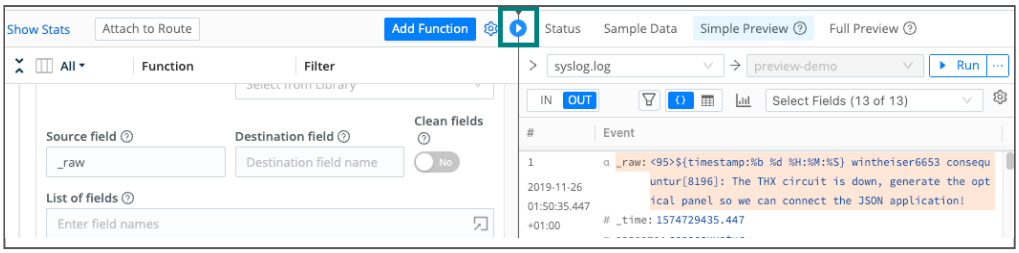
The **OUT** tab displays the same Event versus Table buttons as the IN tab. It also displays the same **Advanced Settings** menu options – and here, you can use the menu's **Show Dropped Events**, **Show Internal Fields**, and **Enable Diff** toggles to clarify how the data has been transformed by the Pipeline.

Enable **Show Internal Fields** to discover fields that Cribl Stream adds to events, as well as Source-specific fields that Cribl Stream forwards from upstream senders.

Use **Enhance Metric Output** to control how the OUT tab presents the **Metric name expression** resulting from the Publish Metrics Function. When the setting is disabled (default), the **Metric name expression** is represented as literal expression string. Enable the setting to see the expression evaluated in the OUT tab.

Manage the Preview Pane

On the pane divider between Route or Pipeline and the preview, select Collapse to hide the Preview pane. This allows the Route or Pipeline configuration to expand to your browser's full width. (The Preview pane collapses automatically on narrow viewports.)



Collapse / Expand toggle

Select Expand at your browser's right edge to restore the split view. The pane divider will snap back to wherever you last dragged it.

13.8. Data Onboarding

Onboarding data into Cribl Stream can vary in complexity, depending on your organization's needs, requirements, and constraints. Proper onboarding from all Sources is key to system performance, troubleshooting, and ultimately the quality of data and decisions both in Cribl Stream and in downstream Destinations.

General Onboarding Steps

Typically, a data onboarding process revolves around these steps, both before and after turning on the Source:

- Create configuration settings.
- Verify that settings do the right thing.
- Iterate.

Below, we break down individual steps.

Before Turning On the Source

Cribl recommends that you take the following steps to verify and tune incoming data, before it starts flowing.

Preview Sample Data

Use a sample of your real data in Data Preview. Sample data can come from a sample Source file that you upload or paste into Cribl Stream.

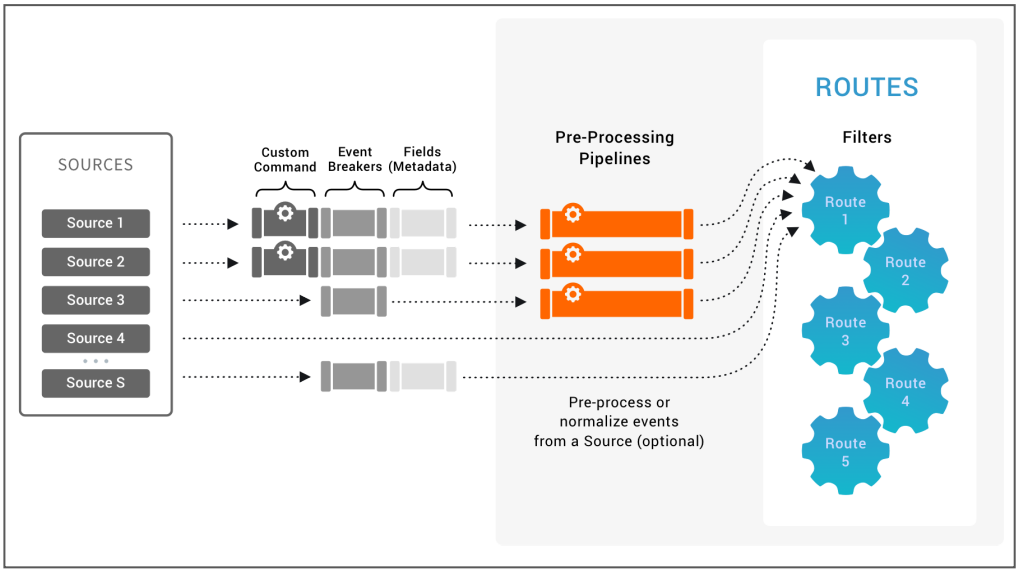
You can also obtain sample data in a live data capture from a Source. One way to do this **before** going to production is to configure your Source with a **devnull** Pipeline (which just drops all events) as a pre-processing Pipeline. Then, let data flow in for just long enough to capture a sufficient sample.

Very Large Integer Values

Cribl Stream's JavaScript implementation can safely represent integers only up to the Number.MAX_SAFE_INTEGER constant of about 9 quadrillion (precisely, {2^53}-1). Data Preview will round down any integer larger than this, and trailing 0's might indicate such rounding down.

Check the Processing Order

While events can be processed almost arbitrarily by Functions in Cribl Stream Pipelines, make sure you understand the event processing order. This is very important, as it tells you exactly where certain processing steps occur. For instance, as we'll see just below, quite a few steps can be accomplished at the Source level, before data even hits Cribl Stream Routes.



Source-level processing options

Custom Command

Where supported, data streams will be handled by **custom commands**. These are external system commands that can (optionally) be used to pre-process the data. You can specify any command, script, etc., that consumes via `stdin` and outputs via `stdout`.

Verify that such commands are doing what's expected, as they are the very **first** in a series of processing steps.

Event Breakers

Next, data streams are handled by Event Breakers, which:

- Convert data streams into discrete events.
- Extract and assign timestamps to each event.

If the resulting events do not look correct, feel free to use **non-default** breaking rules and timestamp recognition patterns. Downstream, you can use the Auto Timestamp Function to modify `_time` as needed, if timestamps were not recognized properly. Examples of such errors are:

- Timestamps too far out in the future or past
- Wrong timezone.

- Incorrect timestamp is selected from multiple timestamps present in the event.

Fields

Next, events can be enriched with Fields . This is where you'd add static or dynamic fields to all events delivered by a particular Source.

Pre-Processing Pipeline

Next, you can optionally configure a pre-processing Pipeline on a particular Source. This is extremely useful in these cases:

- Drop non-useful events as early as possible (so as to save on CPU processing).
- Normalize events from this Source to conform a certain shape or structure.
- Fix/touch up events accordingly. E.g., if event breakers assigned the wrong timestamp, this is the best place to use the Auto Timestamp Function to adjust `_time`.

We Can't Say This Enough

Verify, verify, verify, data integrity before turning on the Source.

After Turning On the Source

Use data Destinations to verify that certain metrics of interest are accurate. This will depend significantly on the capabilities of each Destination, but here's a basic checklist of things to ensure:

- Timestamps are correct.
- All necessary fields are assigned to events.
- All expected events show up correctly. (E.g., if a Drop or Suppress Function was configured, ensure that it's not dropping unintended events.)
- Throughput – both in bytes and in events per second (EPS) – is what's expected, or is within a certain tolerance.

Iterate

Iterate on the steps above as necessary. E.g., adjust fields values and timestamps as needed.

Remember that there is almost always a workaround. Any arbitrary event transformation that you need

> is likely just a Function or two away.

14. Functions

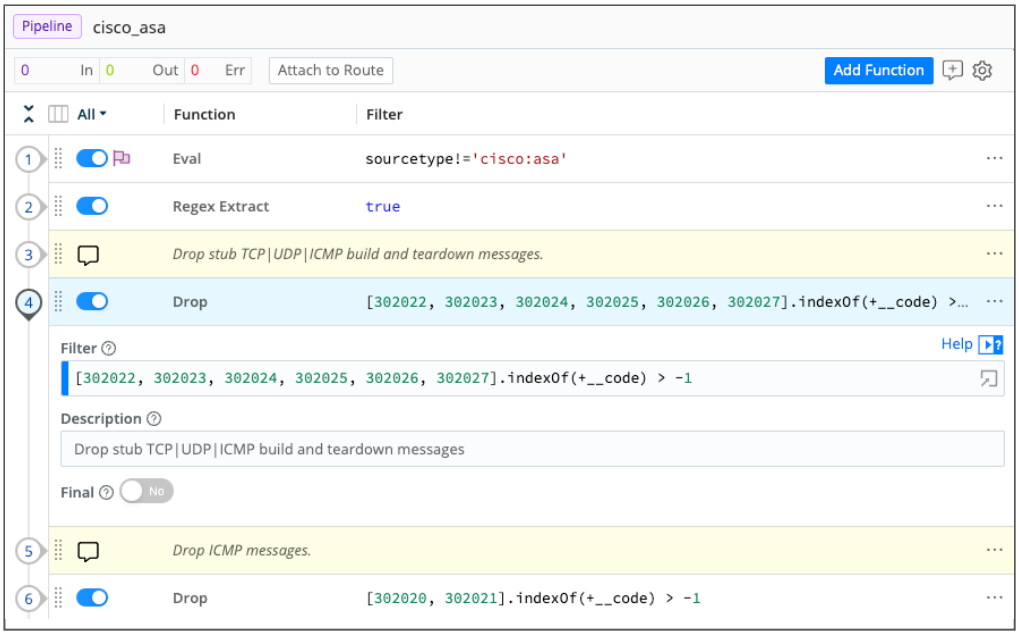
When events enter a Pipeline, they're processed by a series of Functions. At its core, a Function is code that executes on an event, and it encapsulates the smallest amount of processing that can happen to that event.

The term "processing" means a variety of possible options: string replacement, obfuscation, encryption, event-to-metrics conversions, etc. For example, a Pipeline can be composed of several Functions – one that replaces the term `foo` with `bar`, another one that hashes `bar`, and a final one that adds a field (say, `dc=jfk-42`) to any event that matches `source=='us-nyc-application.log'`.

How Do They Work

Functions are atomic pieces of JavaScript code that are invoked on each event that passes through them. To help improve performance, Functions can be configured with filters to further scope their invocation to matching events only.

You can add as many Functions in a Pipeline as necessary, though the more you have, the longer it will take each event to pass through. Also, you can enable and disable Functions within a Pipeline as necessary. This lets you preserve structure as you optimize or debug.



Functions stack in a Pipeline

You can reposition Functions up or down the Pipeline stack to adjust their execution order. Use a Function's left grab handle to drag and drop it into place.

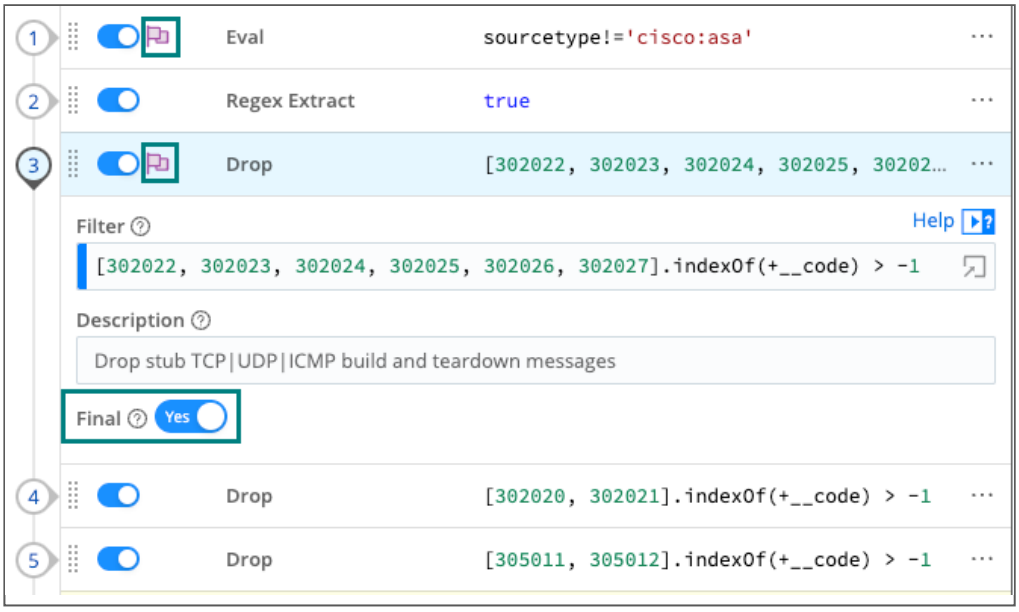
The `Final` Toggle

The `Final` toggle in Function settings controls what happens to the results of a Function.

When `Final` is toggled to `No` (default), events will be processed by this Function, **and** then passed on to the next Function below.

When `Final` is toggled to `Yes`, the Function "consumes" the results, meaning they will not pass down to any other Function below.

A flag in Pipeline view indicates that a Function is `Final`.



The Eval and first Drop Functions bearing the Final flag

Functions and Shared-Nothing Architecture

Cribl Stream is built on a shared-nothing architecture, where each Node and its **Worker Processes operate separately, and process events independently of each other**. This means that all Functions operate strictly in a Worker Process context – state is not shared across processes.

For example, consider two events that meet a Pipeline's criteria to be aggregated. If these two events arrive on **separate** Workers or Worker Processes, Cribl Stream will **not** aggregate them together.

This is particularly important to understand for certain Functions that might imply state-sharing, such as Aggregations, Rollup Metrics, Dynamic Sampling, Sampling, Suppress, etc.

If you have a large number of Worker Processes, consider implementing a distributed caching tier, such as Redis, to aggregate events across Workers. (See our Redis Function topic.)

Out-of-the-Box Functions

Cribl Stream ships with several Functions out-of-the-box, and you can chain them together to meet your requirements. For more details, see individual **Functions**, and the **Use Cases** section, within this documentation.

Accessing Event Fields with __e

The special variable `__e` represents the `(context)` event inside a JavaScript expression. Using `__e` with square bracket notation, you can access any field within the event object, for example, `__e['hostname']`. Functions use `__e` extensively. You also **must** use this notation for fields that contain a special character, like `-`, `.`, or `@`.

Supported JavaScript Standard

Cribl Stream supports the ECMAScript® 2015 Language Specification.

Very Large Integer Values

Cribl Stream's JavaScript implementation can safely represent integers only up to the Number.MAX_SAFE_INTEGER constant of about 9 quadrillion (precisely, {2^53}-1). Cribl Stream Functions will round down any integer larger than this, in Data Preview and other contexts. Trailing 0's might indicate such rounding down of large integers.

What Functions to Use When

- Add, remove, update fields: Eval, Lookup, Regex Extract
- Find & Replace, including basic `sed`-like, obfuscate, redact, hash, etc.: Mask, Eval
- Add GeoIP information to events: GeoIP
- Extract fields: Regex Extract, Parser
- Extract timestamps: Auto Timestamp
- Drop events: Drop, Regex Filter, Sampling, Suppress, Dynamic Sampling
- Sample events (e.g, high-volume, low-value data): Sampling, Dynamic Sampling
- Suppress events (e.g, duplicates, etc.): Suppress
- Serialize events to CEF format (send to various SIEMs): CEF Serializer
- Serialize / change format (e.g., convert JSON to CSV): Serialize
- Serialize compliant events into SNMP traps: SNMP Trap Serialize
- Convert JSON arrays into their own events: JSON Unroll, XML Unroll

- Flatten nested structures (e.g., nested JSON): Flatten
- Aggregate events in real-time (i.e., statistical aggregations): Aggregations
- Convert events to metrics format: Publish Metrics, Prometheus Publisher (beta)
- Transforms dimensional metrics events into the OTLP (OpenTelemetry Protocol) format: OTLP Metrics
- Resolve hostname from IP address: Reverse DNS (beta)
- Extract numeric values from event fields, converting them to type `number`: Numerify
- Send events out to a command or a local file, via `stdin`, from any point in a Pipeline: Tee
- Convert an XML event's elements into individual events: XML Unroll
- Duplicate events in the same Pipeline, with optional added fields: Clone
- Break events **within**, instead of before they reach, a Pipeline: Event Breaker
- Add a text comment within a Pipeline's UI, to label steps without changing event data: Comment

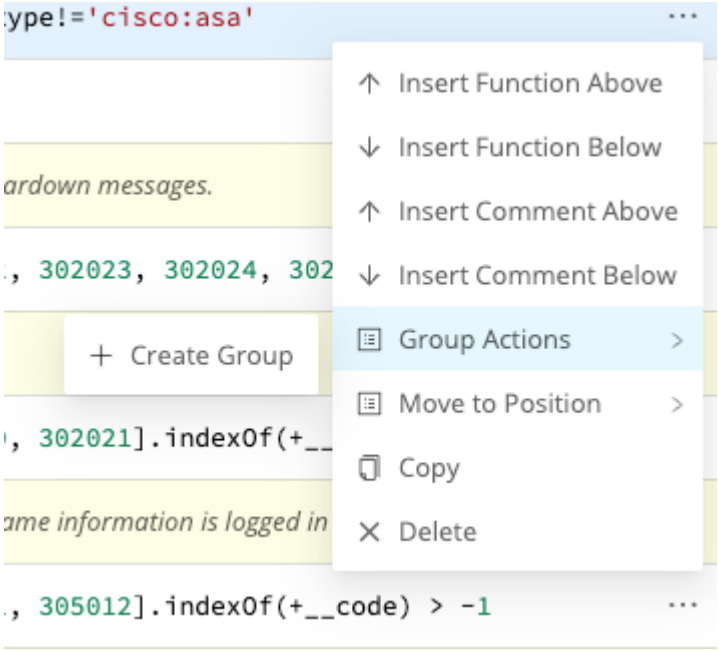
For more usage examples, download Cribl's Stream Cheat Sheet (Quick Reference Card).

Function Groups

A Function group is a collection of consecutive Functions that can be moved up and down a Pipeline's Functions stack together. Groups help you manage long stacks of Functions by streamlining their display. They are a UI visualization only: While Functions are in a group, those Functions maintain their global position order in the Pipeline.

Function groups work much like Route groups.

To build a group from any Function, click the Function's ••• (Options) menu, then select **Group Actions** > **Create Group**.



Creating a group

You'll need to enter a **Group Name** before you can save or resave the Pipeline. Optionally, enter a **Description**.

Once you've saved at least one group to a Pipeline, other Functions' ••• (Options) > **Group Actions** submenus will add options to **Move to Group** or **Ungroup/Ungroup All**.

You can also use a Function's left grab handle to drag and drop it into, or out of, a group. A saved group that's empty displays a dashed target into which you can drag and drop Functions.

Drag-and-drop target

14.1. Auto Timestamp

The Auto Timestamp Function extracts time to a destination field, given a source field in the event. By default, Auto Timestamp makes a first best effort and populates `_time`. When you add a sample (via paste or a local file), you should accomplish time and event breaking at the same time you add the data.

This Function allows fine-grained and powerful transformations to populate new time fields, or to edit existing time fields. You can use the Function's Additional timestamps section to create custom time fields using regex and custom JavaScript `strptime` functions.

The Auto Timestamp Function uses the same basic algorithm as the Event Breaker Function and the C.Time.timestampFinder() native method.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. The default `true` setting passes all events through the Function.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Source field: Field to search for a timestamp. Defaults to `_raw`.

Destination field: Field to place extracted timestamp in. Defaults to `_time`. Supports nested addressing.

Default timezone: Select a timezone to assign to timestamps that lack timezone info. Defaults to `Local`. (This drop-down includes support for legacy names: `EST5EDT`, `CST6CDT`, `MST7MDT`, and `PST8PDT`.)

Additional timestamps: To extract additional timestamp formats, click **Add Timestamp** to define each format. Each row will provide these fields:

- **Regex**: Regex, with first capturing group matching the timestamp.
- **Strptime format**: Select or enter the `strptime` format for the captured timestamp.

Advanced Settings

Time expression: Expression with which to format extracted time. Current time, as a JavaScript Date object, is in global `time`. Defaults to `time.getTime() / 1000`. You can access other fields' values via `__e.<fieldName>`.

For details about Cribl Stream's Library (native) time methods, see: C.Time – Time Functions.

Start scan offset: How far into the string to look for a time string.

Max timestamp scan depth: Maximum string length at which to look for a timestamp.

Default time: How to set the time field if no timestamp is found. Defaults to **Current time**.

Two fields enable you to constrain (clamp) the parsed timestamp, to prevent the Function from mistakenly extracting non-time values as unrealistic timestamps:

- **Earliest timestamp allowed**: Enter a string that specifies the latest allowable timestamp, relative to now. (Sample value: `-42years`. Default value: `-420weeks`.) Parsed values earlier than this date will be set to the **Default time**.
- **Future timestamp allowed**: Enter a string that specifies the latest allowable timestamp, relative to now. (Sample value: `+42days`. Default value: `+1week`.) Parsed values after this date will be set to the **Default time**.

Format Reference

This references https://github.com/d3/d3-time-format#locale_format. Directives annotated with a `(†)` symbol might be affected by the locale definition.

```
%a - abbreviated weekday name. (†)
%A - full weekday name. (†)
%b - abbreviated month name. (†)
%B - full month name. (†)
%c - the locale's date and time, such as %x, %X. (†)
%d - zero-padded day of the month as a decimal number [01,31].
%e - space-padded day of the month as a decimal number [ 1,31]; equivalent to %_d.
%f - microseconds as a decimal number [000000, 999999].
%H - hour (24-hour clock) as a decimal number [00,23].
%I - hour (12-hour clock) as a decimal number [01,12].
%j - day of the year as a decimal number [001,366].
%m - month as a decimal number [01,12].
%M - minute as a decimal number [00,59].
%L - milliseconds as a decimal number [000, 999].
%p - either AM or PM. (†)
%Q - milliseconds since UNIX epoch.
%s - seconds since UNIX epoch.
```

```
%S - second as a decimal number [00,61].
%u - Monday-based (ISO 8601) weekday as a decimal number [1,7].
%U - Sunday-based week of the year as a decimal number [00,53].
%V - ISO 8601 week of the year as a decimal number [01, 53].
%w - Sunday-based weekday as a decimal number [0,6].
%W - Monday-based week of the year as a decimal number [00,53].
%x - the locale's date, such as %-m/%-d/%Y. (†)
%X - the locale's time, such as %-I:%M:%S %p. (†)
%y - year without century as a decimal number [00,99].
%Y - year with century as a decimal number.
%Z - time zone offset, such as -0700, -07:00, -07, or Z.
%% - a literal percent sign (%).
```

Complying with the Format

In order to use auto timestamping upon ingestion, the formatting used must match the `%Z` parameters above. E.g., this Function will automatically parse all of these formats:

- `2020/06/10T17:17:35.004-0700`
- `2020/06/10T17:17:35.004-07:00`
- `2020/06/10T17:17:35.004-07`
- `2020/06/10T10:17:35.004Z`
- `2020/06/10T11:17:35.004 EST`

To parse other formats, you can use the Additional Timestamps section's internal **Regex** or **Strptime Format** operators.

Basic Example

Filter: `name.startsWith('kumquats') && value=='specific string here'`

This will allow the Auto Timestamp Function to act only on events matching the specified parameters.

Sample event:

```
Sep 20 12:03:55 PA-VM 1,2019/09/20 13:03:58,CRIBL,TRAFFIC,end,2049,2019/09/20
14:03:58,314.817.108.226,10.0.0.102,314.817.108.226,10.0.2.65,cribl,,,incomplete,vsys1,u
forwarding-default,2018/09/20
13:03:58,574326,1,53722,8088,53722,8088,0x400064,tcp,allow,296,296,0,4,2018/09/20
```

```
13:03:45,7,any,0,730277,0x0,United States,10.0.0.0-10.255.255.255,0,4,0,aged-out,0,0,0,0,,PA-VM,from-policy,,,0,,0,,N/A,0,0,0,0
```

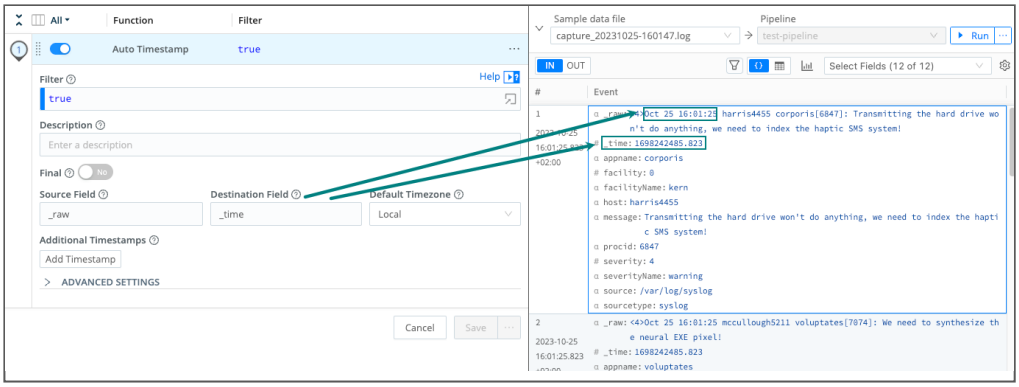
To add this sample (after creating an Auto Timestamp Function with the above **Filter** expression): Go to **Preview** > **Add a Sample** > **Paste a Sample**, and add the data snippet above. Do not make any changes to timestamping or line breaking, and select **Save as Sample File**.

By default, Cribl Stream will inspect the first 150 characters, and will extract the first valid timestamp it sees. You can modify this character limit under **Advanced Settings** > **Max Timestamp Scan Depth**.

Cribl Stream will grab the first part of the event, and will settle on the first matching value to display for `time`:

- `_time 1698242485.823`
- **GMT**: Oct 25 14:01:25 GMT
- **Your Local Time**: Oct 25 16:01:25 GMT +02:00

Because no explicit timezone has been set (under **Default Timezone**), `_time` will inherit the **Local** timezone, which in this example is `GMT +02:00`.



Timezone Dependencies and Details

Cribl Stream uses ICU for timezone information. It does not query external files or the operating system. The bundled ICU is updated periodically.

For additional timezone details, see: https://www.iana.org/time-zones.

Advanced Settings Example

The `datetime.strptime()` method creates a datetime object from the string passed in by the **Regex** field.

Here, we'll use `datetime.strptime()` to match a timestamp in AM/PM format at the end of a line.

Sample:

```
This is a sample event that will push the datetime values further on inside the event.
This is still a sample event and finally here is the datetime information!:
Server_UTC_Timestamp="04/27/2020 2:30:15 PM"
```

Max timestamp scan depth: `210`

Click to add **Additional timestamps**:

Regex: `(\d{1,2}\/\d{2}\/\d{4}\s\d{1,2}:\d{2}:\d{2}\s\w{2})`

Strptime format: `'%m/%d/%Y %H:%M:%S %p'`

Gnarly Details

- This Function supports the `%f` (microseconds) directive.
- Cribl Stream will truncate timestamps to three-digit (milliseconds) resolution, omitting trailing zeros.
- For further examples, see Extracting Timestamps from Messy Logs.

14.2. Aggregations

The Aggregations Function performs aggregate statistics on event data.

Each Worker Process executes this Function independently on its share of events. For details, see Functions and Shared-Nothing Architecture.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Time window: The time span of the tumbling window for aggregating events. Must be a valid time string (e.g., `10s`). Must match pattern `\d+[sm]$`.

Aggregates: Aggregation function(s) to perform on events.
E.g., `sum(bytes).where(action=='REJECT').as(TotalBytes)`. Expression format: `aggFunction(<FieldExpression>).where(<FilterExpression>).as(<outputField>)`. See more examples below.

When used without `as()`, the aggregate's output will be placed in a field labeled `<fieldName>_<aggFunction>`. If there are conflicts, the last aggregate wins. For example, given two aggregates – `sum(bytes).where(action=='REJECT')` and `sum(bytes)` – the latter one (`bytes_sum`) is the winner.

Group by fields: Fields to group aggregates by. Supports wildcard expressions.

Using the wildcard character `*` causes causes all fields in the event to be included in the aggregation, which can result in high cardinality and increased memory usage. To avoid this impact, first exclude fields that can result in high cardinality, **then** introduce wildcards, if any. For example: `!_time, !_numericValue, *`

Evaluate fields: Set of key-value pairs to evaluate and add/set. Fields are added in the context of an aggregated event, before they're sent out. Does not apply to passthrough events.

Time Window Settings

Cumulative aggregations: If enabled, aggregations will be retained for cumulative aggregations when flushing out an aggregation table event. When set to `No` (the default), aggregations will be reset to `0` on flush.

Lag tolerance: The lag tolerance represents the tumbling window tolerance to late events. Must be a valid time string (e.g., `10s`). Must match pattern `\d+[sm]$`.

Idle bucket time limit: The amount of time to wait before flushing a bucket that has not received events. Must be a valid time string (e.g., `10s`). Must match pattern `\d+[sm]$`.

Output Settings

Passthrough mode: Determines whether to pass through the original events along with the aggregation events. Defaults to `No`.

Metrics mode: Determines whether to output aggregates as metrics. Defaults to `No`, causing aggregates to be output as events.

Sufficient stats mode: Determines whether to output *only* statistics sufficient for the supplied aggregations. Defaults to `No`, meaning output richer statistics.

Output prefix: A prefix that is prepended to all of the fields output by this Aggregations Function.

Advanced Settings

Aggregation event limit: The maximum number of events to include in any given aggregation event. Defaults to unlimited. Must be at least `1`.

Aggregation memory limit: The memory usage limit to impose upon aggregations. Defaults to unlimited (i.e., the amount of memory available in the system). Accepts numerals with multiple-byte units, like KB, MB, GB, etc. (such: as `4GB`.)

Flush on stream close: If set to `Yes` (the default), aggregations will flush when an input stream is closed. If set to `No`, the Time Window Settings will control flush behavior; this can be preferable in cases like the following:

- Your input data consists of many small files.
- You are sending data to Prometheus. Enabling **Flush on stream close** can send Prometheus multiple aggregations from the same Worker Process for the same time period. Prometheus cannot tell the multiple aggregations apart, and will ingest only the first one.

Aggregation Functions

- `avg(expr:FieldExpression)`: Returns the average `expr` values.
- `count(expr:FieldExpression)`: If `expr` is omitted, returns the number of events received over the time window. If `expr` is given, returns the number of events seen where `expr` evaluates to a value other than null or undefined. For example, with these three events in the same time window:
  - `{ _time: 20, _val: 5 }`
  - `{ _time: 22 }`
  - `{ _time: 24, _val: null }`

  `count()` would return `3`, while `count(_val)` would return `1`.
- `dc(expr: FieldExpression, errorRate: number = 0.01)`: Returns the estimated number of distinct values of `expr`, within a relative error rate. Lower error rates increase the accuracy of the result, at the cost of using more memory. For example, with these three events in the same time window:
  - `{ _time: 20, _name: 'Alice' }`
  - `{ _time: 22, _name: 'Bob' }`
  - `{ _time: 24, _name: 'Alice' }`

  `dc(_name)` would return `2`.
- `distinct_count(expr: FieldExpression, errorRate: number = 0.01)`: Identical to `dc(expr)`.
- `earliest(expr:FieldExpression)`: Returns the earliest (based on `_time`) observed `expr` value.
- `first(expr:FieldExpression)`: Returns the first observed `expr` value.
- `histogram(expr:FieldExpression, buckets: number[])`. Returns the average of the values of `expr` and generates a field with the same name as the aggregated output field, suffixed with `_data`.
  - `buckets` must contain at least one numeric value.

  The `_data` field in the output contains three pieces of information:
  - `_sum` – the sum of all values of `expr`.
  - `_count` – the number of events seen where `expr` evaluates to a value other than null or undefined.
  - `_buckets` – an object whose keys are the buckets defined in the function, and whose values are the number of values that fall in that histogram bucket. In addition to the buckets defined by the user, the object will include a bucket labeled `Infinity`, into which all values will be placed. A value of `x` falls into a histogram bucket if it is less than or equal to the value of the bucket. A value of `45` would fall into a bucket with value `50`, but not one with value `40`. Counts are cumulative; all values counted in a bucket will also be counted in every bucket larger than it. For example, with these three events in the same time window:

- `{ _time: 20, age: 20 }`
- `{ _time: 22, age: 25 }`
- `{ _time: 24, age: 30 }`

`histogram(age, [10, 25, 40])` would result in the following on the output event:

```
{
  age_histogram: 25
  age_histogram_data: {
    _count: 3,
    _sum: 75
    _buckets: {
      10: 0,
      25: 2,
      40: 3,
      Infinity: 3
    }
  }
}
```

- `last(expr:FieldExpression)`: Returns the last observed `expr` value.
- `latest(expr:FieldExpression)`: Returns the latest (based on `_time`) observed `expr` value.
- `list(expr:FieldExpression[, max:number, excludeNulls: boolean = true])`: Returns a list of the observed values of `expr`.
  - Optional `max` parameter limits the number of values returned. If omitted, the default is `100`. If set to `0`, will return all values.
  - Optional `excludeNulls` boolean excludes null and undefined values from results. If included, defaults to `true`.
- `max(expr:FieldExpression)`: Returns the maximum `expr` value.
- `median(expr:FieldExpression)`: Returns the middle value of the sorted parameter.
- `min(expr:FieldExpression)`: Returns the minimum `expr` value.
- `mode(expr: FieldExpression[, excludeNulls: boolean = true])`: Returns the single most frequently encountered `expr` value.
  - Optional `excludeNulls` boolean excludes null and undefined values from results. If included, defaults to `true`.
- `per_second(expr:FieldExpression)`: Returns the rate of change of the values of `expr` over the aggregate time window. This is equivalent to `rate(expr, '1s')`. For example, with these three events in the same time window:

    - `{ _time: 20, _val: 5 }`
    - `{ _time: 22, _val: 15 }`
    - `{ _time: 24, _val: 35 }`

  `per_second(_val)` would give back `(35 - 5) / (24 - 20) = 7.5`, meaning that `_val` increased by 7.5 every second over the time window.
- `perc(level: number, expr: FieldExpression)`: Returns `<level>` percentile value of the numeric `expr` values.
- `rate(expr:FieldExpression, timeString: string = '1s')`: Returns the rate of change of the values of `expr` over the aggregate time window. Calculated as (latest value - earliest value) / (latest timestamp - earliest timestamp) * number of seconds in `timeString`. For example, with these three events in the same time window:
    - `{ _time: 20, _val: 5 }`
    - `{ _time: 22, _val: 15 }`
    - `{ _time: 24, _val: 35 }`

  `rate(_val, '2s')` would give back `(35 - 5) / (24 - 20) * 2 = 15`, meaning that `_val` increased by 15 every 2 seconds over the time window.
- `stdev(expr:FieldExpression)`: Returns the sample standard deviation of the `expr` values.
- `stdevp(expr:FieldExpression)`: Returns the population standard deviation of the `expr` values.
- `sum(expr:FieldExpression)`: Returns the sum of the `expr` values.
- `summary(expr:FieldExpression)[, quantiles: number[]])`: Returns the average of the `expr` values and generates a field with the same name as the aggregate output field, suffixed with `_data`.
    - Optional: `quantiles` values must be between `0` and `1` inclusive.

  The `_data` field in the output contains three pieces of information:
    - `_sum` – the sum of all `expr` values.
    - `_count` – the number of events seen where `expr` evaluates to a value other than null or undefined.
    - `_quantiles` – an object whose keys are the quantiles defined in the function, and whose values are the quantile value across the `expr` values. For example, a quantile key `0.5` and value `500` would indicate that the 50th percentile (or median) of the values seen was 500.
    - For example, with these three events in the same time window:
        - `{ foo: 100 }`
        - `{ foo: 200 }`
        - `{ foo: 300 }`

      `summary(foo, [0.25, 0.5, 0.75])` would result in the following on the output event:

```
{
  foo_summary: 25
  foo_summary_data: {
    _count: 3,
    _sum: 75
    _quantiles: {
      0.25: 100,
      0.5: 150,
      0.75: 225
    }
  }
}
```

- `sumsq(expr:FieldExpression)`: Returns the sum of squares of the `expr` values.
- `top(expr: FieldExpression, count: number[, excludeNulls: boolean = true])`: Returns the most frequently encountered `expr` values, up to `count` number of results.
  - `count` parameter must be a positive integer.
  - Optional `excludeNulls` boolean excludes null and undefined values from results. If included, defaults to `true`.
- `values(expr:FieldExpression[, max: number, excludeNulls: boolean = true, errorRate: number])`: Returns a list of distinct `expr` values.
  - Optional `max` parameter limits the number of values returned; if omitted, the default is `0`, meaning return all distinct values.
  - Optional `excludeNulls` boolean excludes null and undefined values from results. If included, defaults to `true`.
  - Optional `errorRate` parameter controls how accurately the function counts "distinct" values. Range is `0-1`; if omitted, the default value is `0.01`. Higher values allow higher error rates (fewer unique values recognized), with the offsetting benefit of less memory usage.
- `variance(expr:FieldExpression)`: Returns the sample variance of the `expr` values.
- `variancep(expr:FieldExpression)`: Returns the population variance of the `expr` values.

Safeguarding Data

Upon shutdown, Cribl Stream will attempt to flush the buffers that hold aggregated data, to avoid data loss. If you set a **Time window** greater than 1 hour, Cribl recommends adjusting the **Aggregation memory limit** and/or **Aggregation event limit** to prevent the system from running out of memory.

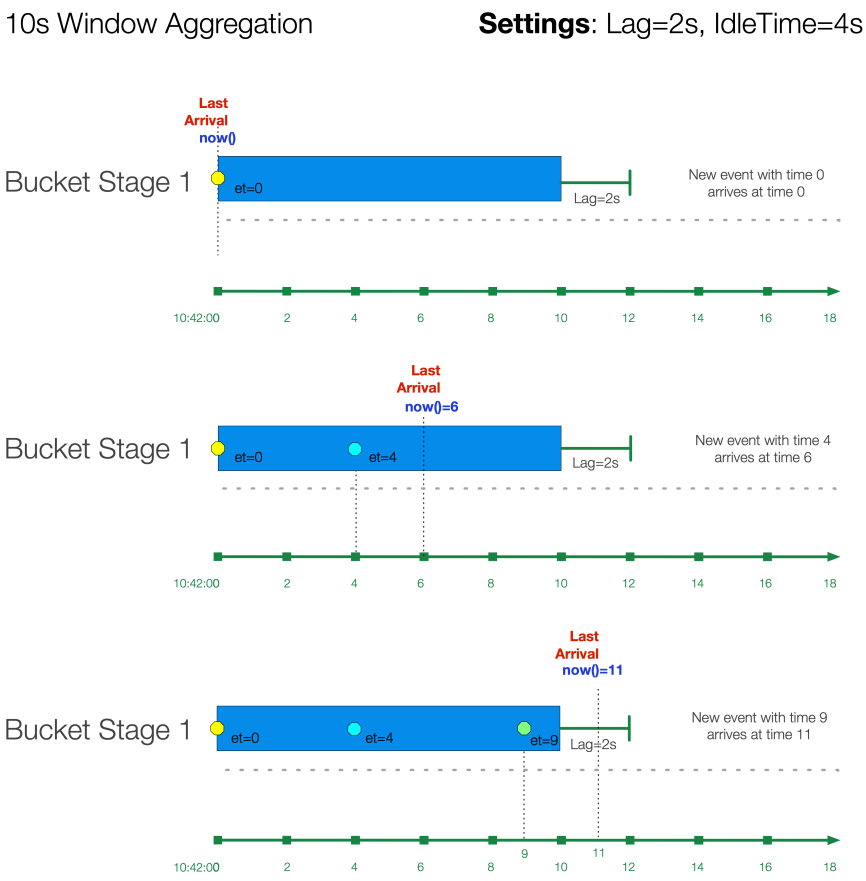
This is especially necessary for high-cardinality data. (Both settings default to unlimited, but we recommend setting defined limits based on testing.)

How Do Time Window Settings Work?

Lag Tolerance

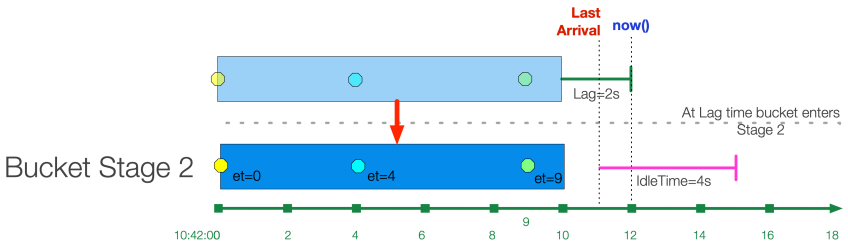
As events are aggregated into windows, there is a good chance that most will arrive later than their event time. For instance, given a `10s` window (`10:42:00 - 10:42:10`), an event with timestamp `10:42:03` might come in 2 seconds later at `10:42:05`.

In several cases, there will also be late, or lagging, events that will arrive **after** the latest time window boundary. For example, an event with timestamp `10:42:04` might arrive at `10:42:12`. Lag Tolerance is the setting that governs how long to wait – after the latest window boundary – and still accept late events.



The "bucket" of events is said to be in Stage 1, where it's still accepting new events, but it's not yet finalized. Notice how in the third case, an event with event time `10:42:09` arrives 1 second past the window boundary at `10:42:11`, but it's still accepted because it happens before the lag time expires.

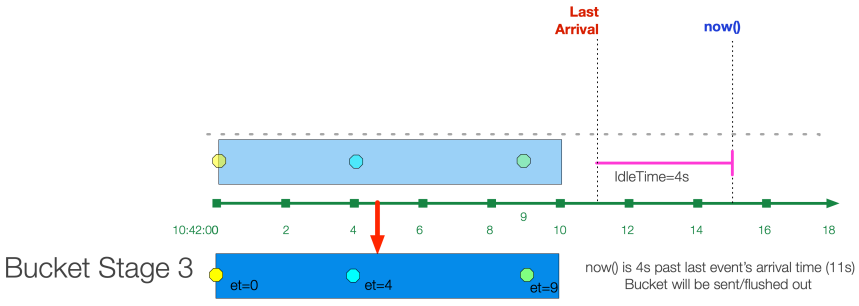
After the lag time expires, the bucket moves to Stage 2.



If the bucket is created from a historic stream, then the bucket is initiated in Stage 2. Lag time is not considered. A "historic" stream is one where the latest time of a bucket is before `now()`. E.g., if the window size is 10s, and `now()=10:42:42`, an event with `event_time=10` will be placed in a Stage 2 bucket with range `10:42:10 - 10:42:20`.

Idle Bucket Time Limit

While Lag Tolerance works with event time, Idle Bucket Time Limit works on arrival time (i.e., real time). It is defined as the amount of time to wait before flushing a bucket that has not received events.



After the Idle Time limit is reached, the bucket is "flushed" and sent out of the system.

Examples

Assume we're working with VPC Flowlog events that have the following structure:

```
version account_id interface_id srcaddr dstaddr srcport dstport protocol packets bytes
start end action log_status
```

For example:

```
2 99999XXXXX eni-02f03c2880e4aaa3 10.0.1.70 10.0.1.11 9999 63030 6 6556 262256
1554562460 1554562475 ACCEPT OK 2 496698360409 eni-08e66c4525538d10b 37.23.15.38
10.0.2.232 4373 8108 6 1 52 1554562456 1554562466 REJECT OK
```

Scenario A:

Every 10s, compute sum of `bytes` and output it in a field called `TotalBytes`.

Time Window: `10s` Aggregations: `sum(bytes).as(TotalBytes)`

Scenario B:

Every 10s, compute sum of `bytes`, output it in a field called `TotalBytes`, group by `srcaddr`.

Time Window: `10s` Aggregations: `sum(bytes).as(TotalBytes)` Group by fields: `srcaddr`

Scenario C:

Every 10s, compute sum of `bytes` but only where action is `REJECT`, output it in a field called `TotalBytes`, group by `srcaddr`.

Time Window: `10s` Aggregations: `sum(bytes).where(action=='REJECT').as(TotalBytes)` Group by Fields: `srcaddr`

Scenario D:

Every 10s, compute sum of `bytes` but only where action is `REJECT`, output it in a field called `TotalBytes`. Also, compute distinct count of `srcaddr`.

Time Window: `10s` Aggregations:
`sum(bytes).where(action=='REJECT').as(TotalBytes)`
`distinct_count(srcaddr).where(action=='REJECT')`

For further examples, see Engineering Deep Dive: Streaming Aggregations Part 2 – Memory Optimization.

14.3. CEF Serializer

The CEF Serializer takes a list of fields and/or values, and formats them in the Common Event Format (CEF) standard. CEF defines a syntax for log records. It is composed of a standard prefix, and a variable extension formatted as a series of key-value pairs.

Format

`CEF:Version|Device Vendor|Device Product|Device Version|Device Event Class ID|Name|Severity|[Extension]`

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Output field: The field to which the CEF formatted event will be output. Nested addressing supported. Defaults to `_raw`.

Header Fields

CEF Header field definitions. The field values below will be written pipe (|)–delimited in the Output Field. Names cannot be changed. Values can be computed with JS expression, or can be constants.

- **cef_version**: Defaults to `CEF:0`.
- **device_vendor**: Defaults to `Cribl`.
- **device_product**: Defaults to `Cribl`.
- **device_version**: Defaults to `C.version`.
- **device_event_class_id**: Defaults to `420`.
- **name**: Defaults to `Cribl Event`.
- **severity**: Defaults to `6`.

Extension Fields

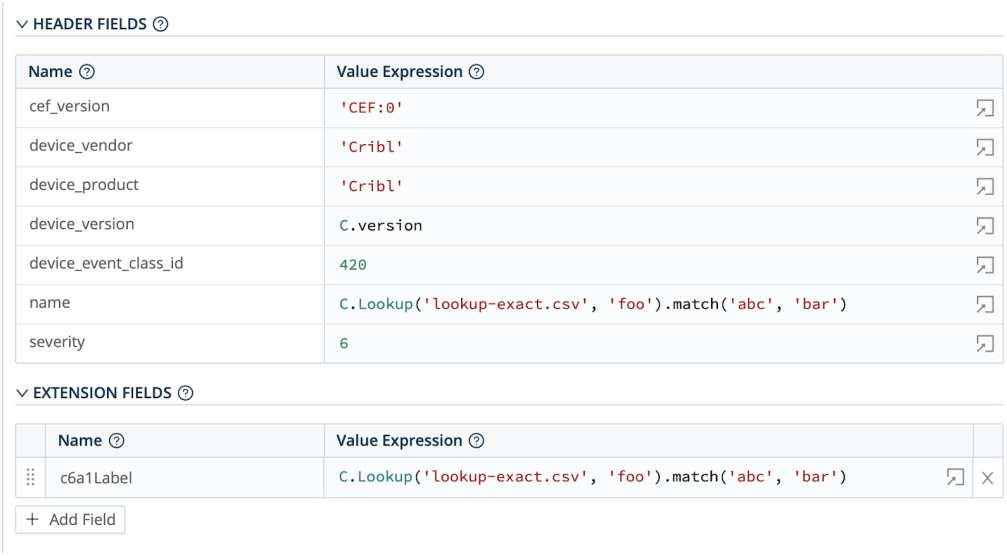
CEF Extension field definitions. Field names and values will be written in `key=value` format. Select each field's Name from the drop-down list. Values can be computed with JS expressions, or can be constants.

Example

For each CEF field, allowed values include strings, plus any custom Cribl function. For example, if using a lookup:

Name: `Name` Value expression: `C.Lookup('lookup-exact.csv', 'foo').match('abc', 'bar')`

This can be used for any of the `CEF` **Header Fields**.



The resulting event has the following structure for an **Output Field** set to `_CEF_out`:

```
_CEF_out:CEF:0|Cribl|Cribl|42.0-61c12259|420|Business Group
6|6|c6a1Label=Colorado_Ext_Bldg7
```

14.4. Chain

The Chain Function does one thing: It chains data processing from a Pipeline or Pack to another Pipeline or Pack. This can be useful for sequential processing, or just to separate groups of related Functions into discrete Pipeline or Pack units that make intuitive sense.

Control Flow

The chained Pipeline or Pack will, upon completion, normally return control to the parent Pipeline/Pack containing the Chain Function. However, if the chained Pipeline/Pack contains any Function with the **Final** flag enabled, processing will stop there. In this case, back in the parent Pipeline/Pack, no Function below Chain will execute.

Cycle Detection and Throughput

The Chain Function includes guardrails against circular references. In v.4.3 and later, Cribl Stream detects cycles when you configure your Pipeline. This early detection (compared to earlier versions' runtime detection) means that:

- If you try to save a Pipeline with a cyclical reference, Cribl Stream will throw an error.
- If an existing Pipeline's configuration contains a cycle, Cribl Stream will disable the final Chain Function involved in the cycle.

Despite these safeguards, Cribl recommends that you keep chained configurations simple and understandable by all your users. Also, keep in mind that inserting a Chain Function can impose a slight performance hit, compared to including all processing in the original Pipeline or Pack.

Pipeline Versus Pack Scope

You will see different scope restrictions when using Chain in a Pipeline versus in a Pack:

- In a Pipeline, the **Processor** drop-down displays both Pipelines and Packs as targets to chain to.
- In a Pack, the **Processor** drop-down offers only Pipelines contained within that Pack.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

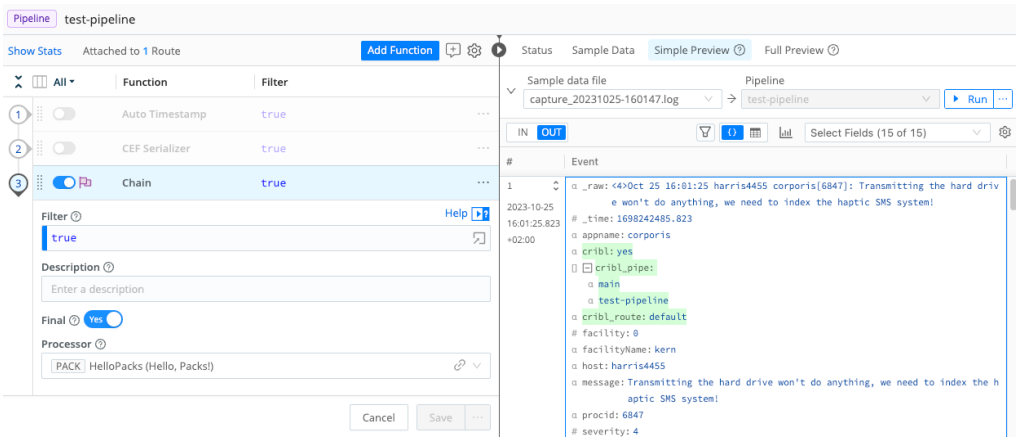
Description: Optionally, add a simple description of this Function's purpose. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`. (Note that this will not prevent data from flowing to the Function's defined **Processor**.)

Processor: Use this drop-down to select a configured Pipeline or Pack through which to forward events.

Example

This shows a simple preview of a `pipeline-1` Pipeline, which chains to a `pipeinpipe` Pipeline. Notice that each event's added `cribl_pipe` field lists all Pipelines/Packs through which the event was chained.



cribl_pipe field shows whole processing path

14.5. Clone

The Clone Function creates a copy of events in the same Pipeline, with optional added fields. Cloned events go to the same Destination as the original event, because they are in the same Pipeline. If your Destination is an Output Router, you can use filters to send cloned events to different Destinations.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Clones: Create clones with the specified fields added and set.

Fields: Set of key-value pairs to add. Nested addressing is supported.

Examples

Staging Example

In this example, the Destination will receive a clone with an `env` field set to `staging`.

Field: `env` **Value**: `staging`

Index Example

In this scenario, we insert a Clone Function at the beginning of a Pipeline to create cloned events. We can later use these events as a baseline to compare against the original events, after various Functions have processed them.

You can assign any meaningful fields to the cloned events – anything that will help you identify them when comparing. This example simply assigns a key-value pair of `index: clones`.

Field: `index` **Value**: `clones`

To keep the cloned events from being processed by Functions later in the same Pipeline, you'll need to specify `index!='clones'` in their **Filter** expressions.

14.6. Code

If you need to operate on data in a way that can't be accomplished with Cribl Stream's out-of-the-box Functions, the Code Function enables you to encapsulate your own JavaScript code. This Function is available in Cribl Stream 3.1+, and imposes some restrictions for security reasons.

Restrictions

Generally speaking, anything forbidden in JavaScript strict mode is forbidden in the context of the Code Function. Specifically, the following are **not allowed**:

- `console`, `eval`, `uneval`, `Function (constructor)`, `Promises`, `setTimeout`, `setInterval`, `global`, `globalThis`, `window`, and `set`.

Code Functions **can** include `for` loops, `while` loops, and JavaScript methods such as `map`, `reduce`, `forEach`, `some`, and `every`. For further details, see Supported JavaScript Options.

Cribl Stream's predefined Functions, such as Eval, cover the vast majority of scenarios that users typically need to implement. You should use Code Functions only as a last resort, when you need to construct a complex block of code.

Also, only skilled JavaScript developers should define Code Functions. This is to avoid unintended results – such as creating infinite loops, or otherwise failing to return – that could needlessly add to your throughput burden.

Usage

When added to a Pipeline, the Code Function offers the following configuration options:

Filter: JavaScript filter expression that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Optionally, add a simple description of this Function.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Code: The mini-editor where you type your JavaScript code.

Advanced Settings

Maximum number of iterations: The maximum number of iterations per instance of this Code Function. Defaults to `5,000`; highest allowed value is `10000`.

Error log sample rate: Specifies the rate at which this Code Function logs errors. For example, a value of `1` logs every error; a value of `10` logs every tenth error. The highest allowed value is `5000`. Defaults to `1`.

Use unique log channel: When enabled, Cribl Stream sends logs from this function to a unique channel in the form `func:code:${pipelineName}:${functionIndex}`. Toggle off to use the generic `func:code` log channel instead.

Notes and Examples

Functions (including the Code Function) always use the special variable `__e` to access the `(context)` event inside JavaScript expressions.

Possibly the simplest Code Function creates a new field and then assigns it a value:

A Basic Code Function

```
__e['foo'] = 'Hello, Goats!'
```

For more ambitious implementations, see Code Function Examples.

JavaScript Support

Cribl Stream supports the ECMAScript® 2015 Language Specification.

With some exceptions, the Code Function supports the options described in the following MDN JavaScript Guide topics:

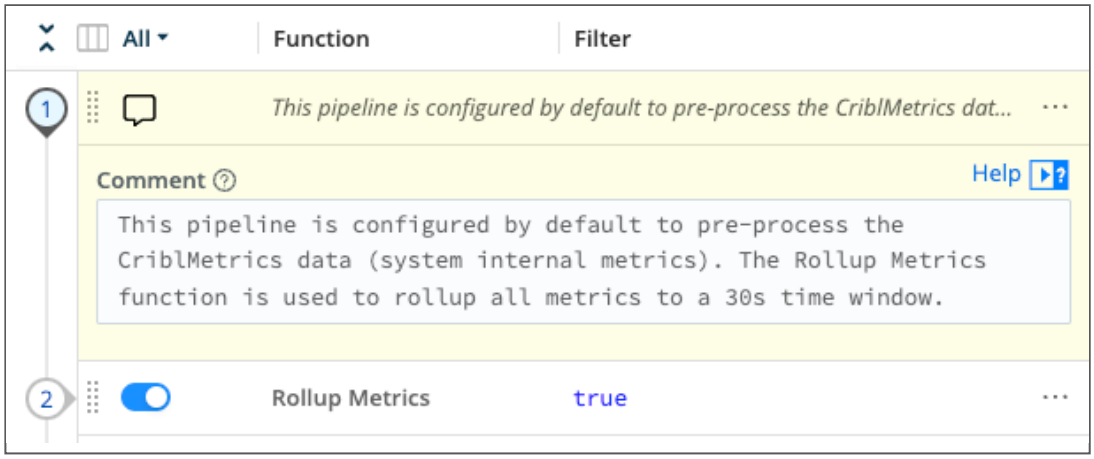
- Expressions and Operators
- Global variables
- Control flow and error handling
- Loops and iteration
- Functions
- Numbers and dates
- Text formatting
- Regular Expressions
- Indexed collections
- Keyed collections
- Working with Objects

14.7. Comment

The Comment Function adds a text comment in a Pipeline. It makes no changes to event data. The added comment is visible only within the Pipeline UI, where it is useful for labeling Pipeline steps. The Comment Function always has a minimum, non-zero processing time.

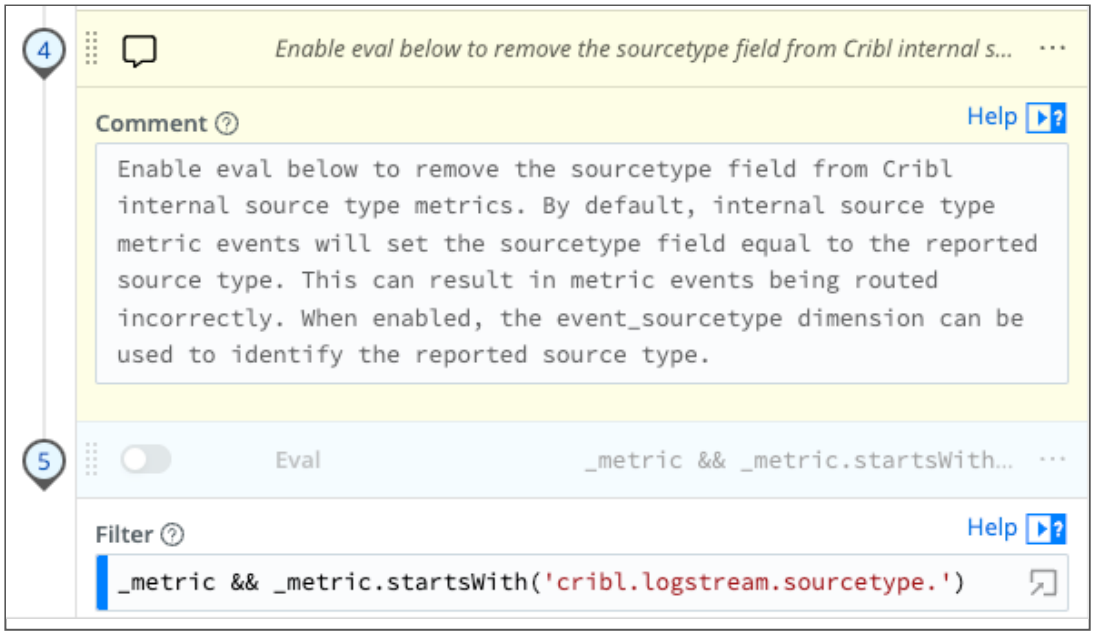
Usage

Comment: Add your comment as plain text in this field.



Examples

This comment labels the Pipeline's next function:



14.8. DNS Lookup

The DNS Lookup Function offers two operations useful in enriching security and other data:

- DNS lookups based on host name as text, resolving to A record (IP address) or to other record types.
- Reverse DNS Lookup. (This duplicates the behavior of Cribl Stream's prior Reverse DNS Function, which was deprecated as of v.2.4, and has been removed as of v.4.0.)

To reduce DNS lookups and minimize latency, the DNS Lookup Function incorporates a configurable DNS cache (including resolved and unresolved lookups). If you need additional caching, consider enabling OS-level DNS caching on each Cribl Stream Worker that will execute this Function. (OS-level caching options include DNSMasq, nscd, systemd-resolved, etc.)

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

DNS Lookup Fields Section

Lookup field name: Name of the field containing the domain to look up.

Resource record type: DNS record type (RR) to return. Defaults to `A`' record.

Output field name: Lookup result(s) will be added to this field. Leave blank to overwrite the original field specified in **Lookup field name**.

Reverse DNS Lookup Field(s) Section

Lookup field name: Name of the field containing the IP address to look up.

If the field value is not in IPv4 or IPv6 format, the lookup is skipped.

Output field name: Name of the field in which to add the resolved hostname. Leave blank to overwrite the original field specified in **Lookup field name**.

Fallback Resolving Methods

This section contains settings for resolving DNS short names.

Use /etc/resolv.conf: Toggle to `Yes` if you want Cribl Stream to resolve DNS short names using the search or domain directive from `/etc/resolv.conf`. Defaults to `No`. Not applicable for Windows hosts.

Use search or domain fallback(s): Add fallback value(s) for the DNS resolver to use when it cannot resolve a DNS short name.

Fall back to DNS.lookup(): Toggle to `Yes` if you want Cribl Stream to make a `DNS.lookup()` call to resolve a DNS short name it can't resolve by other methods.

If you enable all of these methods at once. Cribl Stream will attempt to resolve short names by trying each method in the following order:

1. **Use /etc/resolv.conf**.
2. **Use search or domain fallback(s)**.
3. **Fall back to DNS.lookup()**.

If Cribl Stream can't resolve the short name after trying all of these methods, it will drop the output field from the event.

Potential Performance Impact

Making a `DNS.lookup()` call might degrade performance in unrelated areas of Cribl Stream. Use this method only if you have not been able to resolve DNS short names using other settings.

Advanced Settings

DNS server(s) overrides: IP address(es), in RFC 5952 format, of the DNS server(s) to use for resolution. IPv4 examples: `1.1.1.1`, `4.2.2.2:53`. IPv6 examples: `[2001:4860:4860::8888]`, `[2001:4860:4860::8888]:1053`. If this field is not specified, Cribl Stream will use the system's DNS server.

Cache time to live (minutes): Determines the interval on which the DNS cache will expire, and its contents will be refetched. Defaults to `30` minutes. Use `0` to disable cache expiration/refresh behavior.

Maximum cache size: Maximum number of DNS resolutions to cache locally. Before changing the default `5000`, consider the implications for your system. Higher values will increase memory usage. Highest allowed value is `100000`.

Monitoring DNS Cache State

When the DNS Lookup Function succeeds in looking up a value it has stored in the DNS cache, that is called a **hit**. Each hit enables the Function to skip contacting a DNS server outside of Cribl Stream to perform the DNS lookup. The resulting performance improvement is the main benefit that the DNS cache provides.

When the DNS Lookup Function looks for a value in the DNS cache, but cannot find it, that is called a **miss**. In this case, the Function must contact a DNS server to perform the lookup.

Cribl Stream logs the DNS cache's state in the `func:dns_lookup` channel. The table below explains some typical messages.

Log Message	Meaning
`hits`	Number of successful lookups from cache.
`misses`	Number of unsuccessful lookups from cache.
`keys`	Number of entries in cache.
`ksize`	Approximate amount of memory occupied by keys, in bytes.
`vsize`	Approximate amount of memory occupied by values, in bytes.

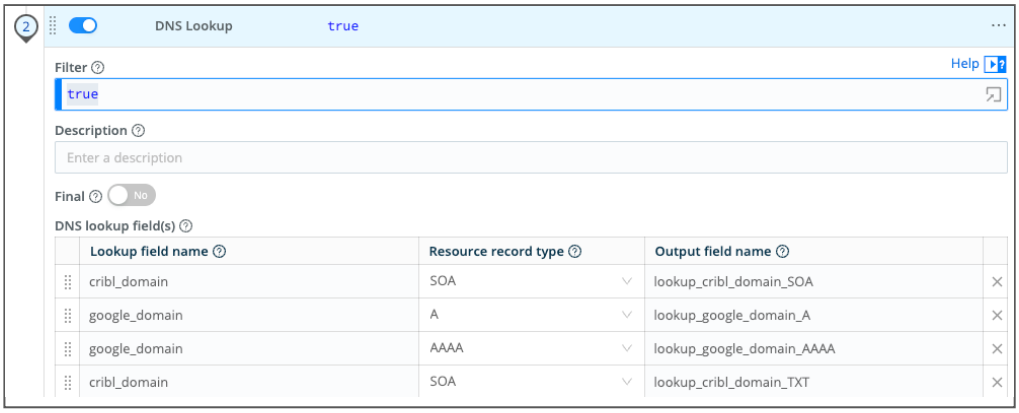
See Monitoring for a general explanation of logging in Cribl Stream.

Example

This example Pipeline chains two Functions. First, we have an **Eval** Function that defines key-value pairs for two alphabetical domain names and two numeric IP addresses.

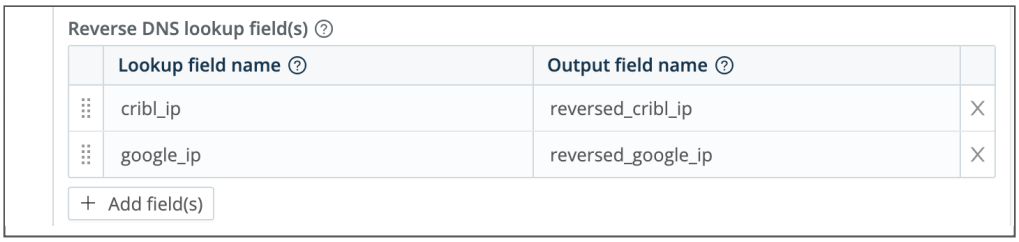
DNS Lookup: Eval Function

Next, the DNS Lookup Function looks up several record types for the two domain names, placing each retrieved record type in its own output field.



DNS Lookup: multiple record types

Finally, the same Function's **Reverse DNS lookup** section retrieves domain names for the two IP addresses.

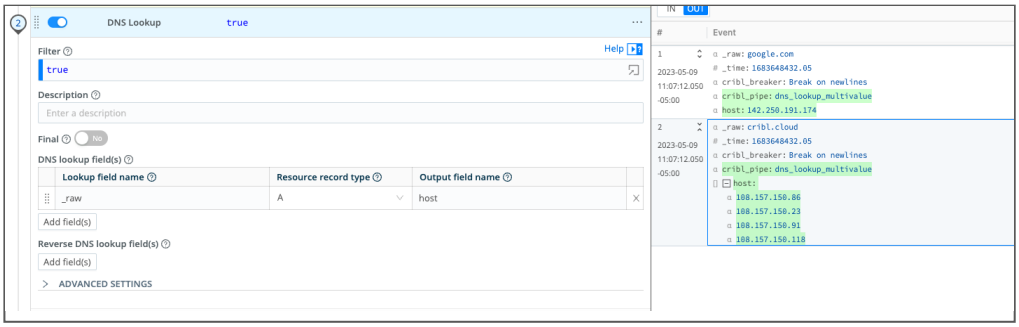


DNS Lookup: reverse lookups

Working with Multi-value Results

DNS records can contain single values mixed together with multi-value results. While this can be challenging to work with, the right code can adjust your results to the desired values.

In the screenshot below, the DNS lookup for `google.com` (event 1) returns a single record, while the `cribl.cloud` lookup (event 2) returns four addresses.



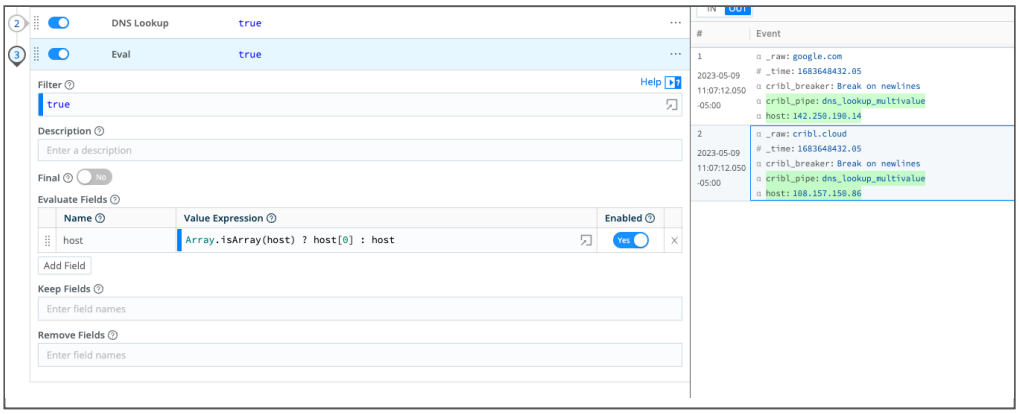
DNS lookup with multi-value result

Sometimes a receiver is unable to consume the data in an array format. One solution to this problem is to pick the first result and convert it into a string. Here's a JavaScript eval to do this:

```
Array.isArray(host) ? host[0] : host;
```

This function checks whether the value of the `host` field is an array.

- If true, the result is the left side of the ternary expression – in this case, `host[0]`, which is the first element in the array, converted into a string. See event 2 in the screenshot below.
- If false, the result is the single-value string in the `host` field. See event 1.



DNS lookup multi-value result converted into a single value

Another option is to **randomly** pick an address from the result. To do this, use a modified version of the JavaScript eval:

```
Array.isArray(host) ? host[Math.floor(Math.random() * host.length)] : host
```

Here, instead of picking the first element, the code uses `Math.floor(Math.random() * host.length)` to randomly pick an element from the array.

14.9. Drop

The Drop Function drops (deletes) any events that meet its Filter expression. This is useful when you want to prevent certain events from continuing to a Pipeline's downstream Functions.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Examples

Scenario A:

Assume that we care only about errors, so we want to filter out any events that contain the word "success," regardless of case: "success," "SUCCESS," etc.

In our Drop Function, we'll use the JavaScript `search()` method to search the `_raw` field's contents for our target pattern. We know that `search()` returns a non-negative integer to indicate the starting position of the first match in the string, or `-1` if no match. So we can evaluate the Function as true when the return value is `>= 0`.

Filter: `_raw.search(/success/i)>=0`

Scenario B:

You can filter out specific JSON events based on their key-value pairs.

The following Filter expression uses a strict inequality operator to check, per event, whether `channel` has a different data type **or** value from `auth`. Matching events will drop, ensuring that only events with `"channel":"auth"` will pass to the next Function.

Filter: `channel !== 'auth'`

14.10. Dynamic Sampling

The Dynamic Sampling Function filters out events based on an expression, a sample mode, and the volume of events. Your sample mode's configuration determines what percentage of incoming events will be passed along to the next step.

Each Worker Process executes this Function independently on its share of events. For details, see Functions and Shared-Nothing Architecture.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Sample mode: Defines how sample rate will be derived. For formulas and usage details, see Sample Modes below. Supported methods:

- Logarithmic (the default): `log(previousPeriodCount)`.
- Square root: `sqrt(previousPeriodCount)`.

Sample group key: Expression used to derive sample group key. For example: `${domain}:${httpCode}`. Each sample group will have its own derived sampling rate, based on the volume of events. Defaults to `` `${host}` ``.

All events without a host field passing through the Function will be associated with the same group and sampled the same.

Advanced Settings

- **Sample period Sec**: How often (in seconds) sample rates will be adjusted. Defaults to `30`.
- **Minimum events**: Minimum number of events that must be received, in previous sample period, for sampling mode to be applied to current period. If the number of events received for a sample group is less than this minimum, a sample rate of 1:1 is used. Defaults to `30`.
- **Max sampling rate**. Maximum sampling rate. If the computed sampling rate is above this value, the rate will be limited to this value.

How Does Dynamic Sampling Work

Compared to static sampling, where users must first select a sample rate, Dynamic Sampling allows for **automatically adjusting** sampling rates, based on the volume of incoming events per sample group. This Function allows users to set only the aggressiveness/coarseness of this adjustment. Square Root is more aggressive than Logarithmic mode.

As an event passes through the Function, it's evaluated against the Sample Group Key expression to determine the sample group it will be associated with. For example, given an event with these fields: `...ip=1.2.3.42, port=1234...`, and a Sample Group Key of `` `${ip}:${port}` ``, the event will be associated with the `1.2.3.42:1234` sample group.

If the Sample Group Key is left at its `` `${host}` `` default, all events without a host will be associated with the same group and sampled the same.

When a sample group is new, it will initially have a sample rate of `1:1` for `Sample Period` seconds (this value defaults to 30 seconds). Once `Sample Period` seconds have elapsed, a sample rate will be derived based on the configured `Sample Mode`, using the sample group's event volume during the **previous** sample period.

For example, assuming a Logarithmic Sample Mode:

**Period 0 (first 30s): ** Number of events in sample group: `1000`, Sample Rate: `1:1`, Events allowed: `ALL`
Sample Rate calculation for **next** period: `Math.ceil(Math.log(1000)) = 7`

Period 1 (next 30s) – Number of events in sample group: `4000`, Sample Rate: `7:1`: Events allowed: `572`
Sample Rate calculation for **next** period: `Math.ceil(Math.log(4000)) = 9`

Period 2 (next 30s) – Number of events in sample group: `12000`, Sample Rate: `9:1`: Events allowed: `1334`
Sample Rate calculation for **next** period: `Math.ceil(Math.log(12000)) = 10`

Period 3 (next 30s) – Number of events in sample group: `2000`, Sample Rate: `10:1`: Events allowed: `200`
Sample Rate calculation for **next** period: `Math.ceil(Math.log(2000)) = 8`
...

Sample Modes

1. Logarithmic – The sample rate is derived, for each sample group, using a natural log: `Math.ceil(Math.log(lastPeriodVolume))`. This mode is **less aggressive**, and drops fewer events.

2. Square Root – The sample rate is derived, for each sample group, using: `Math.ceil(Math.sqrt(lastPeriodVolume))`. This mode is **more aggressive**, and drops more events.

Example

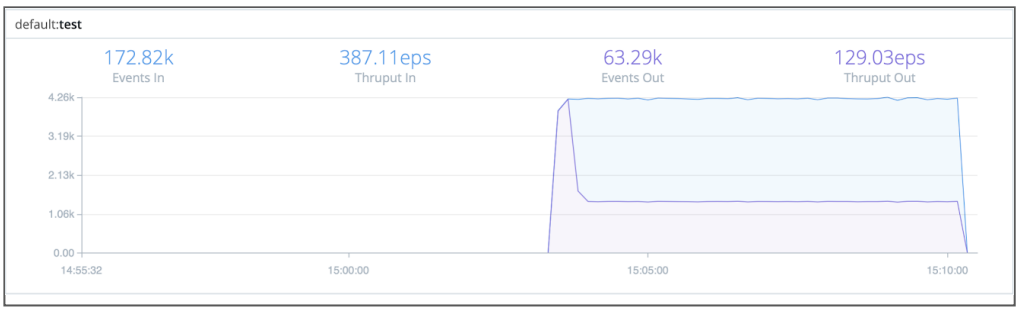
Here's an example that illustrates the effectiveness of using the Square Root sample mode.

Settings:

Sample Mode: `Square Root` Sample Period (sec): `20` Minimum Events: `3` Max. Sampling Rate: `3`

Results:

Events In: 4.23K Events Out: 1.41K



In this generic example, we reduced the incoming event volume from 4.23K to 1.41K. Your own results will vary depending on multiple parameters – the **Sample Group Key**, **Sample Period**, **Minimum Events**, **Max Sampling Rate**, and rate of incoming events.

For further examples, see Getting Smart and Practical With Dynamic Sampling.

See Also

- Sampling Function: Filter out events based on an expression and a sampling rate.

14.11. Eval

The Eval Function adds or removes fields from events. (In Splunk, these are index-time fields.)

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Evaluate fields: Table of event fields to evaluate and add/set. Click **Add Field** to add each field as a key-value pair, in a row with the following controls:

- **Name**: Enter the new (or modified) field's name.
- **Value Expression**: Enter a JavaScript expression to set the field's value – this can be a constant. Expressions can contain nested addressing. When you insert JavaScript template literals, strings intended to be used as values must be delimited with single quotes, double quotes, or backticks. (For details, see Cribl Expression Syntax.)
- **Enabled**: Toggle this off to disable evaluating individual expressions, while retaining their configuration in the table. Useful for iterative development and debugging.

Keep fields: List of fields to keep in the event after processing by this Function. Supports wildcards (*) and nested addressing. Takes precedence over **Remove fields** (below). To reference a parent object and all children, you must use the (*) wildcard. For example, if `_raw` is converted to an object then use `_raw*` to refer to itself and all children.

Remove fields: List of fields to remove from the event. Supports wildcards (*) and nested addressing. Cannot remove fields that match against the **Keep fields** list. Cribl Stream internal fields that start with `__` (double underscore) **cannot** be removed via wildcard. Instead, you must specify them individually. For example, `__myField` cannot be removed by specifying `__myF*`.

Using Keep and Remove

A field matching an entry in *both* **Keep** (wildcard or not) and **Remove** will *not* be removed. This is useful for implementing "remove all but" functionality. For example, to keep only `_time, _raw, source, sourcetype, host`, we can specify them all in **Keep**, while specifying `*` in **Remove**.

Negated terms are supported in both **Keep fields** and **Remove fields**. The list is order-sensitive when negated terms are used. Examples:

- `!foobar, foo*` means "All fields that start with 'foo' except `foobar`."
- `!foo*, *` means "All fields except for those that start with 'foo'."

Examples

Note that Functions use the special variable `__e` to access the `(context)` event inside JavaScript expressions.

Scenario A: Create field `myField` with static value of `value1`:

- **Name:** `myField`
- **Value Expression:** `'value1'`

Scenario B: Set field `action` to `blocked` if `login==error`:

- **Name:** `action`
- **Value Expression:** `login=='fail' ? 'blocked' : action`

Scenario C: Create a multivalued field called `myTags`. (i.e., array):

- **Name:** `myTags`
- **Value Expression:** `['failed', 'blocked']`

Scenario D: Add value `error` to the multivalued field `myTags`:

- **Name:** `myTags`
- **Value Expression:** `login=='error' ? [...myTags, 'error'] : myTags`

(The above expression is literal, and uses JavaScript spread syntax.)

Scenario E: Rename an `identification` field to the shorter `ID` – copying over the original field's value, and removing the old field:

- **Name**: `ID`
- **Value Expression**: `identification`
- **Remove Field**: `identification`

See Also

For more usage examples, see these Better Practices topics:

- Ingest-time Fields, which demonstrates both adding and removing fields.
- Reducing Windows XML Events, which demonstrates using Eval with the `C.Text.parseWinEvent` expression method to parse `_raw` Windows XML events into prettified JSON objects.

Usage Notes

Consider the following when working with Eval Functions.

Create Parent Objects First

Before you can use the Eval function on a new child object, you must create the parent object – then define the children using Eval Functions.

Example:

```
parent  =  (parent || { child1: child1Value })
parent.child2 = child2Value
parent.child3 = child3Value
<some other Evals, if you need them>
```

To Append:

```
parent =  Object.assign(parent, { child2: child2Value })
```

To Create a New Field:

```
parent2 =  Object.assign(parent, { child2: child2Value, child3: child3Value })
```

Execution Without Assignment

The Eval Function can execute expressions **without** assigning their value to the field of an event. You can do this by simply leaving the left-hand side input empty, and having the right-hand side do the assignment.

Example: Parse and Merge to Existing Field

`Object.assign(foo, JSON.parse(bar), JSON.parse(baz))` on the right-hand side (and left-hand side empty) will JSON-parse the strings in `bar` and `baz`, merge them, and assign their value to `foo`, an already

existing field.

Example: Reference Event with `__e`

To parse JSON, enter `Object.assign(__e, JSON.parse(_raw))` on the right-hand side (and left-hand side empty). `__e` is a special variable that refers to the `(context)` event **within** a JS expression. In this case, content parsed from `_raw` is added at the top level of the event.

14.12. Event Breaker

This Function enables you to split large blobs or streams of events into discrete events within a Pipeline. This is useful for Sources like Azure Event Hubs, which do not natively support Event Breakers.

Even with Sources that do support Event Breakers (like Raw HTTP), it sometimes makes sense to use both a Source-configured Event Breaker on the incoming stream, and an Event Breaker Function within a Pipeline.

Limitations

The Event Breaker Function operates only on data in `_raw`. For other events, move the array to `_raw` and stringify it before applying this Function.

The largest event that this Function can break is about about 128 MB (`134217728` bytes). Events exceeding this maximum size will be split into separate events, but left unbroken. Cribl Stream will set these events' `__isBroken` internal field to `false`.

Unlike regular Event Breakers, Event Breaker Functions do not have names, only descriptions.

Usage

Use the following options to define this Event Breaker Function.

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Existing or New?: Whether to use an existing ruleset or create a new one. Defaults to `Use Existing`.

- When **Existing or New?** is set to `Use Existing`, the **Existing Ruleset?** drop-down appears and you choose a ruleset from there.
- When **Existing or New?** is set to `Create New`, the ruleset creation UI appears and you configure its settings.

Advanced Settings

Add to cribl_breaker: Whether to add the `cribl_breaker` field to output events. Defaults to `Yes`.

How this field behaves depends on whether you are **also** using a regular Event Breaker with your Source. That matters because a regular Event Breaker **always** adds the `cribl_breaker` field to events, which it does **before** the data reaches your Event Breaker Function.

When you are **not** using a regular Event Breaker, there is no `cribl_breaker` field yet when the data reaches your Event Breaker Function. At this point, `cribl_breaker` is added, and:

- When **Existing or New?** is set to `Use Existing`, `cribl_breaker`'s value is set to the name of the existing ruleset you chose.
- When **Existing or New?** is set to `Create New`, the `cribl_breaker`'s value is set to `"event_breaker_func"`. Since Event Breaker Functions do not have names, the string `event_breaker_func` serves as a kind of generic name that represents whatever new Event Breaker Function you created.

When you **are** also using a regular Event Breaker, the `cribl_breaker` field already exists when the data reaches your Event Breaker Function. At this point, the value of `cribl_breaker` is changed from a string to an array, with the first item in the array being the value originally set by the regular Event Breaker, and the second item determined as follows:

- When **Existing or New?** is set to `Use Existing`, the second item's value is set to the name of the existing ruleset you chose.
- When **Existing or New?** is set to `Create New`, the second item's value is set to `"event_breaker_func"`. Since Event Breaker Functions do not have names, the string `event_breaker_func` serves as a kind of generic name that represents whatever new Event Breaker Function you create.

Cribl Stream truncates timestamps to three-digit (milliseconds) resolution, omitting trailing zeros.

In Cribl Stream 3.4.2 and above, where an Event Breaker Function has set an event's `_time` to the current time – rather than extracting the value from the event itself – it will mark this by adding the internal field `__timestampExtracted: false` to the event.

Examples

Handling syslog data and nested JSON data are two primary use cases for Event Breaker Functions.

Event Breaker Functions for syslog Data

Event Breaker Functions can help you deal with syslog data that does not break correctly. Examples include multi-line syslog data, and, the kinds of non-standard syslog data emitted by Blue Coat proxy appliances, Layer7 API Gateways, and other appliances. See the Cribl video Scaling syslog for an in-depth discussion.

(In this context, “non-standard” means syslog data that only partly conforms to the standard Syslog Protocol defined in RFC 5424, or its predecessor, the BSD syslog Protocol defined in RFC 3164.)

Event Breaker Functions for Nested JSON Data

Kafka-based data from Confluent, Azure Event Hubs, Google Pub Sub, or Kafka itself, is nicely structured as events according to the Kafka protocol. But when these events contain JSON objects which you want to break into their constituent objects, you can use an Event Breaker Function to do that.

Troubleshooting

If you notice fragmented events, check whether Cribl Stream has added a `__timeoutFlush` internal field to them. This diagnostic field’s presence indicates that the events were flushed because the Event Breaker buffer timed out while processing them. These timeouts can be due to large incoming events, backpressure, or other causes.

14.13. Flatten

The Flatten Function flattens fields out of a nested structure. It pulls up nested key-value pairs (fields) to a higher level in the object. You can specify:

- Individual fields to flatten.
- The depth at which to flatten fields.
- The delimiter to use when concatenating keys.
- An optional prefix to add to transformed field names.

The Flatten Function creates fully qualified names for promoted fields. If you simply need to promote fields without transforming their names, use the `eval` Function.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Fields: List of top-level fields to include for flattening. Defaults to an empty array, which means all fields. Limit to specific fields by typing in their names, separated by hard returns. Supports wildcards (`*`). Supports double-underscore (`__`) internal fields only if individually enumerated – not via wildcards.

Prefix: Prefix string for flattened field names. Defaults to empty.

Depth: Number representing the nested levels to consider for flattening. Minimum `1`. Defaults to `5`.

Delimiter: Delimiter to use for flattening. Defaults to `_` (underscore).

Example

Add the following test sample in **Preview** > **Paste a Sample**:

input

```
{
        "accounting": [{
                "firstName": "John",
                "lastName": "Doe",
                "age": 23
        }, {
                "firstName": "Mary",
                "lastName": "Smith",
                "age": 32
        }],
        "sales": [{
                "firstName": "Sally",
                "lastName": "Green",
                "age": 27
        }, {
                "firstName": "Jim",
                "lastName": "Galley",
                "age": 41
        }]
}
```

Under **Select Event Breaker**, choose **ndjson** (newline-delimited JSON), and click **Save as a Sample File**.

Here's sample output with all settings at default:

output

```
{
  "accounting_0_firstName": "John",
  "accounting_0_lastName": "Doe",
  "accounting_0_age": 23,
  "accounting_1_firstName": "Mary",
  "accounting_1_lastName": "Smith",
  "accounting_1_age": 32,
  "sales_0_firstName": "Sally",
  "sales_0_lastName": "Green",
  "sales_0_age": 27,
  "sales_1_firstName": "Jim",
  "sales_1_lastName": "Galley",
  "sales_1_age": 41,
}
```

Using the Flatten Function's default settings, we successfully create top-level fields from the nested JSON structure, as expected.

See Also

- Reducing Windows XML Events, which demonstrates flattening within `_raw` events ingested via Windows XML.

14.14. GeoIP

The GeoIP Function enriches events with geographic fields, given an IP address. It works with MaxMind's GeoIP binary database.

Prerequisite

You need to host the `.mmdb` database file from MaxMind. The following steps cover this process at a high level. They link to our Managing Large Lookups topic, where you can find additional details.

1. Download and extract the `.mmdb` database file.
2. Determine where to place the database file. We recommend the `$CRIBL_HOME/state/` subdirectory, which is already listed in the default `.gitignore` file that ships with Cribl Stream.
   You always have the option to upload the file to Cribl Stream's Lookups Library. In a Cribl.Cloud deployment, this is currently the only option. For details, see Reducing Deploy Traffic.
3. Place the database file on your Worker Node(s). In a distributed deployment, we recommend having the file on the Leader and all Worker Nodes. Smaller deployments can get away with hosting the file only on the Leader Node.
4. Optionally, set up automatic updates of the database file.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

GeoIP file (.mmdb): Path to a MaxMind database, in binary format, with `.mmdb` extension.

If the database file is located within the lookup directory (`$CRIBL_HOME/data/lookups/`), the **GeoIP file** does not need to be an absolute path.

In distributed deployments, ensure that the MaxMind database file is in the same location on the Leader Node and all Worker Nodes. However, if you've uploaded `.mmdb` files via Cribl Stream's Lookups Library UI, just click this combo box to display and select them on a drop-down list. Your selection here will handle the path management automatically.

IP field: Field name in which to find an IP to look up. Can be nested. Defaults to `ip`.

Result field : Field name in which to store the GeoIP lookup results. Defaults to `geoip`.

Examples

Assume that you are receiving SMTP logs, and need to see geolocation information associated with IPs using the SMTP service.

Here's a sample of our data, from IPSwitch IMail Server logs:

```
03:19 03:22 SMTPD(00180250) [192.168.1.131] connect 74.136.132.88 port 2539 03:19 03:22 SMTPD(00180250) [74.136.132.88] EHLO msnbc.com 03:19 03:22 SMTPD(00180250) [74.136.132.88] MAIL FROM:<info-jjgcdshx@test.us> 03:19 03:22 SMTPD(00180250) [74.136.132.88] RCPT To:<user@domain.com>
```

In this example, we'll chain together three Functions. First, we'll use a Regex Extract Function to isolate the host's IP. Next, we'll use the GeoIP Function to look up the extracted IP against our geoIP database, placing the returned info into a new `__geoip` field. Finally we'll use an Eval Function to parse that field's city, state, country, ZIP, latitude, and longitude.

Function 1 – Regex Extract

Regex: `\[(?<ip>\S+)\]` Source field: `_raw` Result: `74.136.132.88`

Function 2 – GeoIP

Event's IP field: `ip` Result field: `__geoip`

Function 3 – Eval

Name	Value Expression
City	`__geoip.city.names.en`
Country	`__geoip.country.names.en`
Zip	`__geoip.postal.code`
Lat	`__geoip.location.latitude`
Long	`__geoip.location.longitude`

In the Eval Function's **Remove fields** setting, you could specify the `__geoip` field for removal, if desired. However, its `__` prefix makes it an internal field anyway.

For a hosted tutorial on applying the GeoIP Function, see Cribl's GeoIP and Threat Feed Enrichment Sandbox.

14.15. Grok

The Grok Function extracts structured fields from unstructured log data, using modular regex patterns.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Optional description of this Function's purpose in this Pipeline. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Pattern: Grok pattern to extract fields. Cick the Expand button at right to open a preview/valdiation modal. Syntax supported: `%{PATTERN_NAME:FIELD_NAME}`.

Click **Add pattern** to chain more patterns.

Source field: Field on which to perform Grok extractions. Defaults to `_raw`.

Management

You can add and edit Grok patterns via Cribl Stream's UI by selecting **Knowledge** > Grok Patterns.
Pattern files are located at: `$CRIBL_HOME/(default|local)/cribl/grok-patterns/`

Example

Example event:

```
{"_raw": "2020-09-16T04:20:42.45+01:00 DEBUG This is a sample debug log message"}
```

Pattern: `%{TIMESTAMP_ISO8601:event_time} %{LOGLEVEL:log_level} %{GREEDYDATA:log_message}` **Source Field**: `_raw`

Event after extraction:

```
{"_raw": "2020-09-16T04:20:42.45+01:00 DEBUG This is a sample debug log message",
  "_time": 1600226442.045,
  "event_time": "2020-09-16T04:20:42.45+01:00",
  "log_level": "DEBUG",
  "log_message": "This is a sample debug log message",
}
```

Note the new fields added to the event: `event_time`, `log_level`, and `log_message`.

References

- Syntax for a Grok pattern is `%{PATTERN_NAME:FIELD_NAME}`. E.g.: `%{IP:client} %{WORD:method}`.
- Useful link for creating and testing Grok patterns: http://grokconstructor.appspot.com
- Additional patterns are available here: https://github.com/logstash-plugins/logstash-patterns-core/tree/main/patterns

14.16. JSON Unroll

The JSON Unroll Function accepts a JSON object string `_raw` field, unrolls/explodes an **array** of **objects** therein into individual events, while also inheriting top level fields. See example(s). Cribl highly recommends not using this JSON Unroll function for certain types of data. Instead, perform the unrolling using an event breaker for those inputs which support configuring an event breaker. Specifying the event breaker type **JSON Array** and toggling the **JSON Extract Fields** option to **Yes** will accomplish the same unrolling but much more efficiently. This is recommended, for example, for CloudTrail and Office635 events, which are collected as JSON arrays.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Path: Path to array to unroll, e.g., `foo.0.bar`.

New name: The name that the exploded array element will receive in each new event. Leave empty to expand the array element with its original name.

Example(s)

Assume you have an incoming event that has a `_raw` field as a JSON object string like this:

Sample _raw field

```
{"date":"9/25/18 9:10:13.000 PM",
   "name":"Amrit",
   "age":42,
   "allCars": [
       { "name":"Ford", "models":[ "Fiesta", "Focus", "Mustang" ] },
       { "name":"GM", "models":[ "Trans AM", "Oldsmobile", "Cadillac" ] },
       { "name":"Fiat", "models":[ "500", "Panda" ] },
       { "name":"Blackberry", "models":[ "KEY2", "Bold Touch 9900" ] }
   ]
}
```

Settings:

Path: `allCars` **New Name**: `cars`

Output Events:

Resulting Events

```
Event 1:
{"_raw":"{"date":"9/25/18 9:10:13.000 PM","name":"Amrit","age":42,"cars":{"name":"Fo

Event 2:
{"_raw":"{"date":"9/25/18 9:10:13.000 PM","name":"Amrit","age":42,"cars":{"name":"GM

Event 3:
{"_raw":"{"date":"9/25/18 9:10:13.000 PM","name":"Amrit","age":42,"cars":{"name":"Fi

Event 4:
{"_raw":"{"date":"9/25/18 9:10:13.000 PM","name":"Amrit","age":42,"cars":{"name":"Bl
```

Each element under the original **allCars** array is now placed in a **cars** field in its own event, inheriting original top level fields; **date**, **name**, and **age**

See Also

- The Cribl Knowledge Pack provides sample Pipelines that demonstrate converting a JSON string into an object literal, and validating JSON data against a schema.

14.17. Lookup

The Lookup Function enriches events with external fields, using lookup table files in CSV, compressed `.csv.gz`, or binary `.mmdb` format.

CSV files are text-based and untyped. This means all data within the file is treated as strings, regardless of its intended type (like, numbers or dates).

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Lookup file path (.csv, .csv.gz): Path to the lookup file. Select an existing file that you've uploaded via Cribl Stream's UI at Knowledge > Lookups Library, or specify the path. You can reference environment variables via `$`, e.g.: `$CRIBL_HOME/file.csv`.

When you configure this field via a distributed deployment's Leader Node, Cribl Stream will swap `$CRIBL_HOME/groups/<groupname>/` for `$CRIBL_HOME` when validating whether the file exists. In this case, the default upload path changes from `$CRIBL_HOME/data/lookups` (single-instance deployments) to `$CRIBL_HOME/groups/<groupname>/data/lookups/` (distributed deployments).

Match mode: Defines the format of the lookup file, and indicates the matching logic that will be performed. Defaults to `Exact`.

Match type: For CIDR and Regex **Match mode**s, this attribute refines how to resolve multiple matches. `First match` will return the first matching entry. `Most specific` will scan all entries, finding the most specific match. `All` will return all matches in the output, as arrays. (Defaults to `First match`. Not displayed for Exact **Match mode**.)

Lookup fields (.csv): Field(s) that should be used to key into the lookup table.

- **Lookup field name in event**: Exact field name as it appears in events. Nested addressing supported.
- **Corresponding field name in lookup**: The field name as it appears in the lookup file. Defaults to the **Lookup field name in event** value. This input is optional.

Case-Sensitive / Multiple Matches

Lookups are case-sensitive by default. (See the **Ignore case** option below.)

If the lookup file contains duplicate key names with different values, all **Match mode**s of this Function will use **only** the value in the key's **final** instance, ignoring all preceding instances.

Output field(s): Field(s) to add to events after matching the lookup table. Defaults to **all** if not specified.

- **Output field name from lookup**: Field name, as it appears in the lookup file.
- **Lookup field name in event**: Field name to add to event. Defaults to the lookup field name. This input is optional. Nested addressing is supported.
- **Default value**: Optional string value to assign to the field when the lookup entry is not found.

Advanced Settings

Reload period (sec): To periodically check the underlying file for mod-time changes, and reload the file if necessary, change the default `-1` value (disabled) to a positive integer representing the check interval in seconds.

In distributed deployments, enabling a **Reload period** can generate conflicts with configuration updates, causing Pipelines to skip executing some Lookup Functions. Cribl recommends that you enable it only for lookup files not managed by Cribl Stream's UI, or lookup files that can be updated by an external process. (E.g., a threat list that you update via a cron job.)

For lookup files that **are** managed by Cribl Stream's UI, a distributed Cribl Stream deployment will override this setting as necessary – skipping checks to prevent conflicts that could trigger skipped lookups. These restrictions do **not** apply to single-instance deployments.

Ignore case: Ignore case when performing **Match mode: Exact** lookups. Defaults to `No`.

Add to raw event: Whether to append the looked-up values to the `_raw` field, as key=value pairs. Defaults to `No`.

Examples

Example 1: Regex Lookups

Assign a `sourcetype` field to events if their `_raw` field matches a particular regex.

paloalto.csv

```
regex,sourcetype
"^[^,]+,[^,]+,[^,]+,THREAT",pan:threat
"^[^,]+,[^,]+,[^,]+,TRAFFIC",pan:traffic
"^[^,]+,[^,]+,[^,]+,SYSTEM",pan:system
```

Match mode: Regex

Match type: First match

When using the Lookup Function with Regex and `First match`, ensure that your lookup file contains no empty lines - not even at the bottom. Any empty row will cause the function to always return `true`.

Lookup field name in event: `_raw`

Corresponding field name in lookup: `regex`

Events before and after

```
### BEFORE:

{"_raw": "Sep 20 13:03:55 PA-VM 1,2018/09/20 13:03:58,FOOBAR,TRAFFIC,end,2049,2018/0
{"_raw": "Sep 20 13:03:55 PA-VM 1,2018/09/20 13:03:58,FOOBAR,THREAT,end,2049,2018/09/

### AFTER:

{"_raw": "Sep 20 13:03:55 PA-VM 1,2018/09/20 13:03:58,FOOBAR,TRAFFIC,end,2049,2018/0
  "sourcetype": "pan:traffic"
  }
{"_raw": "Sep 20 13:03:55 PA-VM 1,2018/09/20 13:03:58,FOOBAR,THREAT,end,2049,2018/09/
  "sourcetype": "pan:threat"
  }
```

Example 2: CIDR Lookups

Assign a `location` field to events if their `destination_ip` field matches a particular CIDR range.

paloaltoips.csv

```
range,location
10.0.0.0/24,San Francisco
10.0.0.0/16,California
10.0.0.0/8,US
```

Match mode: CIDR

Match type: See options below

Lookup field name in event: `destination_ip`

Corresponding field name in lookup: `range`

In **Match mode: CIDR** with **Match type: Most specific**, the lookup will implicitly search for matches from most specific to least specific. There is no need to pre-sort data.

Note that **Match mode: CIDR** with **Match type: First Match** is likely the most performant with large lookups. This can be used as an alternative to **Most specific**, if the file is sorted with the most specific/relevant entries first. This mode still performs a table scan, top to bottom.

Events before and after

```
### BEFORE:

{"_raw": "Sep 20 13:03:55 PA-VM 1, 2018/09/20 13:03:58,FOOBAR,TRAFFIC,end,2049,2018/(
  "destination_ip": "10.0.0.102"
  }

### AFTER with Match Type: First Match

{"_raw": "Sep 20 13:03:55 PA-VM 1, 2018/09/20 13:03:58,FOOBAR,TRAFFIC,end,2049,2018/(
  "destination_ip": "10.0.0.102",
  "location": "San Francisco"
  }

### AFTER with Match Type: Most Specific

{"_raw": "Sep 20 13:03:55 PA-VM 1, 2018/09/20 13:03:58,FOOBAR,TRAFFIC,end,2049,2018/(
  "destination_ip": "10.0.0.102",
  "location": "San Francisco"
  }

### AFTER with Match Type: All

{"_raw": "Sep 20 13:03:55 PA-VM 1, 2018/09/20 13:03:58,FOOBAR,TRAFFIC,end,2049,2018/(
  "destination_ip": "10.0.0.102",
  "location": [
    "San Francisco",
    "California",
    "US",
  ]}
```

More Examples and Scenarios

For usage examples, see these Better Practices topics and other resources:

- Ingest-time Lookups: Enriching data in motion for fast access and on-demand accuracy.
- Lookups and Regex Magic: Combining the Regex Extract, Lookup, and Eval Functions to enrich events with region, index, and sourcetype data.
- Lookups as Filters for Masks: Using lookups to optimize multiple Mask Functions in a single Pipeline.
- Managing Large Lookups to optimize file locations for large lookup files.

- Updating Lookups in Multiple Packs: Efficiently manage frequent updates to a large lookup file.
- Updating Lookups with a REST API: Using API calls to refresh a lookup file, and commit and deploy it to Worker Groups.
- Lookup Examples Pack: Examples of using the Lookup Function and C.Lookup Expressions.

See Also

- C.Lookup Expressions: Lookup methods that you can use in JavaScript expressions.
- Redis Function for faster lookups using a Redis integration.
- The Cribl Knowledge Pack demonstrates using a Lookup Function to drop Cisco ASA events, or to return a regex for extracting fields.

14.18. Mask

The Mask Function masks, or replaces, patterns in events. This is especially useful for redacting PII (personally identifiable information) and other sensitive data.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Optionally, enter a simple description of this Function.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Masking Rules: This table defines pairs of patterns to match and replace. Defaults to empty. Click **Add Rule** to add each rule. Each row of the resulting table provides the following options:

- **Match Regex**: Pattern to replace. Supports capture groups. Use `/g` to replace all matches, e.g.: `/foo(bar)/g`
- **Replace Expression**: A JavaScript expression or literal to replace all matching content. Capture groups can be referenced with `g` and the group number – e.g., `g2` to reference the second capture group.
- **Enabled**: Toggle this off to disable matching individual rules, while retaining their configuration in the table. Useful for iterative development and debugging.

Apply to Fields: Fields on which to apply the masking rules. Defaults to `_raw`. Add more fields by typing in their names, separated by hard returns. Supports wildcards (`*`) and nested addressing. Supports double-underscore (`__`) internal fields only if individually enumerated – not via wildcards.

Negated terms are supported. When you negate field names, the fields list is order-sensitive. E.g., `!foobar` before `foo*` means "Apply to all fields that start with `foo`, except `foobar`." However, `!foo*` before `*` means "Apply to all fields, except for those that start with `foo`."

Advanced Settings

Evaluate fields: Optionally, specify fields to add to events in which one or more of the **Masking Rules** were matched. These fields can be useful in downstream processing and reporting. You specify the fields as key–value expression pairs, like those in the Eval Function.

- **Name**: Field name.

- **Value Expression**: JavaScript expression to compute the value (can be a constant).

Evaluating the Replace Expression

The **Replace expression** field accepts a full JS expression that evaluates to a value, so you're not necessarily limited to what's under `C.Mask`. For example, you can do conditional replacement: `g1%2==1 ? `fieldA="odd"` : `fieldA="even"``

The **Replace expression** can reference other event fields as `event.<fieldName>`. For example, `` `${g1}${event.source}` ``. Note that this is slightly different from other expression inputs, where event fields are referenced without `event.` Here, we require the `event.` prefix for the following reasons:

- We don't expect this to be a common case.
- Expanding the event in the replace context would have a high performance hit on the common path.
- There is a slight chance that there might be a `gN` field in the event.

The output of the Mask Function is a string even when the **Replace expression** produces a number.

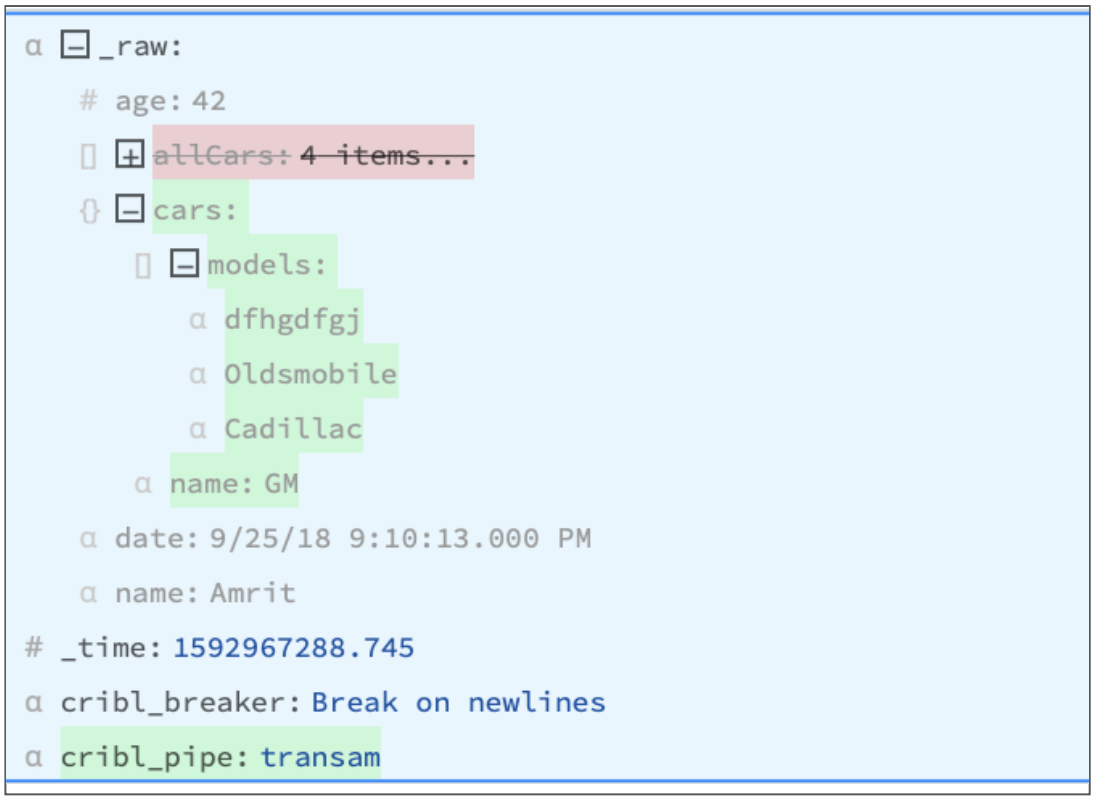
For example, suppose a **Replace expression** that generates a random integer is applied to a field named `bytes` and produces the number `8403`. Cribl Stream will output an event where the value of the `bytes` field is the **string** `8403`.

If you need to convert the string value back to a number, you could add a Numerify Function to your Pipeline.

Examples

Example 1: Transform a String

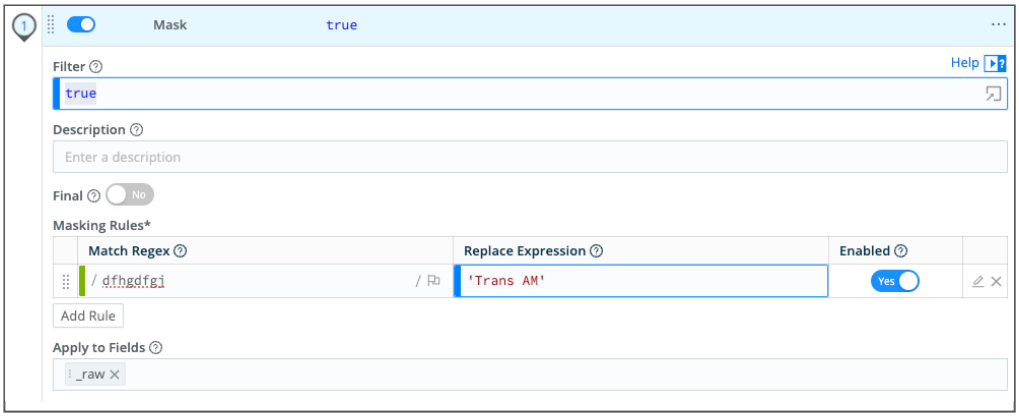
Here, we'll simply search for the string `dfhgdfgj`, and replace that value (if found) with `Trans AM`. This will help close America's muscle-car gap:



Event before masking

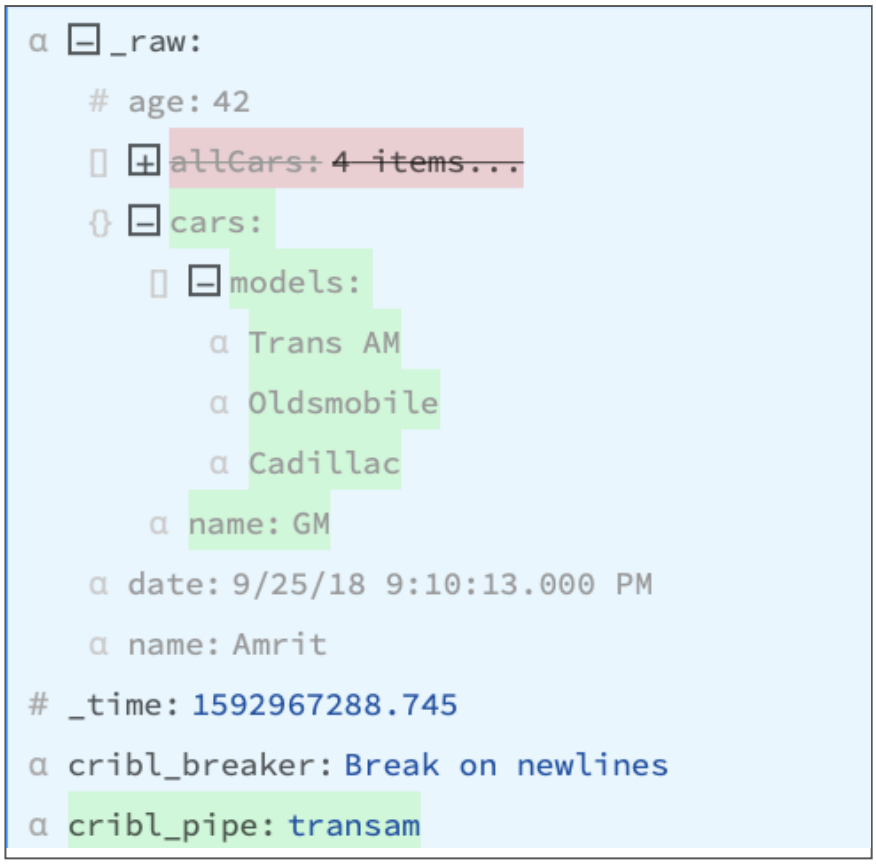
Configure the Mask Function > Masking Rules as follows:

Match Regex: `dfhgdfgj` Replace Expression: `Trans AM`



Mask Function configuration

Result: Vroom vroom!



Event after masking

Example 2: Mask Sensitive Data

Assume that you're ingesting data whose `_raw` fields contain unredacted Social Security numbers in the Key=Value pattern `social=#########`.

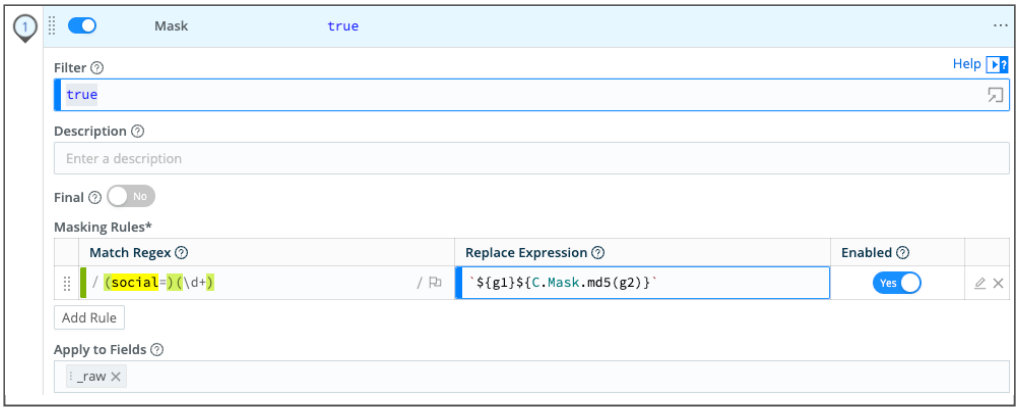
Event with unredacted SSNs

You can use a Mask Function to run an md5 hash of the `social` keys' numeric values, replacing the original values with the hashed values. Configure the Masking Rules as follows:

Match Regex: `(social=)(\d+)` Replace Expression: `` `${g1}${C.Mask.md5(g2)}` ``

In the first example everything in the Match regex field was replaced by the Replace Expression. However if that isn't desired then you can use capture groups in the Match Regex to define individual string components for manipulation or, alternatively, use string literals in the Replace expression for retaining any static text. Any content matching the Match Regex that is not inserted into the Replace expression will not be retained.

In this example, `social=` is assigned to capture group g1 for later reference. The value of `social=` will be hashed by referencing it as g2 in the md5 function. If we didn't make `social=` its own capture group (or specified `social=` as a literal in the Replace Expression) then we cannot reference it using g1 in the Replace expression, the value of `social=` would instead be assigned to g1, and the entire `social=#########` string would be replaced with a hash of the social security number, which probably isn't desired because no one would know the value being hashed without a field name preceding it.



Mask Function configuration

Result: The sensitive values are replaced by their md5 hashes.

In scenarios where you need to send unmodified values to certain Destinations (such as archival stores), you can narrow the Mask Function's scope by setting the associated Route's **Output** field.

Example 3: Replace with an Event Field

In this example, we'll replace the IP address `127.0.0.1` in the `_raw` field with the IP address `192.168.123.25` from an existing field named `source_ip`. The following is a snippet of `_raw`:

```
ProcessId=0x0 IpAddress=127.0.0.1 IpPort=0
```

To match the IP address, we'll define three capture groups. Set **Match Regex** to:

```
/(IpAddress=)((?:\d{1,3}\.){3}\d{1,3})(\s)/
```

In the **Replace Expression**, we'll reference the `source_ip` field by prepending `event` to it, like this:

```
${g1}${event.source_ip}${g3}
```

Note that we've also referenced the first and third capture groups, using `g1` and `g3`. This changes `_raw` to:

```
ProcessId=0x0 IpAddress=192.168.123.25 IpPort=0
```

See Also

For further usage examples, see:

- Masking and Obfuscation illustrates random, repeat, string, and hash masking.
- The Cribl Knowledge Pack provides sample Pipelines that demonstrate using Mask to both encode and decode data, convert hex values to numbers, and create md5 hashes of values using multiple wildcards.

14.19. Numerify

The Numerify Function converts event fields that are numbers to type `number`.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Depth: Controls how deep the function searches nested events. Higher values may slow performance. Defaults to `5`. Maximum is `10`.

Ignore fields: Specify fields to **not** numerify. Type in field names, separated by hard returns. Supports wildcards (`*`) and nested addressing. When empty (the default), Numerify applies to **all** fields. When populated, takes precedence over the **Include expression**. Also supports negated terms. For example, `!foo*` before `*` means "Ignore all fields, except for those that start with `foo`." See Wildcard Lists.

Include expression: Optional JavaScript expression to specify fields to numerify. If empty (the default), the Function will attempt to numerify all fields – except those listed in **Ignore fields**, which takes precedence. Use the `name` and `value` global variables to access fields' names/values. (Example: `value != null`.) You can access other fields' values via `__e.<fieldName>`.

Format: Optionally, reformat or truncate the extracted numeric value. Select one of:

- **None**: Applies no reformatting (the default).
- **Floor**: Rounds the number down to the lower adjacent integer (truncates it).
- **Ceil**: Rounds the number up to the higher adjacent integer, removing decimal digits.
- **Round**: Rounds (truncates) the number to a specified number of digits. This option exposes an extra field:
    - **Digits**: Number of digits after the decimal point. Enter a value between `0`–`20`; defaults to `2`.

Examples

Scenario A:

Assume an event whose text contains a numeric value that must be extracted to perform some numeric analysis. The text looks like this:

```
version=11.5.0.0.1.1588476445
```

We can extract the numeric value by chaining together two Functions:

1. A Regex Extract Function. Set its **Regex** field to `/version=(?<ver>\d+)/`, to capture the first set of digits found in the event string.
2. Then use Numerify.

This captures the substring `11` and converts it to a numeric `11` value.

Scenario B:

Assume email transaction log events like the sample below. The final field is the message's size, in bytes. We want to extract this as a numeric value, for analysis in Cribl Stream or downstream services:

```
03:19 03:22 SMTPD (00180250) [209.221.59.70] C:\IMail\spool\D28de0018025017cd.SMD
3827
```

Again, we can accomplish this with two Functions:

1. A Regex Extract Function. To capture a substring of digits that follows six other substrings (all separated by white space), we set the **Regex** field to: `\S+\s+\S+\s+\S+\s+\S+\s+\S+\s+\S+\s+(?<bytes>\d+)`
2. Then use Numerify.

14.20. OTLP Logs

The OTLP Logs Function ingests logs sent by the Cribl Stream OTel Source, normalizes (that is, formats) and optionally batches them, and sends them on to the Cribl Stream OTel Destination.

How the OTel Source Transforms Log Events

The events that this Function processes can only come from the Cribl Stream OTel Source which itself always ingests events in the form of OTLP logs protocol buffers (protobufs). These protobufs are structures that nest objects within other objects. When you get to the bottom of the nested structure, what you've got is log entries!

Each OTLP logs protobuf contains top-level `ResourceLogs` objects that associate an OTLP Resource with one or more log entries. To get familiar with the internal nomenclature of the OTLP logs protobuf, let's look at its nested objects from the top down.

Object	Description
Log protobuf message	Contains one or more `ResourceLogs`
`ResourceLogs`	Contains one `Resource` and one or more `ScopeLogs`
`ScopeLogs`	Contains one `Scope` and one or more `LogRecords`
`LogRecord`	The log entry

The OTel Source takes these OTLP log protobufs and transforms them into Cribl events that the OTLP Logs Function can ingest.

The OTel Source can send Cribl events in two forms: with or without logs extracted. Which form it sends depends on whether **Advanced Settings** > **Extract logs** is turned on or off in the Source.

When **Extract logs** is off:

- The OTLP Logs Function cannot batch the incoming events, even when **Batch OTLP logs** is turned on. The Function just cleans up the events and sends them on.
- The Cribl events sent to the OTLP Logs Function can include log events, non-log events, or both. The OTLP Function will always send log events through to the OTel Destination. If non-log events arrive, the Function will send them through or drop them, depending on whether its **Drop non-log events** setting is turned on or off.

When **Extract logs** is on:

- The OTLP Logs Function will batch the incoming events if **Batch OTLP logs** is turned on. Otherwise the Function just cleans up the events and sends them on.
- Compared to the original OTLP log protobufs, the Cribl events sent by the OTel Source have a flatter structure: the `resource` and `scope` objects and the extracted records are all peers. The OTLP Logs Function detects this, and if batching is enabled, batches the events such that for each `resource` object there is one `scope_logs` object containing multiple pairs of `scope` and `log_records` objects.

How This Function Batches Logs

For OTLP logs, batching means grouping log events that arrive within a specified time window and whose OTLP Resource Attributes are identical. For example, if the Function receives a thousand events in a period of 30 seconds and those events originate from a set of 100 servers, each event will have a set of Resource Attributes, one or more of which will describe the server where it came from. For simplicity, let's assume that the Resource Attributes of all these events are identical except for the ones that describe the server. The Function will create separate batches for each of those 100 servers because the Resource Attributes differentiate events based on which server it comes from.

Each incoming log event contains both its resource attributes and the log entry itself. In a batch, the resource attributes need only be written once, greatly reducing the amount of data sent over the wire.

For detailed insights into events that passed through the Function but were dropped, set the logging level for channel `func:otlp_logs` to `debug`, and there will be a stats log message output once per minute with the relevant information.

Usage

Ideally, this Function should process events and/or logs **after** other Functions have formatted them. Therefore Cribl recommends that you place this Function last in the Pipeline.

If no metric events appear in Simple or Full Preview, try enabling **Show Dropped Events**: If Cribl Stream processed and dropped events, there's an issue with your data. Either the incoming events are malformed, or, the resource attributes in those events do not match any of the resource attribute prefixes you configured. See **Resource attribute prefixes** below.

Filter: Filter expression (JS) that selects data to feed through the Function. The default `true` setting passes all events through the Function.

Description: Simple description of this Function's purpose in this Pipeline. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Drop non-log events: Whether or not to drop any non-log events. Defaults to `No`.

Batch OTLP logs: Whether to batch OTLP logs by shared top-level `resource` attributes. The Function only tries to batch events where the logs have been extracted – that is, where the sending OTel Source had **Advanced Settings** > **Extract logs** enabled when processing the events.

When enabled, exposes these additional controls:

- **Batch size**: The **number of log records** after which a batch will be sent, regardless of whether the timeout duration has been reached.
- **Batch timeout (ms)**: Time duration after which a batch will be sent regardless of size. Defaults to `200` milliseconds.
- **Batch size limit (kb)**: Maximum batch size **in kilobytes**. `0` means no limit.
- **Batch log metadata keys**: Optionally, add metadata keys that you want the Function to create batcher instances for, in addition to any batching based on resource attributes. When set, this processor will create one batcher instance per distinct combination of values in the metadata.
- **Metadata cardinality limit**: Limits the number of unique combinations of metadata key values that the batcher will process. Once the limit has been reached, the Function will drop events whose metadata key values constitute a new combination. Defaults to `1000`.

Basic Example

Filter: `__inputId=='open_telemetry:open_telemetry'`

This will process all events from an OTel Source; in this example we assume that the Source has **Advanced Settings** > **Extract logs** turned off. Metrics and traces will either be dropped, or emitted without modification, depending on configuration. Unextracted logs will be formatted and emitted; extracted logs will be formatted and either batched or emitted (again depending on configuration).

The Function converts the Cribl event such that the Cribl Stream OTel Destination can ingest it and convert it to an OTLP log event.

See the sample incoming and outgoing events.

Advanced Example

Here, we have two incoming events sent by a OTel Source with **Advanced Settings** > **Extract logs** turned on.

The Function, with **Batch OTLP logs** turned on, batches the Cribl events such that the Cribl Stream OTel Destination can ingest the batch and convert to a batched OTLP log event.

See the sample incoming and outgoing events.

Sample Events

Basic Example Incoming Event

From OTel Source with extract logs turned off.

```
{
    "resource": {
        "attributes": {
            "telemetry.sdk.language": "python",
        }
    },
    "scope_logs": [{
        "scope": {
            "name": "opentelemetry.sdk._logs._internal",
            "version": "unknown",
        },
        "log_records":[{
            "time_unix_nano": 1717010319837985500,
            "observed_time_unix_nano": 0,
            "body": "Recommendation service started, listening on port 9001",
            "dropped_attributes_count": 0,
            "severity_number": 9,
            "severity_text": "INFO"
        }],
    }],
    "_time": 1717010325.183
}
```

Basic Example Outgoing Event

When the OTLP Function processes the incoming event above, the event below is the result. It does not matter whether **Batch OTLP logs** is turned on or off – the Function will not try to batch because in the incoming event, logs were not extracted.

```
{
    "resource": {
        "attributes": [{
            "key": "telemetry.sdk.language",
            "value": {
                "string_value": "python"
            }
        }]
    },
    "scope_logs": [{
        "scope": {
            "name": "opentelemetry.sdk._logs._internal",
            "version": "unknown",
            "attributes": []
        },
        "log_records":[{
            "time_unix_nano": 1717010319837985500,
            "observed_time_unix_nano": 0,
            "body": { "string_value": "Recommendation service started, listening on
            "attributes": [],
            "dropped_attributes_count": 0,
            "severity_number": 9,
            "severity_text": "INFO"
        }],
    }],
    "_time": 1717010325.183
}
```

Advanced Example Incoming Events

In order to show batching in the outgoing events, let's use two incoming events from an OTel Source where **Advanced Settings > Extract logs** is turned on.

Incoming Sample Event 1

```
{
    "schema_url": "https://opentelemetry.io/schemas/1.23.1",
    "resource": {
        "attributes": {
            "telemetry.sdk.language": "python",
        }
    },
    "scope": {
        "name": "kafka.server.KafkaRaftServer",
        "version": "unknown",
    },
    "time_unix_nano": 1717016223073301200,
    "observed_time_unix_nano": 1717016223073302800,
    "body": "[KafkaRaftServer nodeId=1] Kafka Server started",
    "dropped_attributes_count": 0,
    "severity_number": 9,
    "severity_text": "INFO",
    "_time": 1717016223.0733013
}
```

Incoming Sample Event 2

```
{
    "schema_url": "https://opentelemetry.io/schemas/1.23.1",
    "resource": {
        "attributes": {
            "telemetry.sdk.language": "python",
        }
    },
    "scope": {
        "name": "kafka.server.KafkaBoatServer",
        "version": "unknown",
    },
    "time_unix_nano": 1717016223073401200,
    "observed_time_unix_nano": 1717016223073402800,
    "body": "[KafkaBoatServer nodeId=1] Boat Server started",
    "dropped_attributes_count": 0,
    "severity_number": 9,
    "severity_text": "INFO",
    "_time": 1717016224.0733013
}
```

Advanced Example Outgoing Batched Events

When the OTLP Function processes the incoming events above, the event below is the result. Here, **Batch OTLP logs** is turned on – the Function is able to batch because in the incoming events, logs were extracted.

```
{
    "resource": {
        "attributes": [{
            "key": "telemetry.sdk.language",
            "value": {
                "string_value": "python"
            }
        }]
    },
    "scope_logs": [
        {
            "scope": {
                "name": "kafka.server.KafkaRaftServer",
                "version": "unknown",
                "attributes": []
            },
            "log_records":[{
                "time_unix_nano": 1717016223073301200,
                "observed_time_unix_nano": 1717016223073302800,
                "body": { "string_value": "[KafkaRaftServer nodeId=1] Kafka Server s
                "attributes": [],
                "dropped_attributes_count": 0,
                "severity_number": 9,
                "severity_text": "INFO",
                "_time": 1717016223.0733013
            }],
        },
        {
            "scope": {
                "name": "kafka.server.KafkaBoatServer",
                "version": "unknown",
                "attributes": []
            },
            "log_records":[{
                "time_unix_nano": 1717016223073401200,
                "observed_time_unix_nano": 1717016223073402800,
                "body": { "string_value": "[KafkaBoatServer nodeId=1] Boat Server st
                "attributes": [],
                "dropped_attributes_count": 0,
                "severity_number": 9,
                "severity_text": "INFO",
```

```
                "_time": 1717016224.0733013
            }],
        }
    ],
    "_time": 1717010325.183
}
```

14.21. OTLP Metrics

The OTLP Metrics Function transforms dimensional metrics events into the OTLP (OpenTelemetry Protocol) format. This Function can be used to send metric events (events that contain the internal field `__criblMetrics`) to any OpenTelemetry Metrics-capable destinations.

For detailed insights into events that passed through the Function but were dropped, set the logging level for channel `func:otlp_metrics` to `debug`, and there will be a stats log message output once per minute with the relevant information.

This Function will delete the internal attribute `__criblMetrics`, making events only suitable for destinations that use the OTLP format.

Usage

Ideally, this Function should process events and/or metrics **after** other Functions have formatted them. Therefore Cribl recommends that you place this Function last in the Pipeline.

If no metric events appear in Simple or Full Preview, try enabling **Show Dropped Events**: If Cribl Stream processed and dropped events, there's an issue with your data. Either the incoming events are malformed, or, the resource attributes in those events do not match any of the resource attribute prefixes you configured. See **Resource attribute prefixes** below.

Filter: Filter expression (JS) that selects data to feed through the Function. The default `true` setting passes all events through the Function.

Description: Simple description of this Function's purpose in this Pipeline. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Resource attribute prefixes: The prefixes of top-level attributes to add as resource attributes. See the OpenTelemetry documentation for Resource Semantic Conventions.

- Use periods and underscores for precise matching. For example, `process.path`.
- Remove all the prefixes if you want to bring none of the resources over.
- Use the Eval Function to copy nested attributes to the top level for matching. For example, configure **Evaluate Fields** as follows to create a new top-level field named `process_path` with the value copied

from the nested attribute `process.path`. This new field can then be matched using the OTLP Metrics Function's **Resource attribute prefixes**:

- **Name**: `process_path`
- **Value Expression**: `process.path`

Drop non-metric events: Whether or not to drop any non-metric events.

OTLP version: The drop-down offers `0.10.0` (default) and `1.3.1`. See

Batch OTLP metrics: Whether to batch OTLP metrics by shared top-level `resource` attributes. When enabled, exposes these additional controls:

- **Batch size**: The number of metric data points after which a batch will be sent, regardless of whether the timeout duration has been reached.
- **Batch timeout (ms)**: Time duration after which a batch will be sent regardless of size.
- **Batch size limit (kb)**: Maximum batch size. `0` means no limit.
- **Batch metrics metadata keys**: Optionally, add metadata keys that you want the Function to create batcher instances for, in addition to any batching based on resource attributes. When set, this processor will create one batcher instance per distinct combination of values in the metadata.
- **Metadata cardinality limit**: Limits the number of unique combinations of metadata key values that the batcher will process. Once the limit has been reached, the Function will drop events whose metadata key values constitute a new combination.

Choosing or Combining OTLP Versions

Because this Function resides in between Cribl Stream OTel Sources and OTel Destinations, each of which can be independently configured to use the same or different OTLP versions, it's important to know the effects of different choices and combinations.

- Cribl Stream supports starting with OTLP 0.10.0 events and converting them to OTLP 1.3.1 events, but does not support the reverse (1.3.1 to 0.10.0).
- When **OTLP version** is set to `1.3.1`, Cribl Stream will attempt to convert metrics or logs formatted for any previous version to 1.3.1. Since beginning with version 1.0.0, OTLP has introduced no new breaking changes, you can use the Function configured for OTLP 1.3.1 as an "OTLP version 0.x to version 1" converter. Most downstream OTLP receivers comply with OTLP 1.0.0 at minimum; but you should verify this for whatever downstream receiver you use.

Basic Example

Filter: `__inputId=='prometheus_rw:prom_rw_in'`

This will grab all events from a Prometheus Remote Write Source and convert the metrics to OTLP format using only default settings in the Function.

Ensure that the internal attribute `__criblMetrics` does not contain `null` or blank values in any of the child object arrays.

See the sample incoming and outgoing events.

Advanced Example

Here, we have two incoming events sent by a OTel Source with **Advanced Settings** > **Extract logs** turned on.

The Function, with **Batch OTLP logs** turned on, batches the Cribl events such that the Cribl Stream OTel Destination can ingest the batch and convert to a batched OTLP metric event.

See the sample incoming and outgoing events.

Sample Events

Basic Example Incoming Event

Here is an example incoming event.

```
{
  "__criblEventType": "event",
  "__ctrlFields": [],
  "__final": false,
  "__cloneCount": 0,
  "_time": 1700236380.37,
  "_value": 123.456,
  "_metric": "cribl_logstream_health_outputs",
  "_metric_type": "gauge",
  "cribl_host": "P4MD6R-Pv8x",
  "cribl_wp": "w0",
  "event_host": "P4MD6R-Pv8x",
  "event_source": "cribl",
  "host": "P4MD6R-Pv8x",
  "output": "open_telemetry:otel_webhook_dest",
  "source": "cribl",
  "__criblMetrics": [
    {
      "nameExpr": ["_metric"],
      "values": ["_value"],
      "types": ["gauge"],
      "dims": [
        "cribl_host",
        "cribl_wp",
        "event_host",
        "event_source",
        "host",
        "output",

```

Advanced Example Incoming Events

In order to show batching in the outgoing events, let's use two incoming events from an OTel Source where **Advanced Settings** > **Extract metrics** is turned on.

Incoming Sample Event 1 – Gauge Metric

```
{
    "_time": 1700236380.37,
    "resource":
    {
        "attributes":
        [
            {
                "key": "service.name",
                "value":
                {
                    "string_value": "serviceName"
                }
            },
            {
                "key": "service.instanceId",
                "value":
                {
                    "string_value": "serviceInstanceId"
                }
            },
            {
                "key": "system.name",
                "value":
                {
                    "string_value": "systemName"
                }
            },
            {

14.22. OTLP Traces

The OTLP Traces Function ingests traces sent by the Cribl Stream OTel Source, normalizes (that is, formats) and optionally batches them, and sends them on to Cribl Stream Destinations.

How the OTel Source Transforms Trace Events

This Function can process only events coming from the Cribl Stream OTel Source, which always ingests events in the form of OTLP trace protocol buffers (protobufs). These protobufs are structures that nest objects within other objects. Each OTLP trace protobuf contains top-level `ResourceSpans` objects that associate an OTLP Resource with one or more spans.

Object	Description
Trace protobuf message	Contains one or more `ResourceSpans`
`ResourceSpans`	Contains one Resource and one or more `ScopeSpans`
`ScopeSpans`	Contains one Scope and one or more `Span`
`Span`	The trace entry

How This Function Batches Traces

For OTLP traces, batching means grouping extracted spans that arrive within a specified time window and whose OTLP Resource Attributes are identical. The Function will create separate batches for each unique combination of resource attributes and metadata keys.

Usage

Ideally, this Function should process events and/or traces **after** other Functions have formatted them. Therefore, Cribl recommends that you place this Function last in the Pipeline.

Filter: Filter expression (JS) that selects data to feed through the Function. The default `true` setting passes all events through the Function.

Description: Simple description of this Function's purpose in this Pipeline. Defaults to empty.

Final: If toggled to **Yes**, stops feeding data to the downstream Functions. Defaults to **No**.

Drop non-trace events: Whether or not to drop any non-trace events. Defaults to **No**.

OTLP version: Specifies the version of the OTLP protocol used for formatting and sending output events downstream.

- Version `0.10.0` (Default): This version uses the older OTLP format. It is recommended for users who need compatibility with legacy systems.
- Version `1.3.1`: This version supports newer OTLP features, including `scope_spans` instead of `instrumentation_library_spans`, and additional fields like `flags` in `Link` and `Span` objects. It is recommended for users who want to leverage the latest OTLP features and improvements.

Batch OTLP traces: When set to **Yes**, the Function batches together extracted spans that have the same resource and (optionally) metadata keys until they reach a flush criteria. When set to **No**, the Function will emit extracted/unextracted span events that have been normalized, but they will not be combined with other spans - each event passed to the Function will result in one event being returned.

When set to **Yes**, exposes these additional controls:

- **Batch size**: The number of spans after which a batch will be sent, regardless of whether the timeout duration has been reached.
- **Batch timeout (ms)**: Time duration after which a batch will be sent regardless of size. Defaults to `200` milliseconds.
- **Batch size limit (kb)**: Maximum batch size in kilobytes. `0` means no limit.
- **Batch trace metadata keys**: Optionally, add metadata keys that you want the Function to create batcher instances for, in addition to any batching based on resource attributes. When set, this processor will create one batcher instance per distinct combination of values in the metadata.
- **Metadata cardinality limit**: Limits the number of unique combinations of metadata key values that the batcher will process. Once this limit is reached, events with new combinations of metadata key values will be dropped. Defaults to `1000`.

Example

This example demonstrates how the OTLP Traces Function processes and batches trace events when the **Batch OTLP traces** setting is enabled. The settings used in this example are:

- **Batch OTLP traces**: **Yes**
- **Batch size**: 2
- **Batch timeout (ms)**: `200`
- **Batch size limit (kb)**: `0` (no limit)
- **Batch trace metadata keys**: **None**

- Metadata cardinality limit: `1000`
- Drop non-trace events: Yes

Incoming Event 1

```
{
  "resource": {

              }
            }
          ]
        }
      ]
    }
  ]
}
```

14.23. Parser

The Parser Function can be used to extract fields out of events, or to reserialize (rewrite) events with a subset of fields. Reserialization will maintain the format of the events.

For example: If an event contains comma-delimited fields, and `fieldA` and `fieldB` are filtered out, those fields' positions will be set to `null`, but not deleted completely.

Parser cannot remove fields that it did not create. A subsequent Eval Function can do so.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning evaluate all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Operation mode: **Extract** will create new fields. **Reserialize** will extract, filter fields, and then reserialize.

Type: Parser/Formatter type to use. Options:

- CSV – selecting this type requires you to escape certain characters.
- Extended Log File Format (ELFF)
- Common Log Format (CLF)
- K=Value Pairs – selecting this type requires you to escape certain characters.
- JSON Object
- Delimited Values – selecting this type expands the UI.

The following two additional options appear in the drop-down, but can only be used when **Operation mode** is set to **Extract**; both expand the UI:

- Grok
- Regex Extract

Library: Select an option from the Parsers Library. Although specifying a Library will auto-generate an example list of fields, the list may still need to be modified to accommodate the desired fields from the events as well as the actual field order.

Source field: Field that contains text to be parsed. Not usually needed in Reserialize mode.

Destination field: Name of field in which to add extracted and serialized fields. If multiple new fields are created and this field is populated, then all new fields are created as elements of an array. The array's name will be set to this field's value. If you want all new fields to be independent, rather than in an array, then specify them using **List of fields**, below. (Extract and Reserialize modes only.)

Clean fields: This option appears for **Type: K=V Pairs**. Toggle to `Yes` to clean field names by replacing non-alphanumeric characters with `_`. This will also strip leading and trailing `"` symbols.

List of fields: Fields expected to be extracted, in order. If not specified, Parser will auto-generate fields.

List of Fields will not display, when the Parser/Formatter **Type** is set to `JSON Object` or `Key=Value Pairs`. This option is only relevant for structured formats like `CSV`, `CLF`, and `ELFF`. It helps name extracted fields when they aren't explicitly defined in the raw data. For `JSON Object` and `Key-Value Pair` formats, field names are inherent and this option is ignored.

Fields to keep: List of fields to keep. Supports wildcards (`*`). Takes precedence over **Fields to remove**. Supports nested addressing. See details below.

Fields to remove: List of fields to remove. Supports wildcards (`*`). Cannot remove fields matching **Fields to keep**. Supports nested addressing. See details below.

Fields filter expression: Expression to evaluate against each field's `{index, name, value}` context. Return truthy to keep fields, or falsy to remove fields. Index is zero-based. See details below.

Types That Expand the UI

Setting **Type** to **Delimited Values** displays the following extra options:

- **Delimiter**: Delimiter character to split value. Defaults to comma (`,`). You can also specify pipe (`|`) or tab characters.
- **Quote char**: Character used to quote literal values. Defaults to `"`.
- **Escape char**: Character used to escape the delimiter character. Defaults to: `\`
- **Null value**: Field value representing the null value. These fields will be omitted. Defaults to: `-`

Setting **Type** to **Grok** displays the Grok Function UI; setting it to **Regex Extract** displays the Regex Extract UI. These Parser preserve all previewing and editing. Also, **Grok** enables you to bring Grok Patterns into Cribl Search.

Advanced Settings

Allowed key characters: Enter characters permitted in a key name, even though they are normally separator or control characters. Separate entries with a tab or hard return. This setting does not affect how the value is parsed.

Allowed value characters: Enter characters permitted in a value name, even though they are normally separator or control characters. Separate entries with a tab or hard return. This setting does not affect how the key is parsed.

Fields/Values Interaction

This Function's **Filter**, **Type**, **Fields to keep**, **Fields to remove**, and **Fields filter expression** settings interact as follows.

Order of Evaluation

The order is: **Fields to keep** > **Fields to remove** > **Fields filter expression**.

Precedence

If a field is in both **Fields to keep** and **Fields to remove**, **Fields to keep** takes precedence.

If a field is in both **Fields to remove** and **Fields filter expression**, **Fields to remove** takes precedence.

Negation

Both **Fields to remove** and **Fields to keep** support negated terms. When you use negated terms, your fields list is order-sensitive. E.g., `!foobar, foo*` means "All fields that start with `foo`, except `foobar`." However, `!foo*, *` means "All fields, except for those that start with `foo`."

Characters to Escape

Particular characters need special treatment when parsed when you select the Key=Value Pairs or CSV Parser/Formatter type.

Key-Value Pairs

When a Parser Function's **Type** is set to `Key=Value Pairs`: Within your data, field values that contain an `=` delimiter **must** be surrounded by quotes (`"..."`), or the Function will return unexpected results. As an example, here is a set of four fields and values, in which two values are quoted to parse predictably:

```
one=1,two="value=2",three=3,four="value=4"
```

These would resolve to the following parsed values:

Field Name	Value
one	1
two	"value=2"
three	3
four	"value=4"

CSV

When a Parser Function's **Type** is set to CSV: Within your data, column values that contain quotes or commas **must** quote those characters, or the Function will return unexpected results. To illustrate this, here is a properly formatted example of four CSV values:

```
"value with ""escaped"" quotes is 1",2,3,"you know, this is 4"
```

The first value includes quotation marks, which are each escaped with surrounding quotes, and the whole value is delimited by outer quotes. The fourth value includes a comma, so that value is delimited by outer quotes. These four columns would cleanly evaluate to:

---

value with "escaped" quotes is 1
2
3
you know, this is 4

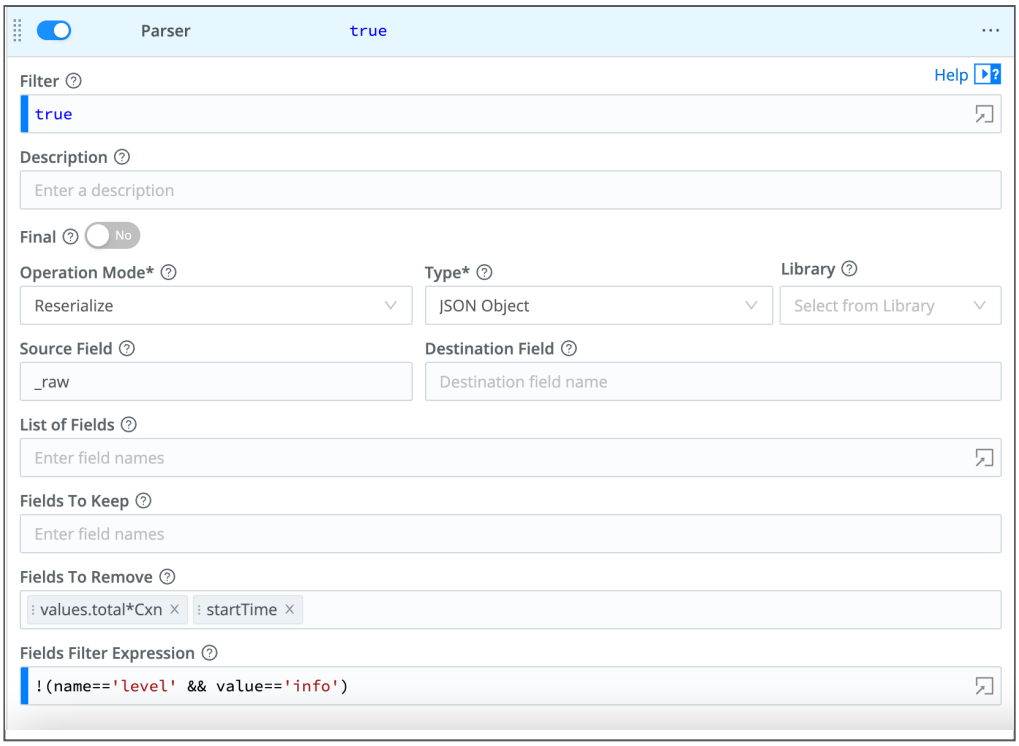
Examples

The following examples show creating and dropping fields, reserialization, and serializing to CSV versus JSON.

Example 1

Insert the following sample, using **Sample Data** > **Import Data**: `2019/06/24 05:10:55 PM Z a=000,b=001,c=002,d=003,e=004,f=005,g1=006,g2=007,g3=008`

Create the following test Parser Function (or import this Pipeline: https://raw.githubusercontent.com/weeb-cribl/cribl-samples/master/parser/functions/parser/parser_1.json).



Parser Function initial configuration

First, set the **Type** to `Key=Value Pairs`.

Scenario A

Keep fields `a, b, c`. Drop the rest.

Expected result: `a, b, c`

- Fields to Keep: `a, b, c`
- Fields to Remove: `*`
- Fields Filter Expression: <empty>

Result: The event will gain four new fields and values, as follows.

- a: `000`
- b: `001`
- c: `002`
- cribl_pipe: `parser2`

Scenario A result

You can check your stats by clicking the **Preview** pane's **Basic Statistics** (chart) button. In the resulting pop-up, the **Number of Fields** should have incremented ty four.

Now that you have the hang of it, try out the other simple scenarios below.

Scenario B

Keep fields `a`, `b`, those that start with `g`. Drop the rest.

Expected result: `a`, `b`, `g1`, `g2`, `g3`

- Fields to keep: `a`, `b`
- Fields to remove: [empty]
- Fields filter expression: `name.startsWith('g')`

Scenario C

Keep fields `a`, `b`, those that start with `g` but only if value is `007`. Drop the rest.

Expected result: `a`, `b`, `g2`

- Fields to keep: `a`, `b`
- Fields to remove: [empty]
- Fields filter expression: `name.startsWith('g') && value=='007'`

Scenario D

Keep fields `a`, `b`, `c`, those that start with `g`, unless it's `g1`. Drop the rest.

Expected result: `a, b, c, g2, g3`

- Fields to keep: `a, b, c`
- Fields to remove: `g1`
- Fields filter expression: `name.startsWith('g')`

Scenario E

Keep fields `a, b, c`, those that start with `g` but only if index is greater than `6`. Drop the rest.

Expected result: `a, b, c, g2, g3`

- Fields to keep: `a, b, c`
- Fields to remove: [empty]
- Fields filter expression: `name.startsWith('g') && index>6`

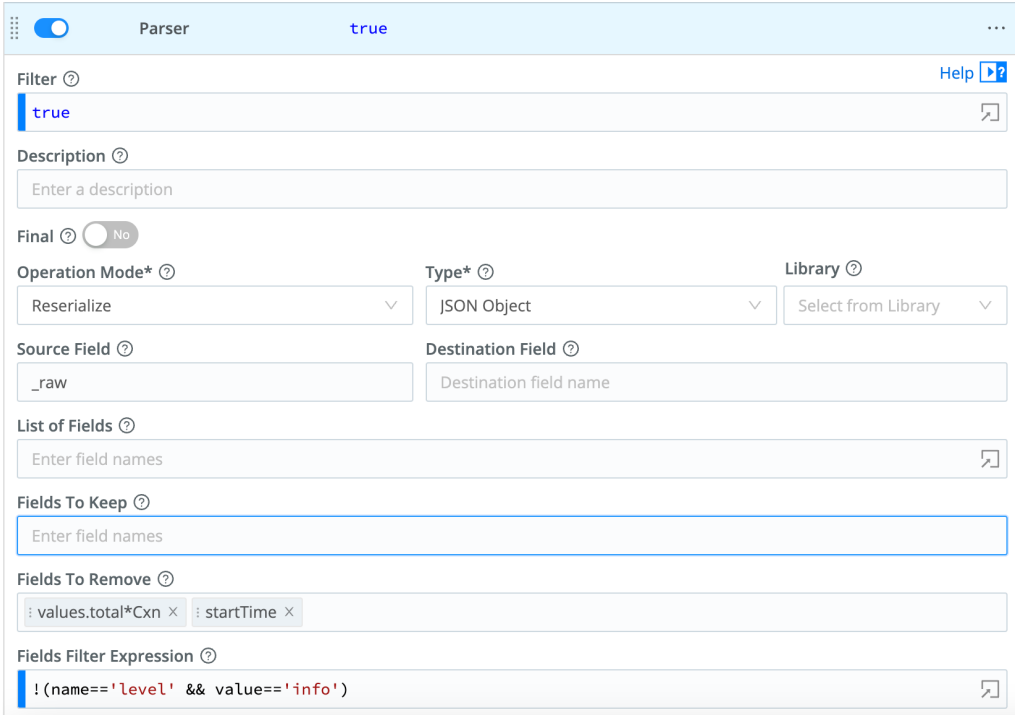
The `index` refers to the location of a field in the array of all fields extracted by **this** Parser. It is zero-based. In the case above, `g2` and `g3` have `index` values of `7` and `8`, respectively.

Example 2

Assume we have a JSON event that needs to be **reserialized**, given these requirements:

1. Remove the `level` field only if it's set to `info`.
2. Remove the `startTime` field, and all fields in the `values.total.` path that end in `Cxn`.

Parser Function configuration:



Parser Function configuration for Example 2

JSON event after being processed by the Function:

Example 2 event transformation

Example 3

Insert the following sample, using **Sample Data** > **Import Data**:

```
2019/06/24 15:25:36 PM Z a=000,b=001,c=002,d=003,e=004,f=005,g1=006,g2=007,g3=008,
```

For all scenarios below, first create a Parser Function to extract all fields, by setting the **Type** to `Key=Value Pairs`. Then add a second Parser Function with the configuration shown under **Parser 2**.

Scenario A

Serialize fields `a, b, c, d` in CSV format.

Expected result: `_raw` field will have this value `000,001,002,003`

Parser 2:

- Operation mode: `Serialize`
- Source field: [empty]
- Destination field: [empty]
- Type: `CSV`
- List of fields: `a, b, c, d` (needed for positional formats)

Scenario B

Serialize fields `a, b, c` in JSON format, under a field called `bar`.

Expected result: `bar` field will be set to: `{"a":"000","b":"001","c":"002","d":"003"}`

Parser 2:

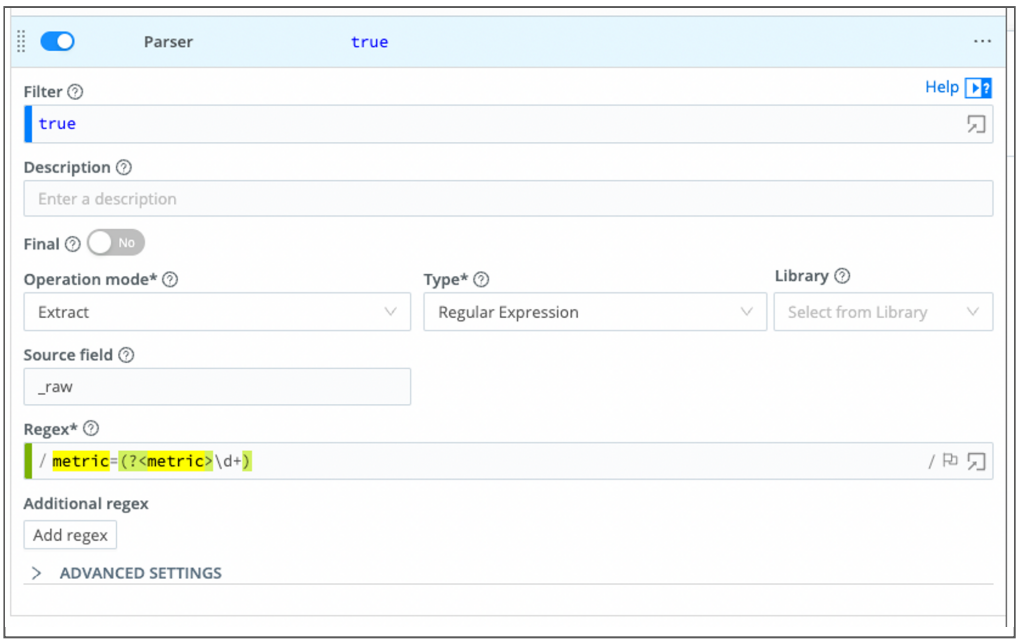
- Operation mode: `Serialize`
- Source field: [empty]
- Destination field: `bar`
- Type: `JSON`
- List of fields: [empty]
- Fields to keep: `a, b, c, d`

Example 4

Assume we have a simple event that looks like this:

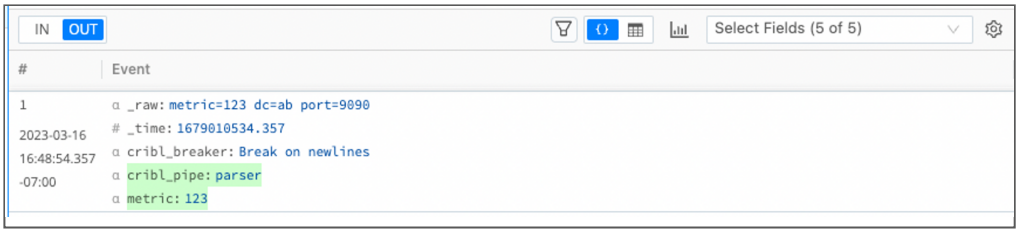
```
metric=123 dc=ab port=9090
```

If we want to extract only the `metric` field, we can configure a Parser of **Type** `Regular Expression`, where the **Regex** field is set to `metric=(?<metric>\\d+)`:



Parser Function configuration for Example 4

The output will look like this:



Parser Function regex output

Example 5

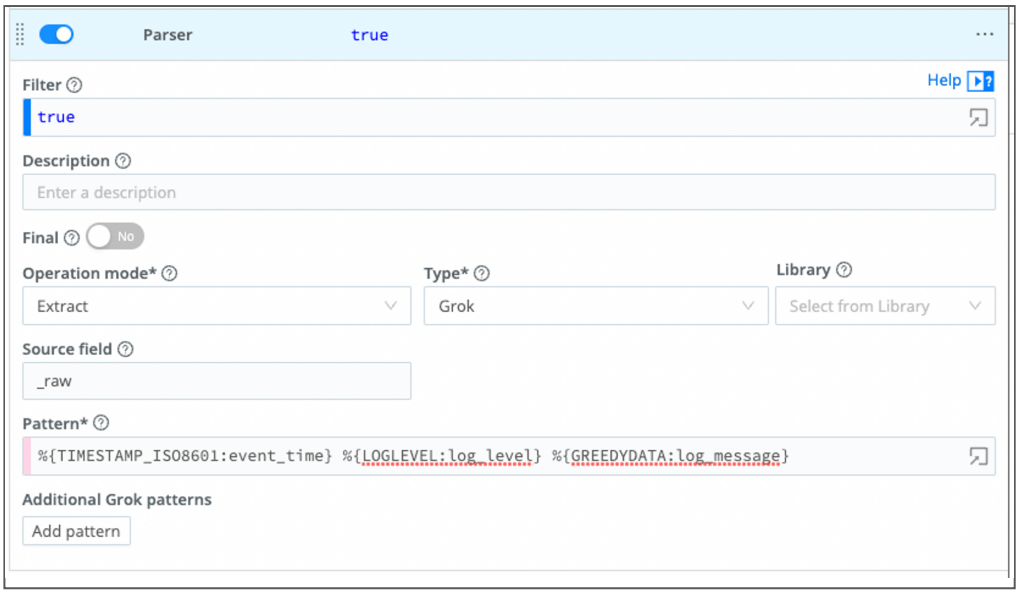
Assume we have an event that looks like this:

```
2020-09-16T04:20:42.45+01:00 DEBUG This is a sample debug log message
```

We can use a Grok pattern to parse the event so that the timestamp, log level, and the message are separated. A Parser of **Type** `Grok` with the following Pattern will work:

```
%{TIMESTAMP_ISO8601:event_time} %{LOGLEVEL:log_level} %{GREEDYDATA:log_message}
```

The Parser Function configuration looks like this:



Parser Function configuration for Example 5

The output will look like this:

Parser Function grok output

14.24. Publish Metrics

The Publish Metrics Function extracts, formats, and outputs metrics from events.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Overwrite: If set to `Yes`, overwrite previous metric specs. Otherwise, append. Defaults to `No`.

Metrics

Add Metrics: List of metrics to extract from the event and format. Destinations can pass the formatted metrics to a metrics aggregation platform. Click **Add Metrics** to add new rows containing the following options:

- **Event field name**: The name of the field (in the event) that contains the metric value. Should contain only letters, numbers, underscores (`_`), and `.` characters (to separate names in nested structures).
- **Metric name expression**: JavaScript expression to evaluate the metric field name. Defaults to the **Event field name** value.

  The JavaScript expression will evaluate the metric field name only after the metrics are processed for transport to the Destination. While in the processing Pipeline, the metric name expression appears as a literal.

  To have metric names evaluated in preview, enable the Enhance Metric Output setting.

- **Metric type**: Select `Gauge` (the default), `Counter`, `Timer`, `Distribution`, `Summary`, or `Histogram`. General definitions that can vary across senders:
  - `Gauge`: A numeric value that can increase or decrease over time – like a temperature or pressure gauge.
  - `Counter`: A cumulative numeric value – it can only increase over time.
  - `Timer`: Generally measures how long a given event type takes (duration), and how often it occurs (frequency).
  - `Distribution`: The statistical distribution of a set of values over a time interval. (This type generally provides raw data, not an aggregation.)

- `Summary`: Tracks the count, sum, and average of the values. Optionally, also tracks quantiles across the values.
- `Histogram`: Tracks the count, sum, and average of the values. Also groups the observations in their corresponding intervals, or buckets.

Remove Metrics: Optionally, enter a List of field names to look for when removing metrics. Where a metric's field name matches an element in this list, Cribl Stream will remove that metric from the event.

Dimensions

Add Dimensions: Optional list of dimensions to include in events. Supports wildcards. If you don't specify metrics, values will be appended to every metric found in the event. When you add a new metric, dimensions will be present only in those new metrics. Defaults to `!_* *`.

Remove Dimensions: Optional list of dimensions to associate with every extracted metric value. Leave blank if this Function processes output from the Aggregations Function as dimensions will be automatically discovered.

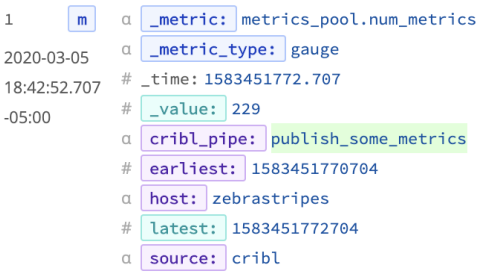
Overwrite: If set to `Yes`, overwrite previous metric specs. Otherwise, append. Defaults to `No`.

The **Add Dimensions** and **Remove Dimensions** fields support wildcards and negated terms. When you use negated terms, the list is order-sensitive. E.g., `!foobar` before `foo*` means "All fields that start with `foo`, except `foobar`." However, `!foo*` before `*` means "All fields, except for those that start with `foo`."

Cribl Stream can send out multi metrics, but this must be configured on compatible Destinations.

Fields Color Coding

On the right Preview pane's **OUT** tab, the Publish Metrics Function adds the following color codes to field labels:



Dimension: purple | **Value**: cyan (light blue) | **Info**: dark blue

These are in addition to the color codes applied to field values, which are listed here.

Examples

Scenario A:

Assume we're working with AWS VPC Flowlog events that have the following structure:

```
version account_id interface_id srcaddr dstaddr srcport dstport protocol packets bytes start end action log_status
```

For example:

```
2 99999XXXXX eni-02f03c2880e4aaa3 10.0.1.70 10.0.1.11 9999 63030 6 6556 262256 1554562460 1554562475 ACCEPT OK
```

... and we want to use values of `packets` and `bytes` as metrics across these dimensions: `action`, `interface_id`, and `dstaddr`.

To reference the `packets` and `bytes` fields by name, as `'packets'` and `'bytes'`, our Pipeline will need a Parser Function before the Publish Metrics Function.

Parser Function

Filter: Set as needed Operation mode: Extract Type: Extended Log File Format (automatically set when specifying a library) Library: AWS VPC Flow Logs Source: `_raw` (No need to specify any other fields.)

Publish Metrics Function

Below, the `metric_name` prefix was arbitrarily chosen. Because there is no JavaScript expression to evaluate – i.e., this is literal text – the strings specified for the **Metric name expression** will be identical to those in the final metrics data sent to the Destination. See Raw Output below.

Metrics

Event Field Name	Metric Name Expression	Metric Type
`bytes`	`` `metric_name.bytes` ``	**Gauge**
`packets`	`` `metric_name.packets` ``	**Gauge**

Dimensions

```
action interface_id dstaddr
```

All specified dimension names must align with those from the original event. When you preview the Function's output, the metrics and dimensions will all have special highlighting to separate them from other fields. Additional highlighting is used to differentiate the metrics from the dimensions. (If one or more metrics/dimensions are not highlighted as expected, check the Function's configuration.)

Raw Output

```
metric_name.bytes:262256|g#action:REJECT,interface_id:eni-
02f03c2880e4aaa3,dstaddr:10.0.1.11

metric_name.packets:6556|g#action:REJECT,interface_id:eni-
02f03c2880e4aaa3,dstaddr:10.0.1.11
```

Compatible Destinations

All text after the `#` symbol represents the dimensions as key-value pairs. In order for dimension data to be included in metrics, the Destination type cannot be standard **StatsD**. However, **StatsD Extended**, **Splunk**, and **Graphite** do support dimensions.

Formatted Output

```
{
  "action": "REJECT",
  "interface_id": "eni-02f03c2880e4aaa3",
  "dstaddr": "10.0.1.11",
  "metric_name.bytes": 262256,
  "metric_name.packets": 6556,
}
```

Scenario B:

Assume that we want to extract some metrics from specific fields in PANOS logs, whose events have the following structure:

```
future_use_0,receive_time, serial_number, type, threat_content_type, future_use_1,
generated_time, source_ip, destination_ip, nat_source_ip, nat_destination_ip,
rule_name, source_user, destination_user, application, virtual_system, source_zone,
destination_zone, inbound_interface, outbound_interface, log_action, future_use_2,
```

```
session_id, repeat_count, source_port, destination_port, nat_source_port,
nat_destination_port, flags, protocol, action, bytes, bytes_sent, bytes_received,
packets, start_time, elapsed_time, category, future_use_3, sequence_number,
action_flags, source_location, destination_location, future_use_4, packets_sent,
packets_received, session_end_reason, device_group_hierarchy_level_1,
device_group_hierarchy_level_2, device_group_hierarchy_level_3,
device_group_hierarchy_level_4, virtual_system_name, device_name, action_source,
source_vm_uuid, destination_vm_uuid, tunnel_id_imsi, monitor_tag_imei,
parent_session_id, parent_start_time, tunnel_type, sctp_association_id, sctp_chunks,
sctp_chunks_sent, sctp_chunks_received
```

For example:

```
Jan 10 10:19:15 DMZ-internal.nsa.gov 1,2019/01/10
10:19:15,001234567890002,TRAFFIC,drop,2304,2019/01/10
10:19:15,209.118.103.150,160.177.222.249,0.0.0.0,0.0.0.0,InternalServer,,,not-
applicable,vsys1,inside,z1-FW-Transit,ethernet1/2,,All traffic,2019/01/10
10:19:15,0,1,63712,443,0,0,0x0,udp,deny,60,60,0,1,2019/01/10
10:19:15,0,any,0,0123456789,0x0,Netherlands,10.0.0.0-10.255.255.255,0,1,0,policy-
deny,0,0,0,0,,DMZ-internal,from-policy,,,0,,0,,N/A,0,0,0,0,1202585d-b4d5-5b4c-aaa2-
d80d77ba456e,0
```

Our goal is to use the four values of `bytes_sent`, `bytes_received`, `packets_sent`, and `packets_received` as metrics across these dimensions: `destination_ip`, `inbound_interface`, `outbound_interface`, and `destination_port`.

Here again, our Pipeline will need a Parser Function before the Publish Metrics Function.

Parser Function

Filter: Set as needed Operation mode: Extract Type: Extended Log File Format (automatically set when specifying a Library) Library: Palo Alto Traffic Source: `_raw` (No need to specify any other fields.)

Publish Metrics Function

Set up the Publish Metrics Function as follows.

Metrics

Event Field Name	Metric Name Expression	Metric Type
`bytes_sent`	`` `metric.${host}.bytes_sent` ``	Counter
`bytes_received`	`` `metric.${host}.bytes_rcvd` ``	Counter
`packets_sent`	`` `metric.${host}.pkts_sent` ``	Counter
`packets_received`	`` `metric.${host}.pkts_rcvd` ``	Counter

Added Dimensions

`destination_ip`, `inbound_interface`, `outbound_interface`, `destination_port`

Raw Output

```
metric.10.10.12.192.bytes_sent:60|c|#destination_ip:160.177.222.249,inbound_interface:et
metric.10.10.12.192.bytes_rcvd:0|c|#destination_ip:160.177.222.249,inbound_interface:eth
metric.10.10.12.192.pkts_sent:1|c|#destination_ip:160.177.222.249,inbound_interface:ethe
metric.10.10.12.192.pkts_rcvd:0|c|#destination_ip:160.177.222.249,inbound_interface:ethe
```

Here again, all text after the `#` symbol represents the dimensions as key-value pairs. (See the Compatible Destinations note above.) Unlike the first example, this example uses JavaScript expressions, which you can see evaluated in the raw output where the `${host}` has been converted to `10.10.12.192`.

14.25. Redis

The Redis Function interacts with Redis stores, setting and getting key-hash and key-value combinations. Redis' in-memory caching of these key pairs enables large lookup tables that would be cumbersome with a CSV or binary lookup file.

You can use Cribl Stream Collectors (for example, a REST Collector) to retrieve reference data from desired endpoints, and then use this Function to store the data on Redis and retrieve it to enrich your data. By default, Cribl Stream does not cache the data returned from this Redis Function, but you can enable client-side caching.

Your Redis Function can interact with three kinds of Redis instances: Standalone (the default); Redis Cluster, which scales horizontally; or Redis Sentinel, a distributed system that provides high availability.

Managing Redis Connections

When using Redis Functions, you must consider how to avoid creating large numbers of TCP connections to the Redis server (which we'll call "Redis connections"). To manage Redis connections, you start by calculating how many Redis connections your Redis Functions, other functions, and Pipelines will create using default settings. Then, to keep the overall number of connections reasonable, you configure Cribl Stream to **reuse** Redis connections.

What causes the number of Redis connections to grow large? By default, Cribl Stream creates a separate TCP connection to Redis for every Redis Function and every **reference to** a Redis Function. This means that certain usage patterns will increase the number of Redis Connections, including: sending the output of a Chain Function to a regular Pipeline that includes a Redis Function; using a Redis Function in a Source's pre-processing Pipeline; and, using a Redis Function in a Destination's post-processing Pipeline.

How can you control the number of Redis connections created? You use the **Reuse Redis connections** control. Then, when a new Redis connection is needed, **and** its connection properties are identical to those of an existing Redis connection, Cribl Stream will try to reuse the existing connection instead of creating a new one. The example below illustrates how powerfully this can affect the demands Cribl Stream places on a Redis server.

What are the connection properties that must be identical for reuse to be possible? For the different kinds of Redis instances, the relevant connection properties are, respectively:

- Standalone: username, password, and URL.
- Cluster: username, password, and all root node hosts and ports.
- Redis Sentinel: username, password, master name, and all root node hosts and ports.

In managing Redis connections, the factors you must account for include: what kind of Redis instance you're connecting to (Standalone, Cluster, or Redis Sentinel); the size of the Redis server; the number of connections

the Redis server is configured to allow; the number of other clients using the same Redis server; and so on.

Where to configure **Reuse Redis connections** in the UI depends on how you have deployed Cribl Stream:

- Distributed deployment: Navigate to **Limits** at the Worker Group level.
- Single-instance deployment: Navigate to **Limits** at the global (**General Settings**) level.

Example: Managing Redis Connections

Referencing a Redis Function from a Pipeline and/or another Function can dramatically multiply the number of Redis connections created, unless we mitigate this effect by applying the **Reuse Redis connections** control. Let's see how this plays out in a detailed example. Suppose we do the following:

1. Create a Pipeline (we'll call it "Pipeline Zero") that contains 10 Redis Functions that connect to the same Redis server, with identical connection properties. Cribl Stream will create 10 TCP connections to the Redis server ("Redis connections").
2. Reference Pipeline Zero in a Chain Function that's in another Pipeline. This creates 10 more connections, for a total of 20 Redis connections.
3. Reference Pipeline Zero in an additional, separate Chain Function that's in yet another Pipeline, creating 10 more connections, for a total of 30 Redis connections.
4. Use Pipeline Zero as a pre-processing Pipeline for a Source, creating 10 more connections, for a total of 40 Redis connections.
5. Use Pipeline Zero as a post-processing Pipeline for a Destination, creating 10 more connections. Now we have a grand total of 50 Redis connections.

Now consider the effect of these Pipelines within Worker Nodes and their Worker Processes. For a typical deployment scenario with 10 Worker Nodes, each of which have 10 Worker Processes, the calculation looks like this:

- 50 connections times 10 Worker Processes = 500 connections, times 10 Worker Nodes = 5000 connections.

A single Redis server can be hard-pressed to handle so many connections. Apart from that, the number of connections is unnecessarily high for the expected throughput. Let's use **Reuse Redis connections** to reduce the number of Redis connections.

Enable **Reuse Redis connections** and set **Max connections** to `4`. Now revise the calculation:

- 4 connections times 10 Worker Processes = 40 connections, times 10 Worker Nodes = 400 connections.

This reduces the number of connections by better than a factor of 10, making our deployment much less likely to overwhelm the Redis server.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Result field: Name of the field in which to store the returned value. (Leave empty to discard the returned value.)

Command: Redis command to perform. Required. (A complete list of Redis commands is at: https://redis.io/commands.)

Key: A JavaScript expression to compute the value of the key to operate on. Can also be a constant such as `username`. This is a required field. Click the icon at right to open a validation modal.

Args: A JavaScript expression to compute arguments to the operation. Click the icon at right to open a validation modal. When the expression you enter is a plain value or an array, it resembles the options and arguments of a Redis command in the Redis CLI.

For example:

- Suppose you want to `SET` a key named `_mascot`. And, of the options that the `SET` command takes, you want to use two: `GET` and `EX`. The first, `GET`, takes no arguments; the second, `EX`, takes an integer in seconds.
- You want to set `_mascot` to the value `goat`, and `EX` to 5 seconds. Here is the array you'd enter in the Args column:
  `['goat', 'GET','EX',5 ]`

Deployment Type

From the drop-down, select `Standalone`, `Cluster`, or `Sentinel`. Some of these options display additional controls below. Hostnames must be JavaScript expressions (which can evaluate to a constant value), enclosed in quotes or backticks. They can be evaluated only at init time.

Standalone

This is the default deployment type. Enter a **Redis URL** to connect to. The format is:
`[redis[s]:]//[[user][:password@]][host][:port][/db-number][?db=db-number[&password=bar[&option=value]]]`

Example:
`redis://user:secret@localhost:6379/0?foo=bar&qux=baz`

Example with no `user` specified:
`redis://secret@localhost:6379/0?foo=bar&qux=baz`

Standalone with TLS

To enable TLS, specify a Redis URL that starts with `rediss://` rather than `redis://`. This URL reveals the TLS section of the config UI.

Example:
`rediss://user:secret@localhost:6379/0?foo=bar&qux=baz`

Example with no `user` specified:
`rediss://secret@localhost:6379/0?foo=bar&qux=baz`

Cluster

Specify **Root Nodes** that the cluster will connect to. A single node is sufficient, but Cribl recommends listing two or more. Each of the **Root Nodes** consists of a **Hostname** and a **Port**.

In multi-key commands, ensure that all keys in the command are in the same hash slot. Otherwise, the command will fail. As a workaround, you can split the multi-key command into separate commands, where each command operates only on keys from a single hash slot.

Scale Reads determines which nodes in the Redis cluster should handle read commands. This setting helps optimize read performance and manage load distribution across the cluster. The available options are:

- **Masters**: Directs all read commands to master nodes only. This ensures strong consistency but may limit read scalability.
- **Replicas**: Directs all read commands to replica nodes only. This can improve read scalability but may result in stale data due to eventual consistency.
- **Masters and Replicas**: Distributes read commands across both master and replica nodes. This option balances load and improves read performance but may occasionally return stale data.

Sentinel

Specify a **Master Group Name**, plus every **Sentinel** in your Redis deployment. Each **Sentinel** consists of a **Hostname** and a **Port**.

Authentication Method

Use the **Authentication method** buttons to select one of the following options, some of which display additional controls below.

- **None**: Select this option where authentication either is not required, or is provided in the URL.
- **Basic**: This displays **Username** and **Password** fields for you to enter your Redis credentials.
- **User Secret**: This option exposes a drop-down in which you can select a stored text secret that references a Redis username and password, as described above. A **Create** link is available to store a new, reusable secret.
- **Admin Secret**: This option exposes a drop-down in which you can select a stored text secret that references a Redis admin password. A **Create** link is available to store a new, reusable secret.

TLS

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (such as the system's CA). Defaults to `Yes`.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting. The minimum TLS version for Redis is version 6.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Minimum TLS Requirement

The minimum Redis version required for TLS support is version 6.

Advanced Settings

Max blocking time: Maximum amount of time (in seconds) before assuming that Redis is down and passing events through. Defaults to `60` seconds. Use `0` to disable timeouts.

Client-side cache: Toggle to `Yes` to enable. Then navigate to **Settings** > **General Settings** > **Limits** > **Redis Cache** to configure the cache, as described in the next section.

Overall Redis Cache Settings

Together, these settings determine how the Cribl Stream client-side cache behaves. We'll start with definitions:

Key TTL in seconds: The maximum time-to-live of a key in the cache, in seconds. `0` means no limit. Defaults to 10 minutes.

Max # of keys: The maximum number of keys the cache can contain. `0` (the default) means no limit.

Max cache size (bytes): The maximum number of bytes the cache can contain. `0` (the default) means no limit.

Service period (seconds): The interval at which the cache checks whether any keys need to be evicted. Defaults to 30 seconds.

Server assisted: This feature requires Redis version 6 or newer. Toggle to `Yes` to enable server-assisted caching and display the **Client tracking mechanism** drop-down. See the Tradeoffs section for an explanation of the available options.

Now here's the context:

For each Redis instance your Redis Functions interact with, Cribl Stream will operate one client-side cache. That cache will be shared between all the Redis Functions instances configured to interact with it. This is why the settings are in a central location, and why you cannot configure the cache at the individual function level.

Once per **Service period**, the cache checks whether any keys need to be evicted. The cache will evict:

- The least-recently-accessed key, if the cache has reached either (1) its **Max cache size (bytes)** or (2) its **Max # of keys**.

- Any key that exceeds its **Key TTL in seconds**.
- Any key that is stale according to a notification to Cribl Stream from your Redis instance. Redis sends these notifications (a.k.a. invalidations, or invalidation messages) only when you have enabled **Server assisted** caching.

The overall benefit that client-side caching provides is having fewer stale keys in your cache for less time. The greater the proportion of `GET`-type, as compared to `SET`-type (write) commands your Cribl Stream-Redis interactions have, the greater that benefit will be. When your Cribl Stream Pipelines either have no `SET`-type operations, or use filters to keep those operations to a minimum, you should consider client-side caching. In sum, you must decide whether more accurate data in your cache is worth the cost of memory and processing.

Tradeoffs Inherent in Server-Assisted Caching

Consider the common scenario where other applications besides Cribl Stream are writing to your Redis instance. Say one of those applications modifies a key's value. Now the value that Cribl Stream client-side cache has for that key is stale. Cribl Stream does not "know" about this, and retains the stale value until its TTL is up. This degrades the overall accuracy of data from the client-side cache.

Server-assisted caching is a remedy for this problem. With server-assisted caching enabled, your Redis instance will notify your client-side cache when Redis determines that a key's value has changed. Then the Cribl Stream client-side cache will immediately evict the stale key. Now the client-side cache is more accurate. Redis also has documentation about server-assisted client-side caching.

There are two mutually-exclusive ways you can have Redis notify Cribl Stream. These are the two modes (delivery mechanisms) available in the **Client tracking mechanism** drop-down:

1. In **Default** mode, the Redis server remembers which keys the Cribl Stream client has requested. Redis only notifies Cribl Stream when the value of one of **those** keys has changed. This is most efficient for Cribl Stream but needs more memory and some extra processing time from the Redis server.
2. In **Broadcast** mode, the Redis server need not remember which keys came from where, because it simply notifies Cribl Stream when the value of **any** key has changed. This is most efficient for Redis, but now the Cribl Stream client needs to inspect every key that Redis says has changed. This consumes some extra processing time on the client, and generates extra network activity to accommodate notifications about keys that Cribl Stream never sees.

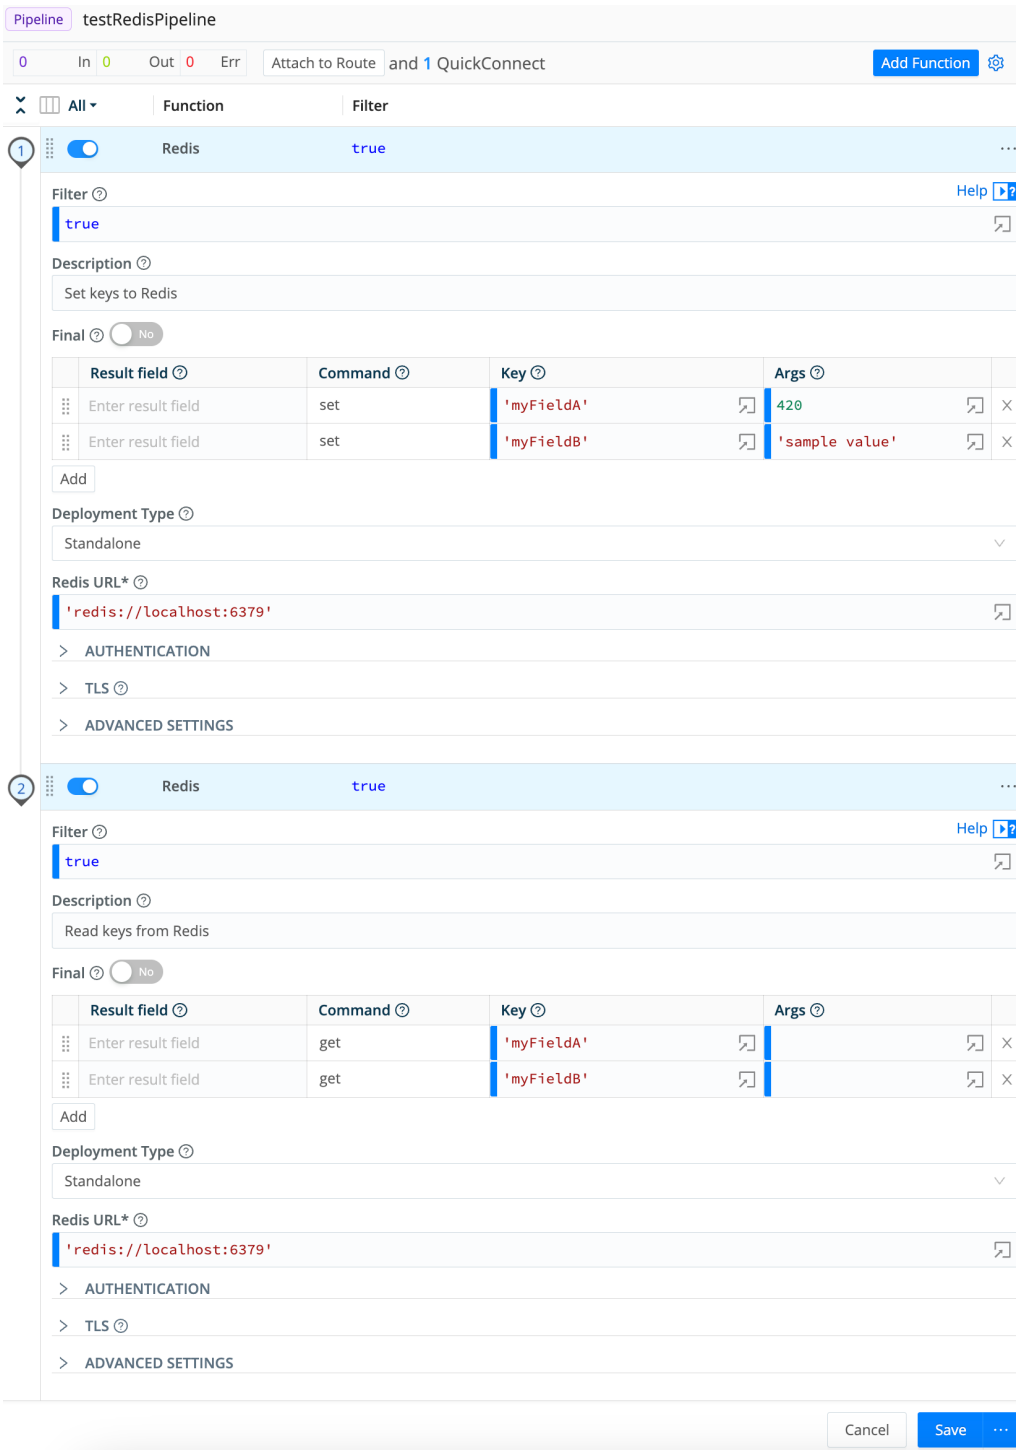
You should select whichever of these mechanisms best suits your environment. Does it make more sense to impose the heavier burden on the Redis server (as in **Default** mode) or on Cribl Stream (as in **Broadcast** mode)?

In both scenarios, for a given key, any write operation from any application (including Cribl Stream) that's interacting with Redis, causes Cribl to evict the key from the client-side cache when Redis notifies Cribl.

Examples

Scenario A: Set and Get

This Pipeline demonstrates the use of a pair of Redis Functions. The first Function sets two key-value pairs in Redis. The second Function gets their values, by key, into two corresponding new **Result field**s.



Redis set and get Functions

Redis Function #1

Description: `Set keys to Redis`

Command: `set` **Key**: `'myFieldA'` **Args**: `420`

Command: `set` **Key**: `'myFieldB'` **Args**: `'sample value'`

Redis Function #2

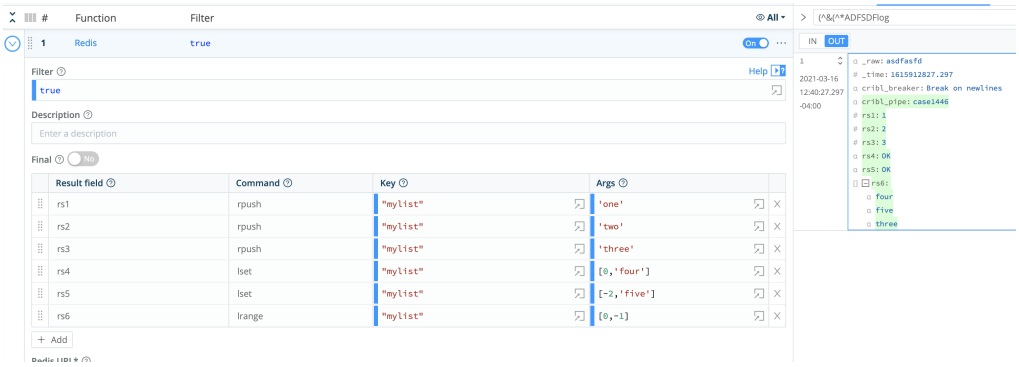
Description: `Read keys from Redis`

Result field: `myField_AA` **Command**: `get` **Key**: `'myFieldA'`

Result field: `myField_BB` **Command**: `get` **Key**: `'myFieldB'`

Scenario B: Multiple-Argument Arrays

This example demonstrates how to configure a Redis Function that supplies an array of multiple arguments to Redis commands (in this example, `lset` and `lrange`).



Redis Function, arrays of multiple arguments, and sample output

Redis Function

Description: `Push arrays of multiple arguments to Redis`

Result field: `rs1` **Command**: `rpush` **Key**: `"mylist"` **Args**: `'one'`

Result field: `rs2` **Command**: `rpush` **Key**: `"mylist"` **Args**: `'two'`

Result field: `rs3` **Command**: `rpush` **Key**: `"mylist"` **Args**: `'three`

Result field: `rs4` **Command**: `lset` **Key**: `"mylist"` **Args**: `[0,'four']`

Result field: `rs5` **Command**: `lset` **Key**: `"mylist"` **Args**: `[-2,'five']`

Result field: `rs6` **Command**: `lrange` **Key**: `"mylist"` **Args**: `[0,-1]`

Try This at Home

The Pipeline below contains only this example Function. You can import it into your own Cribl Stream environment, fill in the `url` with your own credentials, and further modify it to meet your needs.

redis-multiple-args.json

```
{
  "id": "redis-multiple-args",
  "conf": {
    "output": "default",
    "groups": {},
    "asyncFuncTimeout": 1000,
    "functions": [
      {
        "filter": "true",
        "conf": {
          "commands": [
            {
              "outField": "rs1",
              "command": "rpush",
              "keyExpr": "\"mylist\"",
              "argsExpr": "'one'"
            },
            {
              "outField": "rs2",
              "command": "rpush",
              "keyExpr": "\"mylist\"",
              "argsExpr": "'two'"
            },
            {
              "outField": "rs3",
              "command": "rpush",
              "keyExpr": "\"mylist\"",
              "argsExpr": "'three'"
            },
            {
              "command": "lset",
              "keyExpr": "\"mylist\"",

}
}
```

14.26. Regex Extract

The Regex Extract Function extracts fields using named capture groups. (In Splunk, these will be index-time fields). Fields that start with `__` (double underscore) are special in Cribl Stream. They are ephemeral: they can be used by any Function downstream, but will be serialized only to Cribl internal Destinations.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of the Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Regex: Regex literal. Must contain named capturing groups: `(?<foo>bar)`. Can contain special `_NAME_N` and `_VALUE_N` capturing groups, which extract **both the name and value** of a field: `(?<_NAME_0>[^\s=]+)=(?<_VALUE_0>[^\s]+)`. Defaults to empty. See Examples below.

Additional regex: Click **Add Regex** to chain extra regex conditions.

Source field: Field on which to perform regex field extraction. Nested addressing is supported. Defaults to `_raw`.

Overwrite existing fields: Whether to overwrite existing event fields with extracted values. If set to `No` (the default), existing fields will be converted to an array. If toggled to `Yes`, Regex Extract will create array fields if applied multiple times, or if fields exist. For example, if `src_ip` is extracted in an input Pipeline where it is assigned a value of `10.1.2.2`, and is also in a processing Pipeline with a value of `10.2.3.3`, then the resulting field is `["10.1.2.2", "10.2.3.3"]`.

Advanced Settings

Max exec: The maximum number of times to apply the **Regex** to the source field when the global flag is set, or when using `_NAME_N` and `_VALUE_N` capturing groups. Named capturing groups will always use a value of `1`. Defaults to `100`.

Field name format expression: JavaScript expression to format field names when `_NAME_n` and `_VALUE_n` capturing groups are used. For example, to append `XX` to all field names, use: `` `${name}_XX` `` (backticks are literal). If not specified, names will be sanitized using regex: `/^[_0-9]+|[^a-zA-Z0-9_]+/g`. The **original** field name is in the global `name`. You can access other fields' values via `__e.<fieldName>`.

Examples

To test Regex Extract Functions use Data Preview to see the events as they flow into and out of the Pipeline.

Example 1: Single Field from Simple Event

Assume a simple event that looks like this: `metric1=23 metric2=42 dc=23 abc=xyz`

Extract **only** the `metric1` field:

Regex: `metric1=(?<metric1>\d+)` **Result**: `metric1:"23"`

Example 2: Extracting Multiple Fields

Use this sample data:

```
462559d4a487[471]: 172.23.0.6 - - [26/Feb/2024:20:22:38 +0000] "GET /catalog/view/ja
```

Use a regex to extract the fields you know are in the event.

Regex: `^(?<container_id>[^\s]+)\[(?<process_id>\d+)\]:\s+(?<remote_host>[^\s]+)\s+(?<remote_user>-)\s+(?<auth_user>-)\s+\[(?<timestamp>[^\]]+)\]\s+"(?<request_method>\w+)\s+(?<requested_url>[^\s]+)\s+(?<http_version>[^"]+)"\s+(?<status>\d+)\s+(?<bytes>.+)$`

Results:

Example 2 results

Example 3: Key-Value Pairs from Multiple Fields

Use this sample data:

```
rec_type=71 rec_type_simple=RNA dest_port=443 snmp_out=0 netflow_src="00000000-0000-(
```

Use a regex to extract **all** k=v pairs, then use **Field Name Format Expression** to append an `_XX` suffix to each extracted field:

Regex: `(?<_NAME_0>[\w-]+)="?(?<_VALUE_0>(?<=")[^"]*|\S*)` **Field Name Format Expression:** `${name}_XX`

Results:

Example 3 results

Example 4: Multi-Stage Extraction, Complex Events

This example builds on the syntax in Example 3, to tackle a more complex event structure.

In the right **Sample Data** pane, click **Paste** and insert the following sample:

Sample Data

```
<134>1 2020-12-22T17:06:08Z CORP_INT_NLB CheckPoint 18160 - [action:"Accept"; conn_d
```

This event is from a CheckPoint Firewall CMA system. With this type of event structure, properly extracting each event field into a separate metadata field requires two-stage processing. So we'll use two Regex Extract Functions.

The first Regex Function splits the event to separate the actual data from the header information. We'll split after the `CheckPoint 18160` string, by capturing everything between the `[` and `]`:

Regex: `\[(?<__fields>.*)\]` **Source**: `_raw`

Next, add this second Regex Extract Function to extract all k=v pairs:

Regex: `(?<_NAME_0>[^ :]+):(?<_VALUE_0>[^;]+);` **Source**: `__fields`

Results:

Example 4 results

For further examples, see Using Cribl to Analyze DNS Logs in Real Time – Part 2.

14.27. Regex Filter

The Regex Filter Function filters out events based on regex matches.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Regex: Regex to test against. Defaults to empty.

Additional regex: Click **Add Regex** to chain extra regex conditions.

Field: Name of the field to test against the regex. Defaults to `_raw`. Supports nested addressing.

Examples

For a usage example, see our Regex Filtering topic.

14.28. Rename

The Rename Function is designed to change fields' names or reformat their names (e.g., by normalizing names to camelcase). You can use Rename to change specified fields (much like the Eval Function), or for bulk renaming based on a JavaScript expression (much like the Parser Function).

Compared to these alternatives, Rename offers a streamlined way to alter only field names, without other effects.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Optionally, enter a simple description of this step in the Pipeline. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Parent fields: Specify fields whose children will inherit the **Rename fields** and **Rename expression** operations. Supports wildcards. If empty, only top-level fields will be renamed.

This Function cannot operate on internal fields whose names begin with double underscores (`__`).

Note that you can still use `__e` to access fields within the `(context)` object, as long as those fields do not begin with double underscores. That's because `__e` is a special variable, not a field.

Rename fields: Each row here is a key-value pair that defines how to rename fields. The current name is the key, and the new name is the value. Click **Add Field** to add more rows.

- **Current name**: Original name of the field to rename. You must quote literal identifiers (non-alphanumeric characters such as spaces or hyphens).
- **New name**: New or reformatted name for the field. Here again, you must quote literals.

Rename expression: Optional JavaScript expression whose returned value will be used to rename fields. Use the `name` and `value` global variables to access fields' names/values. Example: `name.startsWith('data') ? name.toUpperCase() : name`. You can access other fields' values via `event.<fieldName>`.

A single Function can include both **Rename fields** (to rename specified field names) and **Rename expression** (to globally rename fields). However, the **Rename fields** strategy will execute first.

Advanced Settings

Parent field wildcard depth: For wildcards specified in **Parent fields**, sets the maximum depth within events to match and rename fields. Enter `0` to match only top-level fields. Defaults to `5` levels down.

Example

Change the `level` field, and all fields that start with `out`, to all-uppercase.

Example event:

```
{"inEvents": 622,
  "level": "info",
  "outEvents": 311,
  "outBytes": 144030,
  "activeCxn": 0,
  "openCxn": 0,
  "closeCxn": 0,
  "activeEP": 105,
  "blockedEP": 0
}
```

Rename Fields:

Current name: `level`
New name: `LEVEL` **Rename expression**: `name.startsWith('out') ? name.toUpperCase() : name`

Event after Rename:

```
{"inEvents": 622,
  "LEVEL": "info",
  "OUTEVENTS": 311,
  "OUTBYTES": 144030,
  "activeCxn": 0,
  "openCxn": 0,
  "closeCxn": 0,
  "activeEP": 105,
  "blockedEP": 0
}
```

Applications

1. Remove filename prefix `<myPrefix>`:

Rename expression: `name.replace(/<myPrefix>/, '')`

2. Add a wildcard to rename a set of fields named `json.record[0]`, `json.record[1]`, etc., preserving the variable numbers in the brackets:

Rename expression: `name.replace(/(json)\.(\w+)/,'MYNEWNAME-$2-$1')`

See Also {see-also}

- Reducing Windows XML Events, which demonstrates using Rename to remove unnecessary prefixes from field names, reducing events' size.

14.29. Rollup Metrics

The Rollup Metrics Function merges/rolls up frequently generated incoming metrics into more manageable time windows.

Each Worker Process executes this Function independently on its share of events. For details, see Functions and Shared-Nothing Architecture.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Optional description of this Function's purpose in this Pipeline. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Dimensions: List of data dimensions across which to perform rollups. Supports wildcards. Defaults to `*` wildcard, meaning all original dimensions.

Time window: The time span over which to roll up (aggregate) metrics. Must be a valid time string (e.g., `10s`). Must match pattern: `\d+[sm]$`.

With high-cardinality data, beware of setting long time windows. Doing can cause high memory consumption and/or lost data, because memory is flushed upon restarts and redeployments.

Gauge update: The operation to use when rolling up gauge metrics. Defaults to **Last**; other options are **Maximum**, **Minimum**, or **Average**.

Examples

Scenario A:

Assume that you have metrics coming in at a rate that is too high. For example, Cribl Stream's internal metrics come in at a 2s interval.

To roll up these metrics to 1-minute granularity, you would set up the Rollup Metrics Function with a **Time Window** value of `60s`.

Scenario B:

Assume that you have metrics coming up with multiple dimensions – e.g. `host`, `source`, `data_center`, and `application`. You want to aggregate these metrics to eliminate some dimensions.

Here, you would configure Rollup Metrics Function with a **Time Window** value that matches the metrics' generation – e.g., `10s`. In the **Dimensions** field, you would remove the default `*` wildcard, and would specify only the dimensions you want to keep – e.g.: `host, data_center`.

14.30. Sampling

The Sampling Function filters out events, based on an expression and a sampling rate.

Each Worker Process executes this Function independently on its share of events. For details, see Functions and Shared-Nothing Architecture.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Sampling rules: Events matching these rules will be sampled at the rates you specify:

- **Filter**: Filter expression matching events to be sampled. Use `true` to match all.
- **Sampling rate**: Enter an integer `N`. (Defaults to `1`.) Sampling will pick `1/N` events matching this rule.

How It Works

Setting this Function's **Sampling rate** to `30` would mean that only 1 of every 30 events would be kept.

Let's assume that we save this setting, and then capture data from a datagen Source by selecting **Preview** > **Start a Capture** > **Capture**. In the **Capture Sample Data** modal, select: `100` seconds, `100` events, and **As they come in**. Then start the capture, and **Save as Sample File**.

Next, in the **Preview** pane, click **Simple** beside the new file's name. If you then click the **Basic Statistics** (chart) button, you should see that we've kept about 4 of the original 100 events, or close to 1 in 30.

	Full Event Length ⓘ	Number of Fields ⓘ	Number of Events ⓘ
IN	28.82KB	41	100
OUT	1.42KB	38	4
DIFF	↓ -95.08%	↓ -7.32%	↓ -96.00%

Examples and Scenarios

For usage examples, see these Better Practices topics:

- Sampling: Sampling verbose or voluminous data at ingest time, to make analysis and troubleshooting more efficient.
- Sample Logs: Sampling event data for efficient onbaording into Cribl Stream.
- Access Logs: Apache, ELB, CDN, S3, Etc.: Sampling voluminous logs from sources like Amazon S3, Amazon Cloudfront, and AWS ELBs.
- Firewall Logs: VPC Flow Logs, Cisco ASA, Etc.: Sampling voluminous logs from firewalls.

See Also

- Dynamic Sampling Function: Filter out events based on an expression, a sample mode, and the volume of events

14.31. Serialize

Use the Serialize Function to serialize an event's content into a predefined format.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Type: Data output format. Defaults to `CSV`. Options:

- **CSV**
- **Extended Log File Format** – Extended Log File Format.
- **Common Log Format** – Common Log Format.
- **Key=Value Pairs** – selecting this type displays additional options:
    - **Clean Fields**: Toggle to `Yes` to clean field names by replacing non-alphanumeric characters with `_`. This will also strip leading and trailing `"` symbols.
    - **Pair delimiter**: Delimiter used to separate `key=value` pairs. Defaults to a single space character. Multiple characters are allowed. Cannot be an equal sign (`=`).
- **JSON Object**
- **Delimited values** – selecting this type displays additional options:
    - **Delimiter**: Delimiter character to split value. If left blank, defaults to comma (`,`). You can also specify pipe (`|`) or tab characters.
    - **Quote char**: Character used to quote literal values. If left blank, defaults to `"`.
    - **Escape char**: Character used to escape delimiter or quote characters. If left blank, defaults to **Quote char**.
    - **Null value**: Field value representing the null value. These fields will be omitted. Defaults to: `-`

Library: Browse Parser/Formatter library.

Fields to serialize: You must specify individual fields with the `CSV`, `ELFF`, `CLF`, and `Delimited values` Types. All other formats support wildcard field lists. With these formats, the default entry here will specify some excluded fields (indicated by `!`), followed by a `*` wildcard to serialize all remaining fields.

All field names or wildcards that you want to exclude from serialization must precede all field names or wildcards that you want to include.

Source field: Field containing the object to serialize. Leave blank to serialize top-level event fields.

Destination field: Field to serialize the data into. Defaults to `_raw`.

Examples

Scenario A: JSON to CSV

Assume a simple event that looks like this: `{"time":"2019-08-25T14:19:10.240Z","channel":"input","level":"info","message":"initializing input","type":"kafka"}`

We want to serialize these fields: `_time`, `channel`, `level`, and `type` into a single string, in CSV format, stored in a new destination field called `test`.

To properly extract the key-value pairs from this event structure, we'll use a built-in Event Breaker:

1. Copy the above sample event to your clipboard.
2. In the **Preview** pane, select **Paste a Sample**, and paste in the sample event.
3. Under **Select Event Breaker**, choose **ndjson** (newline-delimited JSON), and click **Save as a Sample File**.

Now you're ready to configure the Serialize Function, using the settings below:

Type: CSV Fields to Serialize: `_time channel level type` Destination Field: `test` Source Field: [leave empty] **Result**: `test: 1566742750.24,input,info,kafka`

In the new `test` field, you now see the `time`, `channel`, `level`, and `type` keys extracted as top-level fields.

Scenario B: CSV to JSON

Let's assume that a merchant wants to extract a subset of each customer order, to aggregate anonymized order statistics across their customer base. The transaction data is originally in CSV format, but the statistical data must be in JSON.

Here's a CSV header (which we don't want to process), followed by a row that represents one order:

```
orderID,custName,street,city,state,zip 20200622102822,john smith,100 Main St.,Anytown,AK,99911
```

To convert to JSON, we'll need to first parse each field from the CSV to a manipulable field in the Pipeline, which the Serialize Function will be able to reference. In this example, the new manipulable field is `message`.

Use the `Parser` Function:

Filter: `true` Operation mode: `Extract` Type: CSV Source field: `_raw` Destination field: `message` List of fields: `orderID custName street city state zip`

Now use the Serialize Function:

Filter: `true` Type: JSON Fields to serialize: `city state` Source field: `message` Destination field: `orderStats`

14.32. SNMP Trap Serialize

Use the SNMP Trap Serialize Function to serialize compliant events into SNMP traps for sending out through SNMP Trap Destinations that were modified within a Pipeline from an SNMP Trap Source. This ensures compatibility with existing SNMP infrastructure and supports integration with network management tools that use SNMP for monitoring and alerting.

Limitations

- The SNMP Trap Source the events came from must have **Include varbind types** enabled for this function to work. The SNMP Trap Serialize Function needs the varbind types to correctly serialize the events.
- For v2c events, `sysUpTime` and `snmpTrapOID` appear both at the top level and within varbinds. During serialization, the Function uses the values in varbinds as they reflect the event's generation time. If the values differ, varbinds take precedence. Modifying the top-level values will not affect serialization.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Enforce required fields: When toggled to `Yes` (default), v2c and v3 traps must meet the following requirements:

- At least two varbinds must be present.
- The first varbind must have the `sysUpTime` OID (`1.3.6.1.2.1.1.3.0`) and type `67` (`TimeTicks`).
- The second varbind must have the `snmpTrapOid` OID (`1.3.6.1.6.3.1.1.4.1.0`) and type `6` (`OID`).

These requirements are mandated by RFC 3416 Section 4.2.6, RFC 1066 Section 5.1, and RFC 1905 Section 3.1.2. While traps can be serialized without these fields, downstream receivers may drop them. With this option enabled, non-compliant traps are dropped before being sent downstream.

Drop failed events: When toggled to `Yes` (default), events that fail to serialize into valid traps are dropped entirely, preventing them from passing through the Pipeline. This is useful when sending to an SNMP Trap Destination, as invalid traps will not be sent.

When toggled to `No`, the event will pass through without `__snmpRaw` and will include a `snmpSerializeErrors` field for troubleshooting.

Regardless of whether the toggle is set to `Yes` or `No`, if an event fails to serialize, the `__snmpRaw` field is deleted, preventing the event from leaving the SNMP Trap Destination.

Recommended setup flow:

1. Get a sample of the traps to modify and configure the SNMP Trap Serialize Function.
2. Enable **Drop failed events** and run a Preview.
3. Modify the SNMP Trap Serialize Function and preceding Eval Function until no `snmpSerializeErrors` remain.
4. Disable **Drop failed events** when confident in the Pipeline setup and ready to flow actual data.

SNMPV3 User: SNMPv3 provides enhanced security by enabling user authentication and data encryption. These settings are crucial for ensuring that only authorized users can send SNMP traps and that the data remains secure during transmission.

- **Username**: The username for SNMP v3 authentication. Ensure the username matches the one configured on the SNMP manager.
- **Authentication protocol**: The protocol to use for SNMP v3 authentication. Options include `None`, `MD5`, `SHA1`, `SHA224`, `SHA256`, `SHA384`, and `SHA512`.
    - **V3 authentication key**: The key used for SNMPv3 authentication. This field appears when an **Authentication protocol** is selected.
    - **Privacy protocol**: The protocol to use for SNMPv3 encryption. This field appears when an **Authentication protocol** is selected, as it is not possible to have an encrypted trap without authentication. Options include:
        - `None`
        - `AES128`
        - `AES256b (Blumenthal)`
        - `AES256r (Reeder)`
    - **V3 privacy key**: The key used for SNMPv3 encryption. This field appears when a **Privacy protocol** is selected.

Maintain Original Source IP in SNMP Traps

This setup maintains the original source IP in SNMP traps by adding it to the varbinds array, ensuring accurate data transmission even when traps traverse network devices that alter IP headers.

Before the SNMP Trap Function in your Pipeline, use the Eval Function to append a new object to the varbinds array. The object includes an OID, type, and the value from the host field, effectively capturing the original source IP. For example:

- **Name**: `varbinds`
- **Value expression**: `[...varbinds, {oid: '.1.3.6.1.6.3.18.1.3', type: 64, value: __e.host}]`

Next, for the SNMP Trap Serialize Function we recommend enabling both **Enforce required fields** and **Drop failed events**. This will ensure that the SNMP trap is serialized correctly, enforcing necessary fields and dropping events that fail serialization.

Change Authorization and/or Privacy Level

To change the authorization or privacy level of an SNMP v3 trap, you must modify two settings:

- **SNMPV3 User**: Update the user configuration within the SNMP Trap Serialize Function.
- **msgFlags**: Set the appropriate value at the top level of the event in an Eval Function before the serialization.

The `msgFlags` value should be a string representation of the desired number:

- `00`: No authorization, no privacy
- `01`: Authorization, no privacy
- `03`: Authorization and privacy

Change the SNMPv3 User

To change the SNMPv3 user, you need to update the `msgUserName` field within the SNMP Trap object.

Before the SNMP Trap Function in your Pipeline, use the Eval Function to update `msgSecurityParams.msgUserName` to the new intended username. For example, **Eval expression**: `msgSecurityParams.msgUserName = 'newUser';`

14.33. Suppress

The Suppress Function suppresses events over a time period, based on evaluating a key expression.

Each Worker Process executes this Function independently on its share of events. For details, see Functions and Shared-Nothing Architecture.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Key expression: Suppression key expression used to uniquely identify events to suppress. For example, `` `${ip}:${port}` `` will use the fields `ip` and `port` from each event to generate the key.

Number to allow: The number of events to allow per time period. Defaults to `1`.

Suppression period (sec): The number of seconds to suppress events after 'Number to allow' events are received. Defaults to `30`.

Drop suppressed events: Specifies if suppressed events should be dropped, or just tagged with `suppress=1`. Defaults to `Yes`, meaning drop.

Advanced Settings

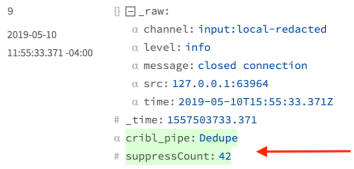
Maximum cache size: The maximum number of keys that can be cached before idle entries are removed. Before changing the default `50000`, contact Cribl Support to understand the implications.

Suppression period timeout: The number of suppression periods of inactivity before a cache entry is considered idle. This defines a multiple of the **Suppression period (sec)** value. Before changing the default `2`, contact Cribl Support to understand the implications.

Num events to trigger cache clean-up: Check cache for idle sessions every N events when cache size exceeds the **Maximum cache size**. Before changing the default `10000`, contact Cribl Support to understand the implications.

Seeing the Results

If you've enabled **Drop suppressed events**, such events will be omitted from logs as they exit this Function. However, the next event allowed through will include a `suppressCount: N` field, whose `N` value indicates the number of events dropped in the preceding **Suppression period**.



suppressCount shows number of events dropped

Examples

In the examples below, **Filter** is the Function-level Filter expression:

1. Suppress by the value of the `host` field: Filter: `true` Key expression: `host` Number to allow: `1` Suppression period (sec): `30`
   Using a datagen sample as a source, generate at least 100 events over 2 minutes.

Result: One event per unique `host` value will be allowed in every 30s. Events without a `host` field will **not** be suppressed.

2. Suppress by the value of the `host` and `port` tuple : Filter: `true` Key expression: `` `${host}:${port}` `` Number to allow: `1` Suppression period (sec): `300`

Result: One event per unique `host:port` tuple value will be allowed in every 300s.

Suppression will **also** apply to events without a `host` or a `port` field. The reason is that if `field` is not present, `` `${field}` `` results in the literal `undefined`.

3. To **guarantee** that suppression applies **only** to events with `host` and `port`, check for their presence using a Filter: Filter: `host && port!=null` Key expression: `` `${host}:${port}` `` Number to allow: `1` Suppression period (sec): `300`
4. Decorate events that qualify for suppression: Filter: `true` Key expression: `` `${host}:${port}` `` Number to allow: `1` Suppression period (sec): `300` Drop suppressed events: `No`

Result: No events will be suppressed. But all qualifying events will gain an added field `suppress=1`, which can be used downstream to further transform these events.

For further use cases, see Cribl's Streaming Data Deduplication with Cribl blog post. For further details on filter usage, see Filters.

14.34. Tee

The Tee Function tees events out to a command of choice, via `stdin`. The output is one JSON-formatted event per line. You can send the events to (for example) a local file on the Cribl Stream worker. This can be useful in verifying the data being processed in a Pipeline.

The Filesystem/NFS Destination offers similar capability, but only after the data leaves the Pipeline. Tee, by comparison, can be inserted at any point in the Pipeline.

In Cribl.Cloud, the Tee Function is only available on customer-managed hybrid Worker Nodes.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Command: Command to execute and receive events (via `stdin`) – one JSON-formatted event per line.

Args: Click **Add Arg** to supply arguments to the command.

Restart on exit: Restart the process if it exits and/or we fail to write to it. Defaults to `Yes`.

Environment variables: Environment variables to set or overwrite. Click **Add Variable** to add key-value pairs.

Communication Protocol

Data is passed to the command through its `stdin`, using the following protocol:

- First line: Metadata serialized in JSON, containing the following fields:
  - **format**: Serialization format for event. Defaults to `JSON`.
  - **conf**: Full Function configuration.
- Remaining: Payload.

Examples

Assume that we are parsing PANOS Traffic logs, and want to see how they look at a particular step in the processing Pipeline We'll assume that the `Parser` Function is already in place, so we'll insert the Tee Function at any (arbitrary) later point in the Pipeline.

Scenario A:

The Tee Function itself requires only that we define the **Command** field. In this particular example, that **Command** will be `tee` itself.

We've also clicked **Add Arg**, to specify a local output file in the resulting **Args** field. (A file path would normally be the first argument to a `tee` command executed from the command line. The Cribl Stream user must have write permission on the specified file path.)

Command: `tee`

Args: `/opt/cribl/foo.log`

In this first scenario, assume that we have the `Parser` configured to parse, but not keep any fields. After changes are deployed and PANOS logs are received, if we tail `foo.log`, we'd see the following:

```
Line 1: {"format":"json","conf":{"restartOnExit":true,"env":{},"command":"tee","args":
["/opt/cribl/foo.log"]}
```

```
Line 2: {"_raw":"Oct 09 10:19:15 DMZ-internal.nsa.gov 1,2019/10/09
10:19:15,001234567890002,TRAFFIC,drop,2304,2019/10/09
10:19:15,209.118.103.150,160.177.222.249,0.0.0.0,0.0.0.0,InternalServer,,,not-
applicable,vsys1,inside,z1-FW-Transit,ethernet1/2,,All traffic,2019/10/09
10:19:15,0,1,63712,443,0,0,0x0,udp,deny,60,60,0,1,2019/10/09
10:19:15,0,any,0,0123456789,0x0,Netherlands,10.0.0.0-10.255.255.255,0,1,0,policy-
deny,0,0,0,0,,DMZ-internal,from-policy,,,0,,0,,N/A,0,0,0,0,1202585d-b4d5-5b4c-aaa2-
d80d77ba456e,0","_time":1593185574.663,"host":"127.0.0.1"}
```

In Line 2 above, note that the `_raw` field makes up most of the contents, with only the `_time` and `host` fields added.

Scenario B:

Assume that we use the Tee Function, using the same **Command** and arguments, but we've modified the `Parser` Function to retain five fields: `receive_time`, `source_port`, `destination_port` `bytes_received`, and `packets_received`.

This time, if we tail `foo.log`, we'll see something like the following. If you compare this output to the previous output example, you'll notice the five fields appended to this event:

```
Line 3: {"_raw":"Oct 09 10:19:15 DMZ-internal.nsa.gov 1,2019/10/09
10:19:15,001234567890002,TRAFFIC,drop,2304,2019/10/09
10:19:15,209.118.103.150,160.177.222.249,0.0.0.0,0.0.0.0,InternalServer,,,not-
applicable,vsys1,inside,z1-FW-Transit,ethernet1/2,,All traffic,2019/10/09
10:19:15,0,1,63712,443,0,0,0x0,udp,deny,60,60,0,1,2019/10/09
10:19:15,0,any,0,0123456789,0x0,Netherlands,10.0.0.0-10.255.255.255,0,1,0,policy-
deny,0,0,0,0,,DMZ-internal,from-policy,,,0,,0,,N/A,0,0,0,0,1202585d-b4d5-5b4c-aaa2-
d80d77ba456e,0","_time":1593185606.965,"host":"127.0.0.1","receive_time":"2019/10/09
10:19:15","source_port":"63712","destination_port":"443","bytes_received":"0","packets_r
```

In this Function's **Command** field, you can specify commands other than `tee` itself. For example: By using `nc` as the command, and specifying `localhost` and a port number (as two separate arguments), you'll see event data being received via `nc` on the specified port.

14.35. Unroll

The Unroll Function accepts an array field – or an expression to evaluate an array field – and breaks/unrolls the array into individual events.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Source field expression: Field in which to find/calculate the array to unroll. E.g.: `_raw`, `_raw.split(/\n/)`. Defaults to `_raw`.

Destination field: Field (within the destination event) in which to place the unrolled value. Defaults to `_raw`.

Example

Assume we want to break/unroll each line of this event:

Sample Event

```
USER       PID %CPU %MEM    VSZ   RSS TTY      STAT START   TIME COMMAND
root         1  0.0  0.5  38000  5356 ?        Ss    2018   2:02 /lib/systemd/systemd
root         2  0.0  0.0      0     0 ?        S     2018   0:00 [kthreadd]
root         3  0.0  0.0      0     0 ?        S     2018   1:51 [ksoftirqd/0]
root         5  0.0  0.0      0     0 ?        S<    2018   0:00 [kworker/0:0H]
root         7  0.0  0.0      0     0 ?        S     2018   3:55 [rcu_sched]
root         8  0.0  0.0      0     0 ?        S     2018   0:00 [rcu_bh]
```

Settings

Source field expression: `_raw.split(/\n/)`

The `split()` JavaScript method breaks `_raw` into an ordered set of substrings/values, puts these values

into an array, and returns the array.

Destination field: `_raw`

Resulting Events

```
Event 1:
USER       PID %CPU %MEM    VSZ   RSS TTY      STAT START   TIME COMMAND

Event 2:
root         1  0.0  0.5  38000  5356 ?        Ss    2018   2:02 /lib/systemd/systemd

Event 3:
root         2  0.0  0.0      0     0 ?        S     2018   0:00 [kthreadd]

Event 4:
root         3  0.0  0.0      0     0 ?        S     2018   1:51 [ksoftirqd/0]

Event 5:
root         5  0.0  0.0      0     0 ?        S<    2018   0:00 [kworker/0:0H]

Event 6:
root         7  0.0  0.0      0     0 ?        S     2018   3:55 [rcu_sched]

Event 7:
root         8  0.0  0.0      0     0 ?        S     2018   0:00 [rcu_bh]
```

14.36. XML Unroll

The XML Unroll Function accepts a proper XML event with a set of elements, and converts the elements into individual events.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Unroll elements regex: Path to the array to unroll. E.g.: `^root\.child\.ElementToUnroll$`

Copy elements regex: Regex matching elements to copy into each unrolled event. E.g.: `^root\.(childA|childB|childC)$`

Unroll index field: Cribl Stream will add a field with this name, containing the 0-based index at which the element was located within the event. In Splunk, this will be an index-time field. Supports nested addressing. Name defaults to `unroll_idx`.

Pretty print: Whether to pretty print the output XML.

Examples

Assume that the following sample is ingested as a single event:

sample.xml

```
<?xml version="1.0" encoding="UTF-8"?>
<Parent>
    <myID>123456</myID>
    <branchLocation>US</branchLocation>
    <Child>
        <state>NY</state>
        <city>New York</city>
    </Child>
    <Child>
        <state>NJ</state>
        <city>Edgewater</city>
    </Child>
    <Child>
        <state>CA</state>
        <city>Oakland</city>
    </Child>
    <Child>
        <state>CA</state>
        <city>San Francisco</city>
    </Child>
</Parent>
```

If you insert this sample using **Preview** > **Add a Sample** > **Paste a Sample**, adjust Event Breaker settings to add the sample as a single event. One way to do this is to add a regex Event Breaker that (by design) will not match anything present in the sample. For example: `/[\n\r]+donotbreak(?!\s)/`. In current Cribl Stream versions, you can also use the built-in **Do Not Break** Ruleset.

Set up the XML Unroll Function using these settings:

Unroll elements regex: `^Parent\.Child$` **Copy elements regex**: `^Parent\.(myID|branchLocation)$`

Output 4 Events:

Resulting Events

```
# Event 1
<?xml version="1.0"?>
<Child>
  <myID>123456</myID>
  <branchLocation>US</branchLocation>
  <state>NY</state>
  <city>New York</city>
</Child>

# Event 2
<?xml version="1.0"?>
<Child>
  <myID>123456</myID>
  <branchLocation>US</branchLocation>
  <state>NJ</state>
  <city>Edgewater</city>
</Child>

# Event 3
<?xml version="1.0"?>
<Child>
  <myID>123456</myID>
  <branchLocation>US</branchLocation>
  <state>CA</state>
  <city>Oakland</city>
</Child>

# Event 4
<?xml version="1.0"?>
<Child>
  <myID>123456</myID>
  <branchLocation>US</branchLocation>
  <state>CA</state>
  <city>San Francisco</city>
</Child>
```

- Reducing Windows XML Events, which demonstrates using several Cribl Stream Functions to parse WindowsXML events and significantly reduce their volume.

14.37. Prometheus Publisher (Deprecated)

This Function was deprecated as of Cribl Stream 3.0, and has been removed from Cribl Stream as of v.4.0. Please instead use the Prometheus Destination to send metrics to Prometheus-compatible endpoints.

The Prometheus Publisher Function allows for metrics to be published to a Prometheus-compatible metrics endpoint. These can be upstream metrics received by Cribl Stream, or metrics derived from the output of Cribl Stream's `Publish Metrics` or `Aggregation` Functions. A Prometheus instance is responsible for collecting the metrics at that endpoint, and for performing its own processing of the metric data.

In the current Cribl Stream version, the endpoint is: `http://<worker_node_IP>:<api-port>/metrics`. Within Cribl Stream, that endpoint redirects from `http://<worker_node_IP>:9000/metrics` to `http://<worker_node_IP>:9000/api/v1/metrics`.

If used, this Function **must** follow any Publish Metrics or Aggregations Functions within the same Pipeline. This is to ensure that any data **not** originating from a metrics input is transformed into metrics format.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Fields to publish: Wildcard list of fields to publish to the Prometheus endpoint.

Advanced Settings

Batch write interval: How often, in milliseconds, the contents should be published. Defaults to `5000`.

Passthrough mode: If set to `No` (the default), overrides the **Final** setting, and suppresses output to downstream Functions' Destinations. Toggle to `Yes` to allow events to flow to consumers beyond the Prometheus endpoint. In effect, when previewing the pipeline output what you'll see is your event fields will have strikethrough font applied to them. This does not mean the Prometheus function is not matching your events but rather indicative of the Passthrough being disabled.

Update mode: On the default `No` setting, suppresses output to downstream Functions' Destinations. (This overrides the **Final** setting.) Toggle to `Yes` to allow events to flow to consumers beyond the Prometheus endpoint.

Example

This example uses the same PANOS sample data as the Publish Metrics Function, and is similarly preceded in a Pipeline by a Parser Function that extracts fields from the PANOS log.

Filter: Set as appropriate. **Fields to publish**: Set as appropriate. We'll use the default of `*` for this example. **Advanced settings**: Accept defaults.

After committing and deploying changes, you should be able to use a `curl` command (-L needed to follow the redirect mentioned above) to verify that metrics are being published, just a few seconds after data is ingested on an idle system.

curl output

```
$ curl -L http://<worker_node_IP>:9000/metrics
# TYPE perf_192_168_1_248_bytes_sent counter
metric_192_168_1_248_bytes_sent {destination_ip="160.177.222.249",inbound_interface="

# TYPE perf_192_168_1_248_bytes_rcvd counter
metric_192_168_1_248_bytes_rcvd {destination_ip="160.177.222.249",inbound_interface="

# TYPE perf_192_168_1_248_pkts_sent counter
metric_192_168_1_248_pkts_sent {destination_ip="160.177.222.249",inbound_interface="

# TYPE perf_192_168_1_248_pkts_rcvd counter
metric_192_168_1_248_pkts_rcvd {destination_ip="160.177.222.249",inbound_interface="
```

Now, we need to have Prometheus scrape the metrics. In this very basic example, you can add the target endpoint to the `prometheus.yml` file, under the `scrape_configs` -> `static_configs` section. Specify the endpoint in `IP:port` syntax, because Prometheus assumes (and requires) `/metrics` for all endpoints.

Restart Prometheus. Within just a few seconds, you should be able to use its query interface to retrieve metrics published by Cribl Stream.

14.38. Reverse DNS (Deprecated)

The Reverse DNS Function resolves hostnames from a numeric IP address, using a reverse DNS lookup.

This Function was deprecated as of v.2.4, and has been removed from Cribl Stream as of v.4.0. Please instead use the DNS Lookup Function's reverse lookup feature.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description of this Function. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Lookup Fields

Lookup field name: Name of the field containing the IP address to look up.

If the field value is not in IPv4 or IPv6 format, the lookup is skipped.

Output field name: Name of the field in which to add the resolved hostname. Leave blank to overwrite the lookup field.

Reload period (minutes): How often to refresh the DNS cache. Use `0` to disable refreshes. Defaults to `60` minutes.

Example

Lookup field name: `dest_ip` **Output field name**: `dest_host` **Result**: See the `dest_ip` field, and the newly created `dest_host` field, in the events.

14.39. Trim Timestamp (Deprecated)

The Trim Timestamp Function removes timestamp patterns from events, and (optionally) stores them in a specified field.

This Function is deprecated as of Cribl Stream 4.7, and will be removed in the next major version. Please use the Eval Function instead.

This Function looks for a timestamp pattern that exists between the characters indicated by numeric `timestartpos` and `timeendpos` fields. **From events whose `timestartpos` value is set to `0`**, the Function removes `timestartpos` and `timeendpos` along with the timestamp pattern.

Usage

Filter: Filter expression (JS) that selects data to feed through the Function. Defaults to `true`, meaning it evaluates all events.

Description: Simple description about this step in the Pipeline. Defaults to empty.

Final: If toggled to `Yes`, stops feeding data to the downstream Functions. Defaults to `No`.

Field name: Name of field in which to save the timestamp. (If empty, timestamp will not be saved to a field.)

Example

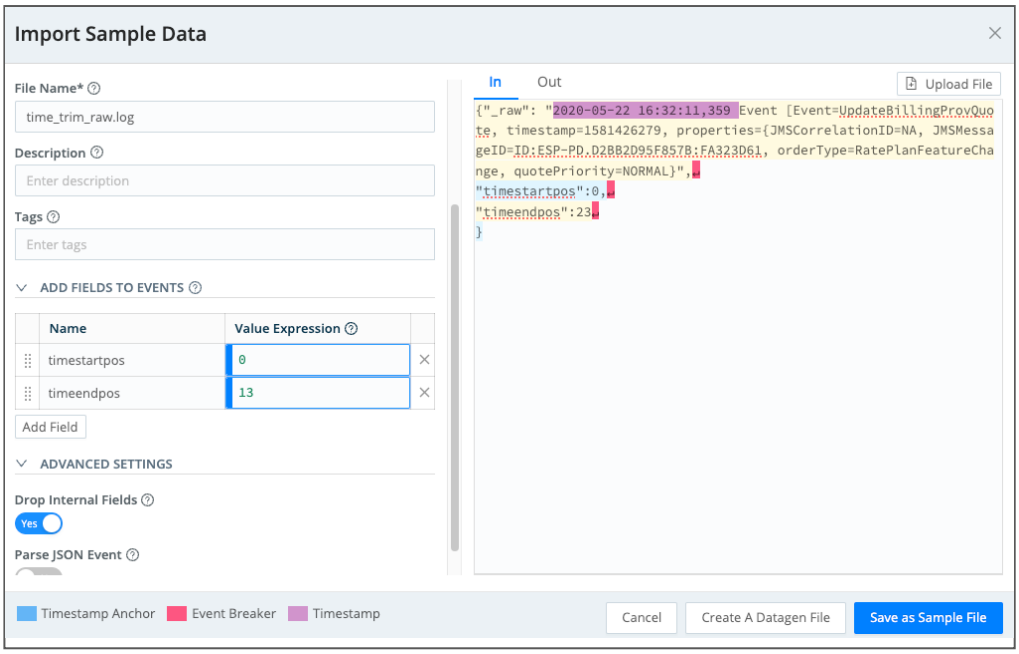
Remove the timestamp pattern (indicated by `timestartpos` and `timeendpos`) from `_raw`, and stash it in a field called `time_field`.

Field name: `time_field`

Example event before:

```
{"_raw": "2020-05-22 16:32:11,359 Event [Event=UpdateBillingProvQuote, timestamp=158
"timestartpos":0,
"timeendpos":23
}
```

To create this example payload, we selected **Sample Data** > **Import**, pasted the `_raw` field's original contents into the resulting modal, and then added the two required position fields:

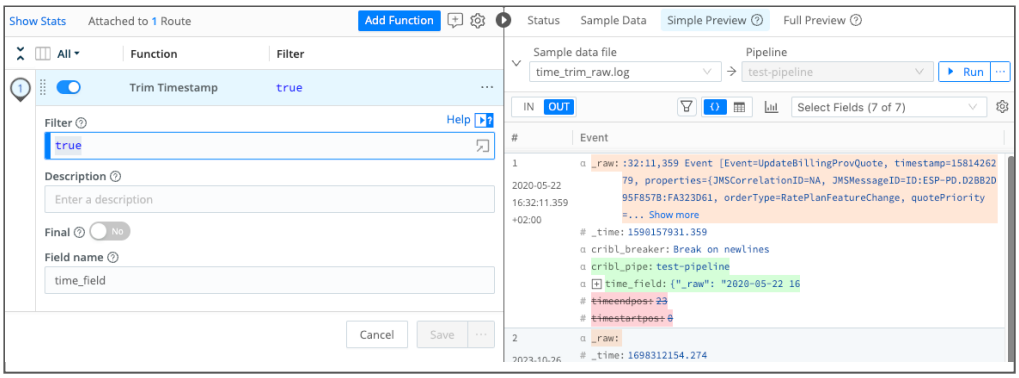


Example event setup

Example event after:

```
{"_raw": "Event [Event=UpdateBillingProvQuote, timestamp=1581426279, properties={JMS
"time_field":"2020-05-22 16:32:11,359"
}
```

In the Preview pane's **OUT** view, the original timestamp has been removed from `_raw`, and lifted into the new `time_field` we specified in the Function. The `timestartpos` and `timeendpos` fields have been removed.



Example event, saved and transformed

15. Integrations

Integrations enable seamless data flow between various systems. They encompass both Sources and Destinations, allowing you to get data from multiple origins and deliver processed data to various endpoints. Integrations are the entry and exit points in the event processing order.

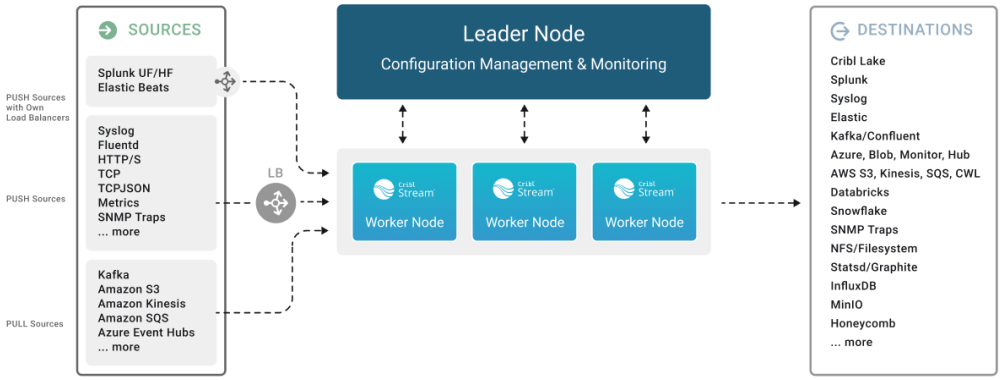
- Sources are configurations that enable Cribl to receive data from various origins. They serve as the entry points in the event processing order, enabling the collection of raw data for subsequent processing.
- Destinations are configurations that define where Cribl sends processed data. They act as the exit points in the event processing order, sending enriched and transformed events to the appropriate systems for storage, analysis, or further processing.

Key Concepts for Optimal Data Flow

- Destination Backpressure Triggers: Understanding the conditions that can cause backpressure in Destinations is crucial for preventing data loss and ensuring smooth data flow, especially during peak load periods.
- Persistent Queues: To safeguard against data loss when integrations are slow or unavailable (backpressure events), persistent queues provide a temporary storage mechanism on disk.
- Load Balancing: Distributing data evenly across multiple Sources and Destinations is essential for maximizing performance and reliability.

15.1. Sources Overview

Cribl Stream can receive continuous data input from various Sources, including Splunk, HTTP, Elastic Beats, Kinesis, Kafka, TCP JSON, and many others. Sources can receive data from either IPv4 or IPv6 addresses.



Push and Pull Sources

Sources Summary

Cribl Stream supports a variety of HTTP-, TCP-, and UDP-based Sources. All HTTP-based Sources are proxyable.

Collector Sources

Collectors ingest data **intermittently** in on-demand bursts ("ad hoc collection"), on preset schedules, or by "replaying" data from local or remote stores.

All Collector Sources are proxyable.

These Sources can ingest data only if a Leader is active:

- Amazon S3 (HTTPS only)
- Azure Blob Storage (HTTPS only)
- Cribl Lake
- Database
- File System/NFS
- Google Cloud Storage (HTTPS only)
- Health Check (HTTP/S)
- REST/API Endpoint (HTTP/S)
- Script (executes any shell script you provide and returns the output of that script/command)

- Splunk Search (HTTP/S)

For background and instructions on using Collectors, see:

- Collectors
- Scheduling and Running
- Job Limits

Check out the example REST Collector configurations in Cribl's Collector Templates repository. For many popular Collectors, the repo provides configurations (with companion Event Breakers, and event samples in some cases) that you can import into your Cribl Stream instance, saving the time you'd have spent building them yourself.

Push Sources

Supported data Sources that **send** to Cribl Stream.

These Sources can continue ingesting data even if no Leader is active:

- Amazon Data Firehose (HTTPS only)
- Datadog Agent (HTTP/S)
- Elasticsearch API (HTTP/S)
- Grafana (HTTP/S)
- HTTP/S (Bulk API)
- Raw HTTP/S
- Loki (HTTP/S)
- Metrics (TCP or UDP)
- Model Driven Telemetry (gPRC)
- NetFlow (NetFlow v5 over UDP)
- OpenTelemetry (OTel) (gRPC or HTTP/S)
- Prometheus Remote Write (HTTP/S)
- SNMP Trap (UDP)
- Splunk HEC (HTTP/S)
- Splunk TCP
- Syslog (TCP or UDP)

- TCP JSON
- TCP (Raw)
- UDP (Raw)
- Windows Event Forwarder (HTTP/S)

Data from these Sources is normally sent to a set of Cribl Stream Workers through a load balancer. Some Sources, such as Splunk forwarders, have native load-balancing capabilities, so you should point these directly at Cribl Stream.

Pull Sources

Supported Sources that Cribl Stream **fetches** data from.

- Amazon Kinesis Data Streams (HTTPS only) - requires active Leader
- Amazon SQS (HTTPS only)
- Amazon S3 (HTTPS only)
- Amazon Security Lake (HTTPS only)
- Google Cloud Pub/Sub (HTTPS only)
- Azure Event Hubs (TCP)
- Azure Blob Storage (HTTPS only)
- Confluent Cloud (TCP)
- CrowdStrike FDR (HTTPS only)
- Office 365 Services (HTTPS only) - requires active Leader for job management
- Office 365 Activity (HTTPS only) - requires active Leader for job management
- Office 365 Message Trace (HTTPS only) - requires active Leader for job management
- Prometheus Scraper (HTTP/S) - requires active Leader for job management
- Kafka (TCP)
- Amazon MSK (TCP)
- Splunk Search (HTTP/S) - requires active Leader for job management
- Wiz (HTTPS only) - requires active Leader for job management

Pull Sources fetch data from various external systems, with state management varying by Source. Some Sources, like Kafka, manage state independently, while others, such as Office 365 and Kinesis, require an active Leader for job management. This dependency is noted in the Pull Sources list above, indicating which Sources rely on the Leader for state and job management. For details on how each Source interacts with Cribl Stream, refer to the documentation for each Source.

System Sources

Sources supply information generated by Cribl Stream about itself or move data among Workers within your Cribl Stream deployment.

- AppScope (TCP or Unix socket)
- Datagen
- Exec (on-prem only)
- File Monitor (on-prem only)
- Journal files (on-prem only)
- System Metrics (on-prem only)
- System State (on-prem only)

Internal Sources

Similar to System Sources, Internal Sources also supply information generated by Cribl Stream about itself. However, unlike System Sources, they don't count towards the license usage.

- Cribl HTTP (HTTP/S)
- Cribl TCP
- Cribl Internal

Configure and Manage Sources

For each Source *type*, you can create multiple definitions, depending on your requirements.

From Stream Home, under **Worker Groups**, select a Worker Group to configure. Next, you have two options:

- To configure via QuickConnect:
    1. Select **Routing**, then **QuickConnect** (Stream) or **Collect** (Edge).
    2. Select **Add Source** at left, and select the Source you want from the list, choosing either **Add Existing** or **Add New**.
- To configure via Routing:
    1. Select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge).
    2. Select the Source you want.
    3. Select **Add Source** to open a **New Source** modal.

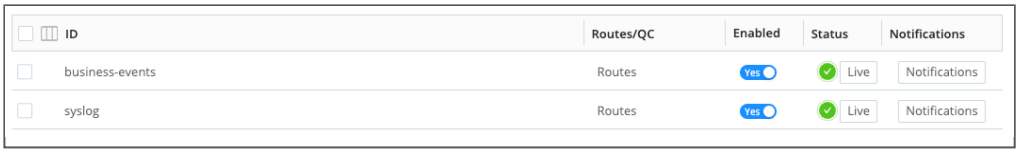
To edit any Source's definition in a JSON text editor, select **Manage as JSON** at the bottom of the **New Source** modal, or on the **Configure** tab when editing an existing Source. You can directly edit multiple values, and you can use the **Import** and **Export** buttons to copy and modify existing Source configurations as `.json` files.

When JSON configuration contains sensitive information, it is redacted during export.

Capture Source Data

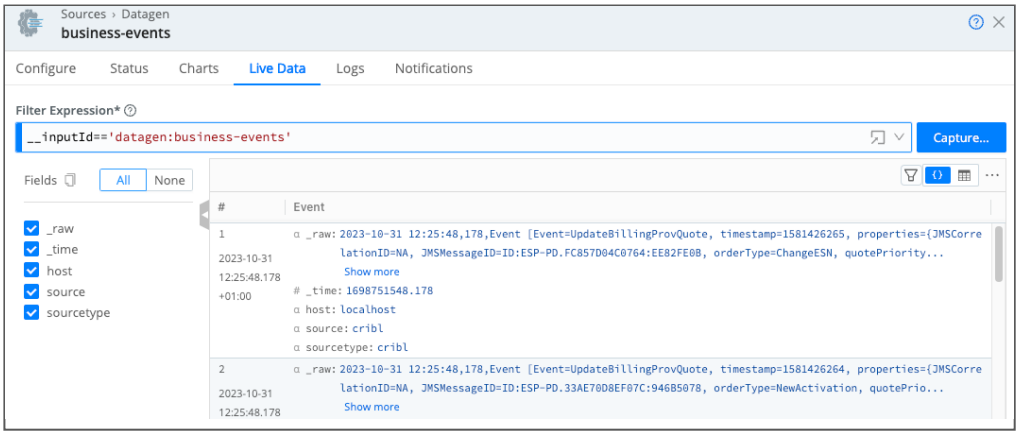
To capture data from a single enabled Source, you can bypass the Preview pane, and instead capture directly from the list of Sources. Just select the Source type, and then select the **Live** button beside the Source you want to capture.

To capture live data, you must have Worker Nodes registered to the Worker Group for which you're viewing events. You can view registered Worker Nodes from the **Status** tab in the Source.



Source > Live button

You can also start an immediate capture from within an enabled Source's config modal by selecting the **Live Data** tab.



Source modal > Live Data tab

Monitor Source Status

You can get a quick overview of Source health status by referring to their status icons.

Additionally, each Source's configuration modal offers two tabs for monitoring: Status and Charts.

Source Status Icons

Source status icons are available on the **Data** > **Destinations** page and for each individual Source in the list for a specific Source type.

The icons have the following meanings:

Icon	Meaning
	Healthy. Operating correctly.
	Warning. Experiencing issues. The Source is not functioning fully. Specific conditions will depend on the Source type.
	Critical. Experiencing critical issues. Drill down to the Source's Status tab to find out the details.
	Disabled. The Source is configured, but not enabled.
	No health metrics available. This may mean that a Source is enabled, but has not been deployed yet.

You can also find status icons on the Cribl Stream front page on Worker Group tiles. ⚠ or ❗ on any tile indicate that one or more Sources or Destinations in this Worker Group are experiencing issues. Hover over the icon to see more details.

Status Tab

The **Status** tab provides details about the Workers in the group and their status. An icon shows whether the Worker is operating normally.

You can select each Worker's row to see specific information, for example, to identify issues when the Source displays an error. The specific set of information provided depends on the Source type. The data represents only process 0 for each Worker Node.

The content of the **Status** tab is loaded live when you open it and only displayed when all the data is ready. With a lot of busy Workers in a group, or Workers located far from the Leader, there may be a delay before you see any information.

The statistics presented are reset when the Worker restarts.

Charts Tab

The **Charts** tab presents a visualization of the recent activity on the Source. The following data is available:

- Events in
- Thruput in (events per second)
- Bytes in
- Thruput in (bytes per second)

This data (in contrast with the status tab) is read almost instantly and does not reset when restarting a Worker.

Preconfigured Sources

To accelerate your setup, Cribl Stream ships with several common Sources configured for typical listening ports, but not switched on. Open, clone (if desired), modify, and enable any of these preconfigured Sources to get started quickly.

On a Cribl.Cloud deployment, **do not delete** any preconfigured Sources. If you don't plan to use them, keep them disabled.

- Syslog – UDP Port 9514, TCP Port 9514, TCP + TLS Port 6514
- Splunk TCP – Port 9997
- Splunk HEC – Port 8088
- TCP JSON – Port 10070
- TCP – Port 10060
- HTTP – Port 10080
- Elasticsearch API – Port 9200
- SNMP Trap – Port 9162 (preconfigured only on on-prem setups)
- OpenTelemetry - Port 4317 (preconfigured only on Cribl.Cloud)

System and Internal Sources:

- Cribl Internal > CriblLogs (preconfigured only on on-prem setups)
- Cribl Internal > CriblMetrics
- Appscope
- Cribl HTTP – Port 10200 (preconfigured only on distributed setups)
- Cribl TCP – Port 10300 (preconfigured only on distributed setups)
- System Metrics (preconfigured only on on-prem setups)
- System State (preconfigured only on on-prem setups)
- Journal files (preconfigured only on on-prem setups)

In a preconfigured Source's configuration, never change the **Address** field, even though the UI shows an editable field. If you change these fields' value, the Source will not work as expected.

After you create a Source and deploy the changes, it can take a few minutes for the Source to become available in Cribl.Cloud's load balancer. However, Cribl Stream will open the port, and will be able to receive data, immediately.

Cribl.Cloud Ports and TLS Configurations

Cribl.Cloud provides several data Sources and ports already enabled for you, plus 11 additional TCP ports (`20000-20010`) that you can use to add and configure more Sources.

The Cribl.Cloud portal's **Data Sources** page displays the pre-enabled Sources, their endpoints, the reserved and available ports, and protocol details. For each existing Source listed here, Cribl recommends using the preconfigured endpoint and port to send data into Cribl Stream.

To access the **Data Sources** page, on the top bar, select **Products**, and then select **Cribl** > **Workspace** > **Data Sources**.

Cribl HTTP and Cribl TCP Sources/Destinations

Use the Cribl HTTP Destination and Source, and/or the Cribl TCP Destination and Source, to relay data between Worker Nodes connected to the same Leader. This traffic does not count against your ingestion quota, so this routing prevents double-billing. (For related details, see Exemptions from License Quotas.)

Backpressure Behavior and Persistent Queues

By default, a Cribl Stream Source will respond to a **backpressure** situation by blocking incoming data. Backpresssure triggers exist when an in-memory buffer is full and/or when downstream Destinations/receivers are unavailable. The Source will refuse to accept new data until it can flush its buffer.

This will propagate block signals back to the sender, if it supports backpressure. Note that UDP senders (including SNMP Traps and some syslog senders) do not provide this support. In this situation, Cribl Stream will simply drop new events until the Source can process them.

Persistent Queues

Push Sources' config modals provide a **Persistent Queue Settings** option to minimize loss of inbound streaming data. Here, the Source will write data to disk until its in-memory buffer recovers. Then, it will drain the disk-queued data in FIFO (first in, first out) order.

When you enable Source PQ, you can choose between two trigger conditions: **Smart** Mode will engage PQ upon backpressure from Destinations, whereas **Always On** Mode will use PQ as a buffer for **all** events.

For details about the PQ option and these modes, see Persistent Queues.

Persistent queues, when engaged, slow down data throughput somewhat. It is redundant to enable PQ on a Source whose upstream sender is configured to safeguard events in its own disk buffer.

Other Backpressure Options

The S3 Source provides a configurable **Advanced Settings > Socket timeout** option, to prevent data loss (partial downloading of logs) during backpressure delays.

Diagnosing Backpressure Errors

When backpressure affects HTTP Sources (Splunk HEC, HTTP/S, Raw HTTP/S, and Amazon Data Firehose), Cribl Stream internal logs will show a `503` error code.

15.1.1. Collector Sources

Unlike other Cribl Stream Sources, Collectors are designed to ingest data intermittently, rather than continuously. You can use Collectors to dispatch on-demand (ad hoc) collection tasks, which fetch or "replay" (re-ingest) data from local or remote locations.

Collectors also support **scheduled** periodic collection jobs – recurring tasks that can make batch collection of stored data more like continual processing of streaming data. You configure Collectors prior to, and independently from, your configuration of ad hoc versus scheduled collection runs.

Collectors are integral to Cribl Stream's larger story about optimizing your data throughput. Send full-fidelity log and metrics data ("everything") to low-cost storage, and then use Cribl Stream Collectors to selectively route ("replay") only needed data to your systems of analysis.

Collector Resources

- Video introduction to Data Collection, in < 2 minutes.
- Video introduction to Data Collection Scheduling, in < 2 minutes.
- Free, interactive try-out of Collectors in Cribl's Data Collection & Replay sandbox.
- Example Collector configurations – ready to import into Cribl Stream – in Cribl's Collector Templates repository.
- Using Collectors guides: S3 Storage and Replay | REST API Collectors | Microsoft Graph API Collection | ServiceNow API Collection | Creating a Custom Collector.

Collector Types

Cribl Stream currently provides the following Collector options:

- Azure Blob – enables data collection and replay from Azure Blob Storage objects.
- Cribl Lake - enabled data collection and reply from Cribl Lake Datasets.
- Database – enables data collection from database management systems like MySQL and SQL Server.
- File System/NFS – enables data collection and replay from local or remote filesystem locations.
- Google Cloud Storage – enables data collection and replay from Google Cloud Storage buckets.
- Health Check – monitors the availability of system endpoints.
- REST/API Endpoint – enables data collection and replay via REST API calls. Provides four Discover options, to support progressively more complex (and dynamic) item enumerations.
- S3 – enables data collection and replay from Amazon S3 buckets or S3-compatible stores.

- Script – enables data collection and replay via custom scripts.
- Splunk Search – enables data collection and replay from Splunk queries. Supports both simple and complex queries, as well as real-time searches.

If you are exploring Collectors for the first time, the File System/NFS Collector is the simplest to configure, while the REST/API Collector offers the most complex configuration options.

How Do Collectors Work

You can configure a Cribl Stream Node to retrieve data from a remote system by selecting **Manage** from the top nav, then a **Worker Group** to configure. Next, click **Data** > **Sources** > **Collectors**. Data collection is a multi-step process:

First, define a Collector instance. In this step, you configure **collector-specific settings** by selecting a Collector type and pointing it at a specific target. (E.g., the target will be a directory if the type is File System, or an S3 bucket/path if the type is Amazon S3.)

Next, schedule or manually run the Collector. In this step, you configure either scheduled-job–specific or run-specific settings – such as the run Mode (Preview, Discovery, or Full Run), the Filter expression to match the data against, the time range, etc.

When a Node receives this configuration, it prepares the infrastructure to execute a collection job. A collection job is typically made up of one or more tasks that: discover the data to be fetched; fetch data that match the run filter; and finally, pass the results either through the Routes or (optionally) into a specific Pipeline and Destination.

Select **Monitoring** > **System** > **Job Inspector** to see the results of recent collection runs. You can filter the display by Worker Group (in distributed deployments), and by run type and run timing.

Advanced Collector Configuration

You can edit the configuration of an existing Collector. Or, you can create a new Collector from a template. A template is just a Collector configuration file (in JSON, as usual) intended to copied and edited.

Editing an Existing Collector

1. When configuring the Collector, click **Manage as JSON** on the **Configure** tab.
2. Cribl Stream will open a JSON editor.
3. Edit the Collector as desired.

4. (Optional) If you want to make the Collector configuration available locally, click **Export**.

When JSON configuration contains sensitive information, it is redacted during export.

5. Click **OK** to exit the **Manage as JSON** modal.
6. Finish configuring the Collector and click **Save**.

Create a New Collector from a Template

You can create a new Collector from a template like those in Cribl's Collector Templates repository.

For many popular Collectors, the Collector Templates repository provides configurations (with companion Event Breakers, and event samples in some cases) that you can import into your Cribl Stream instance, saving the time you'd have spent building them yourself. For many Collectors, you will need to import both the Collector itself (a `collector.json` file) and its Event Breaker (a `breaker.json` file). See the Event Breakers topic for instructions on how to import them.

Collector configurations can contain placeholders defined in the form `<Label|Description>`, where `Label` is the input field label and `Description` is the tooltip text. The Cribl Stream JSON editor makes it easy to work with placeholders, as you'll see in the following procedure and placeholders example.

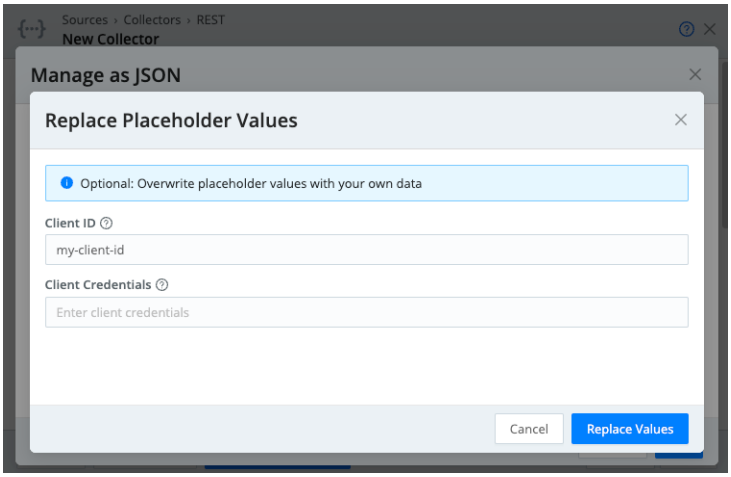
1. Click **Manage as JSON** at the bottom of the **New Collector** modal.
2. Cribl Stream will open a JSON editor.
3. Import the Collector configuration (that is, the template) using either of the two following methods:
    - **Import method**: If your desired Collector configuration file is available locally, click **Import**, navigate to the file, select it, and click **Open**.
    - **Copy and paste method**: If your desired Collector configuration file is open in a local text editor, or is in a Git repository, copy the file. (In the Cribl's Collector Templates repo, navigate to the `collector.json` file in the desired Collector's folder, then click the copy icon.) Back in the JSON text editor, paste the Collector configuration.
4. If the template contains placeholders:
    - If you used the import method, Cribl Stream will open the **Replace Placeholder Values** modal.
    - If you used the copy and paste method, click **OK** to open the modal.
5. Enter desired values for any fields defined as placeholders.
6. (Optional) Edit the configuration further as desired.
7. (Optional) If you want to make the Collector configuration available locally, click **Export**.

When JSON configuration contains sensitive information, it is redacted during export.

8. Click **OK** to exit the **Manage as JSON** modal.
9. Finish configuring the Collector and click **Save**.

Placeholders Example

Here's an example where the configuration defines placeholders for fields named `Client ID` and `Client Credentials`:



Filling in placeholder information

Filling in fields is optional; if you leave a field empty, its placeholder will remain in the JSON configuration, and you can enter a value later.

Scheduled Collection Jobs

You might process data from inherently non-streaming sources, such as REST endpoints, blob stores, etc. Scheduled jobs enable you to emulate a data stream by scraping data from these sources in batches, on a set interval.

You can schedule a specific job to pick up new data from the source – data that hadn't been picked up in previous invocations of this scheduled job. This essentially transforms a non-streaming data source into a streaming data source.

Collectors in Distributed Deployments

In a distributed deployment, you configure Collectors at the Worker Group level, and Worker Nodes execute the tasks. However, the Leader Node oversees the task distribution, and tries to maintain a fair balance across

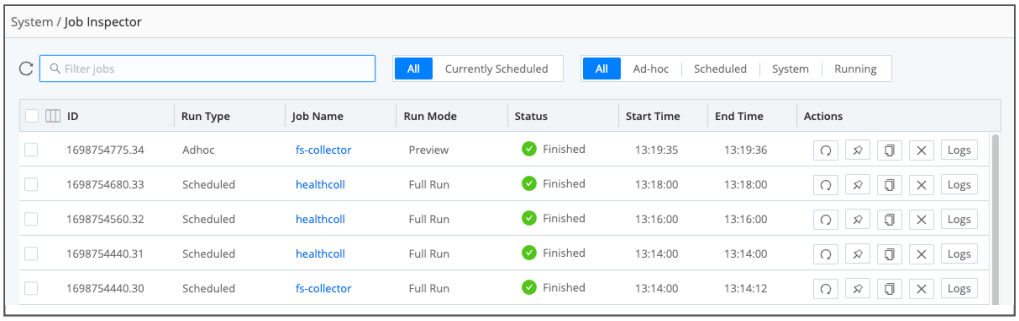
jobs.

When Workers ask for tasks, the Leader will normally try to assign the next task from a job that has the least tasks in progress. This is known as "Least-In-Flight Scheduling," and it provides the fairest task distribution for most cases. If desired, you can change this default behavior by opening **Group Settings** > **General Settings** > **Limits** > **Jobs**, and then setting **Job dispatching** to **Round Robin**.

More generally: In a distributed deployment, you configure Collectors and their jobs on individual Worker Groups. But because the Leader manages Collectors' state, if the Leader instance fails, Collection jobs will fail as well. (This is unlike other Sources, where Worker Groups can continue autonomously receiving incoming data if the Leader goes down.)

Monitor and Inspect Collection Jobs

Select **Monitoring** > **System** > **Job Inspector** to view and manage pending, in-flight, and completed collection jobs and their tasks.



Job Inspector

Here are the options available on the Job Inspector page:

- **All** vs. **Currently Scheduled** tabs: Click **Currently Scheduled** to see jobs forward-scheduled for future execution – including their cron schedule details, last execution, and next scheduled execution. Click **All** to see all jobs initiated in the past, regardless of completion status.
- Job categories (buttons): Select among **Ad-hoc**, **Scheduled**, **System**, and **Running**. (At this level, **Scheduled** means scheduled jobs already running or finished.)
- Group selectors: Select one or more check boxes to display the **Pause**, **Resume**, etc., buttons shown along the bottom.
- Sortable headers: Click any column to reverse its sort direction.
- Search bar: Click to filter displayed jobs by arbitrary strings.
- Action buttons: For finished jobs, the icons (from left to right) indicate: **Rerun**; **Keep job artifacts**; **Copy job artifacts**; **Delete job artifacts**; and **Display job logs** in a modal. For running jobs, the options (again

from left to right) are: **Pause**; **Stop**; **Copy job artifacts**; **Delete job artifacts**; and **Live** (show collection status in a modal).

Troubleshooting

No Discover or Collector Event Results

Sometimes after you configure a Collector you might not see any results even after you verified those results exist outside of Cribl Stream and should have appeared in the run results.

Potential cause: One potential cause is the way time filtering works in Cribl Stream. There are two instances when time filters impact your data:

- When you submit a call for data within a specific time range.
- When you compare the data within a specific time range in Cribl Stream.

When you gather data from a Collector and it returns time-bound data, Cribl Stream runs Event Breakers on the data to break the incoming data into discrete data events. Each discrete event has its own timestamp. If any of those events are outside the `` `${earliest}` `` and `` `${latest}` `` variables as defined for the run, Cribl Stream is going to discard those events by default.

Recommendation Turn off time filtering for that Collector. Typically this setting is under **Advanced Settings**. Set **Disable time filter** to `Yes`, then retry the run.

For additional help with time filtering, see How Time Filtering Works for Scheduled Jobs.

15.1.1.1. Azure Blob Storage Collector

Cribl Stream supports collecting data, and replaying specific events, both from Azure Blob Storage, and from Azure Data Lake Storage Gen2, which implements a hierarchical namespace over blob data. This page covers how to configure the Collector.

For configuration examples, see Resources below.

Configure an Azure Blob Storage Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.
2. In the **New Collector** modal, configure the following under **Collector Settings**:
    - **Collector ID**: Unique ID for this Collector. For example, `azure_42-a`. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.
    - **Description**: Optionally, enter a description.
    - **Auto-populate from**: Optionally, select a predefined Destination that will be used to auto-populate Collector settings. Useful when replaying data.
    - **Container name**: Container to collect from. This value can be a constant, or a JavaScript expression that can be evaluated only at init time. E.g., referencing a Global Variable: `myBucket-${C.vars.myVar}`.

Container names can include only lowercase letters, numbers, and/or hyphens (`-`). This restriction is imposed by Azure.

3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Use this default option to enter your Azure Storage connection string directly. Exposes a **Connection string** field for this purpose. (If left blank, Cribl Stream will fall back to `env.AZURE_STORAGE_CONNECTION_STRING`.)
    - **Secret**: This option exposes a **Connection string (text secret)** drop-down, in which you can select a stored secret that references an Azure Storage connection string. The secret can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need to generate a new secret.
    - **Client secret**: This option allows you to use the Azure service principal's client secret to authenticate, and exposes Azure service principal settings.

- **Certificate**: This option allows you to use a certificate registered with the Azure service principal to authenticate, and exposes Azure service principal settings.

4. Next, you can configure the following **Optional Settings**:
   - **Path**: The directory from which to collect data. Templating is supported (e.g., `myDir/${datacenter}/${host}/${app}/`). Time-based tokens are also supported (e.g., `myOtherDir/${_time:%Y}/${_time:%m}/${_time:%d}/`). More on templates and Filters.
   - **Path extractors**: Extractors allow using template tokens as context for expressions that enrich discovery results.
   - Select **Add Extractor** to add each extractor as a key-value pair, mapping a **Token** name on the left (of the form `/<path>/${<token>}`) to a custom JavaScript **Extractor expression** on the right (e.g., `{host: value.toLowerCase()}`). See an example of the Extractor Expression below.
   - **Recursive**: If set to `Yes` (the default), data collection will recurse through subdirectories.
   - **Include metadata**: With the default `Yes` setting, Cribl Stream will include Azure Blob metadata in collected events (at `__collectible.metadata`).
   - **Include tags**: With the default `Yes` setting, Cribl Stream will include Azure Blob tags in collected events (at `__collectible.tags`). To prevent errors, toggle this to `No` when using a Shared Access Signature connection string, especially on storage accounts that do not support Azure Blob index tags.
   - **Max batch size (objects)**: Maximum number of metadata objects to batch before recording as results. Defaults to `10`. To override this limit in the Collector's Schedule/Run modal, use Advanced Settings > Upper task bundle size.
   - **Encoding**: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, configure any Result, Result Routing, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.
7. To verify that the Collector actually collects data, you can start a single run in the Preview mode.

The sections described below are spread across several tabs.

Collector Sources currently cannot be selected or enabled in the QuickConnect UI.

Cribl Stream supports data collection and replay from Azure's **hot** and **cool** access tiers, but not from the **archive** tier – whose stated retrieval lag, up to several hours, cannot guarantee data availability.

Authentication Options

This section you provides additional details to configure access to the Azure Blog Storage.

Connection String Format

Manual and **Secret** authentication methods use an Azure Storage connection string in this format: `DefaultEndpointsProtocol=[http|https];AccountName=<your-account-name>;AccountKey=<your-account-key>`

A fictitious example, using Microsoft's recommended HTTPS option, is: `DefaultEndpointsProtocol=https;AccountName=storagesample;AccountKey=12345678...32`

Service Principal Settings

Client secret and **Certificate** authentication methods expose the following additional settings:

- **Storage account name**: Enter the name of your Azure Storage Account.
- **Tenant ID**: Enter the service principal's tenant ID.
- **Client ID**: Enter the service principal's client ID.
- **Client secret (text secret)** (with **Client secret** method selected): Select a text secret containing the client secret, or create a new one.
- **Certificate** (with **Certificate** method selected): Select the certificate you registered as credentials for your app in the Azure portal, or create a new one.

Using Shared Access Signature

You can authenticate for Azure Blob Storage using a shared access signature token as connection string.

To employ it successfully, go to your storage account's **Shared access signature** settings and make sure that **Allowed blob index permissions** enables both **Read/Write** and **Filter**.

If you are using Azure Premium storage, you can't set blob index permissions. In such a case, in your collector's setting, enable the **Include Metadata** option. This will allow you to use shared access signature, but as side effect will strip defined tags for downloaded blobs.

Extractor Expression Example

Each expression accesses its corresponding `<token>` through the `value` variable, and evaluates the token to populate event fields. Here is a complete example:

Token	Expression	Matched Value	Extracted Result
`/var/log/${foobar}`	`foobar: {program: value.split('.')[0]}`	`/var/log/syslog.1`	`{program: syslog, foobar: syslog.1}`

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

- **Enabled**: Defaults to `No`. Toggle to `Yes` to enable the custom command.
- **Command**: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).
- **Arguments**: Select **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

- **Event Breaker rulesets**: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`.
- **Event Breaker buffer timeout**: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination. The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. This keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.
- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.
- **Remove Discover fields**: List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).
- **Resume job on boot**: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.

Replay

See these resources that demonstrate how to replay data from object storage. Both are written around Amazon S3-compatible stores, but the general principles apply to Azure blobs as well:

- Data Collection & Replay sandbox: Step-by-step tutorial, in a hosted environment, with all inputs and outputs preconfigured for you. Takes about 30 minutes.
- Using S3 Storage and Replay: Guided walk-through on setting up your own replay.

How the Collector Pulls Data

In the Discover phase, the first available Worker returns the list of files to the Leader Node. In the Collect phase, Cribl Stream spreads the list of files to process spread across 1..N Workers, based on file size, with the goal of distributing tasks as evenly as possible across Workers. These Workers then stream in their assigned files from the remote Azure Blob Storage location.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

- `__collectible` – This object's nested fields contain metadata about each collection job. As mentioned above in Optional Settings, this object will include Azure Blob's own metadata at `__collectible.metadata` and Azure Blob tags at `__collectible.tags`, unless you deselect the corresponding UI toggles.

Resources

For examples of configuring Cribl Stream to interoperate with Azure services, see these guides:

- SSO with Microsoft Entra ID and OIDC (On-Prem).
- SSO with Microsoft Entra ID and SAML (Cribl.Cloud).
- SSO with Microsoft Entra ID and SAML (On-Prem).

Also see these Packs on the Cribl Packs Dispensary, which provide processing Pipelines to transform and optimize incoming Azure data. You can directly import these Pipelines and adapt them to your needs:

- Microsoft Azure NSG Source to Common Schema.

- Azure NSG Flow Logs.
- Azure NSG Flow Logs to OCSF.
- Azure Audit Logs to OCSF.
- Microsoft Office Activity & Azure Logs.

Troubleshooting

When permissions are correct on the object store, and events are reaching the Collector, the Preview pane will show events and the Job Inspector will show an **Events collected** count.

However, if previewing returns no events and throws no error, first check your Filter expression by previewing without it (e.g., simplify the Filter expression to `true`). Then check the Job Inspector: If the **Total size** is greater than `0`, and the **Received size** is `NA` or `0`, make sure you have list and read permissions on the object store.

15.1.1.2. Cribl Lake Collector

The Cribl Lake Collector gathers data from Cribl Lake.

Requirements

Cribl Lake Collector is available only in Cribl.Cloud.

Cribl Lake Collector can gather data from both Cribl-managed Cloud and customer-managed hybrid Stream Worker Groups. Hybrid Worker Groups must be running version 4.8 or higher.

Configure a Cribl Lake Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.
2. In the **New Collector** modal, configure the following under **Collector Settings**:
    - **Collector ID**: Unique ID for this Collector. For example: `myLakeCollector`.
    - **Lake dataset**: Lake Dataset to collect data from.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
3. Optionally, configure any Result and Advanced settings outlined in the below sections.
4. Select **Save**, then **Commit & Deploy**.

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

Event Breaker rulesets: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination. The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, or `GB`. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. This keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Time to live: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.

Remove Discover fields: List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).

Resume job on boot: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.

Verify Data Flow

To verify that the Collector actually collects data, you can start a single run in the Preview mode.

1. Select your Collector's **Run** action.
2. Make sure mode **Preview** is selected and accept other default settings.
3. Confirm with **Run**.
4. Look at the preview screen to check that data is being collected from Cribl Lake.

15.1.1.3. Database Collector

You can configure Database Collectors to pull events from MySQL, Oracle, Postgres, and SQL Server database management systems (DBMSs). This enables you to combine such structured data with unstructured machine data, and then route combined data to downstream systems of analysis to gain new insights.

How the Collector Pulls Data

Like other Cribl Stream Collectors, a Database Collector can perform Preview, Discovery, and Full Run operations in ad hoc or scheduled runs.

Database Collectors rely on Cribl Stream Database Connections Knowledge objects. Before you configure a Collector, configure a Database Connection to negotiate authenticated communication with the appropriate database type.

Database Collectors and Worker Nodes

A Database Collector runs a single `collect` task, which only runs on – and executes a SQL query from – a single Worker Process. However, if the Database Collector is scheduled to run – or run in Preview mode – while the first `collect` task is still running, it will start a simultaneous `collect` task on a different Worker Process.

Configure a Database Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.
2. In the **New Collector** modal, configure the following under **Collector Settings**:
    - **Collector ID**: Unique ID for this Collector. For example, `sh2GetStuff`. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.
    - **Description**: Optionally, enter a description.
    - **Connection**: Use the drop-down to select a Database Connections already configured on your Cribl Stream installation.
    - **SQL query**: Enter a JavaScript expression, enclosed in backticks, that resolves to a query string for selecting data from the database. For details, see SQL Query Example.
3. Next, you can configure the following **Optional Settings**:
    - **Validate query**: Enforces strict query validation that allows only a single `SELECT` statement to be entered in the **SQL query** field. Defaults to `Yes`.

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

Disabling query validation allows potentially destructive queries to be executed, such as data definition language (DDL) and data manipulation language (DML) statements. Such queries can be harmful to your database. Back up your database before running such a query, and proceed with caution.

4. Optionally, configure any Result, Result Routing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.
6. To verify that the Collector actually collects data, you can start a single run in the Preview mode.

The sections described below are spread across several tabs. Click the tab links at left to navigate among tabs.

Collector Sources currently cannot be selected or enabled in the QuickConnect UI.

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

- **Event Breaker rulesets**: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`.
- **Event Breaker buffer timeout**: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination to receive the events. The `No` setting exposes these two fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Optionally, use the drop-down to select an existing Pipeline to process results before sending them to Routes.

This final field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, and so forth. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when you're configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. This keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.
- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.
- **Remove Discover fields** : List of fields to remove from the Discovery results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).
- **Resume job on boot**: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.

SQL Query Example

Supports only a single statement, and only `SELECT`. Has access to the special `${earliest}` and `${latest}` variables, which will resolve to the Collector run's start and end time. - For Oracle, do not include a semicolon `;` at the end of the **SQL query**. - The Database Collector's `earliest` and `latest` variables are formatted using ISO 8601 conventions, unlike other Collectors' corresponding variables.

Here's an example:

```
`SELECT * FROM table_name WHERE timestamp_field > ${earliest} AND timestamp_field < 
```

You can also craft a query that says, in effect, "give me everything new since my last collection job." To do this, you specify a **tracking column** in the query. The tracking column (also known as a **rising column**) must be one whose values you know always increase from one record to the next. See the explanation and example below.

Working with a Tracking Column

You can enable state tracking under the `State Tracking` section when scheduling or performing a full run of the Collector. (Preview and Discovery runs do not support state tracking.) With state tracking enabled, the following field will appear:

Tracking Column: A numeric column whose values increase monotonically. The Collector will track the column's greatest value seen in a previous run.

You can configure the Collector to use a **tracking column** (also known as a **rising column**). This prevents overlap between jobs, which occurs when the Collector fetches the same record more than once. It likewise prevents the occurrence of gaps between data collected by consecutive jobs. (If your database already has mechanisms that protect against overlap and gaps, you probably don't need to use a tracking column.)

For your tracking column, you can choose any column whose values always increase from one record to the next. (A sequence of values that behaves like this is said to increase monotonically.) Many database tables have monotonically increasing `id`, `time`, and/or `date` columns.

State tracking is available only for scheduled and full ad-hoc collection (but not for preview or discovery ad-hoc runs). Once you configure your Collector, you can enable state tracking and specify a tracking column while scheduling a job or performing a full ad-hoc run.

To explain the syntax of queries that work with state tracking, we'll break down a few examples.

Tracking Column Queries: A Basic Example

```
`SELECT * FROM my_table WHERE ${state && state.id ? `id > ${state.id.value}` : '1 = 
```

The `SELECT` statement must satisfy one requirement: that the tracking column be among the columns named. `SELECT * FROM my_table` satisfies this requirement because the wildcard (`*`) means "all columns."

The `WHERE` clause illustrates the key techniques required for state tracking:

- First, we verify that state has been saved (on a prior run of the Collector); and, if it has, that it includes the desired tracking column – for this example, a column named `id`.

```
WHERE ${state && state.id
```

- If state **has** been saved, we'll apply the test right after the `?` in the ternary operator. This determines whether the value of the `id` column for a given row is greater than the last-saved value for that column. If it is not, that means that the row was collected already, and should not be collected again.

```
? `id > ${state.id.value}` : '1 = 1'}`
```

- If state has **not** been saved, this means that the Collector is now about to run **for the first time**.

Calculated temporary columns cannot be used directly in the `WHERE` clause. The `WHERE` clause can only reference existing columns or aliases of existing columns.

The example assumes that we want to collect all rows. To do this, we need an expression that always evaluates to true, so every row gets collected. The expression `'1 = 1'` after the ternary operator's colon (`:`) does exactly that.

Finally, the `ORDER BY` clause, `ORDER BY id`, guarantees that the query returns rows such that the value of the tracking column (here, `id`) increases monotonically from row to row. For state tracking to work correctly, rows **must** be returned such that the value of the tracking column increases monotonically. Some databases have mechanisms that achieve this without an `ORDER BY` clause, but one way or another, this requirement must be satisfied.

Tracking Column Queries: Starting in the Middle

The previous example assumes that you want the Collector's first run to start with the first row of your table. Sometimes, though, you might need the Collector to start somewhere in the middle. If so, you'll need to replace the expression `'1 = 1'` with an expression that finds the desired starting point.

For example:

- If the tracking column is `id` and you want the Collector to begin with the record whose `id` is `4200`, you'd write `id > 4199` instead of `'1 = 1'`.
- Now, the first Collector run will start where `id`'s value is `4200`, and its saved state will include the location where the Collector leaves off.
- In all subsequent runs, the initial test of `state && state.id` will evaluate to true – because there is saved state.
- This means that the Collector will apply `id > ${state.id.value}` and start each new run with next not-yet-collected record.

Tracking Column Queries: Advanced Example

Timestamp columns are a popular choice for state tracking. Here's an example:

```
SELECT id, text_data, timestamp, UNIX_TIMESTAMP(timestamp) as tracking_timestamp FRO
WHERE ${state && state.tracking_timestamp ? `UNIX_TIMESTAMP(timestamp) > ${state.tra
ORDER BY tracking_timestamp
```

This query differs from the basic example above in one important way: We use the SQL function `UNIX_TIMESTAMP()` to convert the value in the database's `timestamp` column, from a date to an integer. (This example assumes that we're dealing with a MySQL database, where the `timestamp` column's value will be a date.)

Cribl Stream requires the tracking column's value to be an integer; and here, we satisfy that requirement by using the `UNIX_TIMESTAMP()` function. In your own queries, depending on the nature of the columns you want to use for tracking, you might be able to adapt this syntax – or you might need to get more creative.

Working with Stateful Columns

You can configure a Database Collector to process tables only when new rows have been added. Two configurations are possible – one using stateful sequence columns and one using stateful timestamp columns.

In either case, using a stateful column is a four-step process:

1. Set up a database if you do not already have one.
2. Create a database connection in Cribl Stream.
3. Create a Database Collector.
4. Configure the Database Collector to track the sequence or timestamp.

The first time your Collector runs, it will process all rows in the relevant table. On subsequent runs, it will process only rows added since the last run.

Creating a Database Connection in Cribl Stream

To create a database connection:

1. Select **Processing** > **Knowledge** > **Database Connections**.
2. Click **Add Database Connection**.
3. Give the connection an ID of your choosing.
4. Select the **Database type** appropriate for your application.
5. Enter a connection string that is appropriate for your database. The following example is for a SQL Server database:
   `Server=<server-name>; Database=<database>;User Id=<user>; Password=<password>;trustServerCertificate=true;`
6. Click **Test Connection** to verify the connection.
7. Click **Save**.
8. Commit and deploy your changes.

Stateful Column Queries: Sequence Example

To set up a Database Collector to use stateful sequence columns:

1. Create a Collector.
2. Give the connection an ID of your choosing.
3. Select the database connection you created previously.
4. For **SQL Query**, input the following string, including the backticks:

```
`SELECT * FROM my_table WHERE ${state && state.id ? `id > ${state.id.value}` : '1
```

1. Click **Save**. The Collector modal will close.
2. Commit and deploy your changes.
3. Reopen your Collector and click **Schedule**.

In the scheduling modal:

1. Enable scheduling for the Collector.

2. Under **State Tracking**, set **Enabled** to `Yes` and **Tracking Column** to the name of the column storing your auto-incrementing ID.
3. Click **Save**.

The Collector will process all rows in the table when you run it for the first time. On subsequent runs, it will process only rows added since the last run.

Stateful Column Queries: Timestamp Example

To set up a Database Collector to use stateful timestamp columns:

1. Create a Collector.
2. Give the connection an ID of your choosing.
3. Select the database connection you created previously.
4. For **SQL Query**, input a string like the following. Include the backticks, and use the table and column names from your own database. In this example, the `DATEDIFF` function is specific to a SQL Server database; the function for your database may differ.
   ```
   `select <id>, <text_data>, <timestamp>, DATEDIFF(s, '1970-01-01 00:00:00', timestamp) as tracking_timestamp from <table-name> where ${state && state.tracking_timestamp ? `DATEDIFF(s, '1970-01-01 00:00:00', timestamp) > ${state.tracking_timestamp.value}` : "1=1"} order by tracking_timestamp`
   ```
5. Click **Save**. The Collector modal will close.
6. Commit and deploy your changes.
7. Reopen your Collector and click **Schedule**.

In the scheduling modal:

1. Enable scheduling for the Collector.
2. Under **State Tracking**, set **Enabled** to `Yes` and **Tracking Column** to the name of the column that contains the timestamp.
3. Click **Save**.

The Collector will process all rows in the table when you run it for the first time. On subsequent runs, it will process only rows added since the last run.

In this example the SQL Server function `DATEDIFF(s, '1970-01-01 00:00:00', <timestampColumn>)` must be used to convert the database date value to a numeric Epic (seconds since Epoch) value. This conversion is needed because most databases return a formatted timestamp string `mm/dd/yyyy hh:mm:ss (2023-07-11 14:24:18)`, which must be converted to a number for

state tracking. In this case, Cribl Stream returns the raw timestamp column as well as the timestamp converted to a number, which is required for state tracking.

Use a Function like Eval to remove `tracking_timestamp` from events if you don't want to send this field to a Destination.

Manage Collector State

See the Manage Collector State topic for instructions on editing or deleting Collector state.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

- `__collectible` – This object's nested fields contain metadata about each collection job.

15.1.1.4. File System/NFS Collector

Cribl Stream supports collecting data from a locally mounted filesystem location that is available on all Worker Nodes.

In Cribl.Cloud, the File System/NFS Collector is only available on customer-managed hybrid Worker Nodes.

Configure a File System Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.
2. In the **New Collector** modal, configure the following under **Collector Settings**:
    - **Collector ID**: Unique ID for this Collector. E.g., `DysonV11Roomba960`. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.
    - **Description**: Optionally, enter a description.
    - **Auto-populate from**: Select a Destination with which to auto-populate Collector settings. Useful when replaying data.
    - **Directory**: The directory from which to collect data. Templating is supported (e.g., `/myDir/${host}/${year}/${month}/`). You can also use templating to specify (e.g.) a Splunk bucket from which to collect. Symlinks will not be followed. More on templates and Filters.
3. Next, you can configure the following **Optional Settings**:
    - **Path extractors**: Extractors allow using template tokens as context for expressions that enrich discovery results.
    - Select **Add Extractor** to add each extractor as a key-value pair, mapping a **Token** name on the left (of the form `/<path>/${<token>}`) to a custom JavaScript **Extractor expression** on the right (e.g., `{host: value.toLowerCase()}`). See an example of the Extractor Expression below.
    - **Recursive**: If set to `Yes` (the default), data collection will recurse through subdirectories.
    - **Max batch size (files)**: Maximum number of lines written to the discovery results files each time. Defaults to `10`. To override this limit in the Collector's Schedule/Run modal, use Advanced Settings > Upper task bundle size.
    - **Destructive**: If set to `Yes`, the Collector will delete files after collection. Defaults to `No`.
    - **Encoding**: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Result, Result Routing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.
6. To verify that the Collector actually collects data, you can start a single run in the Preview mode.

Cribl Stream automatically detects gzip compression where a file name ends in `.gz`.

The sections described below are spread across several tabs. Click the tab links at left to navigate among tabs.

Collector Sources currently cannot be selected or enabled in the QuickConnect UI.

Extractor Example

Each expression accesses its corresponding `<token>` through the `value` variable, and evaluates the token to populate event fields. Here is a complete example:

Token	Expression	Matched Value	Extracted Result
`/var/log/${foobar}`	`foobar: {program: value.split('.')[0]}`	`/var/log/syslog.1`	`{program: syslog, foobar: syslog.1}`

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

Enabled: Defaults to `No`. Toggle to `Yes` to enable the custom command.

Command: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).

Arguments: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

Event Breaker rulesets: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination. The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. This keeps the Collector's configuration self-contained and

separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.
- **Remove Discover fields** : List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).
- **Resume job on boot**: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.
- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

How the Collector Pulls Data

When you run a Filesystem/NFS Collector in Discovery mode, the first available Worker returns the list of available files to the Leader Node.

In Full Run mode, the Leader distributes the list of files to process across 1..*N* Workers as evenly as possible, based on file size. These Workers then stream in their assigned files from the filesystem location.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

- `__collectible` – This object's nested fields contain metadata about each collection job.

15.1.1.5. Google Cloud Storage Collector

Cribl Stream supports collecting data objects from Google Cloud Storage buckets. This page covers how to configure the Collector.

Configure a Google Cloud Storage Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.
2. In the **New Collector** modal, configure the following under **Collector Settings**:
    - **Collector ID**: Unique ID for this Collector. E.g., `gcs_24-7`. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.
    - **Description**: Optionally, enter a description.
    - **Auto-populate from**: Optionally, select a predefined Destination that will be used to auto-populate Collector settings. Useful when replaying data.
    - **Bucket name**: Google Cloud Storage bucket to collect from. This value can be a constant, or a JavaScript expression that can be evaluated only at init time. E.g., referencing a Global Variable: `myBucket-${C.vars.myVar}`.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Auto**: This option uses the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to provide the location of a credential JSON file. When this option is set, Cribl Stream will first check whether the `GOOGLE_APPLICATION_CREDENTIALS` environment variable exists and properly set with valid credentials. If this environmental variable is missing or incorrect, Cribl Stream checks for credentials in two additional fallback locations, as described in the official Google Cloud documentation: How Application Default Credentials works.

    In addition to using the `GOOGLE_APPLICATION_CREDENTIALS` environment variable, you can use credentials attached to your Google Cloud instance.
    - **Secret**: This option exposes a **Connection string (text secret)** drop-down, in which you can select a stored secret that references an Azure Storage connection string. The secret can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need to generate a new secret.
    - **Manual**: Use this default option to enter your Google Cloud Storage connection string directly. Exposes a **Service account credentials** field for this purpose. The **Service account credentials** are the contents of a Google Cloud service account credentials (JSON keys) file. To upload a file, click the upload button at this field's upper right.
    - **Secret**: This option exposes a **Service account credentials (text secret)** drop-down, in which you can select a stored secret that references an Google Cloud Storage connection string. The secret

can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need to generate a new secret.

> You can access service account credentials in the Google Cloud Console under **Service Accounts** > <service account associated with bucket> > **Keys**. The key file must be in JSON format.

4. Next, you can configure the following **Optional Settings**:
    - **Path**: The directory from which to collect data. Templating is supported (e.g., `myDir/${datacenter}/${host}/${app}/`). Time-based tokens are also supported (e.g., `myOtherDir/${_time:%Y}/${_time:%m}/${_time:%d}/`). More on templates and Filters.
    - **Path extractors**: Extractors allow using template tokens as context for expressions that enrich discovery results.
    - Select **Add Extractor** to add each extractor as a key-value pair, mapping a **Token** name on the left (of the form `/<path>/${<token>}`) to a custom JavaScript **Extractor expression** on the right (e.g., `{host: value.toLowerCase()}`). See an example of the Extractor Expression below.
    - **Endpoint**: Google Cloud Storage service endpoint. If empty, the endpoint will be automatically constructed using the service account credentials.
    - **Disable time filter**: Toggle to `Yes` if your Run or Schedule configuration specifies a date range and no events are being collected. This will disable the Collector's event time filtering to prevent timestamp conflicts.
    - **Recursive**: If set to `Yes` (the default), data collection will recurse through subdirectories.
    - **Max batch size (objects)**: Maximum number of metadata objects to batch before recording as results. Defaults to `10`. To override this limit in the Collector's Schedule/Run modal, use Advanced Settings > Upper task bundle size.
    - **Encoding**: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, configure any Result, Result Routing, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.
7. To verify that the Collector actually collects data, you can start a single run in the Preview mode.

> The sections described below are spread across several tabs. Click the tab links at left to navigate among tabs.

> Collector Sources currently cannot be selected or enabled in the QuickConnect UI.

Extractor Expression Example

Each expression accesses its corresponding `<token>` through the `value` variable, and evaluates the token to populate event fields. Here is a complete example:

Token	Expression	Matched Value	Extracted Result
`/var/log/${foobar}`	`foobar: {program: value.split('.')[0]}`	`/var/log/syslog.1`	`{program: syslog, foobar: syslog.1}`

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

- **Enabled**: Defaults to `No`. Toggle to `Yes` to enable the custom command.
- **Command**: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).
- **Arguments**: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

- **Event Breaker rulesets**: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`.
- **Event Breaker buffer timeout**: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination. The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. This keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Pre-processing Pipeline: Pipeline to process results before sending to Routes. Optional, and available only when **Send to Routes** is toggled to `Yes`.

Throttling: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.
- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.

- **Remove Discover fields** : List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).
- **Resume job on boot**: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.

Google Cloud Roles and Permissions

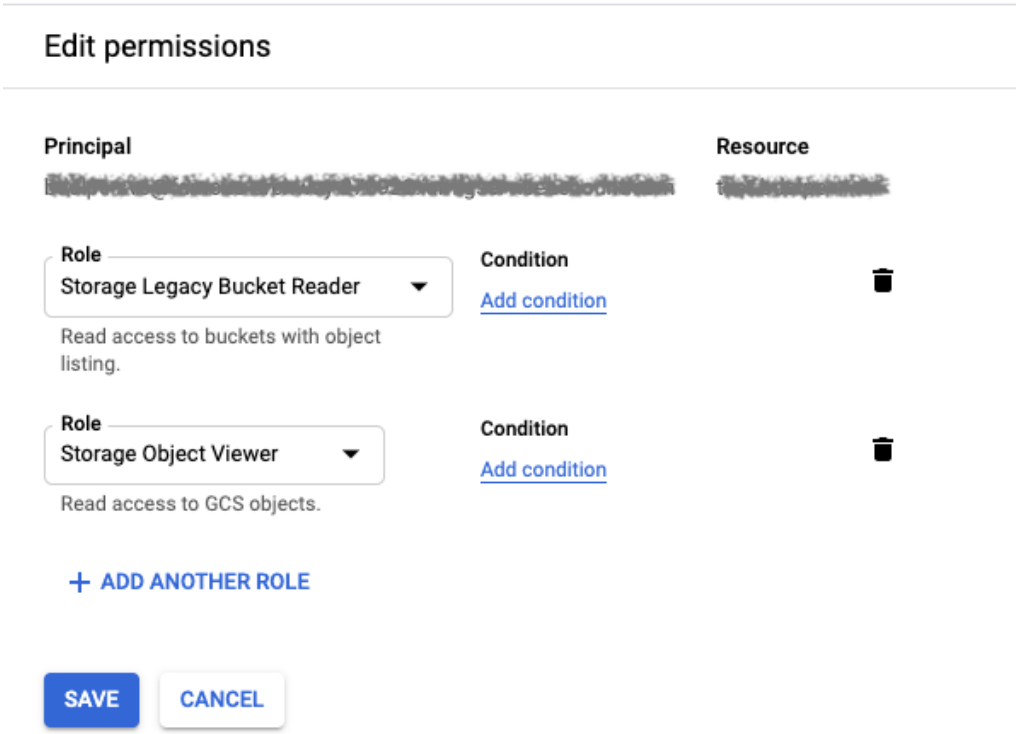
Your Google Cloud service account will need, at a minimum, roles and permissions that enable you to set up a new bucket or modify an existing one:

Roles

- Storage Legacy Bucket Reader: `roles/storage.legacyBucketReader`
- Storage Legacy Object Reader: `roles/storage.legacyObjectReader`

Permissions

- `storage.buckets.get`
- `storage.objects.get`
- `storage.objects.list`



Editing Google Cloud roles and permissions

For additional details, see the Google Cloud Access Control topic.

Replay

See these resources that demonstrate how to replay data from object storage. Both are written around Amazon S3-compatible stores, but the general principles apply to Google Cloud buckets as well:

- Data Collection & Replay sandbox: Step-by-step tutorial, in a hosted environment, with all inputs and outputs preconfigured for you. Takes about 30 minutes.
- Using S3 Storage and Replay: Guided walk-through on setting up your own replay.

How the Collector Pulls Data

In the Discover phase, the first available Worker returns the list of files to the Leader Node. In the Collect phase, Cribl Stream spreads the list of files to process spread across 1..N Workers, based on file size, with the goal of distributing tasks as evenly as possible across Workers. These Workers then stream in their assigned files from the remote Google Cloud Storage location.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

- `__collectible` – This object's nested fields contain metadata about each collection job.

Troubleshooting

When permissions are correct on the object store, and events are reaching the Collector, the Preview pane will show events and the Job Inspector will show an **Events collected** count.

However, if previewing returns no events and throws no error, first check your Filter expression by previewing without it (e.g., simplify the Filter expression to `true`). Then check the Job Inspector: If the **Total size** is greater than `0`, and the **Received size** is `NA` or `0`, make sure you have list and read permissions on the object store.

15.1.1.6. Health Check Collector

The Health Check Collector monitors endpoints by sending requests and generating events based on the responses. This Collector provides multiple Discover types and Health Check options.

Configure a Health Check Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.
2. In the **New Collector** modal, configure the following under **Collector Settings**:
    - **Collector ID**: Unique ID for this Collector. For example, `healthMonitoring`. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.
    - **Description**: Optionally, enter a description.
3. Within the **Discover** accordion, the **Discover type** drop-down provides four options, corresponding to different use cases. Each **Discover type** selection will expose a different set of fields. Below, we cover the **Discover type**s from the simplest to the most complex.
    - Discover type: None matches cases where one simple API call will retrieve all the data you need. This default option suppresses the Discover stage. Use the modal's **Health check** section to specify the endpoint and other details. Cribl Stream will assign the Health Check task to a single Worker.
    - Discover type: Item List matches cases where you want to enumerate a known list of **Discover items** to retrieve, like specific AWS services to identify hosts to check. Discovery will return one Health Check task per item in the list, and Cribl Stream will spread each of those tasks across all available Workers.
    - Discover type: JSON Response provides a **Discover result** field where you can (optionally) define Discover tasks as a JSON array of objects. Each entry returned by Discover will generate a Health Check task, and Cribl Stream will spread each of those tasks across all available Workers.
    - Discover type: HTTP Request matches cases where you need to dynamically discover what you can Health Check from a REST endpoint. This Discover type most fully exploits Cribl Stream's Discover-and-then-health-check architecture. (Example: Make a REST call to get a list of available hosts, then run Health Checks against each of those hosts.) Each item returned will generate a Health Check task, and Cribl Stream will spread each of those tasks across all available Workers.
4. In the **Authentication** accordion, use the **Authentication** drop-down to select one of these options:
    - **None**: Don't use authentication. Compatible with REST servers like AWS, where you embed a secret directly in the request URL.
    - **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.

- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.
- **Login**: Enables you to specify several credentials, then perform a POST to an endpoint during the Discover operation. The POST response returns a token, which Cribl Stream uses for later Health Check operations. Exposes multiple extra fields – see Login Authentication below.
- **Login (credentials secret)**: Like **Login**, except that you specify a secret referencing the credentials, rather than the credentials themselves. Exposes multiple extra fields – see Login Secret Authentication below.
- **OAuth**: Enables you to directly enter credentials for authentication via the OAuth protocol. Exposes multiple extra fields – see OAuth Authentication below.
- **OAuth (text secret)**: Like the **OAuth** option, except that you specify a stored secret referencing the credentials. Exposes multiple extra fields – see OAuth Secret Authentication below.

5. In the **Health Check** accordion, configure the following:
   - **Health check URL**: URL (constant or JavaScript expression) to use for the Health Check operation. Refer to Health Checks below for details.
   - **Health check method**: Select the HTTP verb to use for the Health Check operation – `GET`, `POST`, or `POST with body`.
   - **Health check POST body**: Template for POST body to send with the Health Check request. (This field is displayed only when you set the **Health check method** to `POST with body`.) You can reference parameters from the Discover response using template params of the form: `` `${variable}` ``.
   - **Health check parameters**: Optional HTTP request parameters to append to the request URL. These refine or narrow the request. For details, see Health Check Parameters.
   - **Health check headers**: Optional HTTP request headers to append to the request URL. For details, see Health Check Headers.
   - **Authenticate health check**: Toggle to `Yes` if you want to authenticate Health Checks. When set to `No`, the default, **Authentication** is applied only to Discover.

   By adding the appropriate **Health check headers**, you can specify authentication based on API keys, as an alternative to the **Authentication**: `Basic` or `Login` options below.

6. In the **Retries** accordion, configure the following:
   - **Retry type**: The algorithm to use when performing HTTP retries. Options include `Backoff` (the default), `Static`, and `Disabled`.
   - **Initial retry interval (ms)**: Time interval between failed request and first retry (kickoff). Maximum allowed value is 20,000 ms (1/3 minute). A value of `0` means retry immediately until reaching the retry limit in **Max retries**.

- **Max retries**: Maximum number of times to retry a failed HTTP request. Defaults to `5`. Maximum: `20`. A value of `0` means don't retry at all.
- **Backoff multiplier**: Base for exponential backoff. A value of `2` (default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, etc.
- **Retry HTTP codes**: List of HTTP codes that trigger a retry. Leave empty to use the defaults (`429` and `503`). Cribl Stream does not retry codes in the `200` series.
- **Honor Retry-After header**: When toggled to `Yes` (the default) and the `retry-after` header is present, Cribl Stream honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. Cribl Stream always ignores `retry-after` headers that specify a delay longer than 20 seconds.
  Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).
  When toggled to `No`, Cribl Stream ignores all `retry-after` headers.

7. Next, you can configure the following **Optional Settings**:
   - **Request Timeout (secs)**: Here, you can set a maximum time period (in seconds) for an HTTP request to complete before Cribl Stream treats it as timed out. Defaults to `0`, which disables timeout metering.
   - **Reject unauthorized certificates**: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.
   - **Safe headers**: Optionally, list headers that you consider safe to log in plain text. Separate the header names with tabs or hard returns.
   - **Encoding**: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
8. Optionally, configure any Result, Result Routing, and Advanced settings outlined in the sections below.
9. Select **Save**, then **Commit & Deploy**.
10. To verify that the Collector actually collects data, you can start a single run in the Preview mode.

The sections described below are spread across several tabs, some of which contain collapsible accordions. Click the tab links at left to navigate among tabs. Click **Save** when you've configured your Collector.

See Formatting Expressions below for guidance on this Collector's specific requirement to enter JavaScript expressions as template literals.

> Collector Sources cannot be selected or enabled in the QuickConnect UI.

Discover

This section guides you through configuring Discover Types.

Discover Type: Item List

Setting the **Discover type** to `Item List` exposes this additional field above the Health Check settings:

Discover items: List of items to return from the Discover task. Each returned item will generate a Health Check task, and can be referenced using `${id}` in the **Health Check URL**, the **Health Check parameters**, or the **Health Check headers**. Sample list with Cribl's health endpoint:

```
http://localhost:8080/services/collector/health,http://0.0.0.0:3000/services/collect
```

Discover Type: JSON Response

Setting the **Discover type** to `JSON Response` exposes these additional fields above the Health Check settings:

Discover result: Allows hard-coding the Discover result. Must be a JSON object. Works with the **Discover data field**. Sample JSON entry:

```
`[ {"url": "http://localhost:8088/services/collector/health"},{ "url": "http://loca
```

Discover data field: Within the response, this is the name of the field that contains discovery results. (Leave blank if the result is an array.) Sample JSON entry:

```
items, json: { items: [{id: 'first'},{id: 'second'}] }
```

In an XML response, this is the name of the element that contains discovery results. Sample XML entry:

```
result.items
<response>
 <items>
  <element>
   <id>first</id>
  </element>
  <element>
   <id>second</id>
  </element>
 </items>
</response>
```

Discover Type: HTTP Request

Setting the **Discover type** to `HTTP Request` exposes these additional fields above the Health Check settings:

Discover URL: Enter the URL to use for the Discover operation. This can be a constant URL, or a JavaScript expression to derive the URL.

> Where a URL (path or parameters) includes variables that might contain unsafe ASCII characters, encode these variables using `C.Encode.uri(paramName)`. (Examples of unsafe characters are: space, `$`, `/`, `=`.) Example URL with encoding: `'http://localhost:9000/api/v1/system/logs/' + C.Encode.uri(`${id}`)`.
>
> Request parameters that are not contained directly in the URL are automatically encoded. Cribl Stream URLs/expressions specified in the **Discover URL** field follow redirects.

Discover method: Select the HTTP verb to use for the Discover operation – `GET`, `POST`, or `POST with body`.

Discover POST body: Template for POST body to send with the Discover request. (This field is displayed only when you set the **Discover method** to `POST with body`.)

Discover parameters: Optional HTTP request parameters to append to the Discover request URL. These refine or narrow the request. Click **Add Parameter** to add parameters as key-value pairs:

- **Name**: Parameter name.
- **Value**: JavaScript expression to compute the parameter's value, normally enclosed in backticks (for example, `` `${id}` ``). Can also be a constant, enclosed in single quotes (`'id'`). Values without delimiters (for example, `id`) are evaluated as strings.

Discover headers: Optional Discover request headers.: Click **Add Header** to add headers as key-value pairs:

- **Name**: Header name.
- **Value**: JavaScript expression to compute the header's value, normally enclosed in backticks (for example, `` `${id}` ``). Can also be a constant, enclosed in single quotes (`'id'`). Values without delimiters (for example, `id`) are evaluated as strings.

Discover data field: Within the response JSON, name of the field that contains Discover results. Leave blank if the result is an array.

The following sections describe the remaining tabs, whose settings and content apply equally to all **Discover type** selections.

Health Check

Each request that this Collector sends constitutes one "health check." One source of insight into the health of the endpoint is the internal fields that the Collector emits. For example, to observe how slowly or quickly an endpoint is responding, you can monitor the value of the `elapsedMS` element nested in the `__collectStats` internal field.

Where a URL (path or parameters) includes variables that might contain unsafe ASCII characters, encode these variables using `C.Encode.uri(paramName)`. (Examples of unsafe characters are: space, `$`, `/`, `=`.) Example URL with encoding: `'http://localhost:9000/api/v1/system/logs/' + C.Encode.uri(`${id}`)`.

Request parameters that are not contained directly in the URL are automatically encoded. Cribl Stream URLs/expressions specified in the **Health check URL** field follow redirects.

Health Check Parameters

In **Health check parameters**, select **Add parameter** to add parameters as key-value pairs:

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value, normally enclosed in backticks (for example, `` `${id}` ``). Can also be a constant, enclosed in single quotes (`'id'`). Values without delimiters (for example, `id`) are evaluated as strings.

Health check headers

In **Health check headers**, select **Add Header** to (optionally) add request headers as key-value pairs:

- **Name**: Header name.
- **Value**: JavaScript expression to compute the header's value, normally enclosed in backticks (for example, `` `${id}` ``). Can also be a constant, enclosed in single quotes (`'id'`). Values without delimiters (for example, `id`) are evaluated as strings.

Authentication

This section covers the process of configuring authentication options.

Login Authentication

Selecting `Login` exposes the following additional fields:

- **Login URL**: URL for the login API call, which is expected to be a POST call.
- **Username**: Login username.
- **Password**: Login password.
- **POST body**: Template for POST body to send with the login request. The `${username}` and `${password}` variables specify the corresponding credentials' locations in the message.
- **Token attribute**: Path to the token attribute in the login response body. Supports nested attributes.
- **Authorize expression**: JavaScript expression used to compute the Authorization header to pass in Discover and Health Check calls. Uses `${token}` to reference the token obtained from the login POST request.
- **Authentication headers**: Optionally, click **Add Header** for each custom auth header you want to define. In the resulting table, enter each header row's **Name**.
  The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `id` instead of `` `${id}` `` – will be evaluated as strings.

Login Secret Authentication

Selecting **Login (credentials secret)** exposes the following additional fields:

- **Login URL**: URL for the login API call, which is expected to be a POST call.
- **Credentials secret**: Select a stored text secret in this drop-down, or click **Create** to configure a new secret.
- **POST body**: Template for POST body to send with the login request. The `${username}` and `${password}` variables specify the corresponding credentials' locations in the message.
- **Token attribute**: Path to the token attribute in the login response body. Supports nested attributes.

- **Authorize expression**: JavaScript expression used to compute the Authorization header to pass in Discover and Health Check calls. Uses `${token}` to reference the token obtained from the login POST request.
- **Authentication headers**: Optionally, click **Add Header** for each custom auth header you want to define. In the resulting table, enter each header row's **Name**.
  The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `id` instead of `` `${id}` `` – will be evaluated as strings.

OAuth Authentication

Selecting **OAuth** exposes the following additional fields:

- **Login URL**: Endpoint for the OAuth API call, which is expected to be a POST call.
- **Client secret parameter**: The name of the parameter to send with the **Client secret value**.
- **Client secret value**: The OAuth access token to authorize requests.
- **Extra authentication parameters**: Optionally, click **Add parameter** for each additional OAuth request parameter you want to send in the body of POST requests. Automatically sets the `Content-Type` header to `application/x-www-form-urlencoded`.
  In the resulting table, enter each parameter row's **Name**. The corresponding **Value** is a JavaScript expression to compute the parameter's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `id` instead of `` `${id}` `` – will be evaluated as strings.
- **Token attribute**: Path to the token attribute in the login response body. Supports nested attributes.
- **Authorize expression**: JavaScript expression used to compute the Authorization header to pass in Discover and Health Check calls. Uses `${token}` to reference the token obtained from the login POST request.
- **Authentication headers**: Optionally, click **Add Header** for each custom auth header you want to define. In the resulting table, enter each header row's **Name**.
  The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `id` instead of `` `${id}` `` – will be evaluated as strings.

OAuth Secret Authentication

Selecting **OAuth (text secret)** exposes the following additional fields:

- **Login URL**: Endpoint for the OAuth API call, which is expected to be a POST call.
- **Client secret parameter**: The name of the parameter to send with the **Client secret value**.

- **Client secret value (text secret)**: Select a stored text secret in this drop-down, or click **Create** to configure a new secret.
- **Extra authentication parameters**: Optionally, click **Add parameter** for each additional OAuth request parameter you want to send in the body of POST requests. Automatically sets the `Content-Type` header to `application/x-www-form-urlencoded`.
  In the resulting table, enter each parameter row's **Name**. The corresponding **Value** is a JavaScript expression to compute the parameter's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `id` instead of `` `${id}` `` – will be evaluated as strings.
- **Token attribute**: Path to the token attribute in the login response body. Supports nested attributes.
- **Authorize expression**: JavaScript expression used to compute the Authorization header to pass in Discover and Health Check calls. Uses `${token}` to reference the token obtained from the login POST request.
- **Authentication headers**: Optionally, click **Add Header** for each custom auth header you want to define. In the resulting table, enter each header row's **Name**.
  The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `id` instead of `` `${id}` `` – will be evaluated as strings.

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the Health Check data.

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

- **Enabled**: Defaults to `No`. Toggle to `Yes` to enable the custom command.
- **Command**: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).
- **Arguments**: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

- **Event Breaker rulesets**: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `Cribl`.

- **Event Breaker buffer timeout**: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination.

The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. One use case might be a Health Check Collector that gathers a known, simple type of data from a single endpoint. This approach keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.
- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.
- **Remove Discover fields**: List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).
- **Resume job on boot**: Toggle to `Yes` to resume ad hoc Health Check jobs if Cribl Stream restarts during the jobs' execution.

Formatting Expressions

JavaScript expression fields in this Health Check Collector behave differently from those elsewhere in Cribl Stream. Here, you must enter expressions as template literals, with placeholders referencing variables and JS functions. Here are a few examples:

- To reference the `__collectible.id` internal field in a URL, header, or parameter (etc.), you would write the variable as `` `${id}` ``.
- To reference a function call: `` `${Date.now()}` ``.
- To call a function that references a variable: `` `${Math.floor(earliest)}` ``.

Responses

The Health Check Collector generates error or success events based on the received response from the Health Check request.

Error Events

The Health Check Collector generates error events when no response is received, a request times out, or receives an error (non 200) response. The following is an example error event:

```
{
  "host": "Cribl.local",
  "_raw": "{\"url\":\"http://0.0.0.0:3000/services/collector/health\",\"method\":\"g
  "method": "get",
  "url": "http://0.0.0.0:3000/services/collector/health",
  "statusCode": 404,
  "error": "Http Error, statusCode: 404, details: {\"host\":\"0.0.0.0:3000\",\"port\
  "_time": 1660152577.93,
  "cribl_breaker": "Cribl:ndjson"
}
```

Success Events

The Health Check Collector generates success events when a 200 success status code is received. The following is an example success event:

```
{
  "host": "Cribl.local",
  "_raw": "{\"url\":\"http://0.0.0.0:3000/api/v1/health\",\"method\":\"get\",\"status
  "method": "get",
  "url": "http://0.0.0.0:3000/api/v1/health",
  "statusCode": 200,
  "body": "{\"status\":\"healthy\",\"startTime\":1660152114781}",
  "_time": 1660152114.781,
  "cribl_breaker": "Cribl:ndjson"
}
```

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

- `__collectible` – This object's nested fields contain metadata about each collection job.
- `__collectStats` – This object's nested fields are:
  - `method`: The value you set for **Health Check** > **Health check method**.
  - `url`: The value you set for **Health Check** > **Health check URL**.
  - `elapsedMS`: The time elapsed from the moment the Health Check request was sent until the response was received.

Mitigating Stuck-Job Problems

Occasionally, a scheduled job fails, but continues running for hours or even days, until someone intervenes and cancels it. If left alone, such a "stuck", "orphaned," or "zombie" job will never complete. This can cause missing events in downstream receivers, along with `HTTP timeout` or similar errors in Cribl Stream's logs.

To keep stuck jobs from running excessively long:

- First, try setting **Optional Settings** > **Request Timeout (secs)** – whose default of `0` means "wait forever" – to a desired maximum duration.
- If adjusting **Timeout (secs)** does not fix the problem, try the global setting **Job Timeout** – whose default of `0` allows a job to run indefinitely – to a desired maximum duration. You'll find **Job Timeout** among the task manifest and buffering limits.

Using these settings in tandem works like this:

- **Timeout (secs)** limits the time that Cribl Stream will wait for an HTTP request to complete.
- Then, if a job gets stuck and keeps running beyond that limit, **Job Timeout** can catch and terminate the job, because it monitors the overall time the job has been running.

15.1.1.7. REST / API Endpoint Collector

Cribl Stream supports collecting or pulling data from a REST API endpoint. The REST Collector is versatile and can collect data from a wide variety of upstream services. It provides multiple Discover types and Collect options.

Use REST Collectors when you need to ingest data from:

- Internal APIs built and used inside your Organization.
- External APIs from which your Organization uses data.
- Vendors or upstream API services that you use but which Cribl doesn't yet support natively.

For more usage examples, see Using REST / API Collectors and our adjacent guides.

Once you've configured a REST Collector, you can either run it immediately (ad hoc) to collect data, or schedule it to run on a recurring interval. See Schedule and Run Collector Jobs for more information.

How REST Collectors Handle Data

When the REST Collector runs, Cribl Stream executes a collection job. A collection job consists of tasks, which are the units of work to authenticate, discover, or collect the data. For example, a job that first authenticates and then collects data creates two tasks.

Cribl Stream processes collection jobs that run in these phases:

1. Discovery (optional)
2. Collection
3. Event Breaking
4. Filtering (optional)

Authentication takes place during the Collection phase if needed and can also happen during Discovery for HTTP calls.

You can also filter data based on specific criteria, such as time and/or field values, which you specify during the Collector's ad hoc or scheduled run.

Prerequisites

At a minimum, you need the URL of the API that you intend to collect data from. If the API requires authentication, you will also need authentication credentials.

Configure a REST Collector

Currently, you cannot configure Collector Sources in QuickConnect.

In Cribl Stream, set up a REST Collector:

1. From inside Cribl Stream, select a **Worker Group** to configure. Then, select **Data** > **Sources**. Select **REST** from the list of tiles or the **Collectors** tab. Next, select **Add Collector** to open the **Add Collector** modal.
2. In a simple setup, you only need to fill in the **General** and **Collect** settings in the Collector modal. You will also need the **Authentication** settings if the API requires authentication. Configure the following options under the **General** settings:
    - **Collector ID**: Unique ID for this Collector. This ID must be unique from other Collector IDs in your Cribl Stream instance. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.
    - **Description** Optionally, add an explanation of the function or purpose of the Collector.
3. Configure the following options under the **Collect** settings:
    - **Collect URL**: URL (constant or JavaScript expression) to use for the Collect operation. This URL can use an `authToken` variable to access an auth token. For example, if you define `1234567890` as an auth token and you use `http://myurl.com?authToken=${authToken}` as the Collect URL, the Collect operation will use `http://myurl.com?authToken=1234567890`. See Use JavaScript Expressions to Shape Incoming API Data for more information about using JavaScript with this field.

    If a URL (a path or parameters) includes variables that might contain unsafe ASCII characters, encode these variables using `C.Encode.uri(paramName)`. Considerations:

    - Examples of unsafe characters are: space, `$`, `/`, `=`.
    - Example URL with encoding: `'http://localhost:9000/api/v1/system/logs/' + C.Encode.uri(`${id}`)`. See Cribl Expressions - C.Encode.uri() for more information.
    - Request parameters that are not contained directly in the URL are automatically encoded.
    - Cribl Stream URLs/expressions specified in the **Collect URL** field can follow redirects.

    - **Collect method**: Select the HTTP verb to use for the Collect operation – `GET`, `POST`, `POST with body`, or `Other`.

- **Collect POST body** (displays when you set the **Collect method** to `POST with body`): Template for POST body to send with the Collect request. See Use JavaScript Expressions to Shape Incoming API Data for more information about using JavaScript with this field.
- **Collect verb** (displays when you set the **Collect method** to `Other`): Custom HTTP method to use for the Collect operation.

- **Collect parameters**: Optional HTTP request parameters to append to the request URL. These refine or narrow the request. Select **Add Parameter** to add parameters as key-value pairs:
  - **Name** is the parameter name.
  - **Value** is a JavaScript expression to compute the parameter's value, normally enclosed in backticks (for example, `` `${earliest}` ``). The value can also be a constant, enclosed in single quotes (`'earliest'`). Cribl Stream evaluates values without delimiters (such as `earliest`) as strings.
  - This field can also accept the `${earliest}` and `${latest}` time range variable. See Time Range Variables for more information.

If both the **Collect URL** and **Collect parameters** use the same **Name** (key), the value from the **Collect URL** takes precedence.

- **Collect headers**: Optional collection request headers to add to the API call. Select **Add Header** to add collection request headers as key-value pairs:
  - **Name** is the header name.
  - **Value** is a JavaScript expression to compute the header's value, normally enclosed in single quotes (`'someConstantValue'`). The value can also be a template literal, enclosed in backticks. For example, `` `${new Date().getFullYear()}` ``. Cribl Stream evaluates values without delimiters (such as `someConstantValue`) as strings.
  - This field can also accept the `${earliest}` and `${latest}` time range variable. See Time Range Variables for more information.

You can also use **Collect headers** as an alternative to the Basic, Login, or OAuth authentication options. This method authenticates requests based on API keys using secrets. See How to Use Collect Headers for Authentication for more information.

- **Pagination**: Use this menu to select the pagination scheme for collection results. The available options are:

Option	Description
None	The default selection. Use this option if you do not need a pagination scheme.

Option	Description
Response Body Attribute / Response Header Attribute	Select `Response Body Attribute` to extract a value from the response body that identifies the next page of data to retrieve. Select `Response Header Attribute` to extract this next-page value from the response header. These selections expose additional fields. See Response Body Attribute / Response Header Attribute for information about these fields.
RFC 5988 – Web Linking	Select this option for APIs that follow RFC 5988 conventions to provide the next-page link in a header. This selection exposes three additional fields. See RFC 5988 – Web Linking for information about these fields.
Offset/Limit	Select this option to receive data from APIs that use offset/limit pagination. This selection exposes several additional fields. See Offset/Limit for information about these fields.
Page/Size	Select this option to receive data from APIs that use page/size pagination. This selection exposes several additional fields. See Page/Size for information about these fields.

4. In the **Authentication** settings, select one of the following options from the menu:

Option	Description
None	The default selection. Use this option if you do not need to use authentication. You can also select this option if you decide to embed the authentication secret directly in the request URL, such as with compatible REST servers like AWS. See How to Use Collect Headers for Authentication for more information.
Basic	Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
Basic (credentials secret)	Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.
Login	Enables you to specify several credentials, then perform a POST to an endpoint during the Discover operation. The POST response returns a token, which Cribl Stream uses for later Collect operations. Exposes multiple extra fields. See Login Authentication for more information.
Login (credentials secret)	Like **Login**, except that you specify a secret referencing the credentials, rather than the credentials themselves. Exposes multiple extra fields. See Login Secret Authentication for more information.

Option	Description
OAuth	Enables you to directly enter credentials for authentication via the OAuth protocol. Exposes multiple extra fields. See OAuth Authentication for more information.
OAuth (text secret)	Like the **OAuth** option, except that you specify a stored secret referencing the credentials. Exposes multiple extra fields. See OAuth Secret Authentication for more information.
Google service account OAuth	Uses Google Cloud Platform (GCP) service account credentials to authenticate. Exposes multiple extra fields. See Google Service Account OAuth Authentication for more information.
Google service account OAuth (text secret)	Similar to **Google service account OAuth**, but uses the service account credentials directly as text within the configuration, instead of a separate file. Exposes multiple extra fields. See Google Service Account OAuth Secret Authentication for more information.
HMAC	HMAC (Hash-based Message Authentication Code) authentication allows you to securely authenticate your data collection requests by generating a unique signature for each request. This signature ensures the integrity and authenticity of the request, making it tamper-proof and verifiable by the server. Select an existing HMAC authentication signature or create a new one by selecting **Create a hmacFunction to continue**. See HMAC Function for more information about generating an HMAC signature.

5. For the remaining options, refer to the settings listed for each section:
    - Discover Settings
    - Retries
    - Results
    - Advanced Settings
6. Select **Save**, then **Commit & Deploy**.
7. Verify that data is making it to Cribl Stream by viewing the **Live Data** feed from the Collector.

Configure as JSON

As an alternative to configuring a REST Collector with the user interface, you can configure REST Collectors in JSON mode instead. To toggle to the JSON configuration mode, select the **Configure as JSON** tab at the top of the REST Collector configuration modal. Select the **Configure Collector** tab to return to the user interface configuration mode.

Some important considerations when working in the JSON configuration mode:

- Use this feature with caution. Only experienced and advanced Cribl administrators should configure as JSON.

- The advantage of using the JSON configuration mode is that you can cut and paste or import/export JSON configuration objects, such as from the Cribl Collector Templates repository or your own Git repository where you store version-controlled configurations that you have already validated and which you deploy regularly.
- The JSON configuration editor does not validate your REST Collector configuration. The editor only validates whether your JSON is well-formed, not whether the configuration is valid. Validate your REST Collector configuration with the user interface, not the JSON configuration editor.
- When you make a configuration change in the user interface mode and save it, that change appears in in the JSON configuration mode as well. Similarly, changes made and saved (and vice versa).

Discover Settings

Use the Discover step to better understand what data is available and how it is configured when interacting with a third party API. The results of a Discover call can range in variety and size, depending on the API.

The **Discover type** field provides four options, corresponding to different use cases. Each **Discover type** selection will expose a different set of **Collector Settings** fields:

Discover type	Description	Example use case
HTTP Request	Makes a REST call to dynamically get Discover results. This Discover type matches cases where you need to dynamically discover what you can collect from a REST endpoint. It most fully exploits Cribl Stream's Discover-and-then-Collect architecture. Each item returned will generate a Collect task, and Cribl Stream will spread each of those Collect tasks across all available Workers. As of Cribl Stream 3.0.2, this Discover type supports XML responses.	Make a REST call to get a list of available log files, then run Collect against each of those files.
JSON Response	Use when you need to manually define the Discovery results as a JSON object. This Discover type provides a **Discover result** field where you can (optionally) define Discover tasks as a JSON array of objects. Each entry returned by Discover will generate a Collect task, and Cribl Stream will spread each of those Collect tasks across all available Workers.	You can collect data for specific geo-locations in the National Weather Service API stream of worldwide weather data. This particular API requires multiple parameters in the request URL (latitude, longitude, and so forth), so **Item List** discovery would not work.

Discover type	Description	Example use case
Item List	Use when you need to enumerate Discover results as a list of strings. This Discover type matches cases where you want to enumerate a known list of **Discover items** to retrieve. Discovery will return one Collect task per item in the list, and Cribl Stream will spread each of those Collect tasks across all available Workers.	• Collect network traffic data that is tagged with specific subnets. • Collect weather data for a known list of ZIP codes.
None	Use when you want to skip the Discover step. This default option suppresses the Discover stage. Alternatively, you select this option and use the modal's **Collect** section to specify the endpoint and other details. Cribl Stream will assign the Collect task to a single Worker.	• When one simple API call will retrieve all the data you need. • Collect a list of configured Cribl Stream Pipelines.

Discover Type: HTTP Request

Setting the **Discover type** to `HTTP Request` exposes these additional fields:

- **Discover URL**: Enter the URL to use for the Discover operation. This can be a constant URL, or a JavaScript expression to derive the URL. This field can also accept the `${earliest}` and `${latest}` time range variable. See Time Range Variables for more information.

  If a URL (a path or parameters) includes variables that might contain unsafe ASCII characters, encode these variables using `C.Encode.uri(paramName)`. Considerations:

  - Examples of unsafe characters are: space, `$`, `/`, `=`.
  - Example URL with encoding: `'http://localhost:9000/api/v1/system/logs/' + C.Encode.uri(`${id}`)`.
  - Request parameters that are not contained directly in the URL are automatically encoded.
  - Cribl Stream URLs/expressions specified in the **Collect URL** field follow redirects.

- **Discover method**: Select the HTTP verb to use for the Discover operation – `GET`, `POST`, `POST with body`, or `Other`.
- **Discover POST body**: Template for POST body to send with the Discover request. (This field is displayed only when you set the **Discover method** to `POST with body`.)

- **Discover verb**: Custom HTTP method to use for the Discover operation. (This field is displayed only when you set the **Discover method** to `Other`.)
- **Discover parameters**: Optional HTTP request parameters to append to the Discover request URL. These refine or narrow the request. Select **Add Parameter** to add parameters as key-value pairs:
    - **Name**: Parameter name.
    - **Value**: JavaScript expression to compute the parameter's value, normally enclosed in backticks (for example, `` `${earliest}` ``). Can also be a constant, enclosed in single quotes (`'earliest'`). Values without delimiters (for example, `earliest`) are evaluated as strings.
    - This field can also accept the `${earliest}` and `${latest}` time range variable. See Time Range Variables for more information.
- **Discover headers**: Optional Discover request headers. Select **Add Header** to add headers as key-value pairs:
    - **Name**: Header name.
    - **Value**: JavaScript expression to compute the header's value, normally enclosed in backticks (for example, `` `${earliest}` ``). Can also be a constant, enclosed in single quotes (`'earliest'`). Values without delimiters (for example, `earliest`) are evaluated as strings.
    - This field can also accept the `${earliest}` and `${latest}` time range variable. See Time Range Variables for more information.
- **Pagination**: Use this menu to select the pagination scheme for Discover results. Defaults to `None`. The available options are:

Option	Description
None	The default selection. Use this option if you do not need a pagination scheme.
Response Body Attribute / Response Header Attribute	Select `Response Body Attribute` to extract a value from the response body that identifies the next page of data to retrieve. Select `Response Header Attribute` to extract this next-page value from the response header. These selections expose additional fields. See Response Body Attribute / Response Header Attribute for information about these fields.
RFC 5988 – Web Linking	Select this option for APIs that follow RFC 5988 conventions to provide the next-page link in a header. This selection exposes three additional fields. See RFC 5988 – Web Linking for information about these fields.
Offset/Limit	Select this option to receive data from APIs that use offset/limit pagination. This selection exposes several additional fields. See Offset/Limit for information about these fields.
Page/Size	Select this option to receive data from APIs that use page/size pagination. This selection exposes several additional fields. See

Option	Description
	Page/Size for information about these fields.

- **Discover data field**: Within the response, this is the name of the field that contains discovery results.
  - If the response is a JSON object that contains an array, and you want to generate a separate Collect task for each item in the array, set the **Discover data field** to the key of the array in the JSON object. For example, if the response is `{ "logFiles": ["cribl.log", "cribl.log.1", "cribl.log.2", "audit.log"] }`, setting **Discover data field** to `logFiles` would result in four Collect tasks, one for each log file.
  - If the response itself is a JSON array, like `["cribl.log", "cribl.log.1", "cribl.log.2", "audit.log"]`, leave the **Discover data field** blank for each item in the array to become a collection task.

See Parse Discover Returns With Arrays as JSON Object for an example of how to parse arrays inside JSON objects as separate collection tasks.

- **Format discover result with custom code**: Toggle to `Yes` to provide custom JavaScript code, in the **Format discover result** field, that manipulates the data returned by a Discover request before it's used for collection. This functionality allows you to influence the collection process by transforming Discover results into a specific set of collection tasks.

The custom code operates on the `__e` variable, which is a JSON object or array containing the original Discover results. You can modify the contents of `__e` to define tasks for parallel collection. Here are some key points to remember when working with `__e`:

- Mutable object/array: `__e` is mutable, meaning you can directly modify its contents.
- Response structure: The structure of `__e` depends on the specific response from your Discover request.

For example, to split data by user IDs, assume the Discover result contains user IDs:

```
  [{ "name": "root", "id": 1}, { "name": "joe", "id": 2 }, { "name": "jane", "id": 3 },{ "name": "jose", "id": 4 }]
```

To achieve a collection task that runs for all users except `system`, you'd use:

```
  __e['tasks'] = __e.filter(item => item.name != 'root');
```

As another example, imagine an API with two endpoints:

- Endpoint that returns the count of objects that match search criteria.
- Endpoint for collection that returns items using search criteria that also supports pagination.

You can leverage the **Format discover results** option to do the following:

1. Run a Discover REST API call to return the number of items that match search criteria, like an SQL count query.
2. Use the count matching items to generate collect tasks, one for each page of data to retrieve.

For example, assume the discover REST API call returns the following:

```
{ "numMatchingItems": 100000 }
```

Assume the max page size is 10,000 for the collect API.

The **Format discover result with custom code** option allows you to implement logic that generates an array of collection tasks, one for each page. You can then leverage this array in conjunction with the collection request parameters to retrieve a unique page of data for each collection task.

For example: `http://0.0.0.0:8004/query?sysparm_offset=${offset}&sysparm_limit=${limit}`

Now you'll transform a Discover result of `{ "numMatchingItems": 100000 }` into 10 distinct collect tasks, each retrieving 10,000 results per page. Some of the tasks can be run in parallel depending on job settings and system load.

```
// Expecting: { \"numMatchingItems\" : xxxxx };
if (Array.isArray(__e)) {
  const count = __e['numMatchingItems'];
  let pageSize=10000;
  let numPages=count/pageSize;
  if (count % pageSize) {
     numPages++; // count not evenly divisible by page size, add one more collect ta
  }
  // Add a collect task for each page of data to be retrieved.
  for (let i = 0; i < numPages; i++) {
    __e.push({ offset: i*pageSize, limit: pageSize, count });
  }
}
else {
  __e['__resultOut'] = {"error": "Unexpected - discover result is NOT an array"}
}
```

See another use case example in Using REST/API Collectors.

Discover Type: Item List

Setting the **Discover type** to `Item List` exposes this additional field:

- **Discover items**: List of items to return from the Discover task. Each returned item will generate a Collect task, and can be referenced using `${id}` in the **Collect URL**, the **Collect parameters**, or the **Collect headers**.

Discover Type: JSON Response

Setting the **Discover type** to `JSON Response` exposes these additional fields above the Common Collector Settings:

Discover result: Allows hard-coding the Discover result. Must be a JSON object. Works with the **Discover data field**.

Discover data field: Within the response, this is the name of the field that contains discovery results.

- If the response is a JSON object that contains an array, and you want to generate a separate Collect task for each item in the array, set the **Discover data field** to the key of the array in the JSON object. For example, if the response is `{ "logFiles": ["cribl.log", "cribl.log.1", "cribl.log.2", "audit.log"] }`, setting **Discover data field** to `logFiles` would result in four Collect tasks, one for each log file.
- If the response itself is a JSON array, like `["cribl.log", "cribl.log.1", "cribl.log.2", "audit.log"]`, leave the **Discover data field** blank for each item in the array to become a collection task.

Sample JSON entry:

```
items, json: { items: [{id: 'first'},{id: 'second'}] }
```

In an XML response, this is the name of the element that contains discovery results. Sample XML entry:

```
result.items
<response>
 <items>
  <element>
   <id>first</id>
  </element>
  <element>
   <id>second</id>
  </element>
 </items>
</response>
```

Collect Settings

See Configure a REST Collector for information about most of the settings in the **Collect** section of the REST Collector configuration. The following sections provide additional information about these settings.

How to Use Collect Headers for Authentication

You can use collect headers as an alternative to the Basic, Login, or OAuth authentication options. This method authenticates requests based on API keys using secrets.

To use this authentication method:

1. In the REST Collector configuration **Collect** section, select **Add Header** to add a new header key-value pair.
2. In the **Name** field, assign the header a name.
3. In the **Value** field, use the `C.Secret` Javascript expression method in this field to provide the key-value for the Authentication header. For example, depending on the requirements of your application, you could use this key-value pair:
   `` `Bearer: ${C.Secret('<secretId>', 'text').value}` ``
   or:
   `` `Token: ${C.Secret('<secretId>', 'text').value}` ``
4. In the **Authentication** section, select `None` in the **Authentication** menu.

Pagination Settings

Use the Pagination menu in the **Collect** section to select the pagination scheme for collection results. Defaults to `None`.

Response Body Attribute / Response Header Attribute

Select `Response Body Attribute` to extract a value from the response body that identifies the next page of data to retrieve.

Select `Response Header Attribute` to extract this next-page value from the response header. Either of these selections exposes these additional fields:

- **Response attribute**: Name(s) of attribute(s) in the response payload or header that contain next-page information. If you have multiple attributes with the same name within the response body, you can provide the path to the one you need, for example: `foo.0.bar`. If Cribl Stream cannot find an exact match for a specified attribute name, it will fallback to the last-found partial match.
- **Page limit**: The maximum number of pages to retrieve per Collect task. Defaults to `50` pages. Set to `0` to retrieve all pages.

Selecting `Response Body Attribute` exposes one more field:

- **Last-page expression**: Optionally, enter a JavaScript expression that Cribl Stream will use to determine when the last page has been reached. The values tested by this expression must be present in the **Response attributes** section above. Example expression: `morePages === false`.

Use this expression with APIs like Smartsheet Event Reporting, which return an attribute that signals whether more pages are present, rather than simply returning an empty result set beyond the last page.

RFC 5988 – Web Linking

Select this option with APIs that follow RFC 5988 conventions to provide the next-page link in a header. This selection exposes three additional fields:

- **Next page relation name**: Header substring that refers to the next page in the result set. Defaults to `next`, corresponding to the following example link header: `<https://myHost/curPage>; rel="self" <https://myHost/nextPage>; rel="next"`
- **Current page relation name**: Optionally, specify the relation name within the link header that refers to the current result set. In this same example, `rel="self"` refers to the current page of results: `<https://myHost/curPage>; rel="self" <https://myHost/nextPage>; rel="next"`
- **Page limit**: The maximum number of pages to retrieve. Defaults to `50` pages. Set to `0` to retrieve all pages.

Offset/Limit

Select this option to receive data from APIs that use offset/limit pagination. This selection exposes several additional fields:

- **Offset field name**: Query string parameter that sets the index from which to begin returning records. For example: `/api/v1/query?term=cribl&limit=100&offset=0`. Defaults to `offset`.
- **Starting offset**: (Optional) offset index from which to start request. Defaults to undefined, which will start collection from the first record.
- **Limit field name**: Query string parameter to set the number of records retrieved per request. For example: `/api/v1/query?term=cribl&limit=100&offset=0`. Defaults to `limit`.
- **Record limit**: Maximum number of records to collect per request. Defaults to `50`.
- **Total record count field name**: Identifies the attribute, within the response, that contains the total number of records for the query.
- **Page limit**: The maximum number of pages to retrieve. Defaults to `50`. Set to `0` to retrieve all pages.
- **Zero-based index**: Toggle to `Yes` to indicate that the requested data's first record is at index `0`. The default (No) indicates that the first record is at index `1`.

Page/Size

Select this option to receive data from APIs that use page/size pagination. This selection exposes several additional fields:

- **Page number field name**: Query string parameter that sets the page index to be returned. For example: `/api/v1/query?term=cribl&page_size=100&page_number=0`. Defaults to `page`.
- **Starting page number**: (Optional) page number from which to start request. Defaults to undefined, which will start collection from the first page.
- **Page size field name**: Query string parameter to set the number of records retrieved per request. For example: `/api/v1/query?term=cribl&page_size=100&page_number=0`. Defaults to `size`.
- **Record limit**: Maximum number of records to collect per page. Defaults to `50`.
- **Total page count field name**: Identifies the attribute, within the response, that contains the total number of pages for the query.
- **Total record count field name**: Identifies the attribute, within the response, that contains the total number of records for the query.
- **Page limit**: The maximum number of pages to retrieve. Defaults to `50`. Set to `0` to retrieve all pages.
- **Zero-based index**: Toggle to `Yes` to indicate that the requested data's first record is at index `0`. The default (No) indicates that the first record is at index `1`.

Authentication Settings

See Configure a REST Collector for information about most of the options in the **Authentication** section of the REST Collector configuration. The following sections provide additional information about these authentication

options.

You can also use **Collect headers** as an alternative to the Basic, Login, or OAuth authentication options. This method authenticates requests based on API keys using secrets. See How to Use Collect Headers for Authentication for more information.

Login Authentication

Login is the best authentication type to use for all services that return a JSON web token (JWT) or other authentication token whose content type is `application/json` or `content/plain`.

Selecting **Login** exposes the following additional fields:

- **Login URL**: URL for the login API call, which is expected to be a POST call.
- **Login username**: Login username.
- **Login password**: Login password.
- **POST body**: Template for POST body to send with the login request. The `${username}` and `${password}` variables specify the corresponding credentials' locations in the message. You can also use the `C.Secret()` method within the POST body for dynamic values.
- **Token attribute**: Path to the token attribute in the login response body. Supports nested attributes. If the response from the auth request provides the JWT as `plain/text`, leave this field blank.
- **Authorization header**: Authorization header key to pass in Discover and Collect calls. Defaults to the literal name `Authorization`. (Cribl Stream 4.0 and later.)
- **Authorize expression**: JavaScript expression used to compute an Authorization header to pass in Discover and Collect calls. Uses `${token}` to reference the token obtained from a Login or OAuth authorization request. If you need to pass the token in a Collector or Discover request parameter, URL, or request body, you can access it with `${authToken}`.
- **Authentication headers**: Optionally, select **Add Header** for each custom auth header you want to define. In the resulting table, enter each header row's **Name**.
  The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `earliest` instead of `` `${earliest}` `` – will be evaluated as strings.

Login Secret Authentication

Login is the best authentication type to use for all services that return a JSON web token (JWT) or other authentication token whose content type is `application/json` or `content/plain`.

Selecting **Login (credentials secret)** exposes the following additional fields:

- **Login URL**: URL for the login API call, which is expected to be a POST call.
- **Credentials secret**: Select a stored text secret in this drop-down, or select **Create** to configure a new secret.
- **POST body**: Template for POST body to send with the login request. The `${username}` and `${password}` variables specify the corresponding credentials' locations in the message. You can also use the `C.Secret()` method within the POST body for dynamic values.
- **Token attribute**: Path to the token attribute in the login response body. Supports nested attributes. If the response from the auth request provides the JWT as `plain/text`, leave this field blank.
- **Authorization header**: Authorization header key to pass in Discover and Collect calls. Defaults to the literal name `Authorization`. (Cribl Stream 4.0 and later.)
- **Authorize expression**: JavaScript expression used to compute an Authorization header to pass in Discover and Collect calls. Uses `${token}` to reference the token obtained from a Login or OAuth authorization request. If you need to pass the token in a Collector or Discover request parameter, URL, or request body, you can access it with `${authToken}`.
- **Authentication headers**: Optionally, select **Add Header** for each custom auth header you want to define. In the resulting table, enter each header row's **Name**.
  The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `earliest` instead of `` `${earliest}` `` – will be evaluated as strings.

OAuth Authentication

Selecting **OAuth** exposes the following additional fields:

- **Login URL**: Endpoint for the OAuth API call, which is expected to be a POST call.
- **Client secret parameter**: The name of the parameter to send with the **Client secret value**.
- **Client secret value**: The OAuth access token to authorize requests.
- **Extra authentication parameters**: Optionally, select **Add parameter** for each additional OAuth request parameter you want to send in the body of POST requests. Automatically sets the `Content-Type` header to `application/x-www-form-urlencoded`.
  In the resulting table, enter each parameter row's **Name**. The corresponding **Value** is a JavaScript expression to compute the parameter's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `earliest` instead of `` `${earliest}` `` – will be evaluated as strings.
- **Token attribute**: Path to the token attribute in the login response body. Supports nested attributes.
- **Authorization header**: Authorization header key to pass in Discover and Collect calls. Defaults to the literal name `Authorization`. (Cribl Stream 4.0 and later.)

- **Authorize expression**: JavaScript expression used to compute an Authorization header to pass in Discover and Collect calls. Uses `${token}` to reference the token obtained from a Login or OAuth authorization request. If you need to pass the token in a Collector or Discover request parameter, URL, or request body, you can access it with `${authToken}`.
- **Authentication headers**: Optionally, select **Add Header** for each custom auth header you want to define. In the resulting table, enter each header row's **Name**.
  The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `earliest` instead of `` `${earliest}` `` – will be evaluated as strings.

OAuth Secret Authentication

Selecting **OAuth (text secret)** exposes the following additional fields:

- **Login URL**: Endpoint for the OAuth API call, which is expected to be a POST call.
- **Client secret parameter**: The name of the parameter to send with the **Client secret value**.
- **Client secret value (text secret)**: Select a stored text secret in this drop-down, or select **Create** to configure a new secret.
- **Extra authentication parameters**: Optionally, select **Add parameter** for each additional OAuth request parameter you want to send in the body of POST requests. Automatically sets the `Content-Type` header to `application/x-www-form-urlencoded`.
  In the resulting table, enter each parameter row's **Name**. The corresponding **Value** is a JavaScript expression to compute the parameter's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `earliest` instead of `` `${earliest}` `` – will be evaluated as strings.
- **Token attribute**: Path to the token attribute in the login response body. Supports nested attributes.
- **Authorization header**: Authorization header key to pass in Discover and Collect calls. Defaults to the literal name `Authorization`. (Cribl Stream 4.0 and later.)
- **Authorize expression**: JavaScript expression used to compute an Authorization header to pass in Discover and Collect calls. Uses `${token}` to reference the token obtained from a Login or OAuth authorization request. If you need to pass the token in a Collector or Discover request parameter, URL, or request body, you can access it with `${authToken}`.
- **Authentication headers**: Optionally, select **Add Header** for each custom auth header you want to define. In the resulting table, enter each header row's **Name**.
  The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `earliest` instead of `` `${earliest}` `` – will be evaluated as strings.

Google Service Account OAuth Authentication

Selecting **Google service account OAuth** exposes the following additional fields:

- **Scopes**: OAuth 2.0 scopes used to request access to Google APIs during authentication. See the Google page OAuth 2.0 Scopes for more information. Select **Add Scope** to add a scope.
- **Service account credentials**: Contents of the Google Cloud service account credentials (JSON keys) file. To upload a file, select the upload icon in this field's upper right corner.
- **Impersonated account's email address**: Email address of a user account with super admin permissions to the resources the Collector will retrieve.

Google Service Account OAuth Secret Authentication

Selecting **Google service account OAuth (text secret)** exposes the following additional fields:

- **Scopes**: OAuth 2.0 scopes used to request access to Google APIs during authentication. See the Google page OAuth 2.0 Scopes for more information. Select **Add Scope** to add a scope.
- **Service account credentials (text secret)**: Text secret containing the value of the Google service account credentials. Select an existing text secret or select **Create** to create a new secret.
- **Impersonated account's email address**: Email address of a user account with super admin permissions to the resources the Collector will retrieve.

Retries

The Retries Settings determine how to handle API calls that fail or timeout. It has the following fields:

- **Retry type**: The algorithm to use when performing HTTP retries. Options include `Backoff` (the default), `Static`, and `Disabled`.
- **Initial retry interval (ms)**: Time interval between failed request and first retry (kickoff). Maximum allowed value is 20,000 ms (1/3 minute). A value of `0` means retry immediately until reaching the retry limit in **Max retries**.
- **Max retries**: Maximum number of times to retry a failed HTTP request. Defaults to `5`. Maximum: `20`. A value of `0` means don't retry at all.
- **Backoff multiplier**: Base for exponential backoff. A value of `2` (default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so forth.
- **Longest interval between retries (ms)**: Maximum time to wait between retry attempts. This is useful for APIs with high backoff timeouts, enabling you to configure longer wait times to avoid excessive retry attempts. Defaults to `20000` ms (20 seconds). Supports values up to `900000` ms (15 minutes) to handle longer backoff requirements. Setting a long retry interval can lead to significantly extended job execution times, which could prevent other jobs from running on the Worker because of concurrent task limits.

- **Retry HTTP codes**: List of HTTP codes that trigger a retry. Leave empty to use the defaults (`429` and `503`). Cribl Stream does not retry codes in the `200` series.
- **Honor Retry-After header**: When toggled to `Yes` (the default) and the `retry-after` header is present, Cribl Stream honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. Cribl Stream always ignores `retry-after` headers that specify a delay longer than 20 seconds. Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms). When toggled to `No`, Cribl Stream ignores all `retry-after` headers.
    - Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).
    - When toggled to `No`, Cribl Stream ignores all `retry-after` headers.
- **Retry Connection Timeout**: Toggle to `Yes` to automatically retry a single connection attempt after a timeout (`ETIMEDOUT`) to ensure data continuity.
- **Retry Connection Reset**: Toggle to `Yes` to automatically retry a connection after a peer reset (`ECONNRESET`) to maintain data flow.
- **Retry-After header name**: Optionally, if the service uses a different header name for conveying retry information, specify that custom name here. For example, a service might use `x-ratelimit-retry-after` instead.

Results

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Custom Commands

Custom Command: When enabled, you can pass the data from this input to an external command for processing, before the data continues downstream. Enabling this field exposes these additional fields:

- **Command**: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).
- **Arguments**: Select **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breaking

Event Breaker rulesets: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`. Select **Add Ruleset** to add a new row to the ruleset table. Select the ruleset to see a list of available recommended rulesets for your API. Change the order of the rules to determine which rule is applied in order.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Event Fields

Fields: You can add Fields to each event, using Eval-like functionality. Selecting the **Add Field** button exposes these additional fields:

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Results Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination. The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, and so forth. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. One use case might be a REST Collector that gathers a known, simple type of data from a single endpoint. This approach keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Pre-processing Pipeline: Pipeline to process results before sending to Routes. Optional, and available only when **Send to Routes** is toggled to `Yes`.

Throttling: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, and so forth. (Example: `42 MB`.) Default value of `0` indicates no throttling.

Advanced Settings

The **Advanced Settings** section of the REST Collector configuration has the following options:

- **Request timeout (secs)**: Here, you can set a maximum time period (in seconds) for an HTTP request to complete before Cribl Stream treats it as timed out. Defaults to `0`, which disables timeout metering.
- **Round-robin DNS**: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.
- **Disable time filter**: Toggle to `Yes` if your Run or Schedule configuration specifies a date range and no events are being collected. This will disable the Collector's event time filtering to prevent timestamp conflicts.
- **Decode URL**: When toggled to `No`, Cribl Stream will not decode URLs before sending the HTTP request. This setting applies to collect, authentication, and pagination requests. Defaults to `Yes`.
- **Reject unauthorized certificates**: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.
- **Capture response headers**: Toggle to `Yes` to include the headers from the API response of a collect call under a `resHeaders` key in the `__collectible` object that is added to collected events.
- **Safe headers**: Optionally, list headers that you consider safe to log in plain text. Separate the header names with tabs or hard returns. These headers will not be redacted when exporting the Collector configuration as JSON.
- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.
- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.
- **Remove Discover fields** : List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).
- **Resume job on boot**: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.
- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

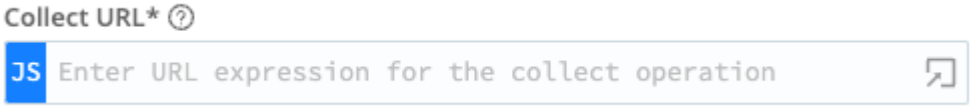
- `__collectible` – This object's nested fields contain metadata about each collection job.
  - `resHeaders` – Added only when **Advanced Settings** > **Capture response headers** is set to `Yes`.
- `__collectStats` – This object's nested fields are:
  - `method`: The value you set for **Collect** > **Collect method**.
  - `url`: The value you set for **Collect Settings (Common)** > **Collect URL**.
  - `elapsedMS`: The time elapsed from the moment the Collector's request was sent until the response was received.

Use JavaScript Expressions to Shape Incoming API Data

While you configure a REST Collector, you may need to translate the incoming data structure from an upstream API into the data structure that Cribl Stream expects and can work with. To effectively translate data, you need to know:

- The data structure of returns sent by the upstream API.
- How that upstream data structure differs from the data structure that Cribl Stream expects to receive.
- How to shape (transform) the data structure from the upstream API into the data structure expected by Cribl Stream.

You can shape incoming API data using JavaScript expressions when you configure a REST Collector. Various fields in the Collector accept JavaScript expressions. Fields that accept JavaScript are set apart by a blue JS bar, such as this example of the **Collect URL** field:



Example of a field that accepts Javascript expressions

JavaScript expression fields in the REST Collector behave differently from other similar JavaScript fields in Cribl Stream. In the REST Collector,you must enter expressions as template literals. Template literals (also known as template strings) allow you to use placeholders to reference dynamic variables and JavaScript functions. Cribl Stream uses some built-in variables or you can build your own custom placeholder variables to transform incoming data as needed.

For example:

- To reference the earliest time variable in a URL, header, or parameter, you would write the variable as `` `${earliest}` ``.
- To reference a function call: `` `${Date.now()}` ``.
- To call a function that references a variable: `` `${Math.floor(earliest)}` ``.

Time and Date Strings

Refer to the API documentation that you want to pull data from to gather information about how the API formats timestamps. The API could return the date in a variety of different formats, such as:

- `yyyy/MM/dd`
- `yyyy-MM-dd`
- `dd-MM-yyyy`

To effectively parse different patterns of dates in Cribl Stream, you may need to use a combination of different settings and JavaScript expressions.

Time Range Variables: `` `${earliest}` `` and `` `${latest}` ``

The following fields accept `` `${earliest}` `` and `` `${latest}` `` variables, which reference any **Time Range** values that have been set in manual or scheduled collection jobs:

Collect settings:

- Collect URL
- Collect parameters
- Collect headers

Discover settings:

- Discover URL
- Discover parameters
- Discover headers

As an example, here is a **Collect URL** entry using these variables: `http://localhost/path?from=${earliest}&to=${latest}`

APIs vary in their requirements for time formatting required. Consult the API documentation for the API to format it correctly.

For additional help with time filtering, see How Time Filtering Works for Scheduled Jobs.

Parse Discover Returns With Arrays as JSON Objects

When events are returned as an array, you need a JSON array event breaker is needed to separate out the individual fields so that the filter can be applied.

Some APIs return data as an array, such as `{ "logFiles": ["file-name-1.log", "file-name-2.log", "file-name-3.log.2", "audit.log"] }`. In this case, Cribl Stream treats each item in the array as a collection task.

However, some APIs return a JSON object that contains an array and you need to tell Cribl Stream to generate a separate Collect task for each item in the array, as in this example:

```
[
  {
    "LogFile": "/collect?filename=1",
    "attributes": {
      "field": 1
    }
  },
  {
    "LogFile": "/collect?filename=2",
    "attributes": {
      "field": 1
    }
  }
]
```

To properly parse the array inside the JSON object:

1. In the **Discover Settings**, select **HTTP Request** as the **Discover type**.
2. Set the options for your API in the standard required fields (such as **Discover URL**) as needed.
3. In the **Discover data field**, type `file` to create a custom property to store the `LogFile` array values.
4. Set the **Format discover result with custom code** option to `Yes`.
5. In the **Format discover result** field, type:

```
__e.file = __e.map(item => item.LogFile)
```

This expression processes an array `__e`, extracts the LogFile property from each element in that array, and assigns the resulting array of `LogFile` values to `__e.file`. Essentially, it creates a new array of log file paths (or similar information) from the original array and stores it in the file property of `__e`. Each property becomes a separate collection task.

This JavaScript expression is performing the following actions:

- `__e.map(...)`: This is using the `map()` method on the JSON object. The `map()` method creates a new array by applying the provided function to each element in the original array.
- `item => item.LogFile`: This is an arrow function that takes each item in the `__e` array and returns the `LogFile` property of that `item`.
- `__e.file =`: The result of the `map()` function, which is a new array containing only the `LogFile` values of each item in the original `__e` array, is assigned to the `file` property of `__e`.

Mutually Exclusive HTTP Request Parameters

Some APIs have mutually exclusive request, query, or URL parameters. In this situation, you may have parameters that cannot be used together in an API call. You must use either one or the other. For example, you may need to send one parameter in the first query and a different parameter for all subsequent queries.

To solve this problem, try using some of the formulas discussed in this Cribl User Group Community video at approximately the 30 minute mark: ServiceNow and Smartsheet.

For example, one user working with the Smartsheet API needed to send `since` in the first pagination query and `streamPosition` in all subsequent pagination queries. This user used these two **Collect Parameters**:

Name	Value
`since`	`${(!nextStreamPosition ? C.Time.strftime(Date.now()/1000-300, '%Y-%m-%d%T%H:%M:%S.000Z') : '')}`
`streamPosition`	`${((moreAvailable==false && nextStreamPosition!=null) ? '' : nextStreamPosition.toString())}`

Then, the user:

1. Set **Pagination** to `Response Body Attribute`.
2. Defined the **Response attribute** as `nextStreamPosition`.

3. Set the **Last-page expression** to `moreAvailable=='false'`.

Work with State Tracking

You can configure the Collector to track state, either by time or another arbitrary value. This can help prevent overlaps between jobs, where subsequent Collector runs may return some of the same results as previous runs. Similarly, it can help prevent gaps in data by allowing a Collector run to pick up from where the last run ended.

State tracking can be particularly useful for tracking the greatest `_time` value for events returned from a collection run, but you can also use it to derive arbitrary state for custom use cases. You can access saved state values in any Collector field that supports JavaScript expressions.

For a hands-on example of setting up a Collector with state tracking enabled, see Using REST/API Collectors.

Track State for Collector Runs

You can enable state tracking under the `State Tracking` section when scheduling or performing a full run of the Collector (Preview and Discover runs do not support state tracking). Once enabled, two more fields will appear for state tracking configuration.

State update expression: JavaScript expression that defines how to update the state from an event. Use the event's data and the current state to compute the new state.

State merge expression: JavaScript expression that defines which state to keep when merging a task's newly reported state with the previously saved state. Evaluates `prevState` and `newState` variables, resolving to the state to keep.

The default values for these fields are configured to track state by the latest `_time` field found in events gathered in a collection run.

Understand State Expression Fields

The **State update** and **State merge** expressions control how state is derived from a collection run and how it is merged with existing state, respectively. They're preconfigured to work with the common use case of tracking state by latest `_time`, but you may need to update them for other use cases. To understand what these fields do, let's break down the default values.

State update expression

This expression has a default value of:

```
__timestampExtracted !== false && {latestTime: (state.latestTime || 0) > _time ? sta
```

__timestampExtracted !== false - the `__timestampExtracted` field is set to false if the Event Breaker was unable to parse time for the event. If this is the case, we don't want to update state (the event's `_time` value defaults to `Date.now()` if the Event Breaker was unable to parse out the correct time). If `_timestampExtracted` is `false`, we take advantage of short-circuit evaluation to not update state.

State values must resolve to an object, such as:

```
{ "latestTime": 17122806161 }
```

If the expression does not resolve to an object, Cribl Stream will ignore the result.

{latestTime: (state.latestTime || 0) > _time ? state.latestTime : _time} - compare `state.latestTime` to the event's `_time` value, keeping whichever value is greater.

State merge expression

This expression has a default value of:

```
prevState.latestTime > newState.latestTime ? prevState : newState
```

It compares `prevState` (the state that was previously saved) to `newState` (the state reported from the most recent collection task), keeping the state with the greatest `latestTime` value.

Manage Collector State

Select **Manage State** to view, modify, or delete Collector state. For more information, see Manage Collector State.

Proxy Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshoot

Response Errors

The Collector treats all non-`200` responses from configured URL endpoints as errors. This includes `1xx`, `3xx`, `4xx`, and `5xx` responses.

On Discovery, Preview, and most Collect jobs, it interprets these as fatal errors. On Collect jobs, the Collector treats these exceptions as non-fatal:

- Where a Collect job launches multiple tasks, and only a subset of those tasks fail, Cribl Stream places the job in failed status, but treats the error as non-fatal. (Note that Cribl Stream does not retry the failed tasks.)
- Where a Collect job receives a `3xx` redirection error code, it follows the error's treatment by the underlying library, and does not necessarily treat the error as fatal.

Mitigate Stuck-Job Problems

Occasionally, a scheduled job fails, but continues running for hours or even days, until someone intervenes and cancels it. If left alone, such a "stuck", "orphaned," or "zombie" job will never complete. This can cause missing events in downstream receivers, along with `HTTP timeout` or similar errors in Cribl Stream's logs.

To keep stuck jobs from running excessively long:

- First, try setting **Optional Settings** > **Request timeout (secs)** – whose default of `0` means "wait forever" – to a desired maximum duration.
- If adjusting **Timeout (secs)** does not fix the problem, try the global setting **Job Timeout** – whose default of `0` allows a job to run indefinitely – to a desired maximum duration. You'll find **Job Timeout** among the task manifest and buffering limits.

Using these settings in tandem works like this:

- **Timeout (secs)** limits the time that Cribl Stream will wait for an HTTP request to complete.
- Then, if a job gets stuck and keeps running beyond that limit, **Job Timeout** can catch and terminate the job, because it monitors the overall time the job has been running.

Error Message: `TypeError [ERR_INVALID_URL]`

The full text of this error message:

```
"reason.stack == `TypeError [ERR_INVALID_URL]: Invalid URL: https%3A%2F%2Ftype.fit%2
```

Cause: This error message is caused by unnecessarily encoding the Discover/Collect URL.

Recommendation: To fix this error message, remove the encoding function for the URL. You will rarely need to encode URLs. When they do, you should only encode the parts that need it. Otherwise, you will see this error because the entire URL is encoded unnecessarily.

Example Invalid URL message

Error Message: "statusCode: 429...Too many requests"

Cause: This error message response is triggered by rapidly repeated requests from the Collector's Discover and Collect phases. It's especially likely when different Workers run multiple Collect tasks.

Recommendation: Gradually increase the **Login rate limit** threshold until you no longer receive this error response. On the Leader or a Single-instance deployment, access this option at **Global Settings** > **General Settings** > **API Server Settings** > **Advanced**. In a Distributed deployment, select **Manage**, select the Worker Group, and then navigate to **Group Settings** > **General Settings** > **API Server Settings** > **Advanced**.

No Discover or Collector Event Results

Sometimes after you configure a REST Collector you might not see any results from API calls in Cribl Stream even after you verified those results exist outside of Cribl Stream and should have appeared in the run results.

Potential cause: One potential cause is the way time filtering works in Cribl Stream. There are two instances when time filters impact your data:

- When you submit a call for data within a specific time range to the API.
- When you compare the data within a specific time range in Cribl Stream.

When you submit a call to an API and it returns time-bound data, Cribl Stream runs Event Breakers on the data to break the incoming data into discrete data events. Each discrete event has its own timestamp. If any of those events are outside the `` `${earliest}` `` and `` `${latest}` `` variables as defined for the run, Cribl Stream is going to discard those events by default.

Recommendation Turn off time filtering. In the REST Collector configuration settings, go to **Advanced Settings** and ensure **Disable time filter** is set to `Yes`. Retry the run.

For additional help with time filtering, see How Time Filtering Works for Scheduled Jobs.

15.1.1.8. S3 Collector

Cribl Stream supports collecting data from Amazon S3 stores. This page covers how to configure the Collector.

For a step-by-step tutorial on using Cribl Stream to replay data from an S3-compatible store, see our Data Collection & Replay sandbox. The sandbox takes about 30 minutes. It provides a hosted environment, with all inputs and outputs preconfigured for you.

Also see our Amazon S3 Better Practices and Using S3 Storage and Replay guides.

How the Collector Pulls Data

When you run an S3 Collector in Discovery mode, the first available Worker returns the list of available files to the Leader Node.

In Full Run mode, the Leader distributes the list of files to process across 1..*N* Workers, as evenly as possible, based on file size. Each Worker then streams the files from the S3 bucket/path to itself.

Compression

Cribl Stream can ingest compressed S3 files if they meet all the following conditions:

- Compressed with the `x-gzip` MIME type.
- End with the `.gz` extension.
- Can be uncompressed using the `zlib.gunzip` algorithm.

Storage Class Compatibility

Cribl Stream does **not** support data preview, collection, or replay from S3 Glacier or S3 Deep Glacier storage classes, whose stated retrieval lags (variously minutes to 48 hours) cannot guarantee data availability when the Collector needs it.

Cribl Stream **does** support data preview, collection, and replay from S3 Glacier Instant Retrieval when you're using the S3 Intelligent-Tiering storage class.

Configure an S3 Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.

2. In the **New Collector** modal, configure the following under **Collector Settings**:
    - **Collector ID**: Unique ID for this Collector. For example, `Attic42TreasureChest`. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.
    - **Description**: Optionally, enter a description.
    - **Auto-populate from**: Select a Destination with which to auto-populate Collector settings. Useful when replaying data.
    - **S3 bucket**: Simple Storage Service bucket from which to collect data.
3. Under **Authentication**, select an **Authentication method** from the dropdown: **Auto** or **Manual**. For details, see Authentication Methods
4. Under the **Assume Role** accordian, configure the following.
    - **Enable Assume Role**: Slide to `Yes` to enable Assume Role behavior.
    - **AssumeRole ARN**: Amazon Resource Name (ARN) of the role to assume.
    - **External ID**: External ID to use when assuming role. Enter this if defined in your IAM policy's trust relationship; otherwise, leave blank. (Usage example: AWS Cross-Account Data Collection.)
    - **Duration (seconds)**: Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).
      When using **Assume Role** to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.
5. Next, you can configure the following **Optional Settings**:
    - **Region**: S3 Region from which to retrieve data.
    - **Path**: Path, within the bucket, from which to collect data. See About Paths for details.
    - **Path extractors**: Extractors enable you to use template tokens as context for expressions that enrich discovery results. For usage details and examples, see Using Path Extractors.
    - **Endpoint**: S3 service endpoint. If empty, Cribl Stream will automatically construct the endpoint from the AWS Region. To access the AWS S3 endpoints, use the path-style URL format. You don't need to specify the bucket name in the URL, because Cribl Stream will automatically add it to the URL path. For details, see AWS' Path-Style Requests topic.
    - **Signature version**: Signature version to use for signing S3 requests. Defaults to `v4`.
    - **Max batch size (objects)**: Maximum number of metadata objects to batch before recording as results.
    - **Recursive**: If set to `Yes` (the default), data collection will recurse through subdirectories.
    - **Reuse connections**: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

- **Reject unauthorized certificates**: Whether to accept certificates that cannot be verified against a valid Certificate Authority, such as self-signed certificates. Defaults to `Yes`.
- **Verify bucket permissions**: Toggle this to `No` if you can access files within the bucket, but not the bucket itself. This resolves errors of the form: `discover task initialization failed...error: Forbidden`.
- **Disable time filter**: Toggle to `Yes` if your Run or Schedule configuration specifies a date range and no events are being collected. This will disable the Collector's event time filtering to prevent timestamp conflicts.
- **Encoding**: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported
- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

6. Optionally, configure any Result, Result Routing, and Advanced settings outlined in the sections below.
7. Select **Save**, then **Commit & Deploy**.
8. To verify that the Collector actually collects data, you can start a single run in the Preview mode.

The sections described below are spread across several tabs. Click the tab links at left to navigate among tabs.

Collector Sources currently cannot be selected or enabled in the QuickConnect UI.

About Paths

Templates and tokens are supported to provide flexibility and automation in defining the directory structure, allowing you to organize data efficiently based on various parameters. This value can be a constant or a JavaScript expression. More on templates and tokens here. If this S3 Collector will be used to round-trip data through our Destination and replay it in Cribl Stream, we have a recommended **Path**. See the Replay Collector for details.

- Templating allows for dynamic insertion of variables like host, year, and month. For example, `/myDir/${host}/${year}/${month}/`).
- Time-based tokens enable time-specific data organization. For example, `myOtherDir/${_time:%Y}/${_time:%m}/${_time:%d}/`.

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

- **Enabled**: Defaults to `No`. Toggle to `Yes` to enable the custom command.
- **Command**: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).
- **Arguments**: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

- **Event Breaker rulesets**: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`.
- **Event Breaker buffer timeout**: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination. The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. This keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.
- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.
- **Remove Discover fields** : List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).
- **Resume job on boot**: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.

Authentication Methods

The **Authentication method** dropdown give you a choice of two options.

The **Auto** option (default) will use environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`, or the attached IAM role. Will work only when running on AWS.

The **Manual** option exposes these fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials. This value can be a constant or a JavaScript expression.
- **Secret key**: Enter your AWS secret key. if not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials. Optional when running on AWS. This value can be a constant or a JavaScript expression.

The **Secret** option swaps in this drop-down:

- **Secret key pair**: Select a secret key pair that you've configured in Cribl Stream's internal secrets manager or (if enabled) an external KMS. Follow the **Create** link if you need to configure a key pair.

The **Manual** option's **Access key** and **Secret key** values override the **Auto** option. For any Workers that you want to associate with an AWS IAM role, using the **Assume Role** controls below ensure that the **Manual** option's key fields are empty.

Using Path Extractors

Click **Add Extractor** to add each extractor as a key-value pair, mapping a **Token** name on the left (a substring of the **Path**) to a custom JavaScript **Extractor expression** on the right. Example `{host: value.toLowerCase()}`

Each expression accesses its corresponding token through its `value` variable, and evaluates the token to populate event fields.

You can define each token in only one **Extractor expression** per S3 Collector config.

Example #1

Here is a simple, complete example, using a single expression:

Token	Extractor Expression	Matched Value	Extracted Result
`/var/log/${foobar}`	`foobar: {program: value.split('.')[0]}`	`/var/log/syslog.1`	`{program: syslog, foobar: syslog.1}`

Example #2

Here is a multi-expression example. Assuming that your S3 bucket path supports the Collector's configured **Path**, this shows how to extract each segment of this example **Path**, and transform it into a reformatted field:

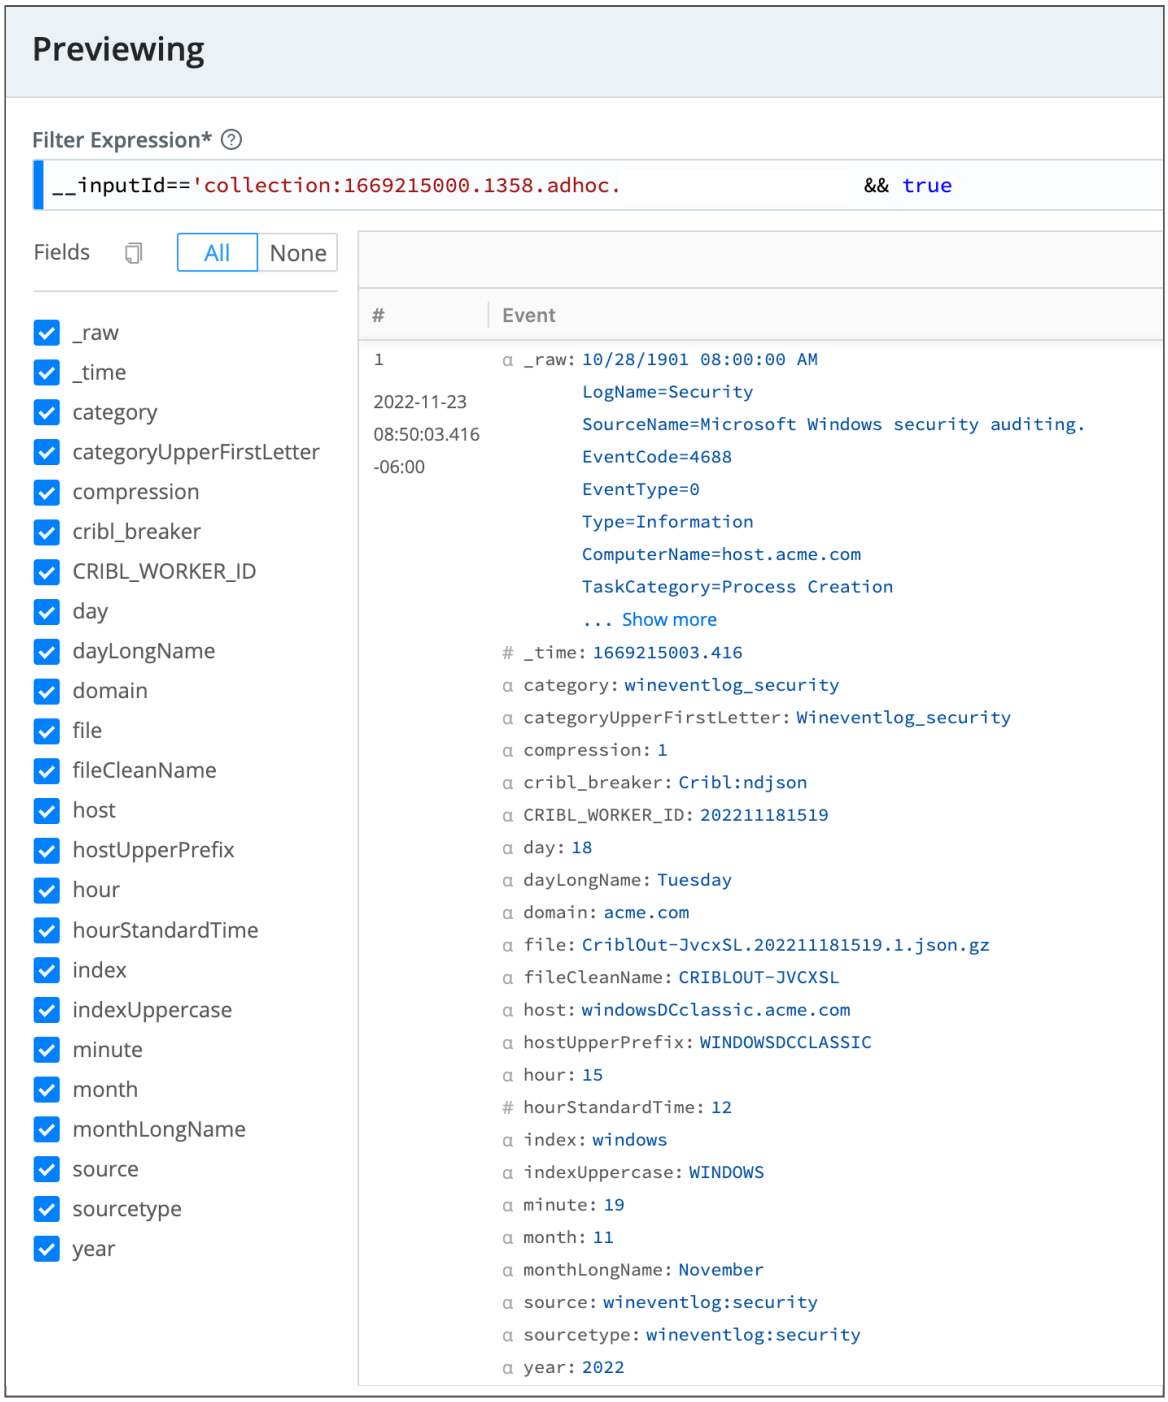
First, the path:

```
/${index}/${_time:%Y}/${_time:%m}/${_time:%d}/${host}/${category}/${_time:%H}/${file}
```

Next, the tokens and extractor expressions:

Token	Extractor Expression	Purpose
`index`	`{"indexUppercase" : value.toUpperCase()}`	Uppercase th `index`
`host`	`{"hostUpperPrefix" : value.toUpperCase().replace(/(.+?)\..+/,'$1'), "domain" : value.match(/.+?\.(.+)/)[1]}`	Use one toke two fields: `hostUpperP` and `domain`
`category`	`{"categoryUpperFirstLetter" : `${value.substring(0,1).toUpperCase()}${value.substring(1)}`}`	Uppercase th `category` st first letter
`file`	`{"fileCleanName" : value.replace(/ARCHIVE-/i,'').toUpperCase().split('.')[0], "CRIBL_WORKER_ID" : value.split('.')[1], "compression" : value.split('.')[2]}`	Split the obje name) into th fields

Here is a corresponding example event, as collected/replayed from S3. The metadata fields at the bottom show the results of the path extractor expressions:



Event with path extractors' transformations

Temporary Access via SSO Provider

You can use Okta or SAML to provide access to S3 buckets using temporary security credentials.

Troubleshooting

When permissions are correct on the object store, and events are reaching the Collector, the Preview pane will show events and the Job Inspector will show an **Events collected** count.

However, if previewing returns no events and throws no error, first check your **Filter** expression by previewing without it by simplifying the **Filter** expression to `true`. Then check the Job Inspector: If the **Total size** is greater than `0`, and the **Received size** is `NA` or `0`, make sure you have list and read permissions on the object store.

If you're still not seeing events, try setting your S3 Collector's **Path expression** to a `/`.

Encrypted Data

To collect encrypted data, such as CloudTrail logs, you'll need to add access to the KMS resources in your KMS Key Policy. Add the IAM user or role to the **Principal** section of your Key Policy and provide the `kms:Decrypt` **Action**. See Amazon's documentation on Key Policies for more information, including how to view and change your policy.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

- `__collectible` – This object's nested fields contain metadata about each collection job.

15.1.1.9. Script Collector

Cribl Stream supports flexible data collection configured by your custom scripts.

In Cribl.Cloud, the Script Collector is only available on customer-managed hybrid Worker Nodes.

How the Collector Pulls Data

When you run a Script Collector in Discovery mode, the first available Worker returns one line of data per discovered item. Each item (line) turns into a Collection task on the Leader Node.

In Full Run mode, the Leader passes the item to collect into the script in the `$CRIBL_COLLECT_ARG` variable, and spreads collection across all available Workers.

If you run the Script Collector with a given Time Range, the `earliest` and `latest` values will be available to the script via the environment variables `EARLIEST` and `LATEST`, respectively.

Important: Secure and Use the Script Collector Properly

Be aware that scripts will allow you to execute almost anything on the system where Cribl Stream is running. Make sure you understand the impact of what you're executing before you do so. These scripts run with the same level of permissions as the user running Cribl Stream. So, if you are running it as `root`, these commands will run with root user permissions. If your system requires greater security, consider disabling the Script Collector. See How to Disable the Script Collector for more information.

Also, always validate and test your scripts before running them on your system. Scripts must finish on their own. The Collector will not stop a script once its task has started. You must ensure scripts do not use infinite loops.

Configure a Script Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.
2. In the **New Collector** modal, configure the following under **Collector Settings**:
    - **Collector ID**: Unique ID for this Collector. E.g., `sh2GetStuff`. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.

- **Discover script**: Script to discover which objects/files to collect. This script should output one task per line in `stdout`. Discovery is especially important in a distributed deployment, where the Leader must track all tasks, and must guarantee that each is run by a single Worker. See Examples below.
- **Collect script**: Script to perform data collections. Pass in tasks from the Discover script as `$CRIBL_COLLECT_ARG`. Should output results to `stdout`.

3. Next, you can configure the following **Optional Settings**:
   - **Shell**: Shell in which to execute scripts. Defaults to `/bin/bash`.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any Result, Result Routing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.
6. To verify that the Collector actually collects data, you can start a single run in the Preview mode.

The sections described below are spread across several tabs. Click the tab links at left to navigate among tabs.

Collector Sources currently cannot be selected or enabled in the QuickConnect UI.

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

- **Enabled**: Defaults to `No`. Toggle to `Yes` to enable the custom command.
- **Command**: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).
- **Arguments**: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

Event Breaker rulesets: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination. The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. This keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.
- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.
- **Remove Discover fields** : List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).
- **Resume job on boot**: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.

How the Collector Pulls Data

In the Discover phase, the first available Worker returns one line of data per item discovered. Each item line turns into a Collect task on the Leader Node. In the Collect phase, the items to collect are passed into the script as the variable `$CRIBL_COLLECT_ARG`, and are spread across all available Workers.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

- `__collectible` – This object's nested fields contain metadata about each collection job.

Examples

Telemetry Collector

You could define this Collector to check for Cribl Stream telemetry errors, which could cause license validation to fail, eventually (after a delay) blocking data input.

Collector type: `Script`

Discover script: `ls $CRIBL_HOME/log/cribl*`

Collect script: `grep 'Failed to send anonymized telemetry metadata' $CRIBL_COLLECT_ARG`

S3 Collector

In this example, the Discover script retrieves file names from a specified Amazon S3 bucket, and then writes them (one per line) to the standard output. The Collect script processes each line as its `$CRIBL_COLLECT_ARG`, and uses `zcat` to decompress the buckets' data.

Collector type: `Script`

Discover script:
```
aws s3api list-objects --bucket <bucket-name> --prefix <subfolder>/ --query
'Contents[].Key' --output text
```

Collect script: `aws s3 cp s3://<bucket-name>/$CRIBL_COLLECT_ARG - | zcat -f`

Simple Collector

This example essentially spoofs the Discover script with an `echo` command, which simply announces what the Collect script (itself simple) will do.

Collector type: `Script`

Discover script: `echo "speedtest"`

Collect script: `speedtest --json`

How to Disable the Script Collector

You can disable the Script Collector if your organization's security policy prevents you from executing deliberate code on your remote nodes. Disabling the Script Collector is done using the Cribl command-line interface (CLI) to prevent potential bad actors from enabling the Script Collector through the API. See Secure and Use the Script Collector Properly for more information about the potential security risks.

Disable the Script Collector with caution. Disabling the Script Collector is not easily reversible. Restoring the Script Collector after disabling it requires a full re-installation of Cribl Stream.

To fully disable the Script Collector in your entire instance of Cribl Stream:

1. Inside the Cribl CLI, navigate to the root directory of your Cribl instance.
2. Run the following command:

```
opt/cribl/bin/cribl limits -c 0
```

If your deployment is configured to use failover and relies on environment variables for that configuration, ensure you also include the following flag: `-d ABSOLUTE/FAILOVER/PATH`.

3. Restart Cribl Stream.
4. Inside Cribl Stream, verify that you have disabled the Script Collector. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Verify that the Script Collector does not show up in the list of Sources.
5. Commit and deploy your changes to disable the Script Collector for all Worker Nodes.

If you create future Groups after running this procedure, they will not include the Script Collector.

15.1.1.10. Splunk Search Collector

Cribl Stream supports collecting search results from Splunk queries. The queries can be both simple and complex, as well as real-time searches. This page covers how to configure the Collector.

Configure a Splunk Search Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Choose the Source and select **Add Collector**.
2. In the **New Collector** modal, configure the following under **Collector Settings**:
   - **Collector ID**: Unique ID for this Collector. E.g., `splunk2search`. If you clone this Collector, Cribl Stream will add `-CLONE` to the original **Collector ID**.
   - **Description**: Optionally, enter a description.
   - **Search endpoint**: Rest API used to conduct a search. Defaults to `services/search/jobs/export`.
   - **Output mode**: Format of the returned output. Defaults to JSON format.To parse the returned JSON, add the Cribl event breaker which parses newline delimited events in the Event Breakers tab.

   Events returned from Splunk search can also be returned in the more compact CSV format. To use CSV format, set the **Output mode** to CSV and specify the CSV event breaker in the Event Breakers tab.
3. Under **Search**, configure the following.
   - **Search**: Enter the Splunk query. For example: `index=myAppLogs level=error channel=myApp OR | mstats avg(myStat) as myStat WHERE index=myStatsIndex`.
   - **Search head**: Enter the search head base URL. The default is `https://localhost:8089`.
   - **Earliest**: You can enter the earliest time boundary for the search. This maybe be an exact or relative time. For example: `2022-01-14T12:00:00Z` or `-16m@m`.
   - **Latest**: You can enter the latest time boundary for the search. This maybe be an exact or relative time. For example: `2022-01-14T12:00:00Z` or `-16m@m`.
4. Under **Authentication**, select an **Authentication method** from the dropdown:
   - **None**: Don't use authentication. Compatible with REST servers like AWS, where you embed a secret directly in the request URL.
   - **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
   - **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or click **Create** to configure a new secret.

- **Bearer Token**: Provide the `token` value configured and generated in Splunk.
- **Bearer Token (text secret)**: Provide the Bearer Token referenced by a secret. Select a stored text secret in the resulting **Token (text secret)** drop-down, or click **Create** to configure a new secret.

You can also use **Extra Headers** as an alternative way of authenticating a request. Select `None` in the **Authentication** drop-down and use the `C.Secret` expression method to provide the value for the `Authentication` header. For example:

```
`Bearer: ${C.Secret('<secretId>', 'text').value}`
```

5. Under **Retries** configure the following.
   - **Retry type**: The algorithm to use when performing HTTP retries. Options include `Backoff` (the default), `Static`, and `Disabled`.
   - **Initial retry interval (ms)**: Time interval between failed request and first retry (kickoff). Maximum allowed value is 20,000 ms (1/3 minute). A value of `0` means retry immediately until reaching the retry limit in **Max retries**.
   - **Max retries**: Maximum number of times to retry a failed HTTP request. Defaults to `5`. Maximum: `20`. A value of `0` means don't retry at all.
   - **Backoff multiplier**: Base for exponential backoff. A value of `2` (default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, etc.
   - **Retry HTTP codes**: List of HTTP codes that trigger a retry. Leave empty to use the defaults (`429` and `503`). Cribl Stream does not retry codes in the `200` series.
   - **Honor Retry-After header**: When toggled to `Yes` (the default) and the `retry-after` header is present, Cribl Stream honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. For details, see Honor Retry-After Header.
   - **Retry Connection Timeout**: Toggle to `Yes` to automatically retry a single connection attempt after a timeout (`ETIMEDOUT`) to ensure data continuity.
   - **Retry Connection Reset**: Toggle to `Yes` to automatically retry a connection after a peer reset (`ECONNRESET`) to maintain data flow.
6. Next, you can configure the following **Optional Settings**:
   - **Extra parameters**: Optional HTTP request parameters to append to the request URL. For details, see Extra Parameters below.
   - **Extra headers**: Click **Add Header** to (optionally) add collection request headers as key-value pairs. For details, see Extra Headers below.
   - In the **Request Timeout (secs)** field, you can set a maximum time period (in seconds) for an HTTP request to complete before Cribl Stream treats it as timed out. Defaults to `0`, which disables timeout metering.When running a real-time search you must update the **Request Timeout**

Parameter to avoid having the collector stuck in a forever running state. Updating the **Request Timeout Parameter** stops the search after the allocated period of time.

- **Round-robin DNS**: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.
- **Disable time filter**: Toggle to `Yes` if your Run or Schedule configuration specifies a date range and no events are being collected. This will disable the Collector's event time filtering to prevent timestamp conflicts.
- **Reject unauthorized certificates**: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.
- **Encoding**: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.
- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's **Manage Sources** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

7. Optionally, configure any Result, Result Routing, and Advanced settings outlined in the sections below.
8. Select **Save**, then **Commit & Deploy**.
9. To verify that the Collector actually collects data, you can start a single run in the Preview mode.

The sections described below are spread across several tabs. Click the tab links at left to navigate among tabs.

Collector Sources currently cannot be selected or enabled in the QuickConnect UI.

Honor Retry-After Header

Cribl Stream always ignores `retry-after` headers that specify a delay longer than 20 seconds. - Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms). - When toggled to `No`, Cribl Stream ignores all `retry-after` headers.

Extra Parameters

The extra paramaters refine or narrow the request. Select **Add Parameter** to add parameters as key-value pairs:

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Extra Headers

By adding the appropriate **Extra headers**, you can specify authentication based on API keys using secrets as an alternative to the **Authentication** options above. The key-value pairs are:

- **Name**: Header name.
- **Value**: JavaScript expression to compute the header's value (can be a constant).

Result Settings

The Result Settings determine how Cribl Stream transforms and routes the collected data.

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

Enabled: Defaults to `No`. Toggle to `Yes` to enable the custom command.

Command: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).

Arguments: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

Event Breaker rulesets: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule.`

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute the field's value (can be a constant).

Result Routing

Send to Routes: If set to `Yes` (the default), Cribl Stream will send events to normal routing and event processing. Toggle to `No` to select a specific Pipeline/Destination combination. The `No` setting exposes these two additional fields:

- **Pipeline**: Select a Pipeline to process results.
- **Destination**: Select a Destination to receive results.

The default `Yes` setting instead exposes this field:

- **Pre-processing Pipeline**: Pipeline to process results before sending to Routes. Optional.

This field is always exposed:

- **Throttling**: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

You might disable **Send to Routes** when configuring a Collector that will connect data from a specific Source to a specific Pipeline and Destination. One use case might be a Splunk Search Collector that gathers a known, simple type of data. This approach keeps the Collector's configuration self-contained and separate from Cribl Stream's routing table for live data – potentially simplifying the Routes structure.

Pre-processing Pipeline: Pipeline to process results before sending to Routes. Optional, and available only when **Send to Routes** is toggled to `Yes`.

Throttling: Rate (in bytes per second) to throttle while writing to an output. Also takes values with multiple-byte units, such as `KB`, `MB`, `GB`, etc. (Example: `42 MB`.) Default value of `0` indicates no throttling.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Time to live: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.

Remove Discover fields : List of fields to remove from the Discover results. This is useful when discovery returns sensitive fields that should not be exposed in the Jobs user interface. You can specify wildcards (such as `aws*`).

Resume job on boot: Toggle to `Yes` to resume ad hoc collection jobs if Cribl Stream restarts during the jobs' execution.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Collector:

- `__collectible` – This object's nested fields contain metadata about each collection job.

How Cribl Stream Pulls Data

This Collector will gather data from the specified **Search head** URL. If you enable scheduled collection, searches will repeat on the interval specified in the **Schedule** modal's **Cron schedule** field.

A single Worker executes each collection job. If the Leader goes down, search jobs in progress will complete, but future scheduled searches will not run until the Leader relaunches.

Mitigating Stuck-Job Problems

Occasionally, a scheduled job fails, but continues running for hours or even days, until someone intervenes and cancels it. If left alone, such a "stuck", "orphaned," or "zombie" job will never complete. This can cause missing events in downstream receivers, along with `HTTP timeout` or similar errors in Cribl Stream's logs.

To keep stuck jobs from running excessively long:

- First, try setting **Optional Settings** > **Request Timeout (secs)** – whose default of `0` means "wait forever" – to a desired maximum duration.
- If adjusting **Timeout (secs)** does not fix the problem, try the global setting **Job Timeout** – whose default of `0` allows a job to run indefinitely – to a desired maximum duration. You'll find **Job Timeout** among the task manifest and buffering limits.

Using these settings in tandem works like this:

- **Timeout (secs)** limits the time that Cribl Stream will wait for an HTTP request to complete.

- Then, if a job gets stuck and keeps running beyond that limit, **Job Timeout** can catch and terminate the job, because it monitors the overall time the job has been running.

15.1.1.11. Manage Collector State In Database And REST API Collectors

Manage State in Database Collector

For the Database Collector, **state** identifies the last row that the Collector has read from the database, as expressed by that row's value in the tracking column. You can view, edit, refresh, or delete that state – and that is what we mean by managing state. Testing or debugging a Collector is the main reason to do this.

Manage State in REST Collector

The REST Collector tracks **state** according to configuration of the expressions **State update** and **State merge**. With state tracking enabled, these expressions default to track state by the greatest event `_time` value.

You can enable state tracking in the REST Collector in **State Tracking** when you schedule or perform a full run.

Manage State

The **Manage State** button is enabled whenever your Collector's state is not empty, and is available from two locations:

- In the **Database** list view of your Database Collectors, at the end of each Collector's row. Click **Manage**, **Data**, **Manage Sources**, **Collectors**, **Database** to reach this UI.
- In the configuration modal for each Collector.

To view state, click the button. This opens the **Manage State** JSON editor, since state is recorded as a JSON object. For example, if you have chosen the `id` column in your database as your tracking column, and your Collector has just read 5 rows, the state object will look like this:

```
{
  "id": {
     "value": 5
  }
}
```

Suppose a particular job did not read the data you expected it to. Viewing state is the most basic troubleshooting step in this kind of situation.

If you know that state was updated because the Collector has run, but the state shown in the editor does not reflect the change you expected, click **Refresh State**.

If you want to start again with no state, click **Delete State**. To learn how and why to use this operation, see Deleting Collector State, below.

Edit Collector State

In the **Manage State** JSON editor, you can change state by editing the JSON, and then click **Save State** to persist the change.

To continue our example, if your Collector has read 1000 rows but you want it to repeat the last 500 rows on the next scheduled run, you would change the state from `1000` to `500`.

Delete Collector State

The **Delete State** and **Delete Collector** buttons are independent of each other. Deleting the Collector does **not** delete its saved state information. Cribl Stream decouples these two operations to provide benefits that we'll explore in this section.

To begin with, note that Collector state is stored on disk, not in Git. Each Collector's state is stored separately.

Secondly, the uses of state-deleting differ depending on whether your Database Collector is on a single-instance deployment of Cribl Stream, or a distributed deployment.

Delete Collector State in a Single-Instance Deployment

When you first configure a Database Collector, you might need to experiment with SQL queries until you arrive at one that returns the desired results. In doing this, you might need the queries you're testing to always start from the same place in the database. If you're using a tracking column, this won't work, because each query will move you further along in the database. The solution is to delete state between iterations of the query you're building.

Delete Collector State in a Distributed Deployment

Just like in single-instance deployments, in distributed deployments it can be useful to delete Collector state when you're testing SQL queries for a Collector with state tracking enabled.

Beyond that, with distributed deployments it's important to know that Cribl Stream decouples the deleting of Collectors themselves from the deleting of their saved state, and to see the benefits of that decoupling.

Suppose you have been running a Collector with state tracking enabled, and it's working its way through a database. At some point you decide you're not happy with that Collector and you click the **Delete Collector** button. What happens next? There are at least three possibilities:

- If you're sure you want to delete the Collector, you should Commit and Deploy. Once you do that, the Leader pushes the change out to the Worker Nodes, and the Collector is gone (although you can recover it by rolling back to a previous commit in Git).
- If you realize that you made a mistake, and want to keep the Collector after all, then you should **not** Commit and Deploy. Instead, click the **Undo All Changes** button in the **Git Changes** modal – this un-deletes the Collector. And, since the Collector's state remains on disk, the Collector will pick up where it left off.
- If you deleted the Collector because you want to create another Collector with the same ID and the same tracking column, but a different configuration, you should Commit and Deploy, then create your new Collector. Because the old Collector's state remains on disk, the new Collector with the same ID picks up the saved state. When you begin using the new Collector, it will pick up where the old Collector left off. On the other hand, if you prefer the new Collector to start from zero, just click the **Delete State** button before you start using it.

In short, Cribl Stream's decoupling of Collector deletion from state deletion gives you control, such that you can avert messy situations where your Collector cannot find the state it needs.

15.1.1.12. Schedule And Run Collector Jobs

Once you've configured a Collector, you can either run it immediately ("ad hoc") to collect data, or schedule it to run on a recurring interval. Scheduling requires some extra configuration upfront, so we cover this option first.

For **ad hoc** collection, you can configure whether a job interrupted by an unintended Cribl Stream shutdown will automatically resume upon Cribl Stream restart.

But regardless of this configuration, if you **explicitly** restart or stop Cribl Stream, this will cancel any currently running jobs. This applies to executing the `./cribl restart` or `./cribl stop` CLI commands, as well as to selecting **Settings** > **Global** > **Controls** > **Restart**.

A **scheduled** job interrupted by a shutdown (whether explicit or unintended) will **not** resume upon restart.

Schedule Configuration

Select **Schedule** beside a configured Collector to display the **Schedule Collector** modal. This provides the following controls.

Enabled: Slide to `Yes` to enable this collection schedule.

The scheduled job will keep running on this schedule forever, unless you toggle **Enabled** back to `Off`. The `Off` setting preserves the schedule's configuration, but prevents its execution.

Cron schedule: A cron schedule on which to run this job.

- The **Estimated schedule** below this field shows the next few collection runs, as examples of the cron interval you've scheduled.

Concurrent run limit: Sets the maximum number of instances of this scheduled job that Cribl Stream will simultaneously run.

Skippable: Skippable jobs can be delayed up to their next run time if the system is hitting concurrency limits. Defaults to `Yes`. Toggling this to `No` displays this additional option:

- **Resume missed runs**: Defaults to `No`. When toggled to `Yes`, if Cribl Stream's Leader (or single instance) restarts, it will run all missed jobs according to their original schedules.

Skippable Jobs and Concurrency Limits

If set to `Yes`, the **Skippable** option obeys these concurrency limits configured separately in **Settings** > **Global** > **General Settings** > **Job Limits**:

- **Concurrent Job Limit**
- **Concurrent Scheduled Job Limit**

See Job Limits for details on these and other limits that you can set in global **Settings**.

When the above limits delay a Skippable job:

- The Skippable job will be granted slightly higher priority than non-Skippable jobs.
- If the job receives resources to run before its next scheduled run, Cribl Stream will run the delayed job, then snap back to the original cron schedule.
- If resources do **not** free up before the next scheduled run: Cribl Stream will **skip** the delayed run, and snap back to the original cron schedule.

Set **Skippable** to `No` if you absolutely must have all your data, for compliance or other reasons. In this case, Cribl Stream will build up a backlog of jobs to run.

You can think of **Skippable**: `No` as behaving more like the TCP protocol, with **Skippable**: `Yes` behaving more like UDP.

All collection jobs are constrained by the following options in **Settings** > **Global** > **General Settings** > **Job Limits**:

- **Concurrent Task Limit**
- **Max Task Usage Percentage**

Run Configuration and Shared Settings

Most of the remaining fields and options below are shared with the **Run Collector** modal, which you can open by selecting **Run** beside a configured Collector.

Mode

Depending on your requirements, you can schedule or run a collector in these modes:

- Preview – Default for Run, but not offered for scheduled jobs.
- Discovery – Default for scheduled jobs.
- Full Run.

Preview

In the Preview mode, a collection job will return only **a sample subset** of matching results (e.g., 100 events). This is very useful in cases when users need a data sample to:

- Ensure that the correct data comes in.
- Iterate on Filter expressions.
- Capture a sample to iterate on Pipelines.

Schedule configuration omits the Preview option, because Preview is designed for immediate analysis and decision making. To configure a scheduled job with high confidence, you can first manually run Preview jobs with the same Collector, to verify that you're collecting the data you expect.

Preview Settings

In Preview mode, you can optionally configure these options:

Capture time (sec): Maximum time interval (in seconds) to collect data.

Capture up to N events: Maximum number of events to capture.

Where to capture: Select the stage in the event processing order where events should be captured during the Preview run. During a Preview run, the first two of the four capture options are available.

- `Before pre-processing Pipeline` (Default): Captures events immediately after they're received.
- `Before the Routes`: Captures events after pre-processing but before they're routed.

Discovery

In Discovery mode, a collection job will return only **the list of objects/files** to be collected, but none of the data. This mode is typically used to ensure that the Filter expression and time range are correct before a Full Run job collects unintended data.

Send to Routes

In Discovery mode, this toggle enables you to send discovery results to Cribl Stream Routes. Defaults to `No`.

This setting overrides the Collector configuration's **Result Routing** > **Send to Routes** setting.

Full Run

In Full Run mode, the collection job is fully executed by Worker Nodes, and will return all data matching the Run configuration. Optionally, for the Database Collector, you can also configure state tracking.

Time Range

Set an **Absolute** or **Relative** time range for data collection. The **Relative** option is the default, and is particularly useful for configuring scheduled jobs.

Absolute

Select **Absolute** to set fixed collection boundaries. Use the **Earliest** and **Latest** controls to set the start date/time and end date/time. Provide the correct time zone in the **Range timezone** drop-down.

Relative

Select **Relative** to set collection boundaries relative to the current epoch time. Next, use the **Earliest** and **Latest** fields to set start and end times like these:

- **Earliest** example values: `-1h`, `-42m`, `-42m@h`
- **Latest** example values: `now`, `-20m`, `+42m@h`

By default, Cribl Stream uses **Earliest** and **Latest** as time-based tokens, which it evaluates in two ways:

- By comparison to time values specified in the directory path.
- By comparison to the `_time` field.

The Google Cloud Storage, REST/API, and Splunk Search Collectors provide a **Disable time filter** option in their **Collector Settings**. When set to `Yes`, scheduling or running these Collectors against a date range will cause Cribl Stream to ignore event time–based filtering entirely.

Relative Time Syntax

For Relative times, the **Earliest** and **Latest** controls accept the following syntax:

```
[+|-]<time_integer><time_unit>@<snap-to_time_unit>
```

To break down this syntax:

Syntax Element	Values Supported
Offset	Specify: `-` for times in the past, `+` for times in the future, or omit with `now`.
<time_integer>	Specify any integer, or omit with `now`.
<time_unit>	Specify the `now` constant, or one of the following abbreviations: `s[econds]`, `m[inutes]`, `h[ours]`, `d[ays]`, `w[eeks]`, `mon[ths]`, `q[uarters]`, `y[ears]`.
@<snap-to_time_unit>	Optionally, you can append the `@` modifier, followed by any of the above `<time_unit>`s, to round down to the nearest instance of that unit. (See the next section for details.)

Cribl Stream validates relative time values using these rules:

- **Earliest** must not be later than **Latest**.
- Values without units get interpreted as seconds. (E.g., `-1 = -1s`.)

Snap-to-Time Syntax

The `@` snap modifier always rounds **down** (backwards) from any specified time. This is true even in relative time expressions with `+` (future) offsets. For example:

- `@d` snaps back to the beginning of today, 12:00 AM (midnight).
- `+128m@h` looks forward 128 minutes, then snaps back to the nearest round hour. (If you specified this in the `Latest` field, and ran the Collector at 4:20 PM, collection would end at 6:00 PM. The expression would look forward to 6:28 PM, but snap back to 6:00 PM.)

Other options:

- `@w` or `@w7` to snap back to the beginning of the week – defined here as the preceding Sunday.
- To snap back to other days of a week, use `w1` (Monday) through `w6` (Saturday).
- `@mon` to snap back to the 1st of a month.
- `@q` to snap back to the beginning of the most recent quarter – Jan. 1, Apr. 1, Jul. 1, or Oct. 1.
- `@y` to snap back to Jan. 1.

Filter

This is a JavaScript filter expression that is evaluated against token values in the provided collector path (see below), and against the events being collected. The **Filter** value defaults to `true`, which matches all data, but

this value can be customized almost arbitrarily.

For example, if a File System or S3 collector is run with this Filter:

```
host=='myHost' && source.endsWith('.log') || source.endsWith('.txt')
```

...then only files/objects with `.log` or `.txt` extensions will be fetched. And, from those, only those events with host field `myHost` will be collected.

At the **Filter** field's right edge are a Copy button, an Expand button to open a validation modal, and a History button. For more extensive options, see Tokens for Filtering below.

Advanced Settings

Log level: Level at which to set task logging. More-verbose levels are useful for troubleshooting jobs and tasks, but use them sparingly.

Lower task bundle size: Limits the bundle size for small tasks. E.g., bundle five 200KB files into one 1MB task bundle. Defaults to `1MB`.

Upper task bundle size: Limits the bundle size for files above the **Lower task bundle size**. E.g., bundle five 2MB files into one 10MB task bundle. Files greater than this size will be assigned to individual tasks. Defaults to `10MB`.

Reschedule tasks: Whether to automatically reschedule tasks that failed with non-fatal errors. Defaults to `Yes`; does not apply to fatal errors.

Task reschedule limit: Maximum number of times a task can be rescheduled. Defaults to `1`.

Job timeout: Maximum time this job will be allowed to run. Units are seconds, if not specified. Sample values: `30`, `45s`, or `15m`. Minimum granularity is 10 seconds, so a `45s` value would round up to a 50-second timeout. Defaults to `60m`. Enter '0' for unlimited time (no timeout).

State Tracking

Enabled: Toggle to `Yes` if you want to enable state tracking when running scheduled or full run jobs.

Subsequent options depend on the type of Collector you're working with.

For Database Collectors, see Working with a Tracking Column to learn how to craft a Collector query for state tracking.

For REST Collectors, see Working with State Tracking to learn how enable and use state in your collection configuration.

State tracking is available only for Database and REST Collectors.

Cribl recommends that when you enable state tracking on a Collector, you configure the schedule to allow only one job to run at a time.

This prevents one run from starting before another has finished, which avoids the collection of duplicate records and/or incorrect state tracking.

Tokens for Filtering

Let's look at the options for path-based (basic) and time-based token filtering.

Basic Tokens

In collectors with paths, such as Filesystem or S3, Cribl Stream supports path filtering via token notation. Basic tokens' syntax follows that of JS template literals: `${<token_name>}` – where `token_name` is the field (name) of interest.

For example, if the path was set to `/var/log/${hostname}/${sourcetype}/`, you could use a Filter such as `hostname=='myHost' && sourcetype=='mySourcetype'` to collect data only from the `/var/log/myHost/mySourcetype/` subdirectory.

Time-based Tokens

In paths with time partitions, Cribl Stream supports further filtering via time-based tokens. This has a direct effect with earliest and latest boundaries. When a job runs against a path with time partitions, the job traverses a minimal superset of the required directories to satisfy the time range, before subsequent event `_time` filtering.

About Partitions and Tokens

Cribl Stream processes time-based tokens as follows:

- For each path, time partitions must be notated in descending order. So Year/Month/Day order is supported, but Day/Month/Year is not.
- Paths may contain more than one partition. E.g., `/my/path/2020-04/20/`.
- In a given path, each time component can be used only once.
  So `/my/path/${_time:%Y}/${_time:%m}/${_time:%d}/...` is a valid expression format, but

`/my/path/${_time:%Y}/${_time:%m}/${host}/${_time:%Y}/...` (with a repeated `Y`) is not supported.

- For each path, all extracted dates/times are considered in UTC.

The following strptime format components are allowed:

- `'Y'`, `'y'`, for years
- `'m'`, `'B'`, `'b'`, `'e'`, for months
- `'d'`, `'j'`, for days
- `'H'`, `'I'`, for hours
- `'M'`, for minutes
- `'S'`, for seconds

Token Syntax

Time-based token syntax follows that of a slightly modified JS template literal: `${_time: <some_strptime_format_component>}`. Examples:

Filter	Matches
`/my/path/${_time:%Y}/${_time:%m}/${_time:%d}/...`	`/my/path/2020/04/20`
`/my/path/${_time:year=%Y}/${_time:month=%m}/${_time:day=%d}/...`	`/my/path/year=2020/`
`/my/path/${_time:%Y-%m-%d}/...`	`/my/path/2020-05-20`

Autoscale with Collection Jobs

Cribl Stream supports autoscaling for streaming data, but not for collection jobs.

If you run a collection job using Workers in an autoscaling group (such as an AWS instance), you must adequately size your Worker Group or Worker Groups and provision the Worker Nodes before you run or schedule a collection job. Otherwise, a race condition may occur between task scheduling and configuration download from the Leader.

How Time Filtering Works for Scheduled Jobs

When filtering Collector returns by time, keep the following considerations in mind:

- You can configure the time filter to send the `${earliest}` and `${latest}` variables as request parameters. Be aware that these variables also filter the events returned.

- When a Collector returns events as an array, make sure you configure your Event Breaker correctly. You may need a JSON array Event Breaker on the source to separate out the individual fields so that it can apply the filter. See Parse Discover Returns With Arrays as JSON Objects for an example of how to use a JSON array Event Breaker with the REST Collector.

The time bounds, `$earliest` and `$latest`, are in UNIX epoch time, seconds since 1970. Some considerations when using these variables:

- When using them in contexts that require milliseconds resolution, multiply them by 1,000 to convert to ms.
- Referencing them without a call to `C.Time.strftime()` or similar will result in an number, not a human readable timestamp.
- APIs vary in their requirements for time formatting required. Consult the API documentation for the API to format it correctly.

See REST Collector - Time Range Variables for more information.

Troubleshoot

No Discover or Collector Event Results

Sometimes after you configure a Collector you might not see any results even after you verified those results exist outside of Cribl Stream and should have appeared in the run results.

Potential cause: One potential cause is the way time filtering works in Cribl Stream. There are two instances when time filters impact your data:

- When you submit a call for data within a specific time range.
- When you compare the data within a specific time range in Cribl Stream.

When you gather data from a Collector and it returns time-bound data, Cribl Stream runs Event Breakers on the data to break the incoming data into discrete data events. Each discrete event has its own timestamp. If any of those events are outside the `` `${earliest}` `` and `` `${latest}` `` variables as defined for the run, Cribl Stream is going to discard those events by default.

Recommendation Turn off time filtering for that Collector. Typically this setting is under **Advanced Settings**. Set **Disable time filter** to `Yes`, then retry the run. Note that this setting is not available for all Collectors.

For additional help with time filtering, see How Time Filtering Works for Scheduled Jobs.

15.1.1.13. Job Limits

You can configure global limits that optimize the execution of all Collectors and scheduled jobs (including Cribl Stream system tasks). To access and set these limits, follow the steps for your deployment type:

- Single-instance deployments: **Settings** > **System** > **General Settings** > **Limits** > **Jobs**.
  These limits apply to all Worker Processes.
- Distributed deployments: From the Leader, [select a Worker Group] > **Group Settings** > **System** > **General Settings** > **Limits** > **Jobs**.
  These limits are applied at the Worker Group level (except where noted), and trickle down to individual Worker Processes in the Group.

Limits Available

The following controls are available at the UI locations listed above.

Job Limits

Disable Jobs/Tasks: Set to `No` by default in Stream Groups. When enabled, Nodes running 4.5.0 and newer will not poll the Leader for jobs/tasks, and Nodes will not use the settings below (even if they're set).

Nodes running 4.4.4 and older still upgrade via jobs and will honor the Jobs settings, even with **Disable jobs/tasks** toggled to `Yes`.

Concurrent Job Limit: The total number of jobs that can run concurrently. Defaults to `10`.

Concurrent System Job Limit: The total number of **system** jobs that can run concurrently. Defaults to `10`. Minimum `1`.

Concurrent Scheduled Job Limit: The total number of **scheduled** jobs that can run concurrently. This limit is set as an offset relative to the **Concurrent Job Limit**. Defaults to `-2`.

Skipped jobs indicate that a Group's **Concurrent Job Limit** has been reached or exceeded. Increase this limit to reduce the number of skippable jobs. For resource-intensive jobs, this might require deploying more Worker Nodes.

Task Limits

Concurrent Task Limit: The total number of tasks that a Worker Process can run concurrently. Defaults to `2`. Minimum `1`.

Concurrent System Task Limit: The number of system tasks that a Worker Process can run concurrently. Defaults to `1`. Minimum `1`.

Max Task Usage Percentage: Value, between `0` and `1`, representing the percentage of total tasks on a Worker Process that any single job may consume. Defaults to `0.5` (i.e., 50%).

Task Poll Timeout: The number of milliseconds that a Worker's task handler will wait to receive a task, before retrying a request for a task. Defaults to `60000` (i.e., 60 seconds). Minimum `10000` (10 seconds).x

Completion Limits

Artifact Reaper Period: Interval on which Cribl Stream attempts to reap jobs' stale disk artifacts. Defaults to `30m`.

Finished Job Artifacts Limit: Maximum number of finished job artifacts to keep on disk. Defaults to `100`. Minimum `0`.

Finished Task Artifacts Limit: Maximum number of finished task artifacts to keep on disk, per job, on each Worker Node. Defaults to `500`. Minimum `0`.

Task Manifest and Buffering Limits

Manifest Flush Period: The rate (in milliseconds) at which a job's task manifest should be refreshed. Defaults to `100` ms. Minimum `100`, maximum `10000`.

Manifest Max Buffer Size: The maximum number of tasks that the task manifest can hold in memory before flushing to disk. Defaults to `1000`. Minimum `100`, maximum `10000`.

Manifest Reader Buffer Size: The number of bytes that the task manifest reader should pull from disk. Defaults to `4kb`.

Job Dispatching: The method by which tasks are assigned to Worker Processes. Defaults to `Least In-Flight Tasks`, to optimize available capacity. `Round Robin` is also available.

Job Timeout: Maximum time a job is allowed to run. Defaults to `0`, for unlimited time. Units are seconds if not specified. Sample entries: `30`, `45s`, `15m`.

Task Heartbeat Period: The heartbeat period (in seconds) for tasks to report back to the Leader/API. Defaults to `60` seconds. Minimum `60`.

15.1.1.14. Using Collectors

15.1.1.14.1. Using S3 Storage And Replay

Cribl Stream's Replay options offer organizations fundamentally new ways to manage data, by providing an easy way to selectively ingest, **and re-ingest**, data into systems of analysis. Let's walk through how to use this feature, step by step.

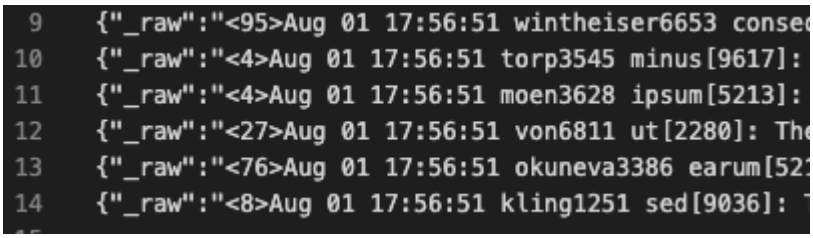
For simplicity, we'll treat the storage destination here as Amazon S3, although it could just as easily be MinIO, or any of several other options.

Choosing JSON vs. Raw Format

You can write data out of Cribl Stream in either of two formats – JSON or raw.

JSON

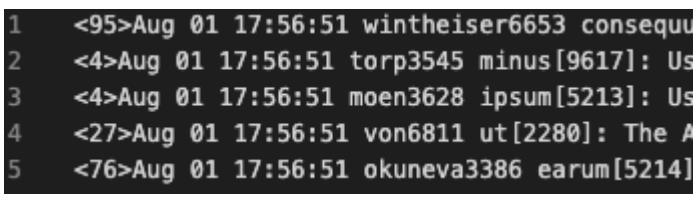
With this option, the parsed event, with all metadata and modifications it contains at the time it reaches the Destination step, will be wrapped in a JSON object. Each event is one line. This is newline-delimited JSON (abbreviated NDJSON). For example, here is syslog data using the JSON format option:



JSON-formatted event

Raw

With this option, the contents of the event's `_raw` field – unparsed, at the time it reaches the Destination step – are written out in plaintext. Each event is one line. For example, here's the same syslog data, except unmodified and unparsed, as written out with the raw option:



Which Format?

Cribl recommends using the default JSON format. Here, we expect that timestamp extractions and other vital enhancements have already been performed. Reusing that information makes sense, and will make your replay simpler.

Notice that in the screen capture above, the **raw** format simply contains the original data. There might be cases where you want this; but usually, exporting the preprocessed event is more desirable.

Cribl Stream supports replaying data that has been exported as Parquet, through any of the following: Amazon S3 Collector, Azure Blob Storage Collector, Google Cloud Storage Collector, or Filesystem Collector.

Writing the Data Out

The Worker Nodes stage files until certain limits are reached: Time open, idle time, size, or number of files. These settings are available on the Destination configuration modal's **Advanced Settings** tab (see S3 details here).

Once any of the configured limits is reached, the Worker gzips the file and drops it into the object store. If you reach the open-file limit, the oldest file will be targeted.

The S3 Destination's settings also allow you to define how the uploaded files are partitioned. Host, time, sourcetype, source – all the metadata is available to you for this purpose. When you're replaying data from the store, these partitions will be handy, to make your replay searches faster.

We can map segments of the path back to variables (including `time`) that you can use to zero in on the exact logs you need to replay, without requiring checking `_raw`.

For examples of the expressions Cribl recommends, see the example Destination definition below.

Retrieving the Events

With events stored in an object store, we can now point Cribl Stream to that store to Replay selected events back through the system. We want to use data in the file path as an initial level of filtering, to exclude as much data as we can from download. Object retrieval and unpacking imposes a big resource hit in the Replay

process, so minimize your impact radius. Searching against `_raw` data is also possible, but should be secondary to `_time`, `sourcetype`, `index`, `host`, etc.

Retrieval details: The Leader picks one Node to do the discovery exploration, to find the potential objects that are in play. That list of targets is then doled out to the Worker Group to actually pull down the objects, and to examine them for content matches, before executing final delivery. All Worker Nodes share the workload of retrieving and re-injecting the data.

Finally, we need to process the data coming back to extract each event. As with any incoming data stream on a compatible Source, Cribl Stream can use default, or custom, Event Breaker definitions. In this case, we recommended above to use JSON as the format of the events when we write to disk, so we'll use the **Cribl** Event Breaker ruleset on this Source. This Event Breaker contains a newline-delimited-JSON definition.

Setting Up and Running Replay

With the above concepts established, let's put them to work. We'll round-trip data through our Destination and replay it in Cribl Stream.

The Store

Object storage, or any shared storage, will work. As long as all the Cribl Stream Nodes can see it, we're ready to go. For the purposes of this post, let's stick with an S3-compatible store.

You'll need all the credentials, keys, secret keys, endpoints, etc., required to access the bucket that you intend to use in your object store. (For details on cross-account access, see this blog post.) Obviously, the bucket should be able to grow to the size intended for your long-term archival needs.

Storage Class Compatibility

Cribl Stream's Collectors and Replay feature do not support the S3 Glacier, S3 Deep Glacier, or Azure archive tier, due to long retrieval times for those storage classes.

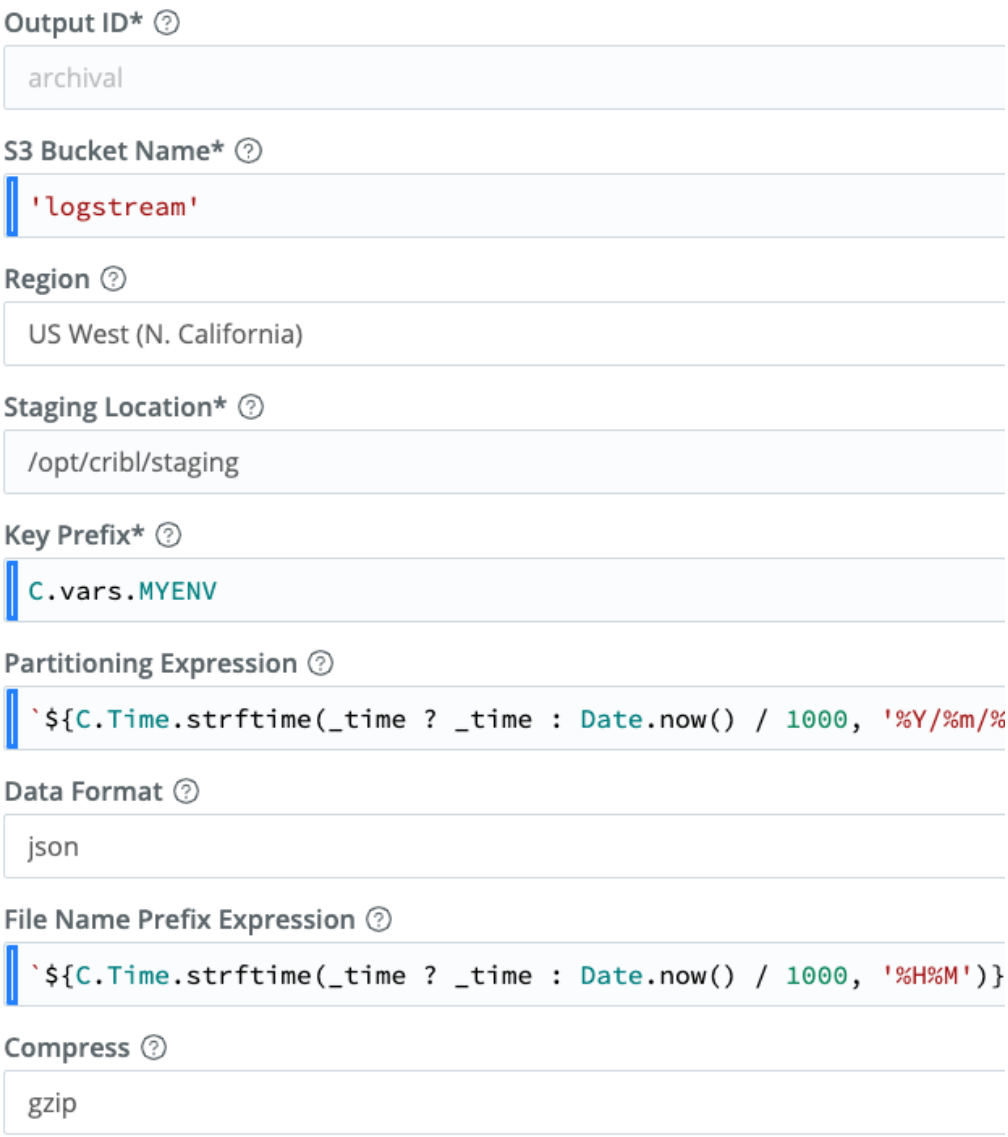
Collectors and Replay **do** support S3 Glacier Instant Retrieval when you're using the S3 Intelligent-Tiering storage class.

The Destination Definition

In your Cribl Stream Worker Group config, create a new S3 Destination. The screenshot below is an example built for this demo.

Use the Destination's **Advanced Settings** tab to adjust the limits, if needed. The defaults are fine for most situations, but depending on your partitioning scheme, we could be talking about 100+ files. So **make sure your staging area has enough space**.

In particular, set the **Max open files** option appropriately. It overrides the size and time limits. We recommend that the staging area be its own volume, so that you don't fill up a more-vital volume by mistake.



Partitioning and filename expressions

The screen capture above includes the partitioning and filename prefix expressions. Below is the full text of each expression. In a nutshell, we're using time and other metadata to construct a path in the object store, which will be useful to us at replay time:

```
Year/Month/Day/index/host/sourcetype/HHMM-foobar.gz
```

Partitioning (one line):

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d')}/${index ? index :
```

Filename:

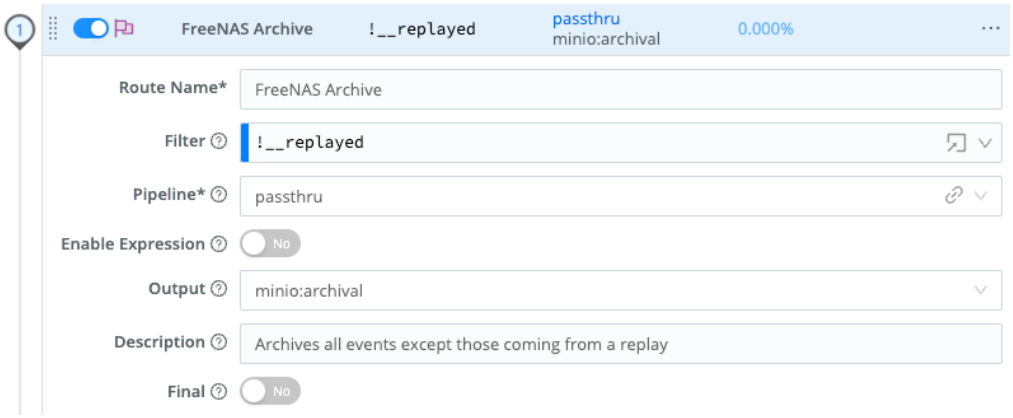
```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%H%M')}`
```

We've also included a Key Prefix from Cribl Stream's **Processing** > **Knowledge** > **Global Variables**. You could use this to partition your logs by environment, or any other qualifier.

The Archival Route

Create a new Cribl Stream Route called `Archival` that matches everything you want to archive. In this case, we've set it to `!__replayed`, and set this internal field in the Source (see the next step). Any event that is **not** coming from the defined Replay process will be archived.

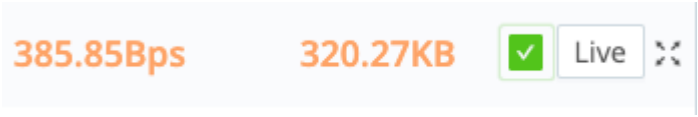
Select the `passthru` Pipeline, or create an empty Pipeline and use that. Select the S3 Destination you created above. And finally, make sure **Final** is **not set**. We want data to flow through this Route, not stop at it. So, position the `Archival` Route at or near the top of the Routing table. Save your work, commit, and deploy.



Pipeline configuration

Once saved and deployed, data should be flowing to your object store. Check your work: Go to the Monitoring dashboard and select **Data** > **Destinations** at the top. You want to see a green checkmark on the right side for your S3 Destination. If it's not green, find out why.

You can also use an S3-capable browser, like Cyberduck, to check the files more manually. (Specific troubleshooting steps are outside the scope of this doc.)



A green (healthy) destination

The Replay Collector

From the top nav of your Cribl Stream Worker Group or single instance, select **Data** > **Sources** > **Collectors** > **S3**, and create a new S3 Collector with the ID `Replay`. Use the **Auto-populate from** option to pull in the configs from your S3 Destination.

In the **Path** field, we need to establish the tokens to extract from the path on the S3 store. If you used the recommended partitioning scheme in the above example Destination definition, we recommend specifying these tokens here:

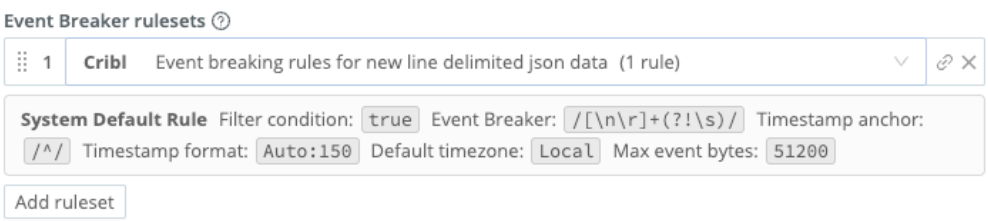
```
/${MYENV}/${_time:%Y}/${_time:%m}/${_time:%d}/${index}/${host}/${sourcetype}/${_time
```

If you chose to leave out `C.Vars.MYENV`, exclude the first segment. It is **vital** that this scheme match your partitioning scheme in the Destination definition.

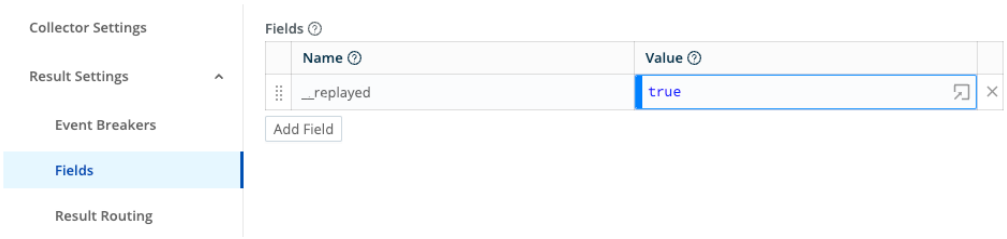
With these tokens defined, you can now define filters that exclude and include relevant files before Cribl Stream is required to download and open them. This cuts down on the work required, by orders of magnitude.

> This is a core concept. We want to avoid having to open files to check for matches, by instead relying on key data in the path. Cribl Stream can immediately exclude, without downloading, the files that have no chance of matching our target events.
>
> Using `_time`, `sourcetype`, `host`, and `index`, it can accurately zero in on the target files. After this high-level filtering, Cribl Stream will download and interrogate the contents of what's left, and will send the matches along to the Routing table.

Finally, under **Result Settings** > **Event Breakers**, select the `Cribl` Ruleset. This Ruleset understands how to parse the JSON packaged events stored by the Archive Destination.



To make it easier to identify events that have been replayed, create a field (**Result Settings** > **Fields**) named `__replayed` and set it to `true`. You could filter on this field in Routes and Pipelines later. Because it's a double-underscore field, it's internal-only, and won't be passed on to your final destinations. In a previous step, we used it to prevent replayed events from being re-archived:



__replayed field

Now save your Collector, and commit and deploy.

Testing Replay

After you've accumulated some data in your S3 store, head over to Pipelines and start a capture. For the filter, use `__replayed`, and run it for 300 seconds, 10 max events.

Once it's running, in a new browser window, navigate back to Collectors, and run your Replay Collector. Filter on `true`, and set the **Earliest** time to `-1h` and the **Latest** to `now`.

You can run it in Preview mode to make sure you get results, and then come back and do a full run. (Or you can just do a full run right off the bat if you're confident.)

With a running job, you can click on the job ID to follow its progress. You can also pop back over to the Capture browser window or tab, and you should see events there.

In a full run, the events will proceed through your Routes as normal, and will land wherever your original Routes and Pipelines dictate. In this case, they landed in Splunk, and we could easily see duplicate events – that is, **exact** duplicate events – in the 1-hour timeframe that the Collector job defined.

Once defined, this Collector can be controlled via scheduling, manual runs, or API calls. And in production use, when configuring the job's **Run configuration** or **Schedule configuration** modal, you'd want to fill in the **Filter** expression to meet your needs.

15.1.1.14.2. Using REST/API Collectors

The REST/API Endpoint Collector is powerful, but complex. This use case demonstrates several examples of building and running REST Collectors to pull data from public and simulated REST endpoints.

Check out the example REST Collector configurations in Cribl's Collector Templates repository. For many popular Collectors, the repo provides configurations (with companion Event Breakers, and event samples in some cases) that you can import into your Cribl Stream instance, saving the time you'd have spent building them yourself.

To configure a Collector for Netskope Events and Alerts, see this Netskope Community topic.

1. Basic HTTP GET

This example performs an HTTP GET operation against an external Joke API. This API uses a license key header to authenticate the user.

Discover type: None

Collect URL: `'https://matchilling-chuck-norris-jokes-v1.p.rapidapi.com/jokes/random'`

Collect parameters: None

Collect headers:

```
accept: 'application/json'

x-rapidapi-key: 'e4068647ffmsh65536596798f49dp17e998jsn342bac862377'

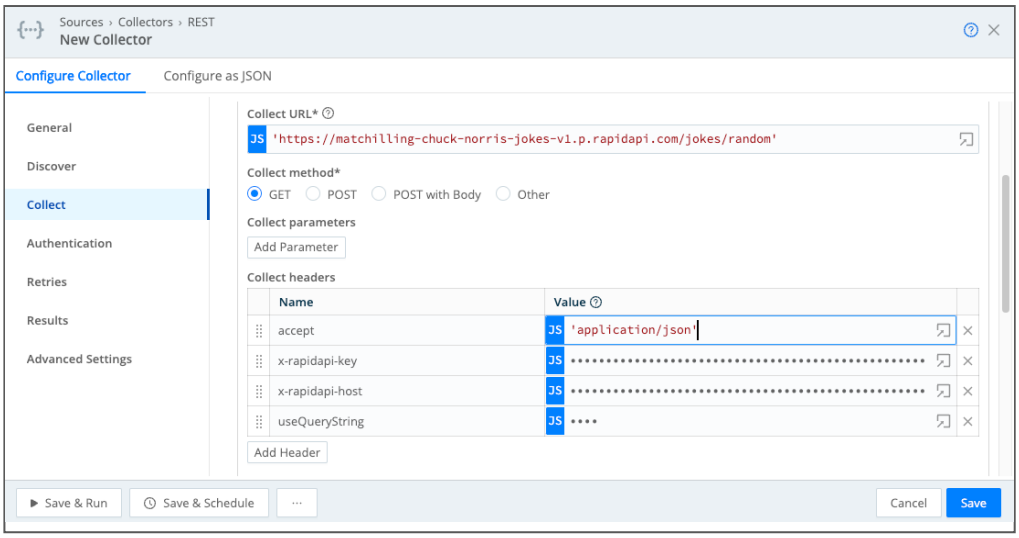
x-rapidapi-host: 'matchilling-chuck-norris-jokes-v1.p.rapidapi.com'

useQueryString: true
```

Pagination: None

Authentication: None

Event Breaker: JSON Newline Delimited – use Cribl Stream's built-in **Cribl > ndjson** rule, and associate it with the Collector to parse the JSON document.



Collector configuration for basic HTTP GET

Results

When run (in Preview mode), the Collector should return a single JSON record. If the Collector is set up with an NDJSON Event Breaker, it will look like this:

Returned event

2. HTTP GET with Pagination via URL Attribute

The REST Collector's Pagination feature allows collection to retrieve 1–*N* pages of data, using attributes returned in either the response body or response header. The returned attribute can either be a URL (referencing the next page), or a token that can be added to subsequent request headers or parameters.

In this example, a returned response-body attribute contains a URL that references the next page. Pagination will continue until either the Collector's **Page limit** setting is reached, or no more pages are present (that is, the returned attribute is not present in the response body).

This example's API retrieves near-Earth asteroid data from NASA. The example uses a JSON Array Event Breaker to extract individual records from an array attribute in the response.

Discover type: None

Collect URL: `'http://www.neowsapp.com/rest/v1/neo/browse?api_key=oDa6w0fjsKEb1N3bMA5dMLhatMJ4WC5XtOBTrLrk'`

Collect parameters: None – Parameters in this example are added to the header. Static parameters (that is, parameters that don't reference variables) can safely be added to the URL. Any parameters that do reference variables should always be added in the **Collect parameters** section, to allow filtering of values that evaluate as undefined.

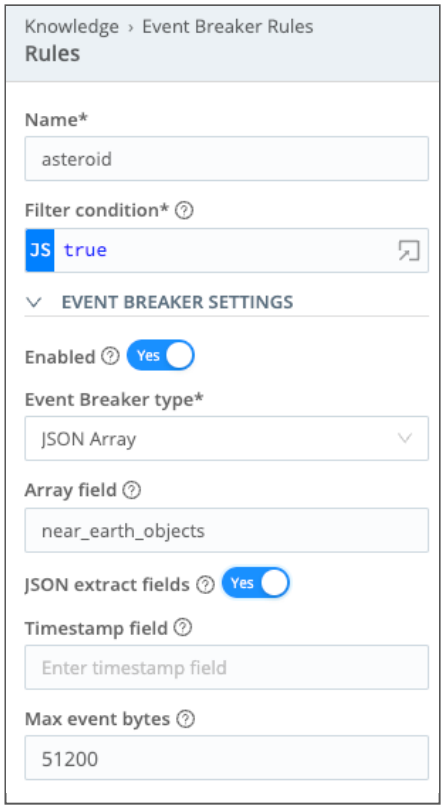
Collect headers: None

Pagination: Response Body Attribute

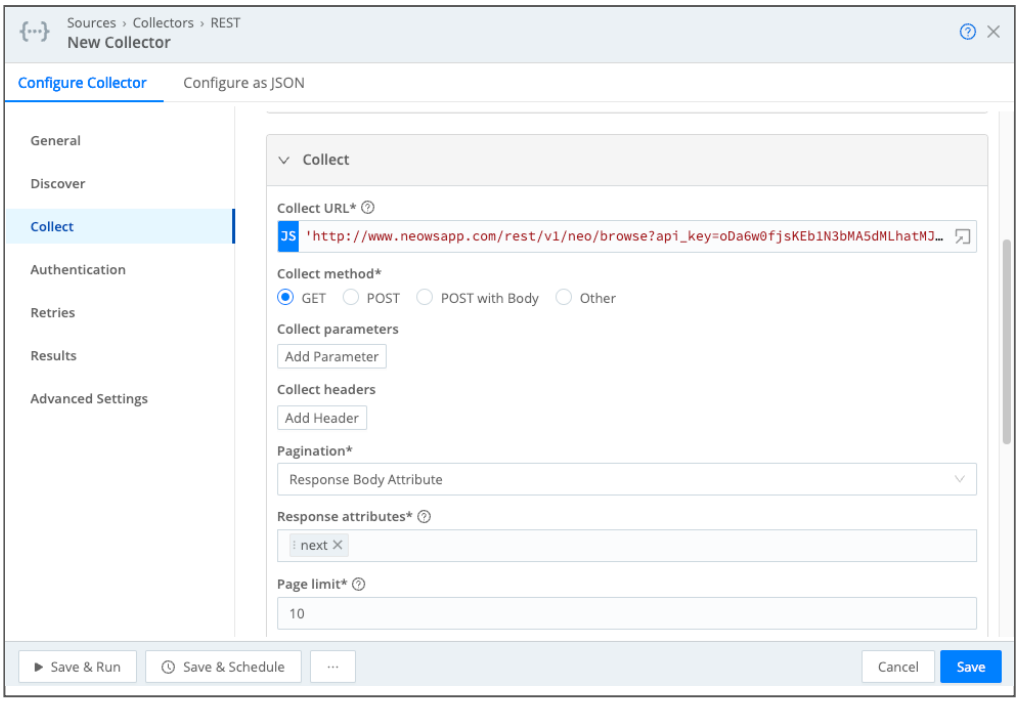
Response attributes: `next`

Authentication: None

Event Breaker: JSON Array

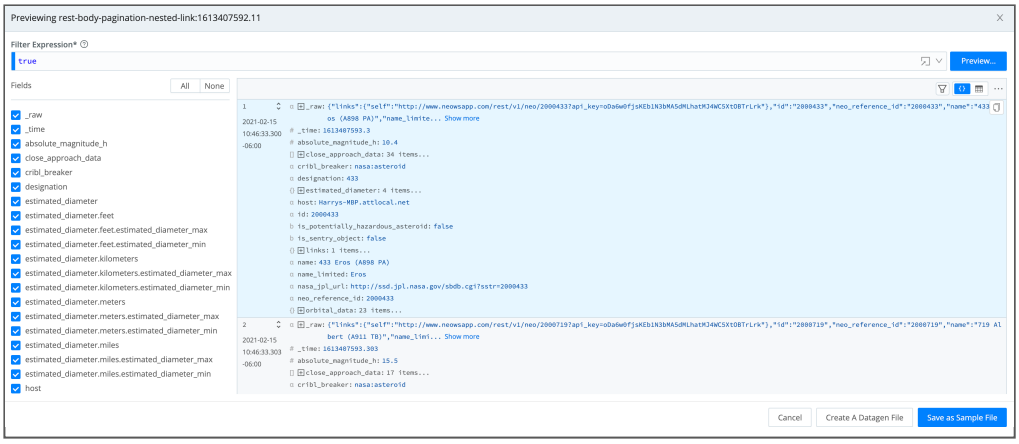


Event Breaker configuration



Collector configuration for HTTP GET, paginated via URL Attribute

When run (in Preview mode), the Collector should return multiple records extracted from the Event Breaker. In this example, we limited output to 10 pages of data. This particular dataset has over 1,000 total pages, so it's a good idea to limit output to avoid a job that runs too long.



Paginated events

This API allows a certain number of calls/month. Cribl recommends that you not schedule this Collector – run it ad-hoc, for testing only.

3. HTTP GET with Pagination via Response Body Attribute

This example uses Response Body Attribute pagination, which returns a token that is passed as a request parameter to retrieve subsequent pages of data. The only difference between this example and Example 2 is how the Response Body Attribute is used.

To authenticate against the GreyNoise endpoint used in this example, set up a trial account according to GreyNoise's Setting Up a Trial Account documentation.

Discover type: None

Collect URL: `'https://api.greynoise.io/v2/experimental/gnql'`

Collect method: `GET`

Collect parameters:

```
query: 'last_seen:1d'
```

```
scroll: `${scroll}`
```

Collect headers:

```
accept: 'application/json'
```

```
key: '<your-GreyNoise-API-key-here>'
```

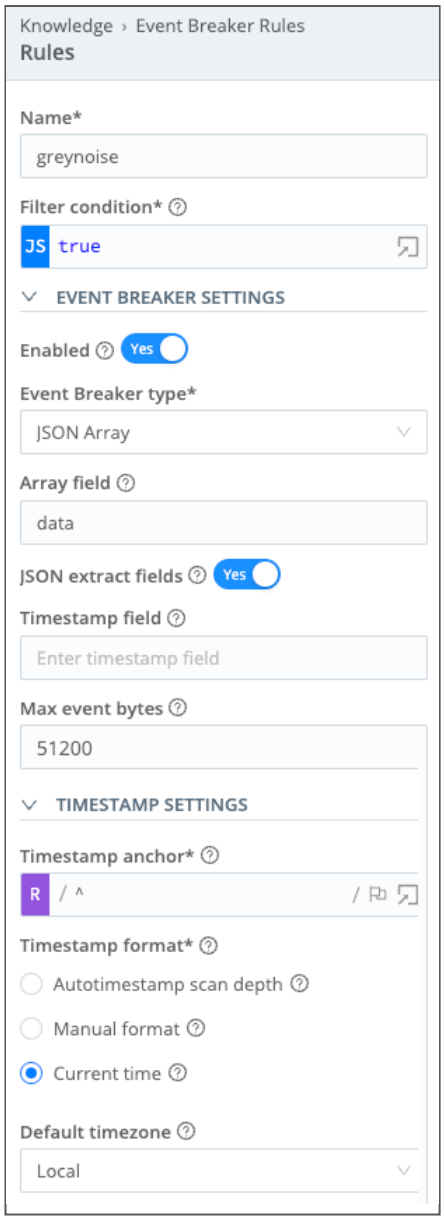
Pagination: Response Body Attribute

Response attributes: `scroll`

Page limit: `10` (or `0` to pull all data)

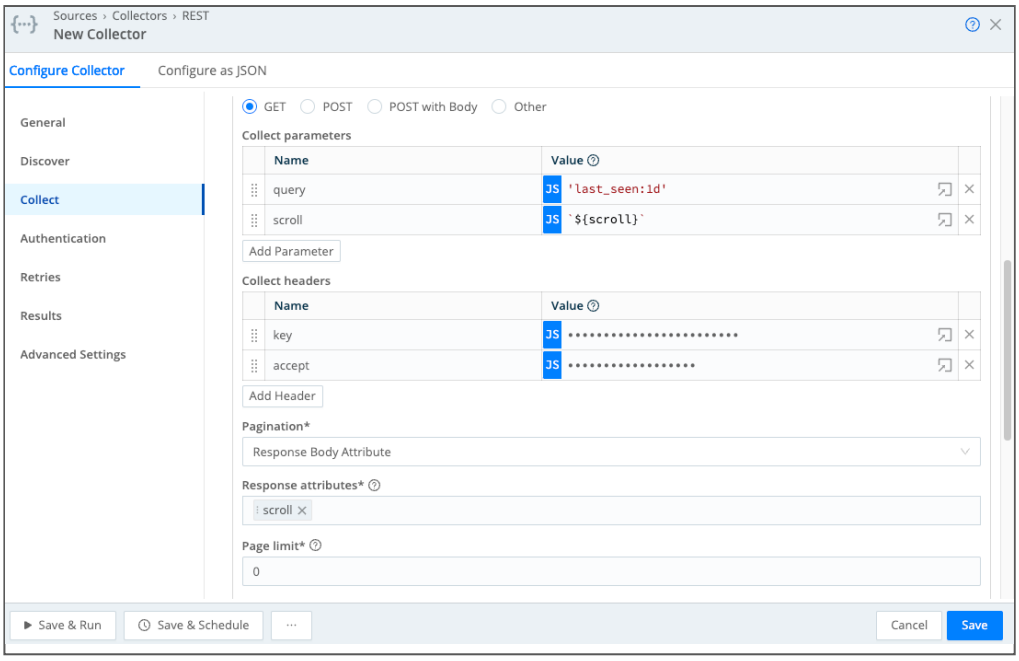
Authentication: None

Event Breaker: JSON Array – use the configuration shown here:



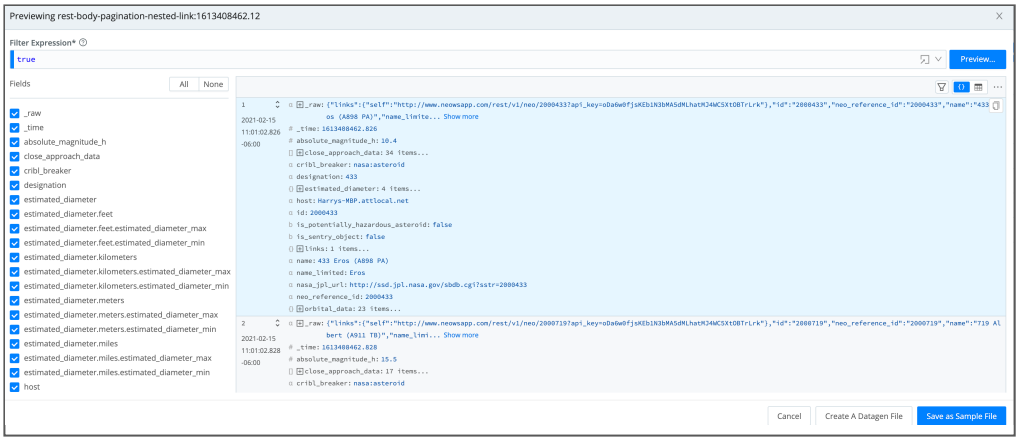
Event Breaker configuration

In this example, the response body returns an attribute named `scroll`, which is a token that references the next page of data to fetch. We reference the attribute in **Collect parameters** using the JavaScript expression: `` `${scroll}` ``. If present, this will be passed to retrieve subsequent pages of data, until either the Collector's **Page limit** setting is reached, or no more pages are present.



Collector configuration for HTTP GET, paginated via Response Body Attribute

Collector Output



Paginated events

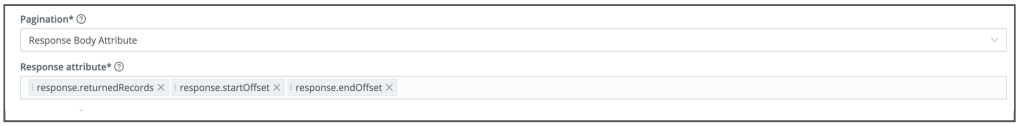
This API allows a certain number of calls/month. Cribl recommends that you not schedule this Collector – run it ad-hoc, for testing only.

For a more detailed use case around this particular API, see Cribl's Enrichment at Scale! blog post.

4. Pagination via Nested Response Body Attributes

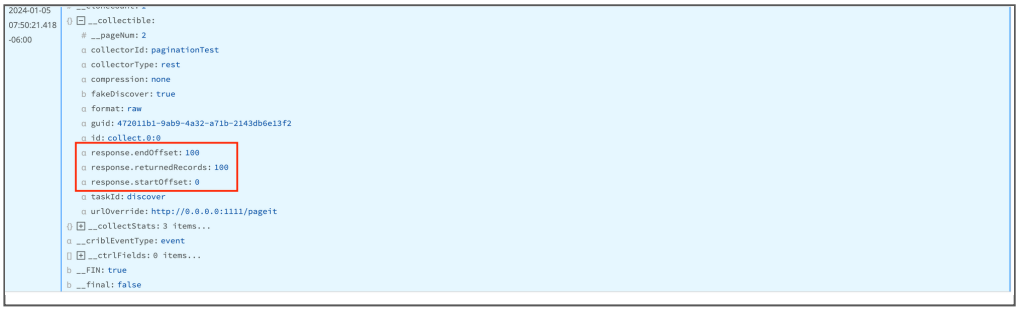
When using Response Body Attribute pagination with nested attributes for determining the next page, the extracted attributes from the response will have dots (`.`) included in their names within `__collectible`. This requires different syntax for accessing these attributes within the **Collect URL**, **Collect parameters**, **Collect POST body**, **Collect headers**, and **Last-page expression** fields.

For example, the following shows attributes two levels deep:



Attributes two levels deep

The attributes are added to `__collectible` with dots (`.`) in the name:

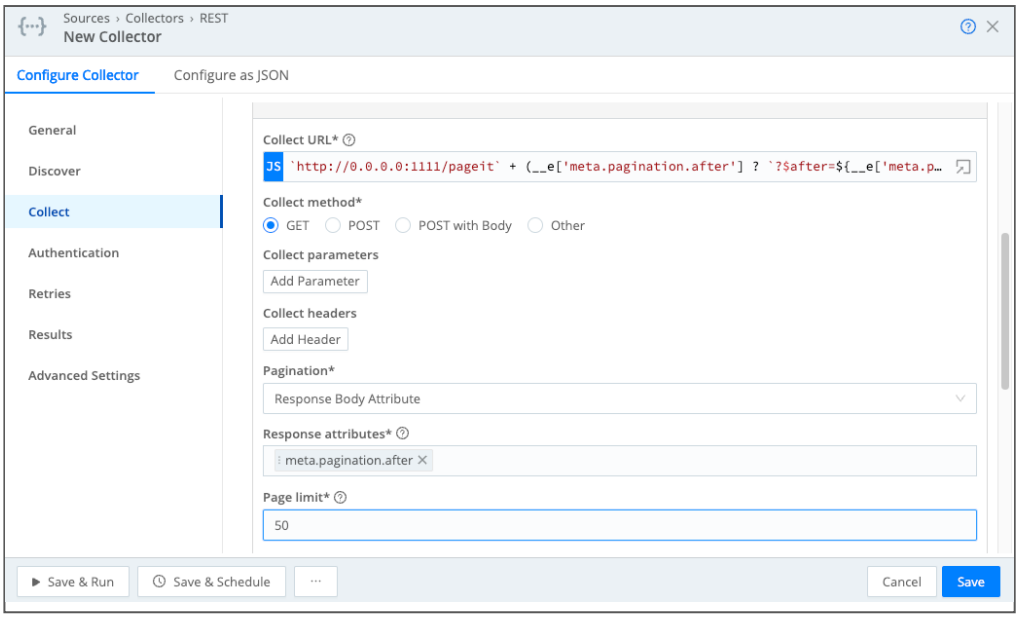


Attributes added to `__collectible`

Special syntax is needed to reference the attributes because they have dots in the name, like this `__e['attribute.name.with.dots']`.

The same syntax referenced in example 3 above, `__e['response.endOffset']`, can be used in the **Collect URL**, **Collect parameters**, **Collect POST body**, **Collect headers**, and **Last-page expression** fields. Here are examples of each.

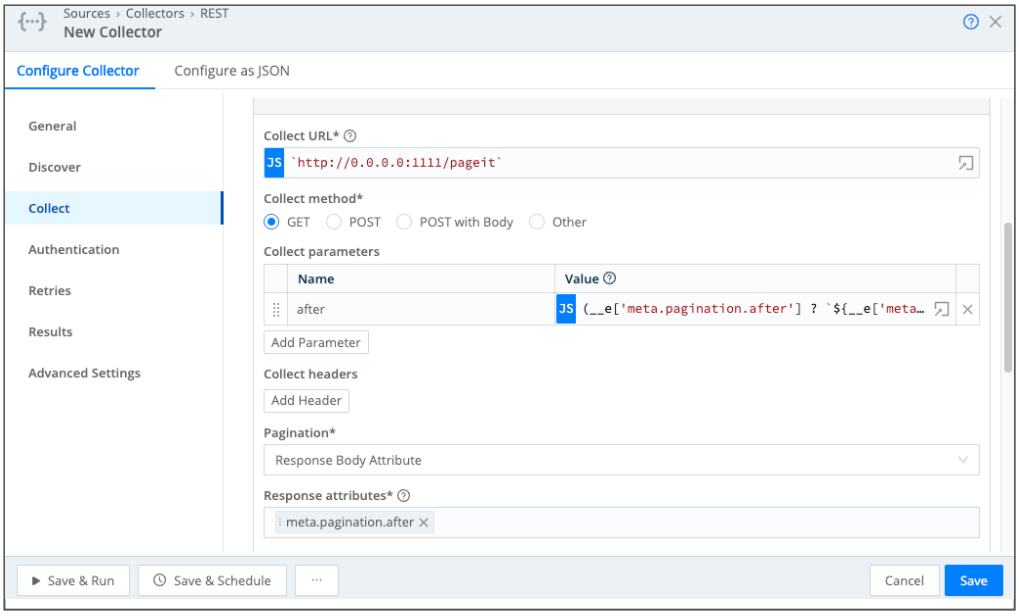
Collect URL: `` `http://0.0.0.0:1111/pageit` + (__e['meta.pagination.after'] ? `?$after=${__e['meta.pagination.after']}` : '') ``



Collect URL

Collect parameters:

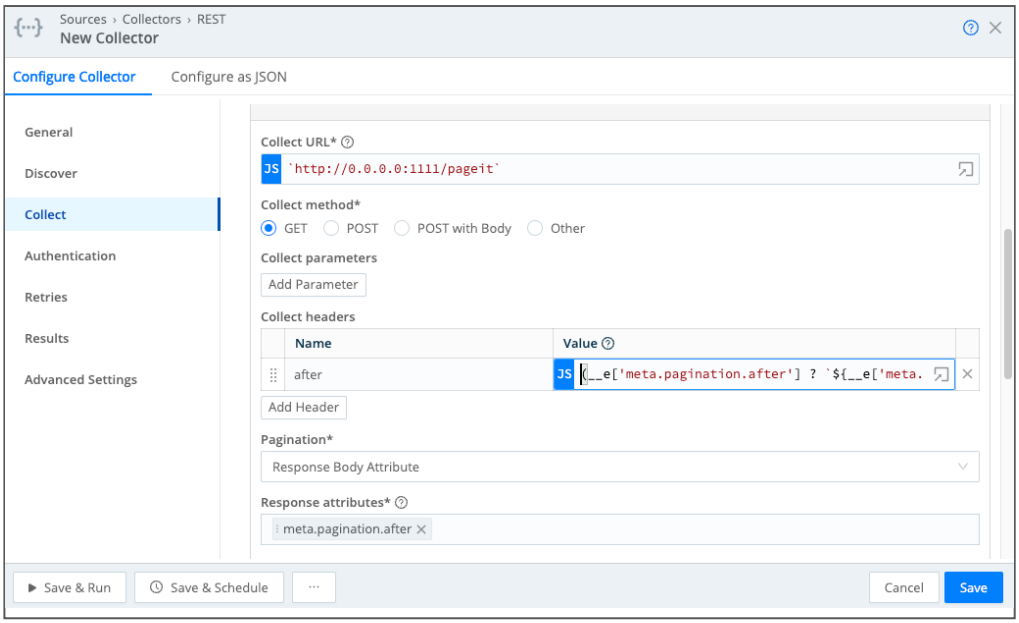
- **Name**: `after`
- **Value**: `(__e['meta.pagination.after'] ? `${__e['meta.pagination.after']}` : '')`



Collect parameters

Collect headers:

- **Name**: `after`
- **Value**: `(__e['meta.pagination.after'] ? `${__e['meta.pagination.after']}` : '')`

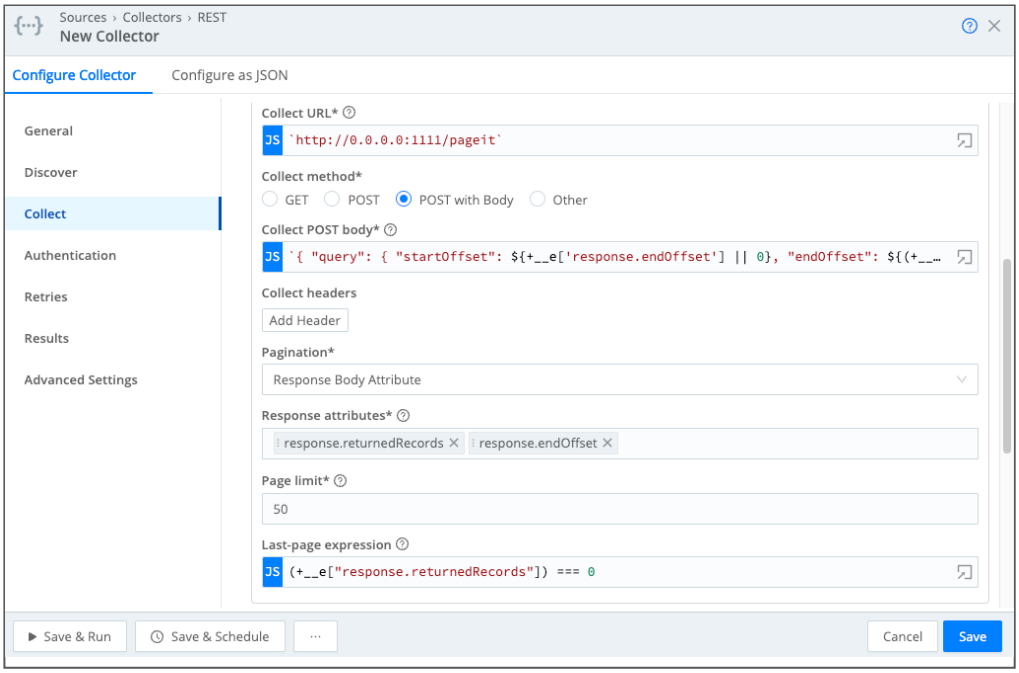


Collect headers

Collect POST body and **Last-page expression**:

- **Collect POST body**: `` `{ "query": { "startOffset": ${+__e['response.endOffset'] || 0}, "endOffset": ${(+__e['response.endOffset'] || 0) + 100} } }` ``
- **Last page expression**: `(+__e["response.returnedRecords"]) === 0`

Here the API passes the `startOffset` and `endOffset` parameters in the POST body to page through data until `response.returnedRecords == 0`. The **Last page expression** field is used to determine when all the available data has been consumed.

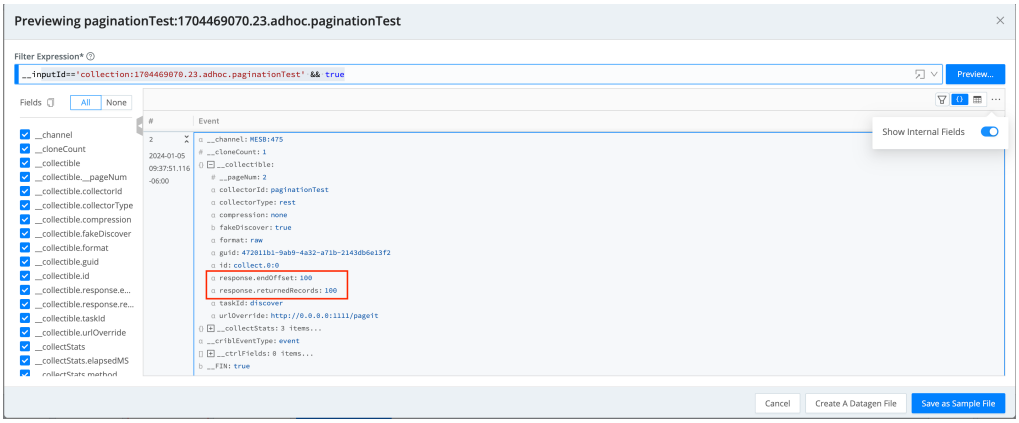


Collect POST body and Last-page expression

Here's sample output from the API showing partial results returned for the first page of data:

```
{
  "response": {
    "totalRecords": "1275",
    "returnedRecords": "100",
    "startOffset": "0",
    "endOffset": "100",
    "data": [
      {
        "one": 1
      },
      {
        "two": 2
      },
      ...
    ]
  }
}
```

Notice that the Collector Response attributes use dotted notation to access `endOffset` and `returnedRecords` as `response.endOffset` and `response.returnedRecords` respectively. This tells the Collector that the attributes of interest are named `response.endOffset` (dot in name) or nested JSON attributes: `{ response : { endOffset: 100 ... } }`. However, the response is structured (dots in attribute name or nested) the Collector will add the attributes to the second page's `__collectible` attribute using dots in the attribute name, for example:



`__collectible` second page of attributes

Now that you have the attributes available in `__collectible`, you can use them in the **Collect URL**, **Collect parameters**, **Collect POST body**, **Collect headers**, and **Last-page expression** fields. The syntax is the same

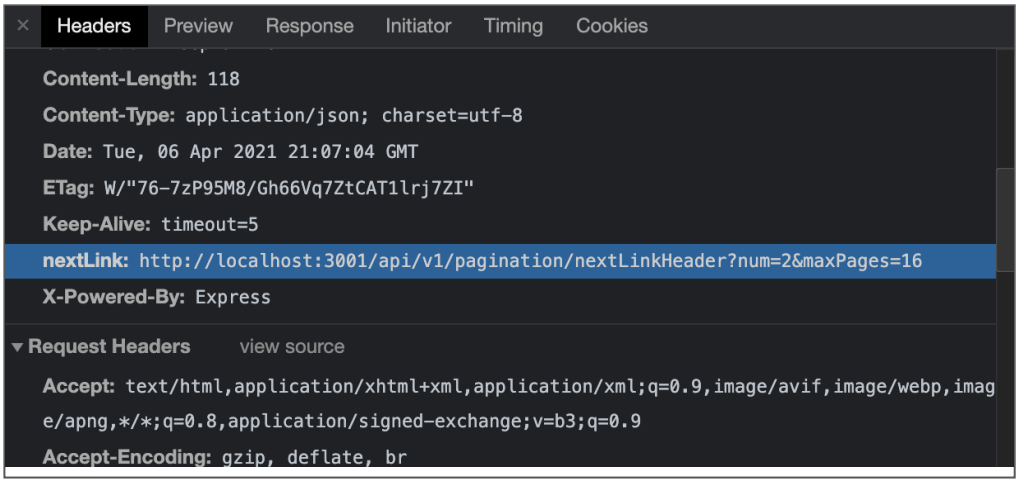
across all these fields. You'll use a special variable, `__e`, which acts like a shorthand for `__collectible` (since you can't use it directly here). Here's how to access specific attributes:

- `response.endOffset`: Use `__e['response.endOffset']`
- `response.returnedRecords`: Use `__e['response.returnedRecords']`

5. HTTP GET with Pagination via Response Header URL

This example leverages pagination using a Response Header Attribute value. The value returned can be either a URL (of the next page) or a token value (a request attribute that is passed to retrieve the next page of data).

This example is based around a local Web server on port 3001. The server returns a response header when another page of data is available, and the header contains the URL of the next page. Here's how the header looks in developer tools:



Next-page URL passed as Response Header Attribute

Collector Configuration

Discover type: None

Collect URL: `'http://localhost:3001/api/v1/pagination/nextLinkHeader?num=1&maxPages=16'`

Collect parameters: None

Collect headers: None

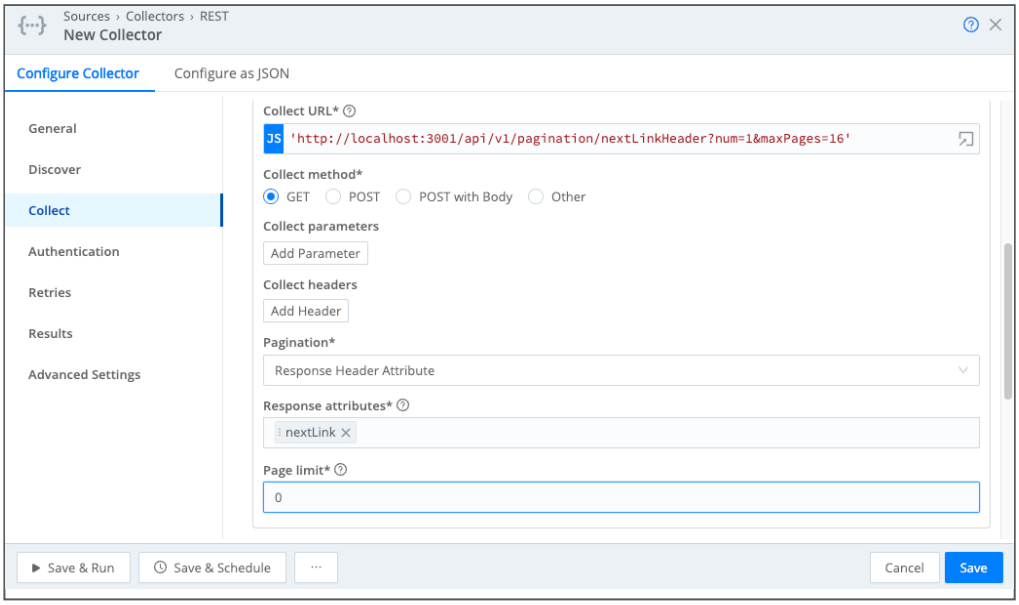
Pagination: Response Header Attribute

Response attributes: `nextLink`

Authentication: None

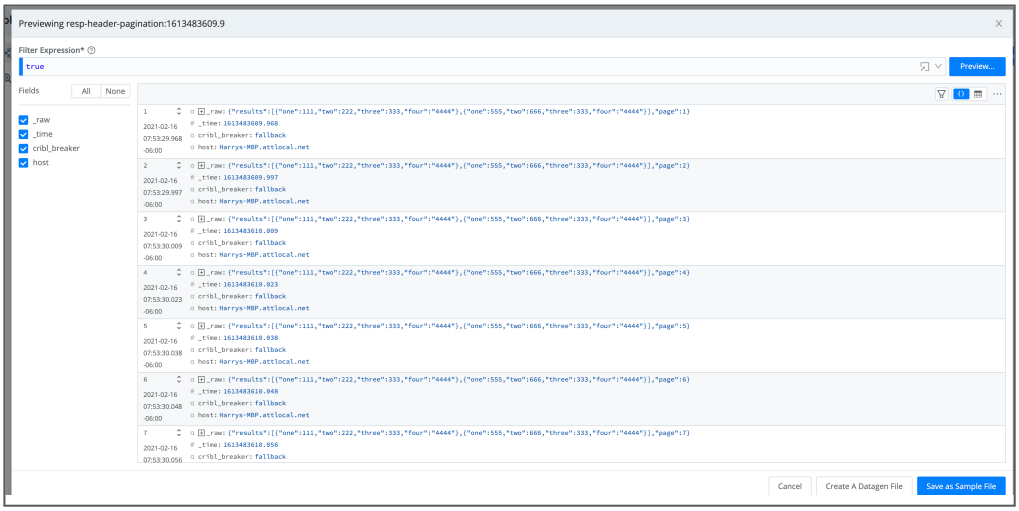
Event Breaker: None

You can modify the `maxPages` URL parameter to control how many pages this call returns.



Collector configuration for HTTP GET, paginated via Response Header URL

Collector Output



Paginated events

6. HTTP Discover and Collect with Login Authentication

In some cases, you must run an HTTP Request discovery to identify the items to collect. This example will do the following:

1. Perform a Login (POST with body containing the login credentials), to obtain an auth token that will passed in the Authorization header in all subsequent REST calls.
2. Run a REST call to discover items to be collected – in this case, log files.
3. For each log file discovered, collect the contents of that file.
4. We'll also demonstrate URL-encoding of a path element. You'd need to manually encode part of the URL in cases where unsafe ASCII characters might be present in the path element (for example, space, `$`, `/`, or `=`).

Discover type: `HTTP Request`

Discover URL: `'http://localhost:9000/api/v1/system/logs'`

Discover method: GET

Discover parameters: None

Discover headers: None

Discover data field: `items`

Collect URL: `'http://localhost:9000/api/v1/system/logs/' + C.Encode.uri(`${id}`)`

Collect method: GET

Collect parameters: None

Collect headers: None

Pagination: None

Authentication: Login

Login URL: `http://localhost:9000/api/v1/auth/login`

Login username: `admin` (or other user)

Login password: `admin` (or other user's corresponding password)

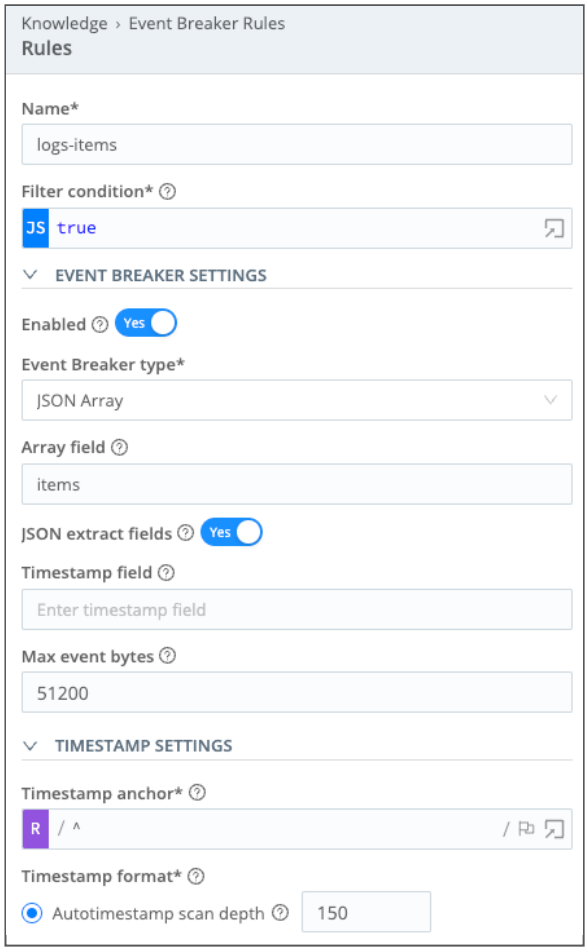
[Authentication] POST Body: `` `{ "username": "${username}", "password": "${password}" }` ``

Token attribute: `token`

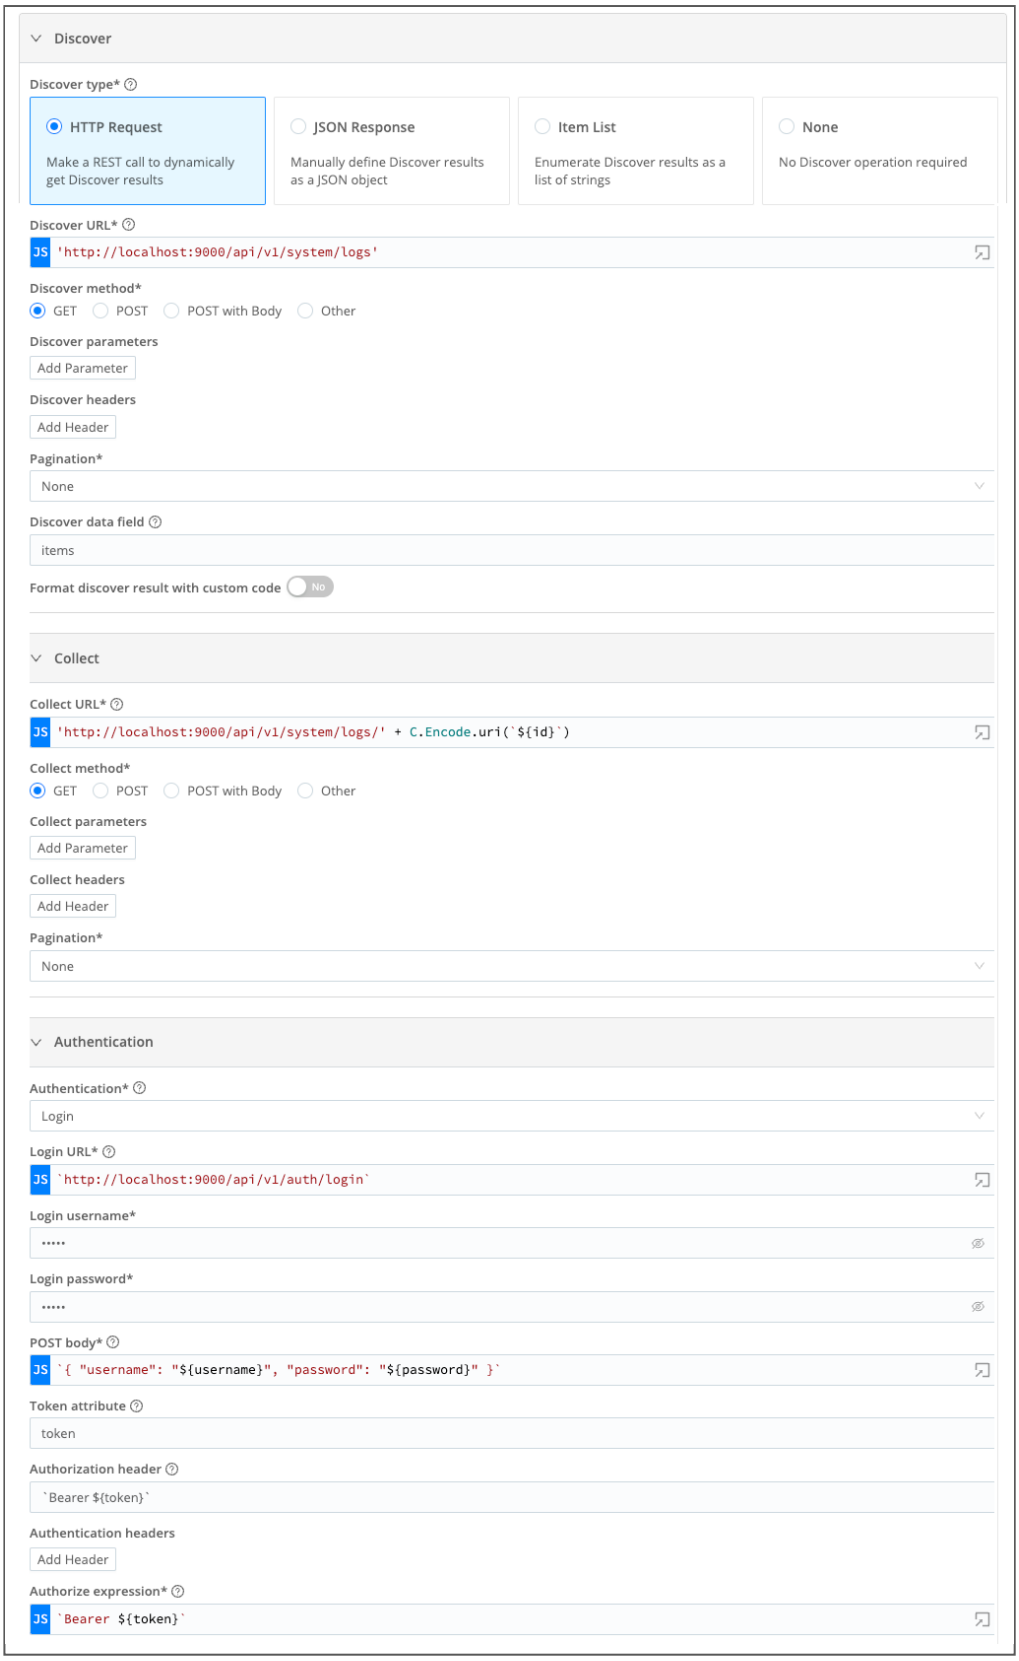
Authorize expression: `` `Bearer ${token}` ``

Event Breaker: JSON Array

- **Array Field**: `items.events`



Event Breaker configuration



Collector configuration for HTTP Discover and Collect with Login authentication

Login

The login call sends a POST to the login URL, passing the string derived from the POST Body JavaScript expression. Note that the variables `${username}` and `${password}` are available to this call, and are taken from the `username` and `password` text fields.

Upon successful login (`200` response code), the login token will be extracted from the response body's token attributes, as specified by the **Token attribute** field.

Finally, the value derived from the **Authorize expression** field will be added to the Authorization header for all subsequent calls (here, both Discover and Collect). Set this to `${token}` to reference the token obtained from the login POST request.

Discover

The Discover call here is used to discover the list of log files that can be collected. The data returned by this call has this format:

```
{
  "count": 0,
  "items": [
        {
        "id": "logFileName",
        "path": "pathToFile"
        }
  ]
}
```

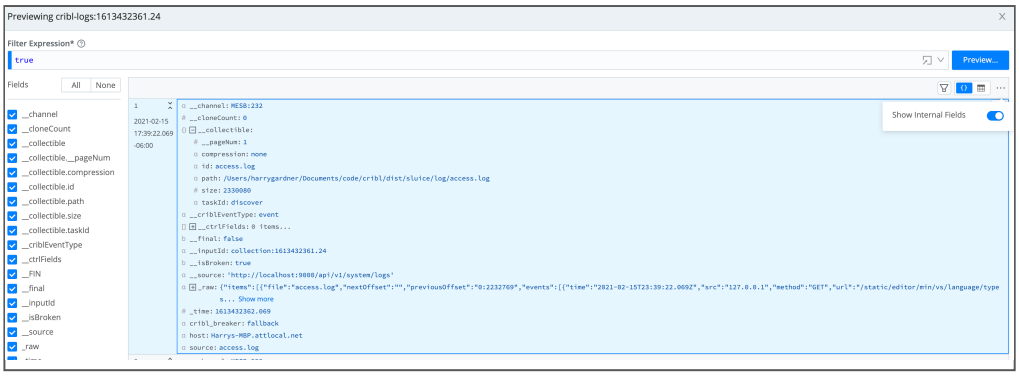
The **Discover Data Field** is used to define the array in Discover results that contains the list of items to discover. Here, each item is an object, with an attribute ID that is referenced in the Collect calls. So the Discover call generates a list of items for which Collect tasks will be created.

Collect

From the Discover task's returned list of items, each item will cause one Collect task to be created and run. An object containing the Discover item (along with some internal variables) will be passed to the Collect task.

You can reference this object's attributes as variables in the Collect task's URL, request parameters, and request headers. When running a preview, you can see the object's contents in the `__collectible` internal variable. (Enable **Show Internal Fields**, and expand `__collectible` to view the variables available).

For example, here's one of the events returned by this example's Collect operation. The `__collectible` attribute contains details identifying the page number and the URL used to obtain the data:



__collectible internal variable, expanded to show its contents

As you can see, `__collectible` contains a `__pageNum` variable, which shows which page of data the event was received in. Also, `__collectible` contains an `id` variable, available for use in the Collect operation. Here's how this variable is referenced in the Collect operation's URL:

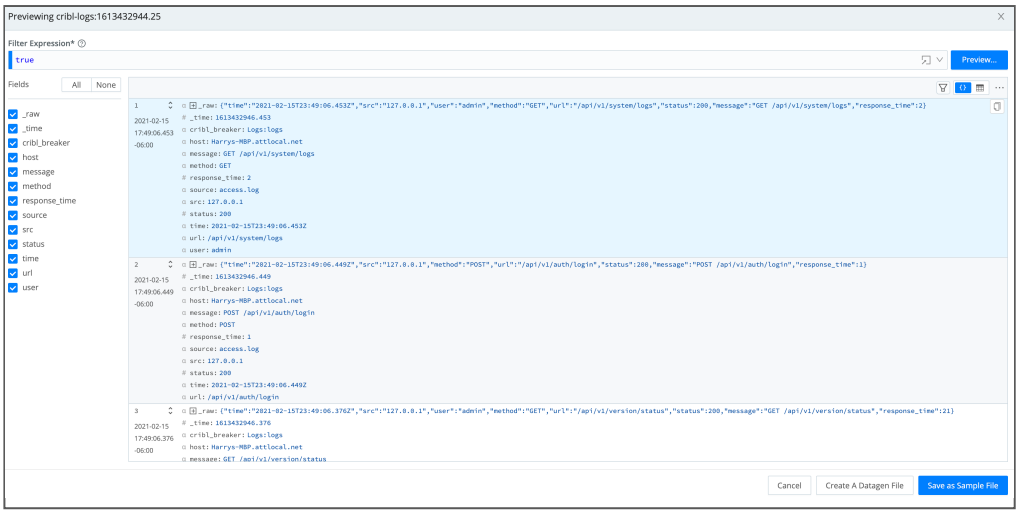
```
'http://localhost:9000/api/v1/system/logs/' + C.Encode.uri(`${id}`)
```

Because the variable is used in the path, and it might contain unsafe ASCII characters (specifically, space), we need to URL-encode the variable. This is the only case where the REST Collector requires URI encoding – variables that are defined directly as part of the URL. (Request parameters, not contained directly in the URL, are automatically encoded.)

The data returned by the Collect call has the following format:

```
{
  "items": [
        {
        "file": "access.log",
        "nextOffset": "",
        "previousOffset": "0:2236637",
        "events": [
        {
        "time": "2021-02-15T23:39:23.043Z",
        "src": "127.0.0.1",
        "user": "admin",
        "method": "GET",
        "url": "/api/v1/jobs/1613432361.24",
        "status": 200,
        "message": "GET /api/v1/jobs/1613432361.24",
        "response_time": 2
        },
        {
        "time": "2021-02-15T23:39:22.366Z",
        "src": "127.0.0.1",
        "user": "admin",
        "method": "GET",
        "url": "/api/v1/system/logs/worker%2F7%2Fcribl.log",
        "status": 200,
        "message": "GET /api/v1/system/logs/worker%2F7%2Fcribl.log",
        "response
...
```

The real data that we want to access is located at `items.events`. We can use a JSON Array event breaker to convert data from `events.items` into individual events that will be sent to Routes and processed by Cribl Stream. The output looks like this in Preview:



Collected data

If this example fails with errors of the form `statusCode: 429...Too many requests` – see Common Errors and Warnings to resolve this by relaxing the login rate limit.

7. Item List Discovery

This example demonstrates situations where the Item List discovery mechanism is useful: enabling collection based on a predefined list of items. Here, we want to collect weather information for a static list of states – each returned from Discover results as a single collection task.

Let's assume we are interested in weather for the following U.S. locations: Nashville, Dallas, and Denver. When the Discover operation runs, it will return a `__collectible` object for each location (each representing its own collection task): `{ id: ''}, {id: 'TX'}, {id: 'TN'}`.

Discover type: `Item List`

Discover items: `Nashville, Dallas, Denver`

Collect URL: `'https://community-open-weather-map.p.rapidapi.com/find'`

Collect parameters:

```
type: 'link'
```

```
units: 'imperial'
```

```
q: `${id}`
```

Collect headers:

```
x-rapidapi-host: 'community-open-weather-map.p.rapidapi.com'

x-rapidapi-key: '78934c846cmsh70cb53f75a8a54bp119d21jsn29df549b4fd6'

useQueryString: true
```

Pagination: None

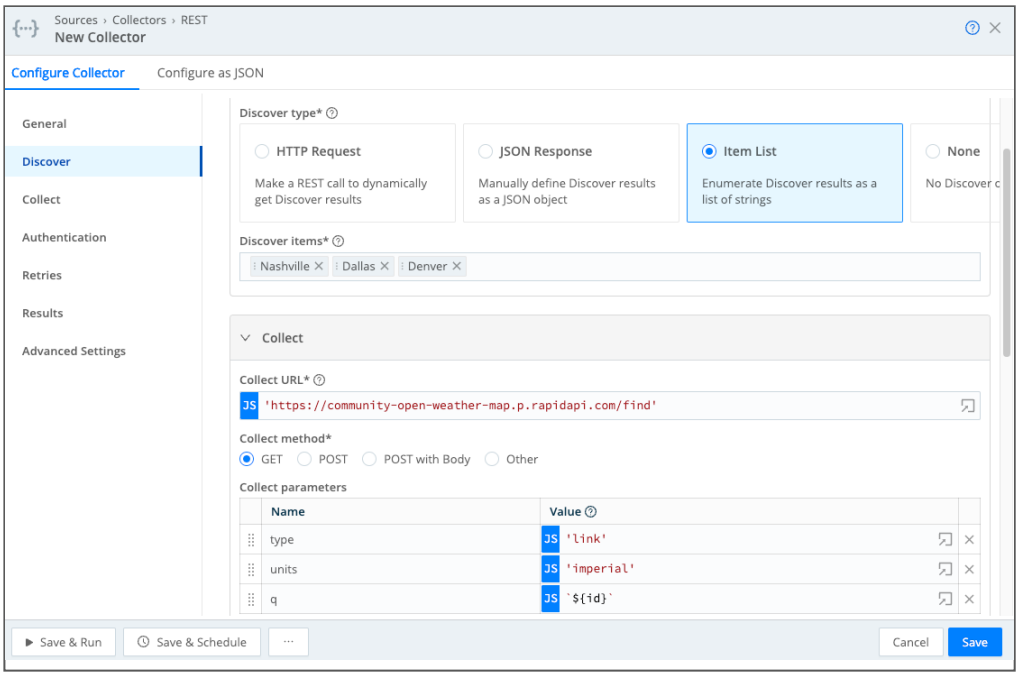
Authentication: None

Event Breaker: JSON Newline Delimited – Use a rule like **Cribl > ndjson** to parse each event and extract fields.

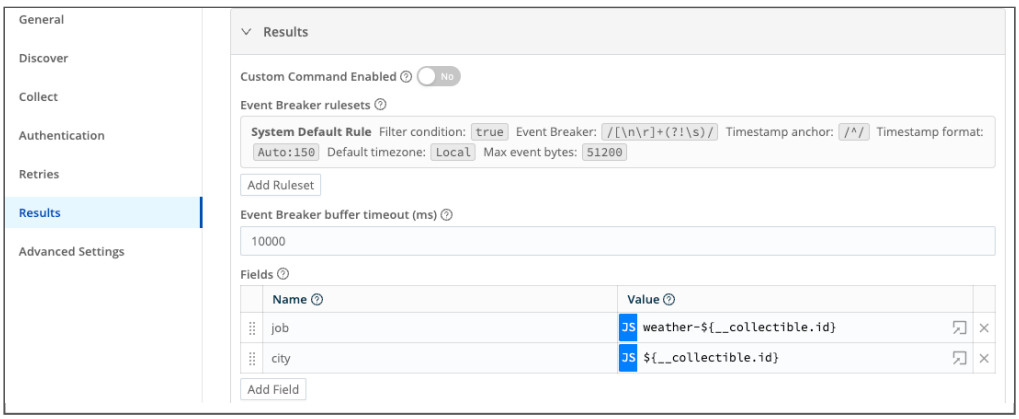
Fields:

```
job: weather-${__collectible.id}

city: ${__collectible.id}
```



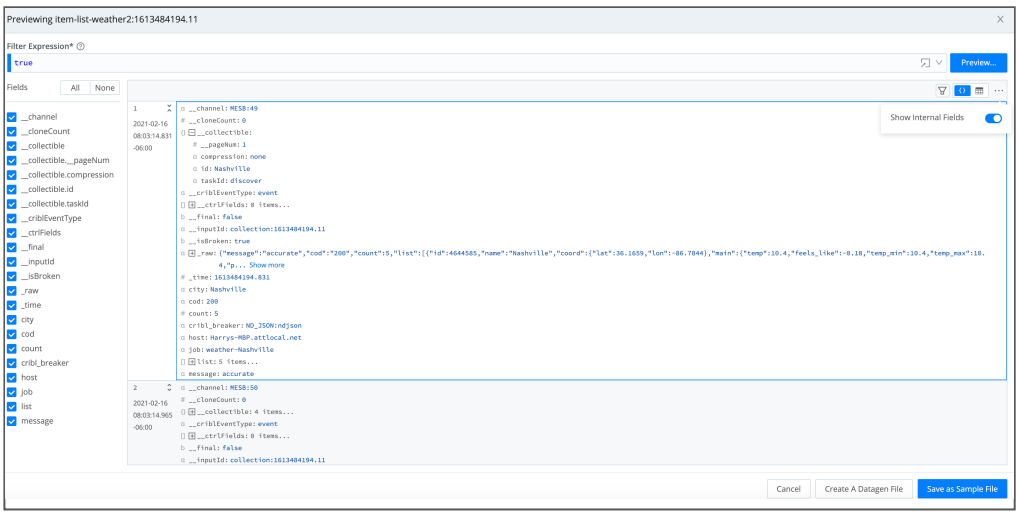
Collector configuration for Discovery via Item List



Collector Output

One interesting thing about this example is the addition of **Fields** to each event, using content from the internal `__collectible` attribute. This `__collectible` attribute contains results from the Discover operation, and is available in each event collected.

This demonstrates how information from the Discover operation can be transferred to events generated during the Collect operation. Note the attributes `__collectible`, `city`, and `job` in the Collector output below:



Collected events

This API allows a certain number of calls/month. Cribl recommends that you not schedule this Collector – run it ad-hoc, for testing only.

8. JSON Response Discovery

Like Item List discovery, **Discover type: JSON Response** allows you to discover a predefined, static list of items. JSON Response's advantage is its ability to return an object containing more than one attribute that the Collect operation can use.

Sticking with our weather example above, imagine that we needed to use both longitude and latitude (instead of just city or state) when performing collection. This is the perfect use case for JSON Response discovery.

Discover type: `JSON Response`

Discover result: `{"items": [{"city": "Nashville", "lat": 36.174465, "lon": 86.767960}, {"city": "Dallas", "lat": 32.779167, "lon": -96.808891}, {"city": "Denver", "lat": 39.742043, "lon": -104.991531}] }`

Discover data field: `items`

Collect URL: `'http://api.openweathermap.org/data/2.5/weather'`

Collect headers: None

Collect parameters:

```
lat: `${lat}`
```

```
lon: `${lon}`
```

```
appid: '438d61a1db9e713240b30140e9ddfea2'
```

Pagination: None

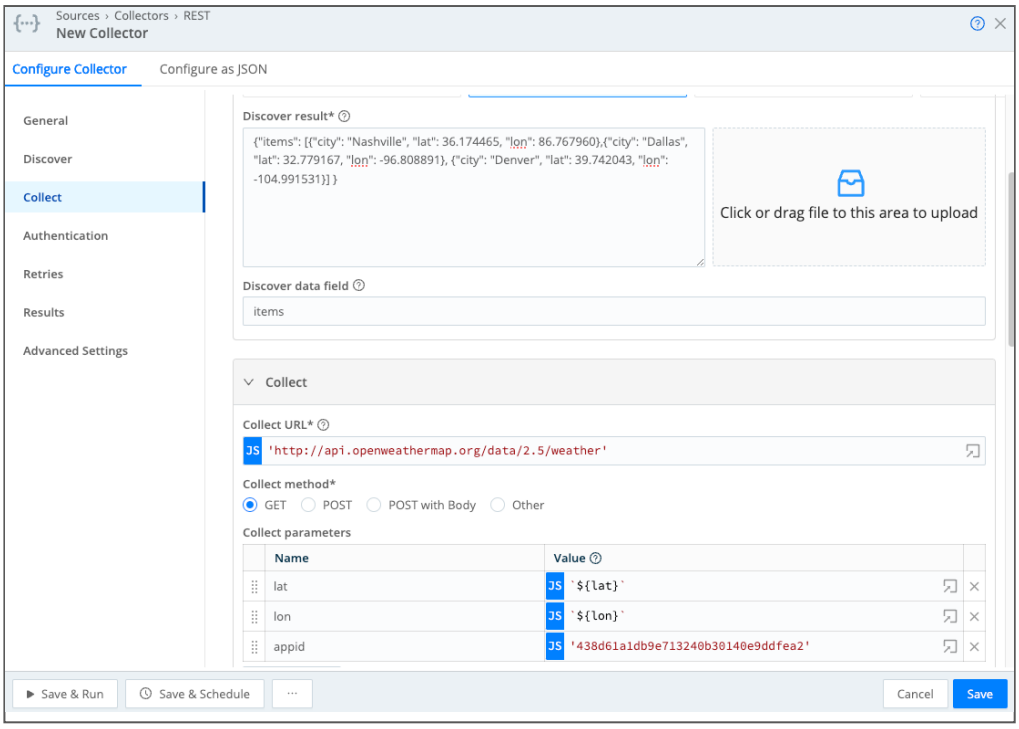
Authentication: None

Event Breaker: JSON Newline Delimited – Use a rule like **Cribl > ndjson** to parse each event and extract fields.

Fields:

```
job: `weather-${__collectible.city}`
```

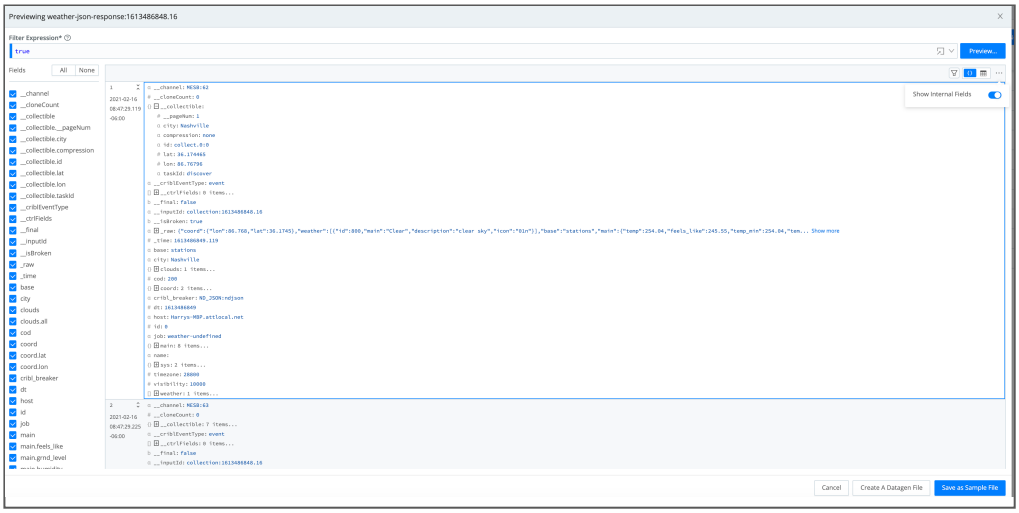
```
city: `${__collectible.city}`
```



Collector configuration for JSON Response Discovery

Notice how attributes present in the **Discover Result** JSON object's `items` array (`` `${lat}` ``, `` `${lon}` ``, `` `city` ``) are used in **Collect Request Parameters**, and in metadata **Fields**. Any other attribute present in the `items` array can similarly be referenced in the URL, request parameters, or request headers.

Collector Output



Item List preview

This API allows a certain number of calls/month. Cribl recommends that you not schedule this Collector – run it ad-hoc, for testing only.

9. HTTP Response Discover Result with Custom Code

Assume the Discover REST API returns a list of individual record IDs matching search criteria, such as:

```
{ "ids": [1,2,3,4,5,6,7,8,...,49,50] }
```

The collect API can accept a list of 1 to 10 individual IDs to collect data: `http://abc.com/collect?Ids=1,2,3,4,5,6,7,8,9,10`

By default, using the `ids` attribute from the Discover call results in 50 individual collect tasks, each retrieving data for a single ID. However, the API supports 1 to 10 IDs at a time. Using the **Format discover results** option, you can manipulate results to use 10 collect tasks, each retrieving data for 10 IDs. Here's how:

```
const pageSize = 10;
let arr = [];
__e['resultOut'] = []; // Store results in the original Discover results object.
__e['ids'].forEach(id => {
  if (arr.length === pageSize) {
    __e['resultOut'].push({ "ids": arr.join(',') });
    arr = [];
  }
  arr.push(id);
});
if (arr.length) __e['resultOut'].push({ "ids": arr.join(',') }); // Add last batch
```

Given 50 unique IDs, the output stores results in `resultOut`:

```
{
  "ids": [1, 2, 3, ..., 49, 50],
  "resultOut": [
    { "ids": "1,2,3,4,5,6,7,8,9,10" },
    { "ids": "11,12,13,14,15,16,17,18,19,20" },
    { "ids": "21,22,23,24,25,26,27,28,29,30" },
    { "ids": "31,32,33,34,35,36,37,38,39,40" },
    { "ids": "41,42,43,44,45,46,47,48,49,50" }
  ]
}
```

Set the **Discover data field** on the REST Collector to `resultOut` to use the array of 5 items during the collect phase, resulting in 5 collect tasks. The collect URL or request parameters can include the `ids` attribute from each array element: `http://abc.com/collect?Ids=${ids}`

10. State Tracking by Latest Time

REST Collector state tracking can help prevent both duplicate data and gaps in data for subsequent collection runs. To demonstrate how to configure a Collector to use state tracking, we'll access Stream's `/system/metrics` endpoint. This guide uses an out-of-the-box Stream configuration – you may need to update endpoints and authentication parameters to match your instance's configuration.

Configure the Event Breaker

For this example we'll use an Event Breaker from Cribl's Collector Templates repository. For more information on Event Breakers, check out the documentation.

1. On the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Event Breaker Rules**.
2. Select **Add Ruleset**.
3. Select **Manage as JSON** to open a text editor view.
4. Paste in the breaker config found here.
5. Select **OK**.
6. Select **Save**.

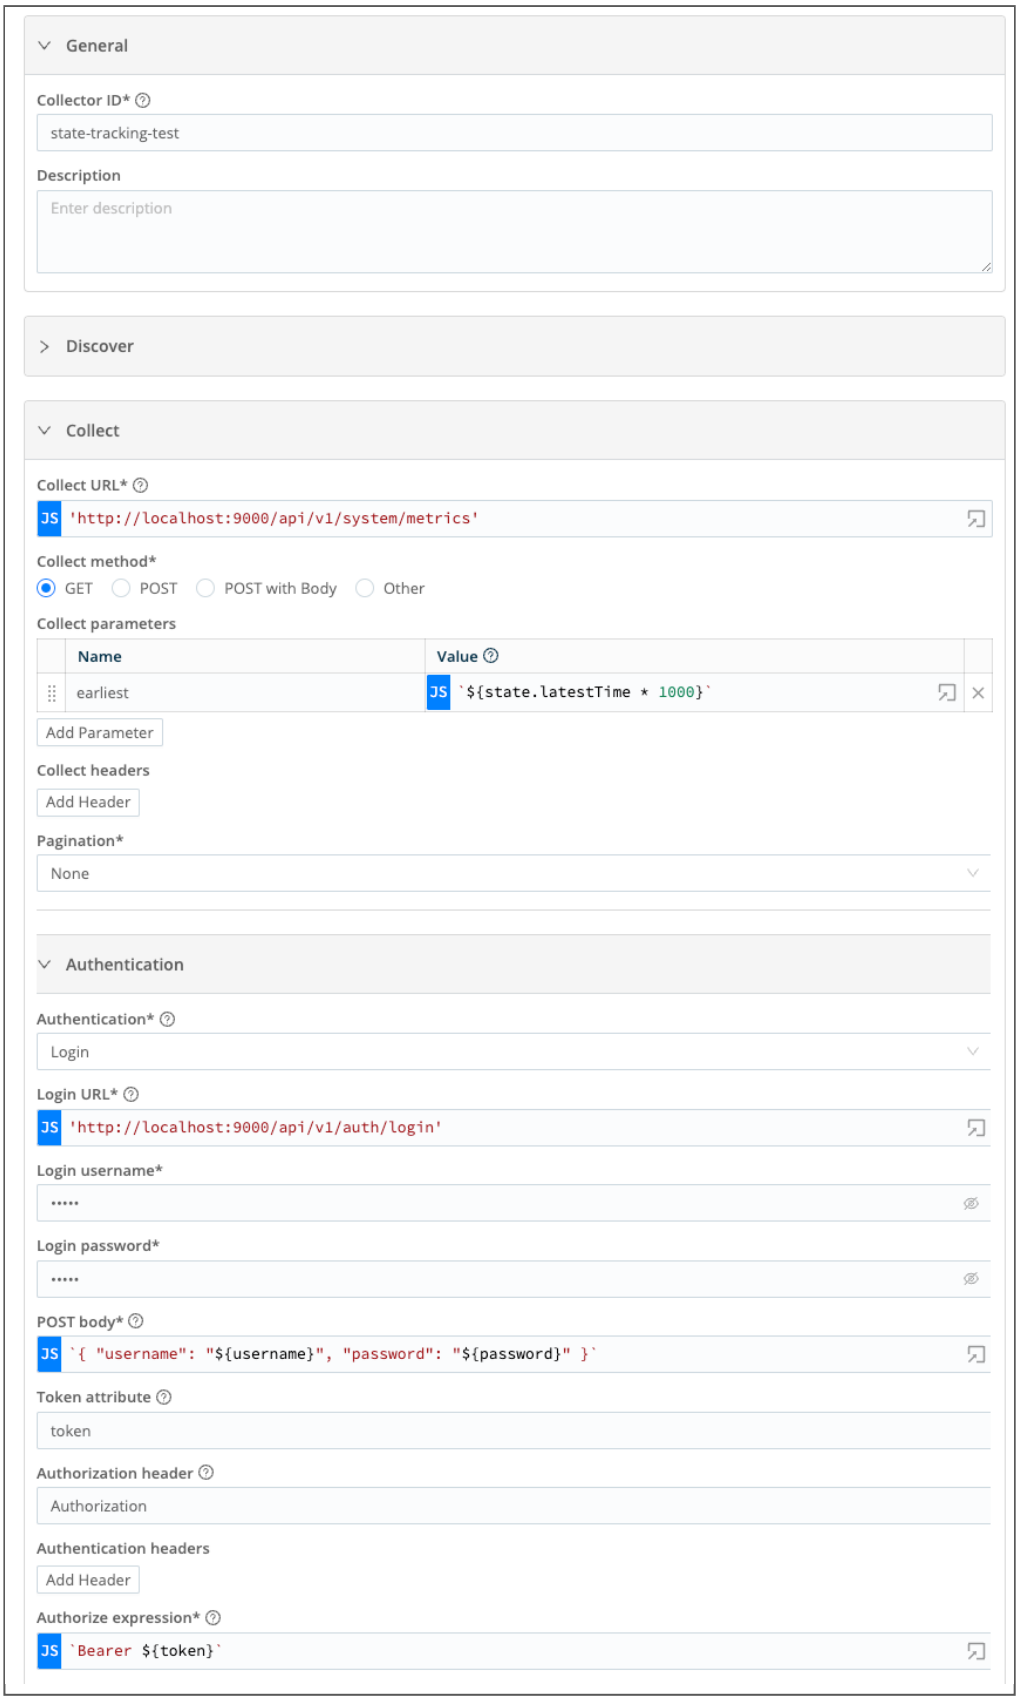
Configure the Collector

Set the following fields in the `Collector Settings` section

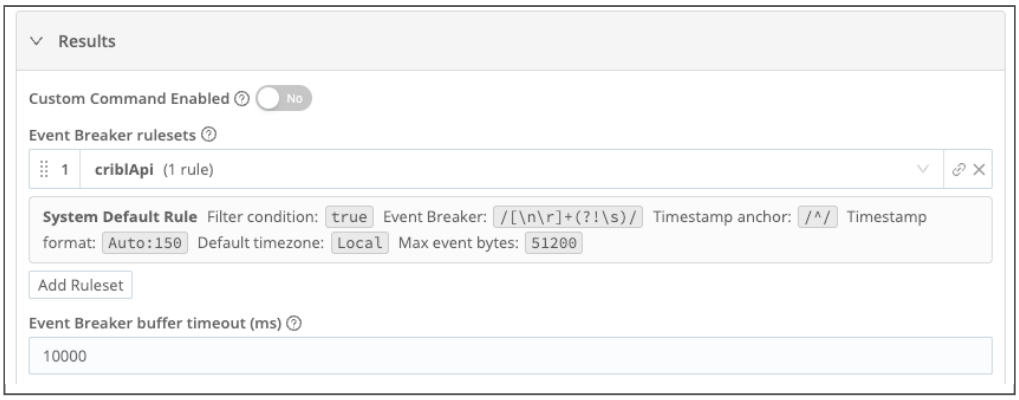
- **Collector ID**: `state-tracking-test`
- **Collect URL**: `'http://localhost:9000/api/v1/system/metrics'`
- **Collect parameters**:
  - **Name**: `earliest` | **Value**: `` `${state.latestTime * 1000}` ``
- **Authentication**: `Login`
- **Login URL**: `'http://localhost:9000/api/v1/auth/login'` (note that this is updated from the default `https` value)
- **Login username**: `admin`
- **Login password**: `admin`
- **Token attribute**: `token`

Select **Result Settings**, then **Event Breakers**. Then select **Add ruleset** and choose the `criblApi` ruleset from the earlier step.

At this point, your configuration should look like this:



Collector Config - Collector Settings



Collector Config - Event Breakers

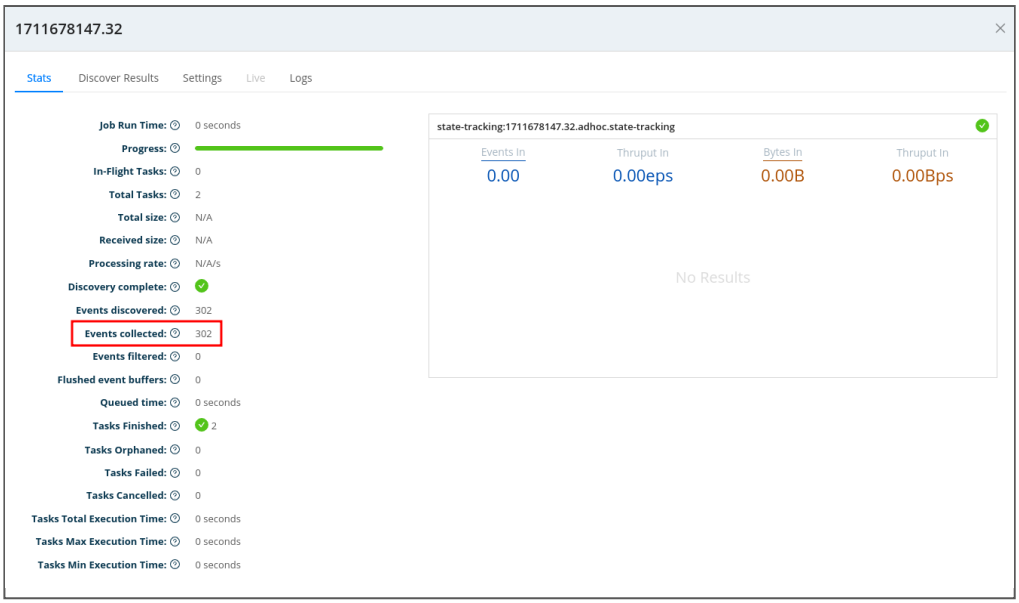
Finally, select **Save**.

Run the Collector

1. From the **Actions** column, select **Run** for your newly configured Collector.
2. Select **Full Run** to select the right collection mode. Preview and Discovery runs do not support state tracking.
3. Expand the **State Tracking** section, then set **Enabled** to `Yes`. We can use the default values for **State update expression** and **State merge expression**. For more information, see Understanding State Expression Fields.
4. Select **Run** to start the collection.

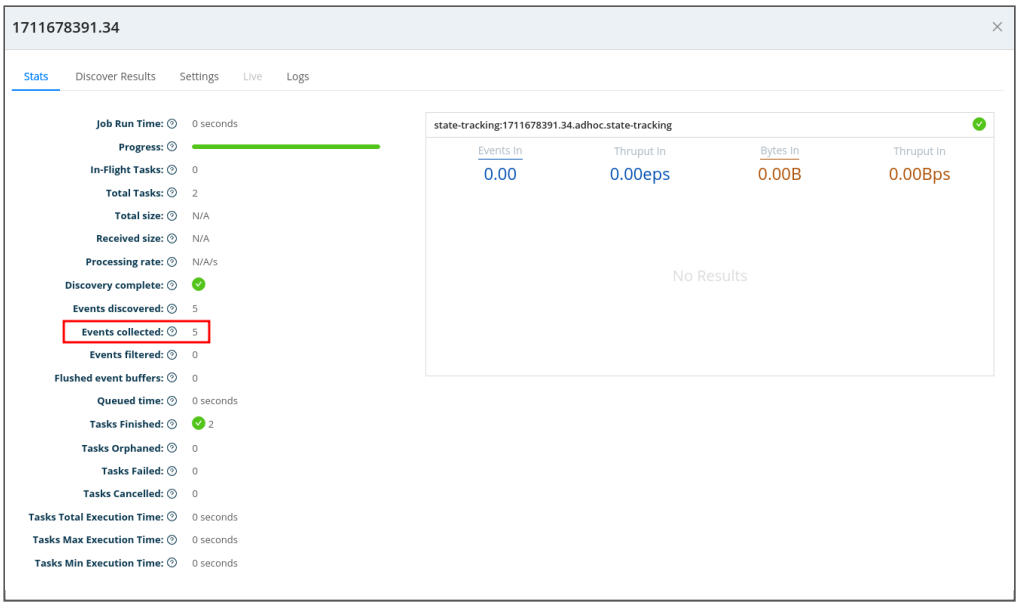
Check the Results

Since this is the first run of the Collector, there was no state value to derive `earliest` from. As a result, many events were likely returned. You can check how many by selecting the link to **Latest Ad Hoc Run** from the Collector list view. From here, check the **Events collected** result.



First Run Results

Now, here's where we can see the value of state tracking. Complete the steps in the **Running the Collector** section again. If you check the `Latest Ad Hoc Run` results again, you'll see that fewer events were collected. This is because the `earliest` parameter resolved to the latest time from the first run, meaning that we only picked up new metrics that were generated since the last run!



Second Run Results

15.1.1.14.3. Lacework API Collection

You can configure the Lacework v2 API within Stream. This enables you to collect data from the Lacework API without introducing custom scripts or add-ons into your Lacework environment.

Your workflow will be based on the Discover and Collect pattern that's standard for REST/API Collectors. In the Lacework API variation described here, the Discover job will generate the access token that the collection job uses in requests to the API. As an example, we'll configure Cribl Stream to collect Host Vulnerability data, using optional filters available in the Lacework API.

Before you begin, make sure you have a Lacework API `KeyID` and `secretKey`, or create them as described in the Lacework docs.

Configuring the REST Collector

Collector Sources currently cannot be selected or enabled in the QuickConnect UI.

For additional details about all the configuration options specified here, see our REST/API Endpoint and Scheduling and Running topics.

1. Navigate to **Products** > **Stream** > **Worker Groups**.
2. Select a Worker Group, then go to **Data** > **Sources**. Choose the Collector and select **Add Collector**.
3. Enter a **Collector ID**, then complete the following options and fields.

Discover Settings

From the **Discover type** drop-down, select `HTTP Request`. Then complete the **Discover** settings as follows.

Discover URL: Enter the URL at which Cribl Stream should access the Lacework `v2/access/tokens` endpoint.

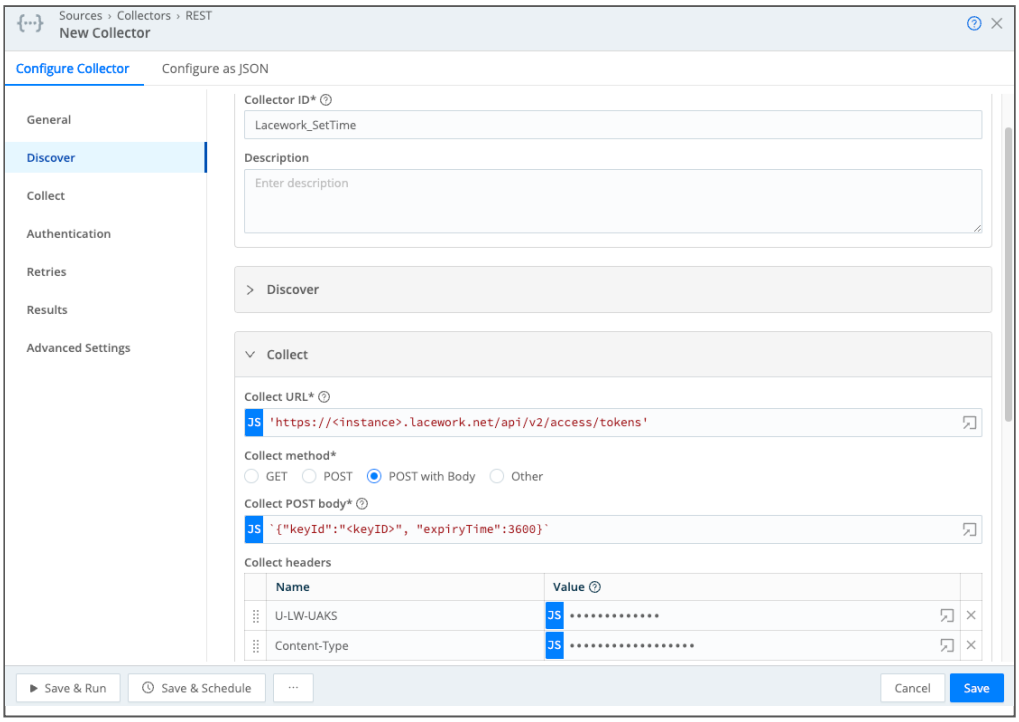
Discover method: From the drop-down, select `POST with Body`.

Discover POST Body: Enter `` `{"keyId":"<keyID>", "expiryTime":3600}` ``, substituting your Lacework API `KeyID` for the placeholder.

Discover headers: Create the two headers specified in the table below, substituting your Lacework API `secretKey` for the placeholder.

Name	Value
`U-LW-UAKS`	`'<secretKey>'`
`Content-Type`	`'application/json'`

Your Collector configuration should look similar to this:



Discover Settings

Collect Settings

Collect URL: Enter the URL at which Cribl Stream should access the Lacework `v2/Vulnerabilities/Hosts/search` endpoint.

Collect method: From the drop-down, select `POST with Body`.

Collect POST body: Enter the following request body.

```
`{"timeFilter": { "startTime": "${C.Time.strftime(earliest || new Date().getTime()/1
```

Here's what's happening in the request body example:

In our example, we've chosen to collect data only about hosts where one particular vulnerability, `CVE-2018-11233`, was detected. To accomplish this, we've added a `filters` element that specifies that the value of the `vulnId` field must equal `CVE-2018-11233`.

Note the `earliest` and `latest` variables. Later, in the **Run Collector** modal, you'll set **Time Range** values that will populate these variables when the Collector runs. Both variables are formatted as UNIX epoch time, in seconds units. (When using them in contexts that require milliseconds resolution, multiply them by 1,000 to convert to ms.) If you omit these variables, jobs will run for a period of 24 hours.

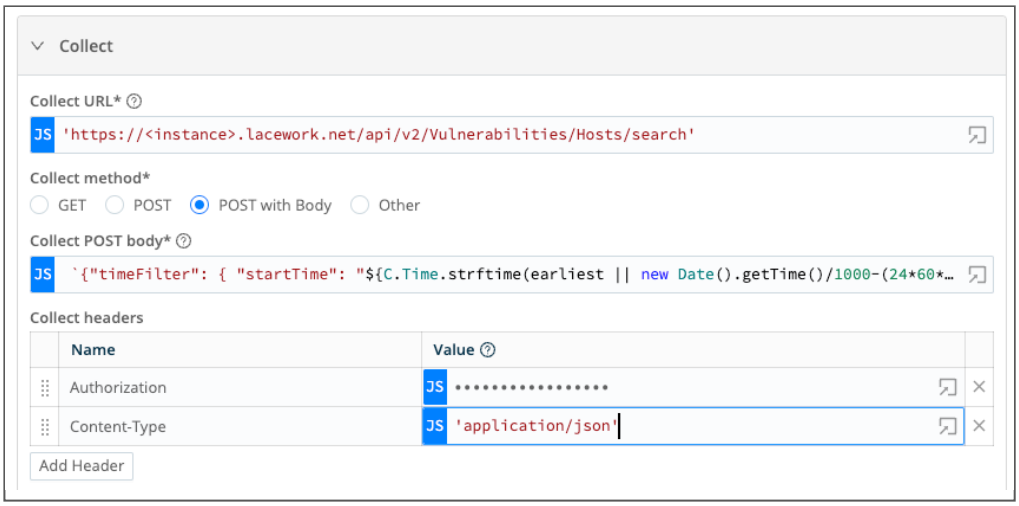
Collect Headers

We know that the Discover job, which we will run before the Collect job, will make a request to the Lacework API `v2/access/tokens` endpoint, and that the Lacework API's response body will include an access token. That means that the access token will be available to the Collect job, to pass in a Collect header.

Create the two **Collect header**s specified in the table below. The first will convey the access token.

Name	Value
`Authorization`	`` `Bearer ${token}` ``
`Content-Type`	`'application/json'`

Your **Collect** settings should look similar to this:

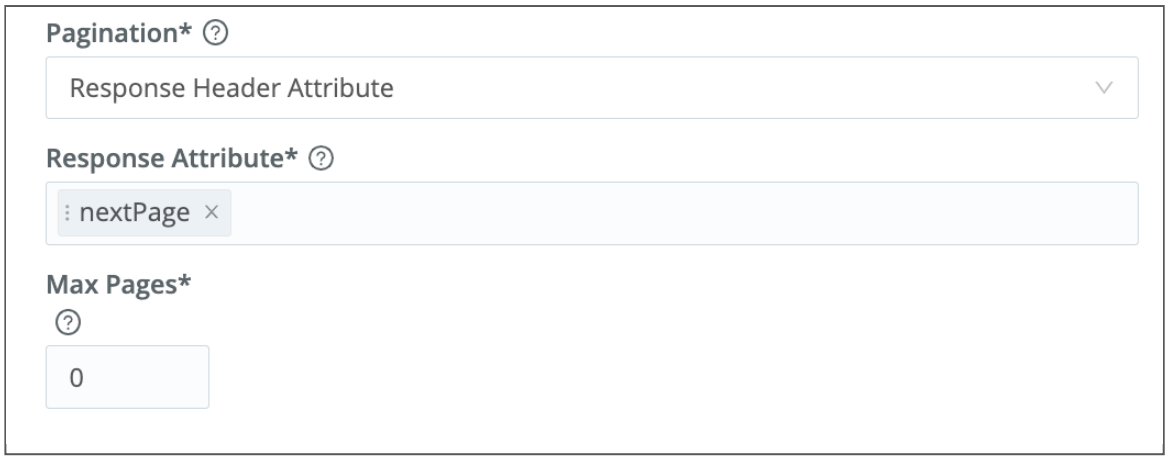


Adding a Collect header

Pagination

From the **Pagination** drop-down, select `Response Header Attribute`. In the **Response Attribute** field, enter `nextPage`. This configures your Collector to work with the Lacework API response body, which includes nested fields of pagination metadata, such that `urls` contains `nextPage`, whose value is the Next Page URL.

You should see something like this:



Configuring pagination

The Lacework API authentication mechanism requires HTTP header parameters. Since Cribl Stream does not (currently) support header parameters for authentication, we cannot use that authentication method, and you should skip the **Authentication** settings. This is why we use the Discover job to obtain an access token, and then include that token in the Collect job.

Additional Settings

Tags: Optionally, add tags that you can use for filtering and grouping in Cribl Stream. Use a tab or hard return between (arbitrary) tag names.

Result Settings

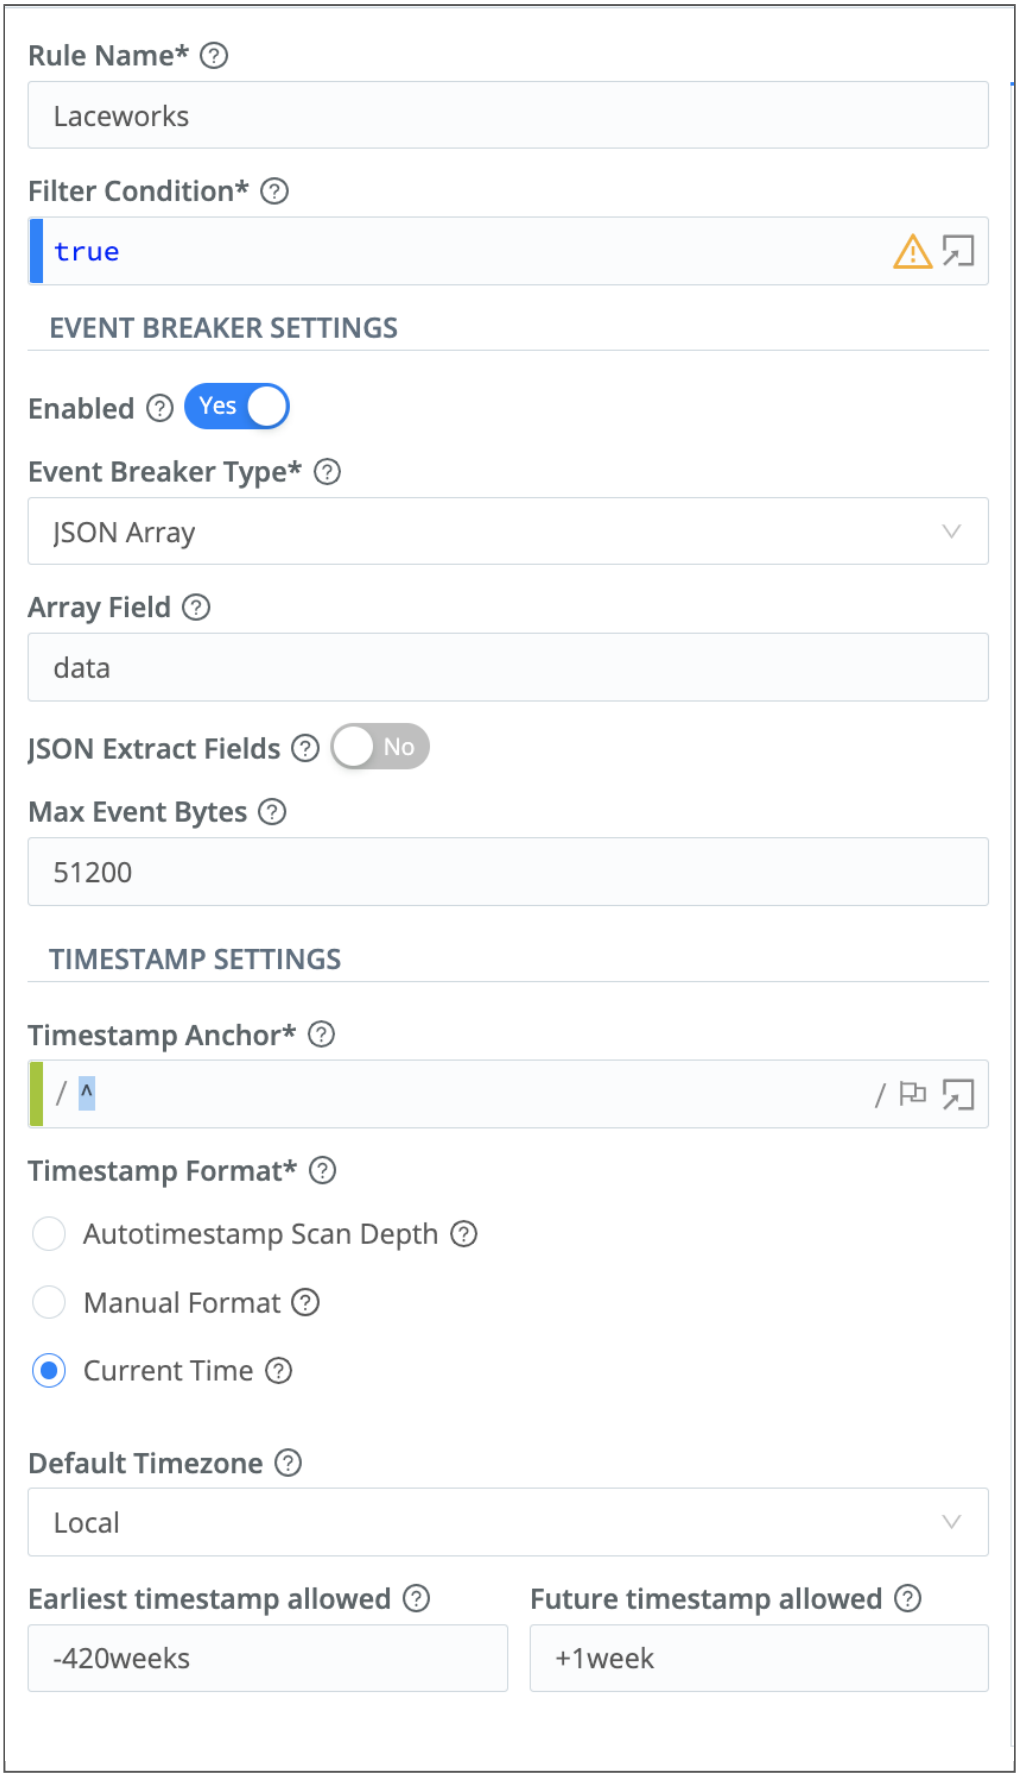
Every call to the Lacework API `v2/Vulnerabilities/Hosts/search` endpoint returns data formatted as a single event. Every event contains multiple nested JSON arrays, where each array is a `data` element. We'll now create an Event Breaker that parses the larger structure into individual events – one for each `data` element.

1. On the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Event Breaker Rules**.
2. From the resulting **Event Breaker Rulesets** form, select **New Ruleset** to open the **New Ruleset** modal.
3. Enter an **ID** for the new ruleset, and optionally add a **Description** and **Tags**.
4. Select **Add Rule**.

In the resulting **Rules** modal, name the Rule, and configure it as follows:

- **Filter Condition**: Enter `true`.
- **Enabled**: Toggle to `Yes`.
- **Event Breaker Type**: Select `JSON Array`.
- **Array Field**: Enter `data`.

Optionally, you can use the **Timestamp Settings** to return events whose timestamp (`_time`) matches the **startTime** or **endTime** field defined in the Lacework data.



Creating a ruleset

Select **OK** to return to the previous **New Ruleset** modal, then select **Save**.

Then return to your REST Collector's configuration modal, and:

1. Select the **Results** section.
2. Under **Event Breaker rulesets**, select **Add Ruleset**.
3. From the drop-down that now appears above the **System Default Rule**, select your new ruleset.
4. Select **Save**.

Discovering and Collecting

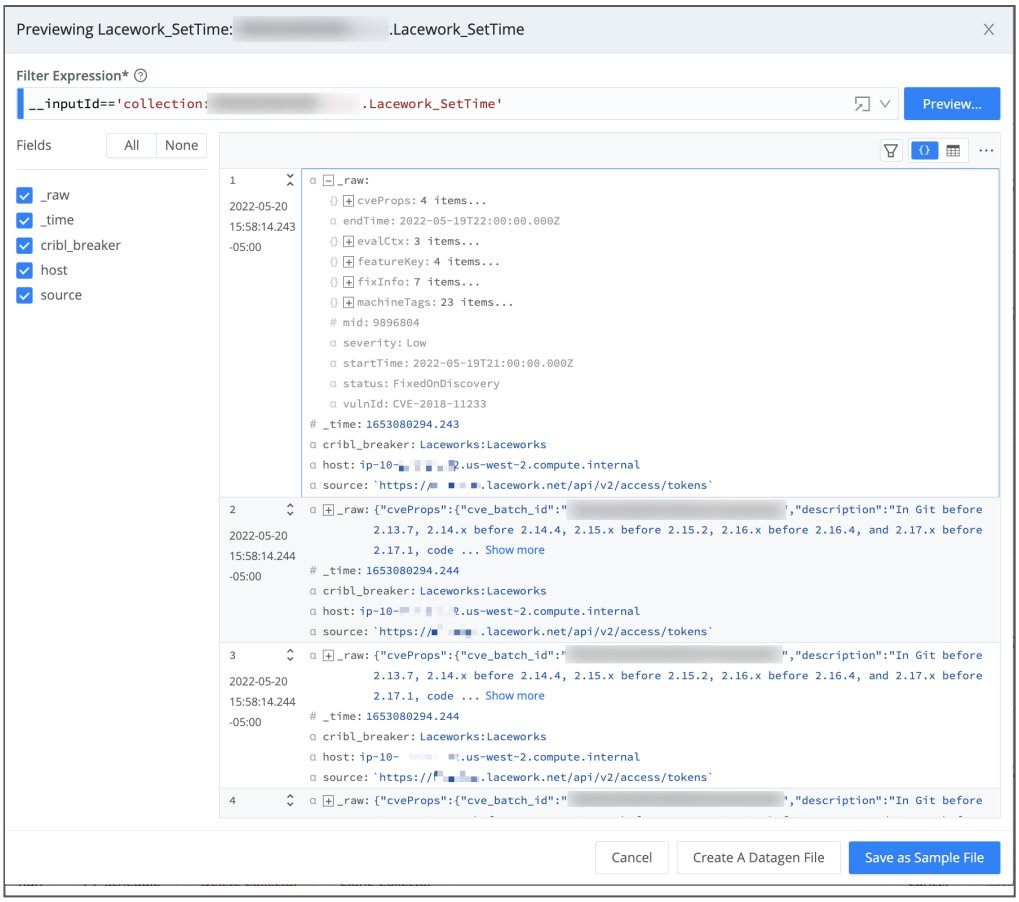
We'll start with the Discovery run:

1. On the **REST** page, select **Run** beside your new Collector.
2. In the resulting **Run Collector** modal, select **Mode** > **Discovery**.
3. Configure a **Time range**, if desired.
4. Select **Run** to retrieve Discovery results.

After inspecting these results, launch the Collector run:

1. Back on the **REST** page, again select **Run** beside your new Collector.
2. In the resulting **Run Collector** modal, this time select **Mode** > **Full Run**.
3. Configure a **Time range**, if desired.
4. Select **Run**.

Once the Lacework API responds, you should see data similar to this:



Data from the Lacework API

15.1.1.14.4. Microsoft Graph API Collection

The Microsoft Graph API provides access to data in the Microsoft Cloud. This page explains how to configure a Cribl Stream REST/API Collector to ingest data using the Microsoft Graph API.

Before you start, you'll need to do the following in the Azure portal:

- Register the app you'll use to interact with Graph API.
- Generate a **Client Secret** for the app.
- Write down the **Application ID**, **Tenant ID**, and **Secret Value** defined for the app.
- Decide which API calls you expect to use, then, for each of those API calls:
    - Configure the corresponding API permissions for your app.
    - Examine how the Graph API structures events, and decide whether you want to change that structure using an Event Breaker.

For example, if you plan to call the Audit Logs API (as demonstrated in this walkthrough), do the following:

- Configure your app with `AuditLog.Read.All` API permissions, which Audit Logs API calls require.
- Notice that the API structures Microsoft Entra ID Audit Logs data as a single JSON object with events nested under the `value` field. With an Event Breaker, you can split this into individual events for each AD Audit Log activity.

How the REST Collector Interacts with Microsoft APIs

To retrieve data using the Microsoft Graph API, your Collector first obtains a Bearer token by sending an HTTP `POST` request to the Microsoft identity platform. Once it has the Bearer token, your Collector can send an HTTP `GET` request to the Graph API, which responds with the data you requested. Configuring your Collector will be more intuitive if you keep this pattern in mind.

Configuring a Graph API REST Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**.
2. Select a Worker Group, then go to **Data** > **Sources**. Choose the Collector and select **Add Collector**.

The sections described below are spread across several tabs. Select the tab links to navigate among tabs. Select **Save** when you've configured your Collector.

Collector Settings

These settings determine how data is collected before processing.

Collector ID: Unique ID for this Collector. Such as `ms_graph_42`.

Collect Settings

Collect URL: An expression that produces a URL for the collect operation. The URL can be any of the Graph API endpoints. In this example, we want to retrieve Microsoft Entra ID Audit logs, so we use the Audit Logs endpoint:

```
`https://graph.microsoft.com/v1.0/auditLogs/directoryAudits`
```

Collect method: `GET`.

Collect headers: Add the following header.

- **Name**: `content-type`.
- **Value**: `application/x-www-form-urlencoded`

To authenticate against the Microsoft Graph API, the REST Collector uses a POST call whose body is a template. The `content-type` header tells the Graph API that the template is a URL-encoded (not JSON-encoded) form. See **Authentication Settings** > **POST body** below.

Authentication Settings

Use the **Authentication method** buttons to select **Login**, then enter the following information:

- **Username**: The **Application (Client) ID** listed on your app's **Overview** page in Azure.
- **Password**: The **Secret Value** listed on your app's **Certificate & Secret** page in Azure.
- **Login URL**: The token API endpoint for the Microsoft identity platform. Use the string: `` `https://login.microsoftonline.com/<tenant_id>/oauth2/v2.0/token` ``, substituting your Microsoft Entra ID tenant ID for `<tenant_id>`.
- A **POST body** template for the token request that the Collector sends to the Microsoft identity platform. Use the string:
  `` `client_secret=${password}&scope=https://graph.microsoft.com/.default&client_id=${u ``
  When the Collector sends the request, it will populate the template with the **Username** and **Password** that you entered above.

- The **Token attribute** is the field that contains the Bearer token, within the Microsoft identity platform's response to the token request. Use `access_token`.
- The **Authorize expression** is a JavaScript expression that computes the `Authorization` header the Collector uses in calls to the Graph API. Use `` `Bearer ${token}` ``. The Collector will populate the `${token}` variable with the token obtained from the Microsoft identity platform.

Result Settings

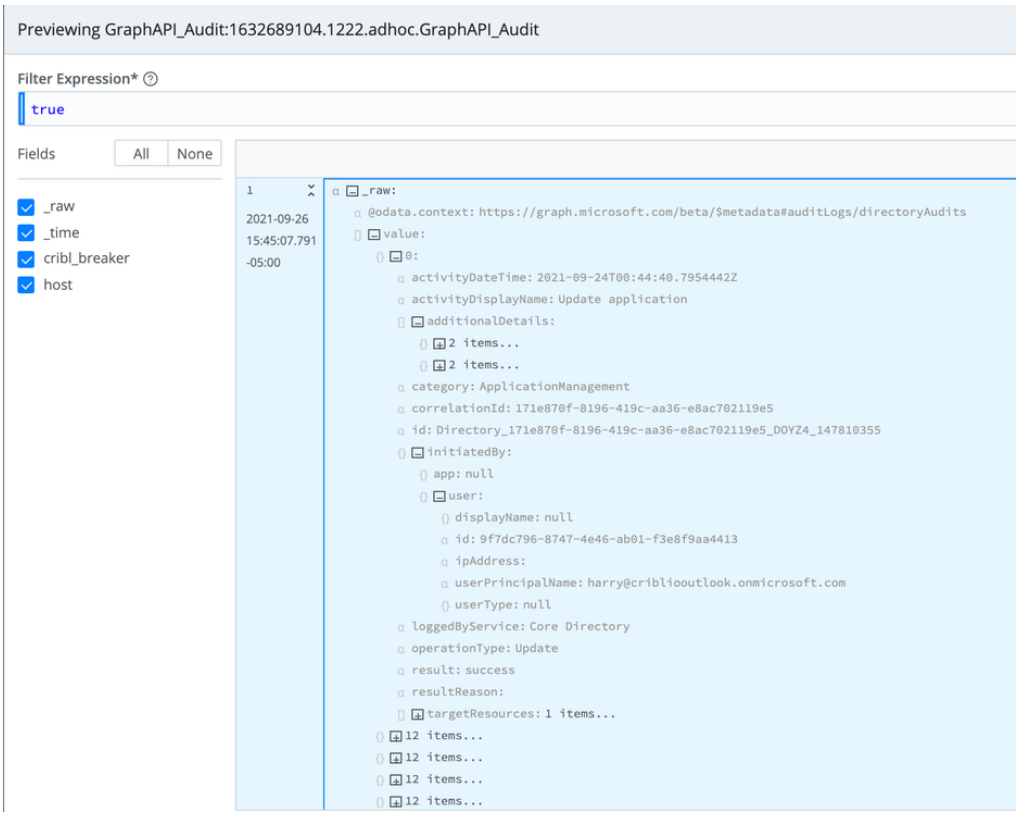
As explained above, the Microsoft Graph API delivers Microsoft Entra ID Audit Logs data as a single JSON object, with events nested under the `value` field. Cribl recommends using an Event Breaker to split this into separate name/value pairs.

You'll create the Event Breaker in the **Results** section. But first, you must save a sample file, and create a ruleset for the Event Breaker to use.

Saving a Sample File

On the **REST** page, select **Run** beside the REST Collector you configured. This opens the **Run configuration** modal, in **Preview** mode. Select **Run** to open the **Capture Sample Data** modal.

When data appears, notice that it's a large JSON object with multiple events nested under the `value` field:



Audit Logs data in original form

Select **Save as Sample File** and note the file name and location.

Creating an Event Breaker Ruleset

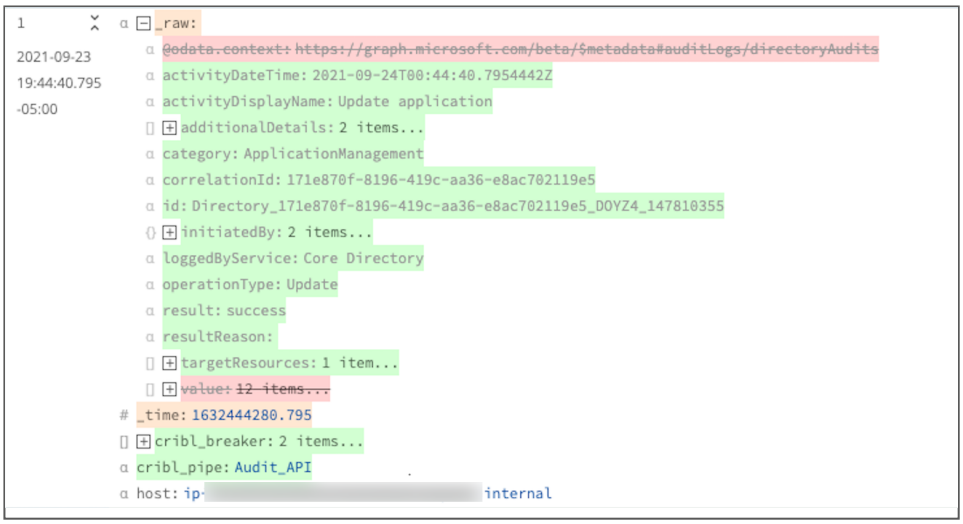
1. On the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Event Breaker Rules**.
2. Select **Add Ruleset**.
3. Enter an ID and a Description for the ruleset, then select **Rules** > **Add Rule** to open the **Rules** modal.

Here's what we want the ruleset to do:

1. Remove the leading `@odata.context` statement. For this example, we'll assume that OData is not important for your use case.
2. Structure each of the fields nested within the `value` element as a separate event, where the value of the `activityDateTime` field becomes the value of the `_timestamp` field.

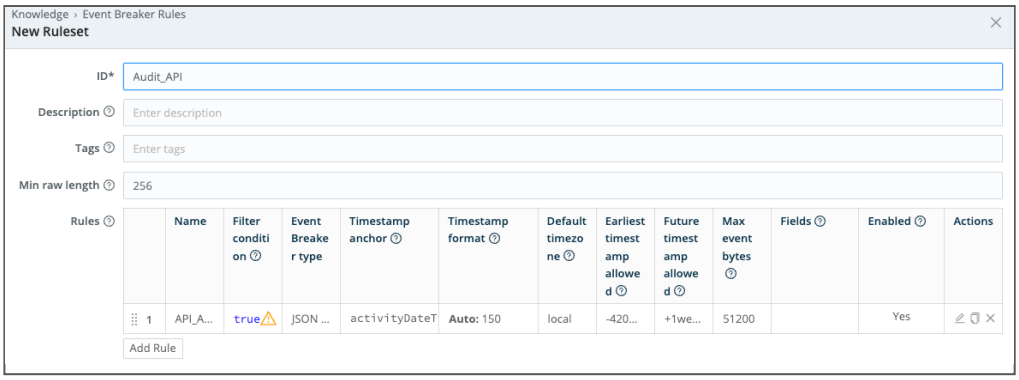
Name the ruleset, then:

- From the **Event Breaker type** drop-down, choose **JSON Array**. This detects that the `value` element is a JSON array, and breaks it into key-value pairs. It also discards the `@odata.context` element, because that falls outside the detected JSON array.
- In the **Timestamp anchor** field, enter `activityDateTime` between the slashes.
- Upload your sample file.
- Compare the **In** and **Out** panes. You should see output similar to this:



Audit Logs data broken into individual events

- Select **OK** to return to the **New Ruleset** modal.
- You should see a result similar to the screenshot below. Select **Save**.



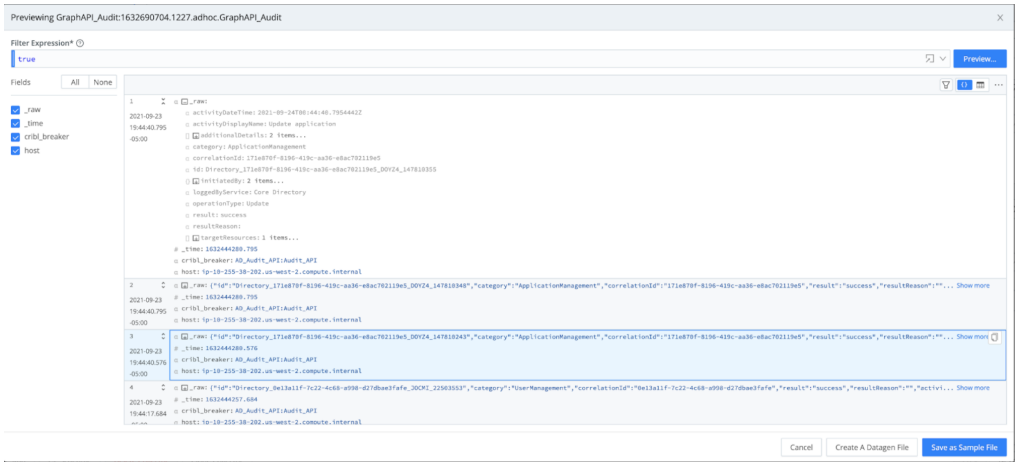
Creating an Event Breaker Ruleset for Audit Logs data

Event Breakers

In the Collector's **Results** section:

- From the **Event Breakers** drop-down, select the ruleset that you created and saved.
- Select **Save**.

Run the Collector again. Now you should see an individual JSON-formatted event for each AD Audit Log activity.



Audit Logs data from the finished Collector

15.1.1.14.5. ServiceNow API Collection

This topic covers how to configure Cribl Stream REST Collectors to gather data via ServiceNow (SNOW) REST APIs and then enrich the data using Pipelines and the Redis Function.

From among the 100-or-so SNOW REST APIs, we've chosen the CMDB Instance for this tutorial. You can adapt this material for use with other SNOW REST APIs. You'll need to create a separate Collector for each SNOW API you connect to.

The prerequisites for this setup are a ServiceNow instance, which you can obtain here, and the URL for the Redis store you wish to use.

Using the Discover and Collect Pattern

A common pattern in REST APIs is to expose two related endpoints:

- One endpoint takes a category identifier as a URL parameter, and returns a list of instances of the category, with an individual identifier for each item in the list.
- A second endpoint takes the instance identifier as a URL parameter, and returns full details about the instance.

The SNOW CMDB Instance REST API follows this pattern. The API is called "CMDB" because it exposes a Configuration Management Database which contains records that describe how pieces of hardware are configured. The categories for different kinds of hardware are specified by "classnames," and the description of an individual piece of hardware is called a Configuration Item (CI) record. The relevant API calls look like this:

- The `GET /now/cmdb/instance/{classname}` call takes a `classname` (for example, `cmdb_ci_appl`, `cmdb_ci_linux_server`, `cmdb_ci_apache_web_server`) as a URL parameter, and returns a list of instances of the classname. Each instance has a `sys_id` and a `name`.
- The `GET /now/cmdb/instance/{classname}/{sys_id}` call takes a `sys_id` as a URL parameter, and returns the detailed CI record for the instance that the `sys_id` refers to.

In this tutorial, you'll create a Collector that uses the first API call to **discover** the systems for a given classname. Then you'll iterate the second API call over the list of `sys_ids` we discovered, to **collect** the CI records of interest. This **discover and collect** pattern works for any Cribl Stream Collector.

You'll have the Collector store the CI data in Redis. Then whatever Source you choose that has events to enrich, can do that by pulling the collected CI record data from Redis. That's the goal: enriching data.

How might this be useful? Here's one scenario: Suppose you have log data in which server names appear. Assuming that the servers in question have records in your CMDB, you can enrich the events with data about the server, such as its `sys_id` or the name of the user who updated it last.

Preparing Pipelines

Before creating the SNOW Collector itself, you'll set up the two Pipelines that the Collector needs. Both pipelines use the Cribl Stream Redis Function.

- The **process** Pipeline attaches to the Collector and performs a `set` to add events to Redis.
- The **enrichment** Pipeline performs a Redis `get` to retrieve the values with which we'll enrich events in the Collector.

Create the Process Pipeline

Create a Pipeline called `SNOW_Instance_Process` with the following Functions and values:

Parser Function

- **Operation Mode**: `Extract`
- **Type**: `JSON Object`
- **Source Field**: `_raw`

Note that each event this Function will parse is the reponse body from a `GET /now/cmdb/instance/{classname}/{sys_id}` call—i.e., a `result` object. That object has an attribute called `attributes` whose value is itself an object containing dozens of key-value pairs. To enrich our data, we'll treat one of those (`name`, meaning server name) as a key whose value will be two more (`sys_id` and `sys_updated_by`), comma-separated. We'll specify all three as **Evaluate Fields** in the next Function.

Eval Function

Evaluate Fields:

Name	Value Expression
`name`	`result.attributes.name`
`sys_id`	`result.attributes.sys_id`
`sys_updated_by`	`result.attributes.sys_updated_by`

Redis Function

The Redis function stores our fields in the key/value relationship described earlier.

- **Command**: `set`.
- **Key**: `` `${name}` ``.
- **Args**: `` `${sys_updated_by},${sys_id}` ``.
- **Redis URL**: The URL for your Redis store, for example, `redis://10.0.0.1:6379`.

Create the Enrichment Pipeline

Create a Pipeline called `SNOW_Instance_Enrich` with the following Functions and values:

Redis Function

- **Command**: `get`.
- **Result field**: `Args`.
- **Key**: `` `${name}` ``.
- **Args**: Leave blank.
- **Redis URL**: The URL for your Redis store, for example, `redis://10.0.0.1:6379`.

Parser Function

- **Operation Mode**: `Extract`.
- **Type**: `CSV`.
- **Source Field**: `Args`.
- **List of Fields**: `sys_updated_by sys_id`.

Eval Function

- **Remove Fields**: `Args`.

Configuring a SNOW Collector

1. Navigate to **Products** > **Stream** > **Worker Groups**.

2. Select a Worker Group, then go to **Data** > **Sources**. Choose the Collector and select **Add Collector**.

The sections described below are spread across several tabs. Select the tab links to navigate among tabs. Select **Save** when you've configured your Collector.

Collector Settings

These settings determine how data is discovered and collected before processing. You'll see the power of the **discover and collect** pattern here: from the results of a single Discover API call, we will generate an entire set of Collect API calls. There is more about this pattern in the REST Collector documentation.

Collector ID: Unique ID for this Collector. For example, `snow_42-a`.

Discover Settings

Discover type: `HTTP Request`

Discover URL: An expression that produces a URL for the discover operation. We can enter this URL as a constant, for example:

```
'https://dev111111.service-now.com/api/now/cmdb/instance/cmdb_ci_appl'
```

Discover method: `GET`

Discover data field: `result`

We specify `result` for the **Discover data field** because that is the key of the JSON array that our Discover call retrieves. For example:

```
"result": [
  {
    "sys_id": "3a290cc60a0a0bb400000bdb386af1cf",
    "name": "PS LinuxApp01"
  },
  {
    "sys_id": "3a5dd3dbc0a8ce0100655f1ec66ed42c",
    "name": "PS LinuxApp02"
  }
]
```

This array becomes the list of items for which Collect tasks will be created. We'll reference one of its attributes, namely `sys_id`, as a variable in the Collect task's URL.

Collect Settings

Collect URL: An expression that produces a URL for the collect operation. We enter the first part of the URL as a constant, then for the final URL parameter, we use an expression to reference the `sys_id` returned by the Discover call:

```
'https://dev111111.service-now.com/api/now/cmdb/instance/cmdb_ci_appl'+ C.Encode.uri
```

We use the C.Encode.uri Cribl expression to encode the `sys_id` in case any `sys_id` contains unsafe characters.

Collect method: `GET`.

Authentication

Use the **Authentication method** drop-down to select one of these options:

- **None**: Don't use authentication.
- **Basic**: Use HTTP token authentication.
- **Basic (credentials secret)**: Select a stored text secret in the resulting drop-down, or select **Create** to configure a new secret.
- **Login**: This option requires you to provide:
  - The **Login username** and **Login password** fields for your HTTP Basic authentication credentials.
  - The **Login URL** that SNOW should use to connect to Cribl Stream.
  - A **POST body** template for the request SNOW uses when logging in. You must edit this if your credentials' location differs from that specified by default.
  - The **Token attribute**, which is the path to the token attribute in login response body. Nested attributes are OK.
  - The **Authorize expression**, a JavaScript expression that computes the `Authorization` header to pass in Discover and Collect calls. The value `${token}` references the token obtained from login.
- **Login (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret. You must also provide the **Login URL**, **POST body**, **Token attribute**, and **Authorize expression**, as in the plain **Login** option.

Result Settings

These settings enable the Collector you've been configuring to use your **process** Pipeline.

Result Routing

Toggle **Send to Routes** to `No`.

Choose the `SNOW_Instance_Process` Pipeline from the dropdown.

Choose whatever **Destination** suits your purposes. A DevNull Destination would make sense given that the purpose of this Collector is simply to get data into Redis.

Adding a Source with Data to Enrich

At this point, you have a Collector which stores CI record data in Redis. Assuming that you have a Source with events you want to enrich, you should now configure that Source to use the **enrich** Pipeline you created earlier.

In **Processing Settings** > **Pre-Processing**, choose `SNOW_Instance_Enrich` from the **Pipeline** drop-down.

Verifying the Enrichment of Events

This procedure should demonstrate that your setup is working, or help you troubleshoot.

1. Send a request to the SNOW Instance API to verify that it returns data.
    - Try the query builder.
2. Run the Collector once. Since you have attached the **process** Pipeline to the Collector, it should update Redis with `set` calls.
    - When you're ready to move towards production, you can run the Collector on a schedule, to update Redis periodically.
3. Run a `get` command on the Redis command line, using the key for your chosen API, to verify that Redis was updated as expected.
4. Check the Source whose data you are enriching, to verify that the fields you added are showing up.

15.1.1.14.6. Creating A Custom Collector

Cribl's flagship product introduced Collectors in Logstream 2.2, and they have since evolved to become a critical part of the platform. You can think of Collectors as jobs that retrieve data from an external service. You can also schedule them to run periodically, like a Linux cron job.

We built the Collection framework to be extensible like Cribl Stream Functions. This means that you can create new Collectors on the fly. This page covers the Collection process, schema files, and their implementation – to give you some context – before walking you though the steps of creating your own Collector.

Collection Process

At its simplest, collection is a two-step process: Discover, and Collect.

Discover

This step identifies the items to collect. The Discover call generates a list of items, and Collect tasks will be created for those items. Note that:

- The Discover call can return zero to many items. The Collection phase will run only if Discover returned at least one item.
- Your Collector's purpose (and definition) determines the actual data that Discover will return.
- If the Collector pulls data from files on disk, the Discover call lists the files in the directory to determine how many items match the criteria (matching by filter and/or date range). Assuming that there are 100 files to collect from, the Discover call will return 100 items (each specifying a file path and size).

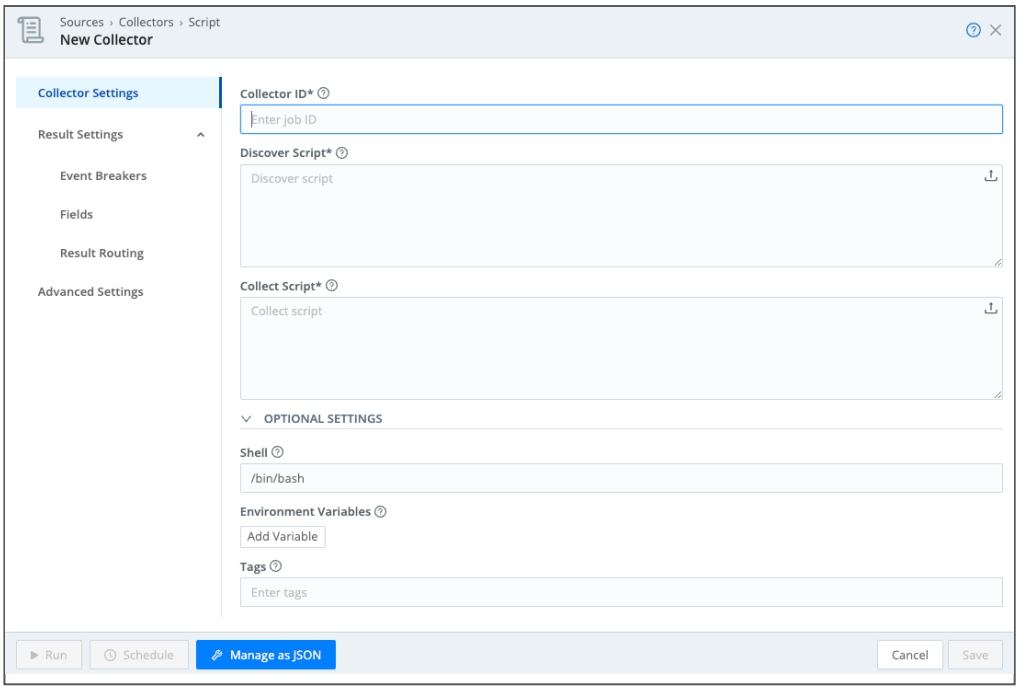
Collect

Each item, from the Discover phase's returned list of items, will trigger one Collect task for Cribl Stream to create and run. More on Collect:

- Generally, there is a single Collect task per item returned by Discover.
- In distributed deployments, you configure Collectors at the Worker Group level, and Worker Nodes execute the tasks. However, the Leader Node oversees the task distribution, and tries to maintain a fair balance across jobs.

Collector Schema Files

The Collector schema files, `conf.schema.json` and `conf.ui-schema.json`, describe the structure of the UI for configuring a new or existing Collector. As an example, here's a Script Collector's Configuration modal:



Script Collector Configuration Screen

The `conf.schema.json` below defines all the fields displayed on that **Collector Settings** form:

```
{
  "type": "object",
  "title": "",
  "required": ["discoverScript", "collectScript"],
  "properties": {
    "discoverScript": {
      "type": "string",
      "title": "Discover Script",
      "minLength": 1,
      "description": "Script to discover what to collect. Should output one task per
    },
    "collectScript": {
      "type": "string",
      "title": "Collect Script",
      "minLength": 1,
      "description": "Script to run to perform data collections. Task passed in as $(
    },
    "shell": {
      "type":"string",
      "title": "Shell",
      "description": "Shell to use to execute scripts.",
      "default": "/bin/bash"
    }
  }
}
```

The `conf-ui-schema.json` file further refines the field specifications in `conf.schema.json`. In the example below, it specifies that the `discoverScript` and `collectScript` fields should use the `TextareaUpload` widget with 5 rows. This file also gives each text field some placeholder (ghost) text, to display when no data is present in the field.

```
{
  "discoverScript": {
    "ui:widget": "TextareaUpload",
    "ui:options": {
      "rows": 5
    },
    "ui:placeholder": "Discover script"
  },
  "collectScript": {
    "ui:widget": "TextareaUpload",
    "ui:options": {
      "rows": 5
    },
    "ui:placeholder": "Collect script"
  }
```

Schemas can be simple, like the Script Collector, or complex like the REST Collector. This guide doesn't cover all the possibilities of working with schemas, which do get complex. However, you can check out other existing Collectors as examples of how to apply schemas for your own use case.

Collector Implementation

The Collector's implementation logic is part of `index.js`, and resides in the same directory as the Collector schema files. You must define the following attributes and methods for the Collector:

```
// Jobs can import anything from the C object, to see what's available use the
// Stream UI and an Eval Function to discover options.
const { Expression, PartialEvalRewrite } = C.expr;
const { httpSearch, isHttp200, RestVerb, HttpError, wrapExpr, DEFAULT_TIMEOUT_SECS }

exports.name = 'Weather';
exports.version = '0.1';
exports.disabled = false; // true to disable the collector
exports.destroyable = false;
exports.hidden = false; // true to hide collector in the UI

// Define Collector instance variables here: i.e.:
// let myVar; // Initialize in init, discover, or collect.

// init is called before the collection job starts. Gives the Collector a chance
// to validate configs and initialize internal state.
exports.init = async (opts) => {
  // validate configs, throw Error if a problem is found.
  // Initialize internal attributes here
}

// The Discover task's main job is to determine 'what' to collect. Each item
// to collect (i.e. a file, an API call, etc) is reported via the job object
// and will execute a collection task.
// Note that different instances of the Collector will be used for the Discover
// and Collect operations. Do not set internal Collector state in Discover
// and expect it to be present in Collect. The _init method will be called
// prior to Discover orCcollect.
exports.discover = async (job) => {
  // Job is an object that the collector can interact with, for example
  // we can use the job to access a logger.
  job.logger().info('Discover called');

  // In this case, reporting 2 hard coded items to be collected. Normally,
  // collectors dynamically report items to collect based on input from
  // an API or library call.
  await job.addResults([{"city": "San Francisco"},{"city": "Denver"}]);
  // Can also add results one at a time using await job.addResult("city": "San Franc
}

// One invocation of the Collect method is made for each item reported by the
// discover method. The collectible object contains the data reported by discover.
```

```
// In our example collect will be called twice, once for each item returned
// by discover's addResults call:
// Invocation 1: {"city": "San Francisco"}
// Invocation 2: {"city": "Denver"}
exports.collect = async (collectible, job) => {
   job.logger().info('In collect', { collectible });
   try {
     // Do actual data collection here. In this case we might make a REST API call
     // to retrieve current weather conditions for the city in collectible.
     const myReadableStream = doGetWeather(collectible.city);
   } catch (error) {
     // If the collector encounters a fatal error, pass the error to the job. This
     // will make the error visible in the Job inspector UI.
     job.reportError(error)
     return;
   }
   // Return result of the collect operation should be Promise<Readable>
   // which will be piped to routes or to the configured pipeline and destination.
   return Promise.resolve(myReadableStream)
}
```

Set Up a New Collector

Now to the exciting part. Here's an overview of how to add a Collector:

1. Create a directory where Collector files will reside. All files associated with the Collector should be in this directory.
2. Create the schema files and add them to the directory. The following schema files describe the structure of the UI for configuring a new or existing Collector:
   - `schema.json`
   - `ui-schema.json`
3. Create a JavaScript file named `index.js`, with naming attributes and required methods.
4. Test and validate the Collector.
5. Install the Collector in Cribl Stream.

Before You Start

A few things to note before we start the process of adding a custom Collector:

1. For a standalone install of a running Cribl Stream instance, add new directories and files to the `$CRIBL_HOME/local/cribl/collectors` directory (example: `/opt/cribl`).
2. The Collector will show up in the UI only if all schema files and the `index.js` file successfully compile. If the Collector is not showing up in the UI, check whether there was a problem compiling one of the files. You can check the errors through the API Server Logs.
3. Develop your Collector in a local test environment, as a best practice. After making changes to the Collector, you might need to restart/and or deploy your system.
4. Collectors can access all Node.js built-in modules, using the `require` directive to import each module.
5. You can include third-party Node.js modules into a custom Collector by installing them in the Collector's home directory.
6. Cribl Stream ships with out-of-the-box Collectors which reside in the `$CRIBL_HOME/default/cribl/collectors` directory. Feel free to copy contents from one of the existing Collectors to your `$CRIBL_HOME/local/cribl/collectors` (local directory) as a starting point/example of how to build more-complex schemas.

Never modify a Collector in the default directory (`$CRIBL_HOME/default/cribl/collectors/*`). Because:

1. Doing so changes the behavior of a Collector in your installed system.
2. Contents of the default directory will be overwritten during upgrades.

When creating your own Collector, always make a copy to a directory in the local `$CRIBL_HOME/local/cribl/collector/<yourCollector>`

Sample Collector Requirements

For this example, our sample Collector's goal is to generate events – containing a random quote obtained from an internal list – for a list of users. Here is a breakdown of this Collector's requirements:

1. Provide a random quote to a predefined or random list of usernames.
2. Accept the names of users for whom to generate quotes.
3. Accept randomly generated usernames, by specifying the number of usernames to generate.
4. Generate a single event containing a random quote for each user.
5. Pick the random quotes from a hard-coded list, or optionally, use a REST API instead.

For this sample Collector, we'll reference a third-party Node module to generate random usernames, and to give you a basic understanding of how to reference external code packages.

Set Up Your Environment

For this guide, we'll build a custom Collector in a standalone Cribl Stream install running in Docker. To adapt the steps for a distributed environment:

1. Build the Collector on the Leader Node.
2. The Collector directory will reside in the filesystem at: `$CRIBL_HOME/groups/<workerGroup>/local/cribl/collectors/quote_generator`. For example, to build in the default Worker Group, work in the directory: `$CRIBL_HOME/groups/default/local/cribl/collectors/quote_generator`.
3. Before running the Collector, commit and deploy changes for the parent Worker Group.

Deploy a Single Instance of Cribl Stream in Docker

1. Start the Docker instance by running the following command:
   `docker run -d -p 19000:9000 cribl/cribl:latest`
2. List Docker containers by running `docker ps`, as shown here:

```
$ docker ps
CONTAINER ID   IMAGE                   COMMAND                  CREATED
544370698fb5   cribl/cribl:3.4.1-RC1   "/sbin/entrypoint.sh…"   4 minutes ago
```

3. Access the Cribl Stream UI at port: `http://localhost:19000`
4. Connect to the container:
   `docker exec -it <Container ID> bash`
   (example: `docker exec -it 544370698fb5 bash`)
5. Update the apt installer:
   `apt update`
6. Install Vim (or an editor of your choice):
   - vim: `apt install vim`
   - nano: `apt install nano`

After this, remain connected to the Docker container, and follow the steps below to create the Collector.

Remember to leave the Docker container running while you work on the Collector. Also, remember to explicitly back up your files before stopping the Docker container.

Build a Collector (Single-Instance Environment)

In your terminal, type the following commands:

1. `cd /opt/cribl/local/cribl`
2. `mkdir collectors`
3. `cd collectors`
4. `mkdir quote_generator`
5. `cd quote_generator`
6. `cp ../../../../default/cribl/collectors/script/* .`
7. `chmod +w index.js *.json`
8. Edit `index.js` to change the following, to assign a unique name to the Collector:

```
exports.name = 'Quote Generator';
```

9. Edit `properties.type` within `conf.schema.json` file to remove `flag` keyword and change the `enum` to `["quote_generator"]`. You should end up with something like this:

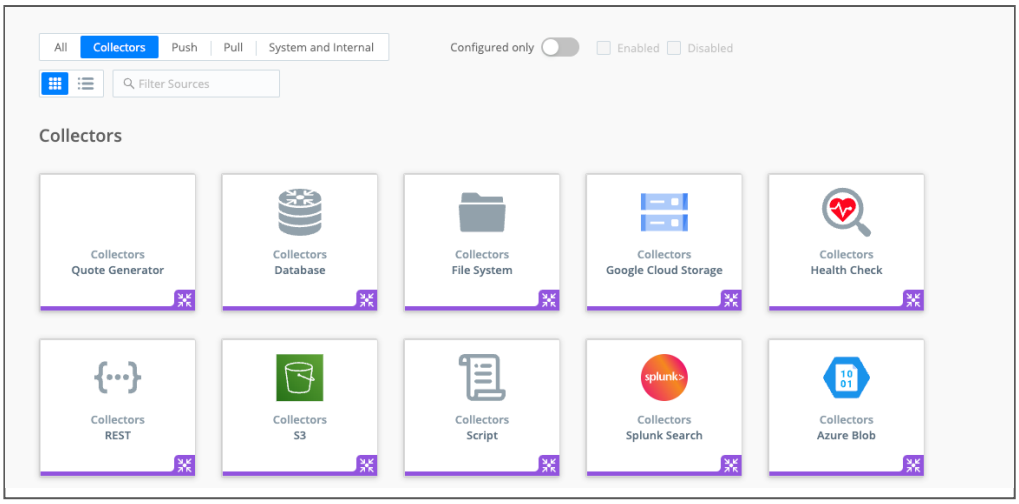
```
{
  "type": "object",
  "title": "",
  "required": ["discoverScript", "collectScript"],
  "properties": {
    "type": {
      "type": "string",
      "enum": ["quote_generator"]
    },
    (...)
```

10. Next, restart Cribl Stream with the following command:
    `$ /opt/cribl/bin/cribl restart`
11. After Cribl Stream restarts, you must log out and log back in for the new Collector tile to display under Sources.

Configure the Collector in Cribl Stream

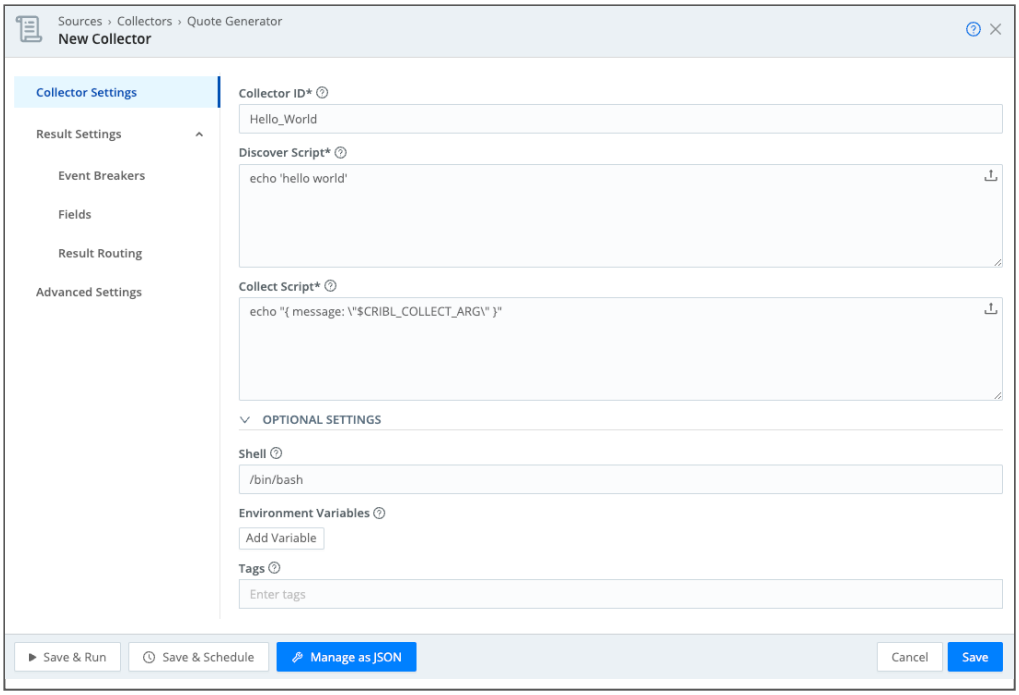
Now you'll configure the custom Quote Generator Collector that you built in the previous section.

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Sources**. Select the **Collectors** button to display the Collectors tiles.



Quote Generator Collector (Missing an Icon)

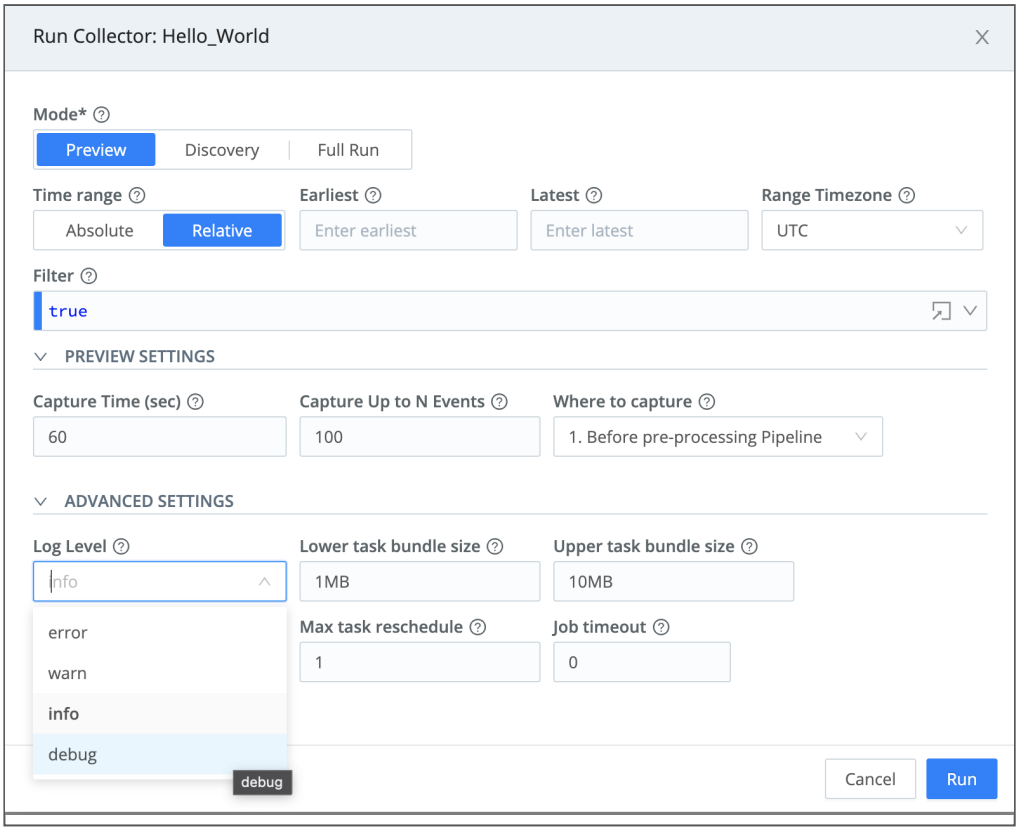
1. Select the **Quote Generator** > **New Collector** modal.
2. Enter the following in the **Collector Settings** tab, then select **Save**:
    - **Collector ID**: `Hello_World`
    - **Discover Script**: `echo "hello world"`
    - **Collect Script**: `echo "{ message: \"$CRIBL_COLLECT_ARG\" }"`



Collector Settings Tab

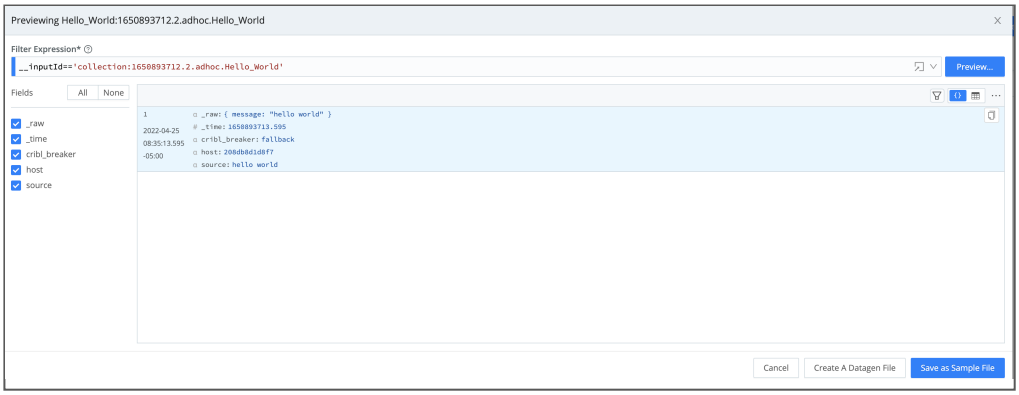
3. On the **Manage Quote Generator Collectors** page, select **Run** next to the Collector.

4. In the **Run configuration** modal, select **Run** again. Note that you can set the Collector's debug level in the modal's **Advanced Options** section. For details, see Run Configurations and Shared Settings.



Run the Collector

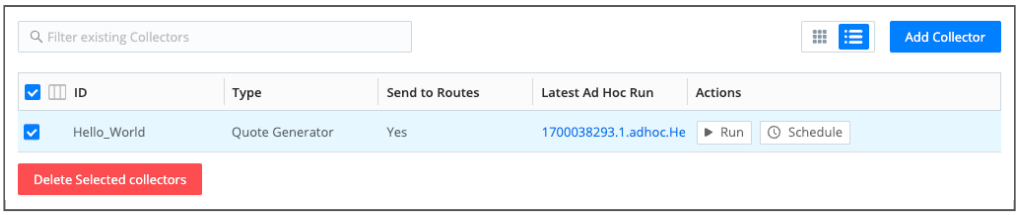
5. After the Collector runs, the following event will be generated:



Run the Collector

Now that we have a basic shell for our Collector, let's change the UI and `index.js` to add our custom Collector logic. Before making any additional changes, delete the Collector we just created.

6. On the **Manage Quote Generator Collectors** page, select the check box next to your Collector, then select **Delete selected Collectors**.



Delete the Collector

Edit the Schema Files

1. Replace the contents of `conf.schema.json` with the following:

```
{
  "type": "object",
  "title": "",
  "required": ["autoGenerateNames"],
  "properties": {
    "autoGenerateNames": {
      "type": "boolean",
      "title": "Auto generate names",
      "description": "Turn on to autogenerate names, use num names to specify ho
      "default": false
    }
  },
  "dependencies": {
    "autoGenerateNames": {
      "oneOf": [
        {
          "required": ["numNames"],
          "properties": {
            "autoGenerateNames": { "enum": [true] },
            "numNames": {
              "type": "number",
              "title": "Num names",
              "minimum": 1,
              "maximum": 1000,
              "description": "The number of names to auto generate, each name wi
            }
          }
        },
        {
          "required": ["names"],
          "properties": {
            "autoGenerateNames": { "enum": [false] },
            "names": {
              "type": "array",
              "title": "Names",
              "minLength": 1,
              "description": "List of user names to retrieve quotes for.",
              "items": {"type": "string"}
            }
          }
        }
      ]
    `
```

```
      }
    }
  }
```

Two interesting things to note in the `conf.schema.json` file:

- When you disable – set to `false` – the boolean toggle `autoGenerateNames`, the UI displays a **Names** field requesting a list of user names for which to retrieve quotes.
- When you enable – set to `true` – the boolean toggle `autoGenerateNames`, the UI displays a **Number of names to enter** field requesting the number of names to auto-generate.

The dependency allows dynamic onscreen behavior based on the field's value.

2. Replace the contents of `conf.ui-schema.json` with the following:

```
{
  "names": {
    "ui:field": "Tags",
    "ui:placeholder": "Enter names",
    "ui:options": {
      "separator": ","
    }
  }
}
```

The UI schema, in this case, further refines the widget ("Tags") used for the Names field. We will see this in action a bit later.

3. Finally, replace the contents of `index.js` with the following:

```
exports.name = 'Quote Generator';
exports.version = '0.1';
exports.disabled = false;
exports.destroyable = false;

const Readable = require('stream').Readable;
const os = require('os');
const host = os.hostname();
const logger = C.util.getLogger('myCollector'); // For use in debugging init, se

let conf;
let batchSize;
let filter;
let autoGenerate = false;
let numNames = 0;
let names;

exports.init = async (opts) => {
  conf = opts.conf;
  //logger.info('INIT conf', { conf });
  batchSize = conf.maxBatchSize || 10;
  filter = conf.filter || 'true';
  autoGenerate = conf.autoGenerateNames
  names = conf.names || [];
  numNames = conf.numNames ?? 3;
  //logger.info('INIT VALUES', { autoGenerate, names, numNames });
  return Promise.resolve();
};

exports.discover = async (job) => {
  for (let i = 0; i < names.length; i++) {
    job.addResult({"name": names[i]});
  }
}

exports.collect = async (collectible, job) => {
  job.logger().debug('Enter collect', { collectible });
  const quote = "Carpe Diem!"; // Hard coded quote for now.

  // Must return a readable stream from the collect method. Here we are returnir
  // the result string wrapped in a Readable.
  const s = new Readable();
```

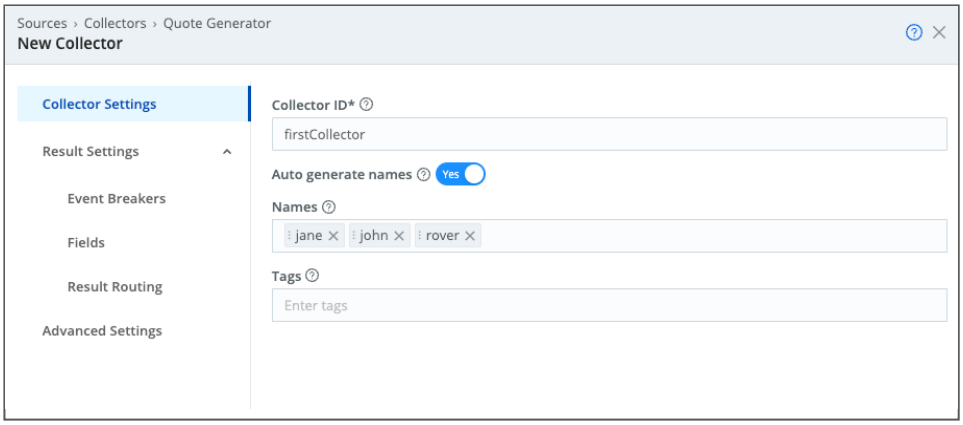
```
    s.push(JSON.stringify({ host, name: collectible.name, quote }));
    s.push(null);

    // Return readable to stream collected data
    return Promise.resolve(s)
  };
```

4. Next, restart Cribl Stream with the following command:
   `$ /opt/cribl/bin/cribl restart`
5. After Cribl Stream restarts, you must log out and log back in for the new Collector tile to display under Sources.

Configure a New Collector Instance

1. In Cribl Stream, navigate to the Quote Generator Collector and select **Add New** to open the **Quote Generator** > **New Collector** modal.
2. Type the following into the **Collector Settings** tab, then select **Save**:
   - **Collector ID**: `firstCollector`
   - **Auto generate names**: `No`
   - **Names**: `Jane, John, Rover`



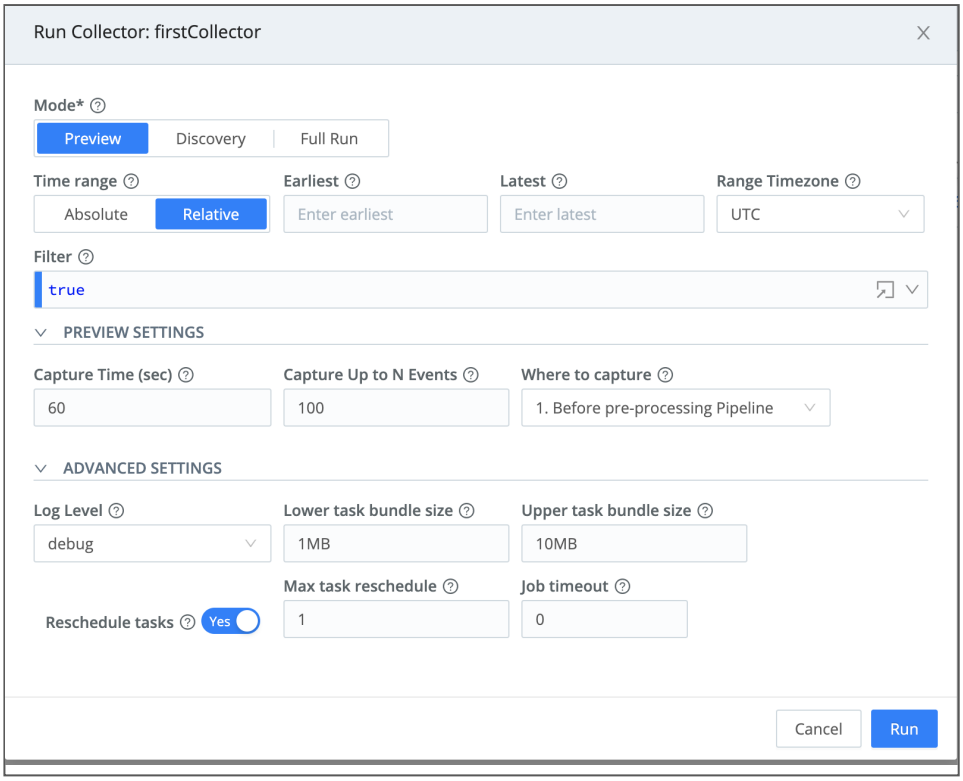
New Collector Settings

3. On the **Manage Quote Generator Collectors** page select **Run** next to the Collector.

Run the Collector

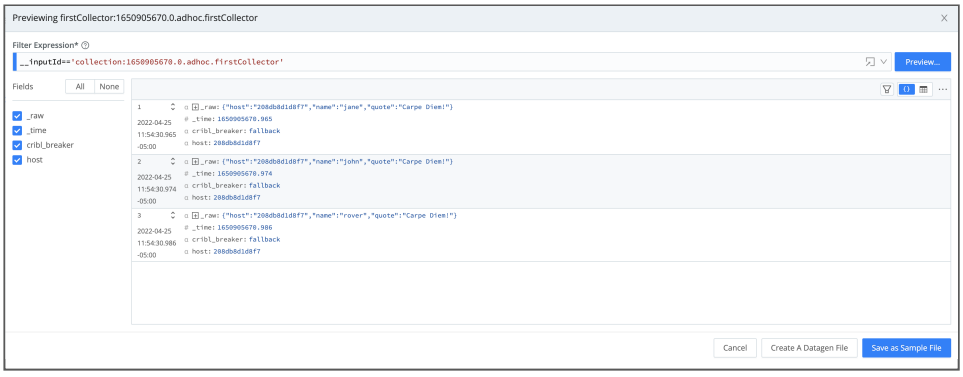
4. In the **Run configuration** modal:
   - For **Mode**, select **Preview**.

- For **Log Level**, select **debug**.
- Select **Run** again.



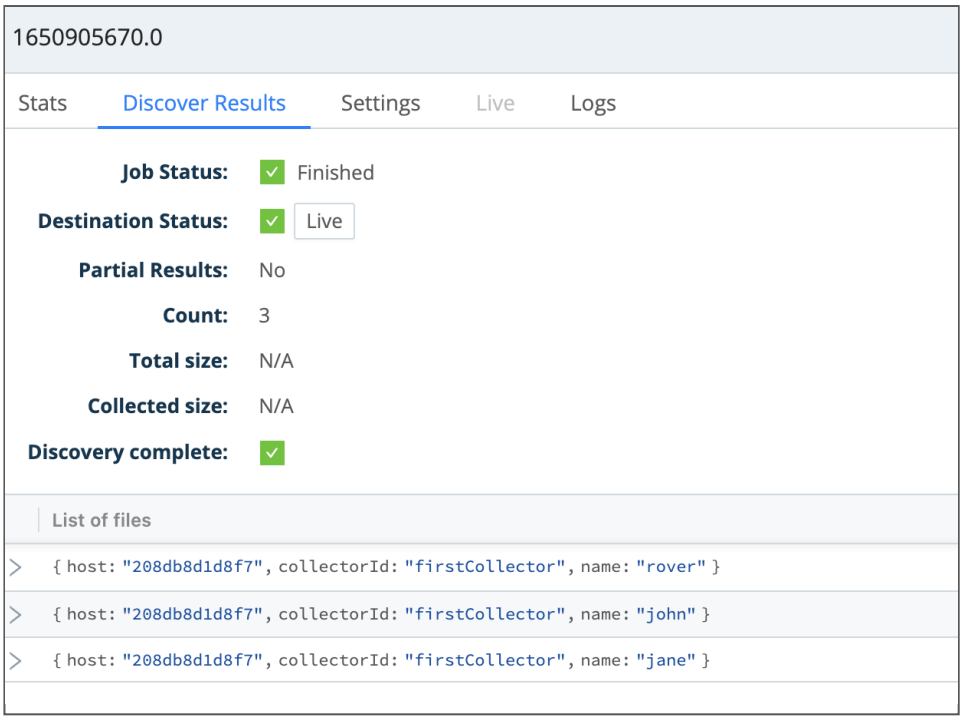
Run Collector Settings

5. If the Collector works, a successful run displays a results dialog, including an event for each name that was added.



Collector Events

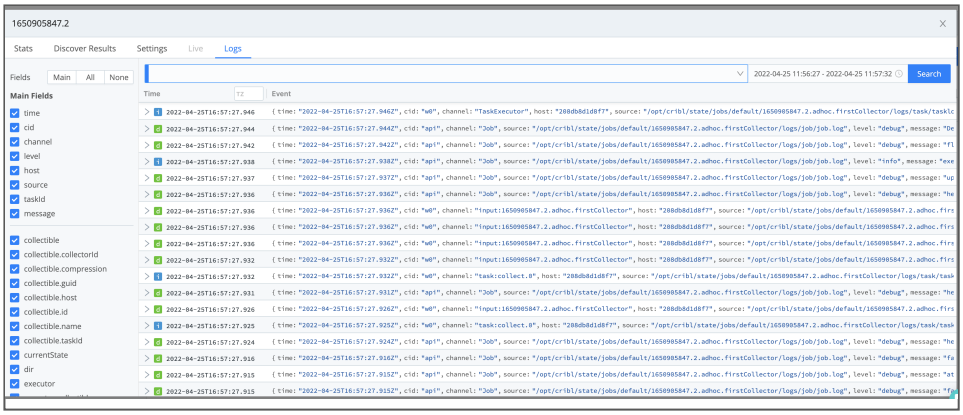
6. Close the **Preview** dialog.
7. On the **Manage Quote Generator Collectors** page, select **Latest ad hoc run**.
8. This will open a dialog from the Job Inspector with information about the run, including job status, items returned by the Discover call, and logs. Select the **Discover Results** tab to see data returned from the Collector's Discover call:



Discover Results

The Collector method separately. invokes each item returned The Collector argument is the content from each row in the table.

9. Select the **Logs** tab to view logs from the run. This is where you can locate anything logged by `job.logger`.



View Logs

The exceptions are anything logged by our Collector in `init`. Notice that `index.js` defined another logger to use when debugging `init`:

```
const logger = C.util.getLogger('myCollector');
```

You can view the relevant Worker Process' logs on the Monitoring page.

Integrate a Third-Party Package

Next, we'll integrate a third-party package to randomly generate names in the Discover method.

1. In your terminal, follow these steps to install npm (Node Package Manager) into the virtual machine running Cribl Stream:
    - `apt update`
    - `apt install npm`
    - When prompted, select a `Region`.
    - When prompted, select a `Timezone`.
2. Run the following commands in your Collector directory:
    - `cd /opt/cribl/local/cribl/collectors/quote_generator`
    - `npm init`: Answer all questions with default answers. The values are not important for our purposes.
    - `npm install username-generator --save`

    This will install the third-party username-generator package in `/opt/cribl/local/cribl/collectors/quote_generator/node_modules`.
3. Next, update the Collector's `index.js` with the following content, to use this new package to auto-generate names:

```
exports.name = 'Quote Generator';
exports.version = '0.1';
exports.disabled = false;
exports.destroyable = false;

const UsernameGenerator = require('username-generator');
const Readable = require('stream').Readable;
const os = require('os');
const host = os.hostname();
const logger = C.util.getLogger('myCollector'); // For use in debugging init, se

let conf;
let batchSize;
let filter;
let autoGenerate = false;
let numNames = 0;
let names;

exports.init = async (opts) => {
  conf = opts.conf;
  //logger.info('INIT conf', { conf });
  batchSize = conf.maxBatchSize || 10;
  filter = conf.filter || 'true';
  autoGenerate = conf.autoGenerateNames
  names = conf.names || [];
  numNames = conf.numNames ?? 3;
  //logger.info('INIT VALUES', { autoGenerate, names, numNames });
  return Promise.resolve();
};

exports.discover = async (job) => {
  if (autoGenerate) {
    // Auto generate usernames using 3rd party package.
    names = [];
    for (let i = 0; i < numNames; i++) {
      names.push(UsernameGenerator.generateUsername('_'));
    }
    job.logger().info('Successfully generated usernames', { numGenerated: names.
  }
  for (let i = 0; i < names.length; i++) {
    job.addResult({"name": names[i]});
  }
`
```

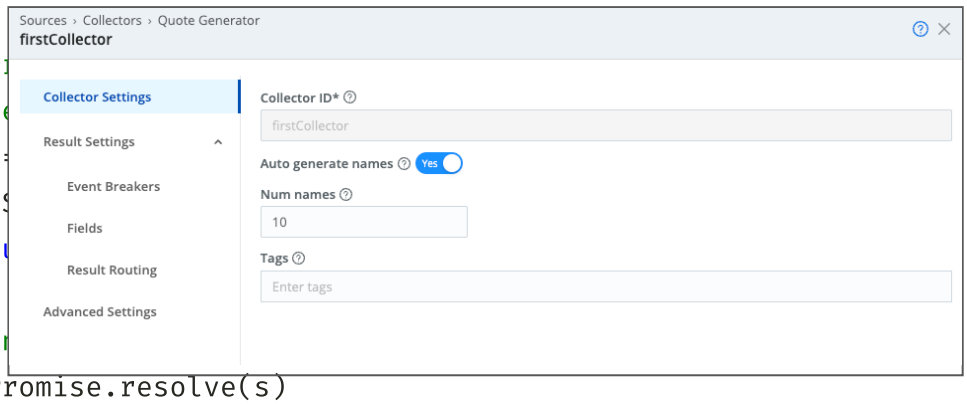
4.

```
}

exports.collect = async (collectible, job) => {
  job.logger().info('Enter collect', { collectible });
  const quote = "Carpe Diem!"; // Hard coded quote for now.

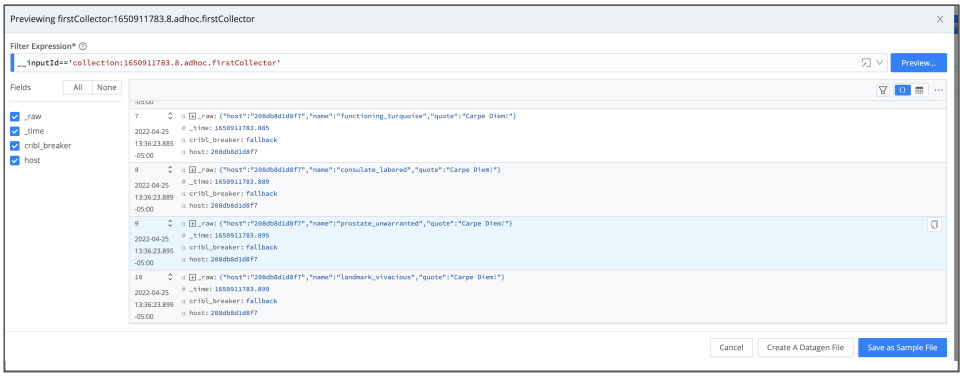
  // Must
  // the re
  const s =
  s.push(JS
  s.push(nu

  // Return
  return Promise.resolve(s)
};
```



Update Existing Collector

5. Run the Collector, notice that 10 Events are now displayed and each username is randomized:



Update Existing Collector

6. Next, update the Collector's `index.js` with the following content to create a static list of random quotes in the Collect method. You can optionally retrieve a random quote from a REST API instead.

```
exports.name = 'Quote Generator';
exports.version = '0.1';
exports.disabled = false;
exports.destroyable = false;

const UsernameGenerator = require('username-generator');
const Readable = require('stream').Readable;
const os = require('os');
const host = os.hostname();
const { httpSearch, isHttp200, RestVerb } = C.internal.HttpUtils;

const logger = C.util.getLogger('myCollector'); // For use in debugging init, se

// Quotes to randomize
const quotes = [

]

let conf;
let batchSize;
let filter;
let autoGenerate = false;
```

```
let numNames = 0;
let names;

exports.init = async (opts) => {
  conf = opts.conf;
  //logger.info('INIT conf', { conf });
  batchSize = conf.maxBatchSize || 10;
  filter = conf.filter || 'true';
  autoGenerate = conf.autoGenerateNames
  names = conf.names || [];
  numNames = conf.numNames ?? 3;
  //logger.info('INIT VALUES', { autoGenerate, names, numNames });
  return Promise.resolve();
};

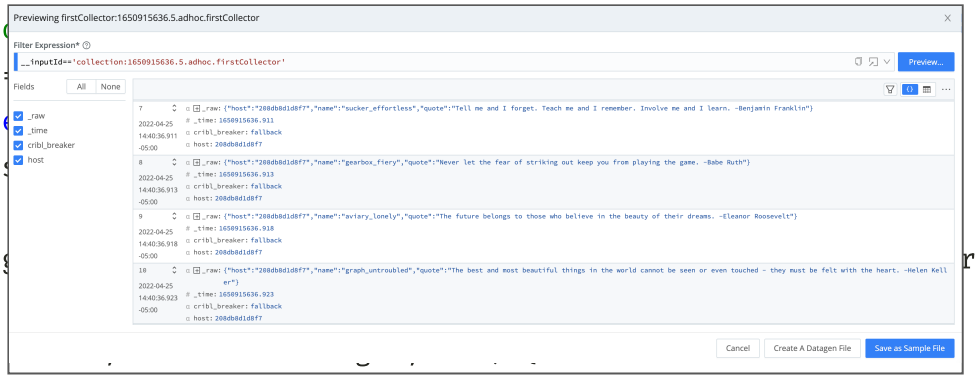
exports.discover = async (job) => {
  if (autoGenerate) {
    // Aut
    names =
    for (le
      name
    }
    job.log                                                    rated: names.
  }
  for (let
    await job.addResult({"name": names[i]});
  }
}

exports.collect = async (collectible, job) => {
  const quote = quotes[Math.trunc(Math.random()*100)%quotes.length];

$ docker ps
CONTAINER ID   IMAGE                    COMMAND                  CREATED
208db8d1d8f7   cribl/cribl:latest   "/sbin/entrypoint.sh…"   6 hours ago   Up 6

  const s = new Readable();
  s.push(JSON.stringify(result));
  s.push(null);

  // Return readable to stream collected data
  return Promise.resolve(s)
};
```



Run the Collector

You can locate the archive file containing the source code in the current directory. After you back up the source code, it is safe to shut down the Docker container.

Building a Collector (Distributed Environment)

When you create a Collector in a distributed environment, the directory path is slightly different from the single–instance example above. For example, for the `default group`, you should create Collectors on the Leader Node in the directory: `opt/cribl/groups/default/local/cribl/collectors`.

The format of the path is: `/opt/cribl/groups/<workerGroup>/local/cribl/collectors`

For example, assuming you want to create a new Collector in group is `myGroup`, the path would be: `/opt/cribl/groups/myGroup/local/cribl/collectors`.

You'd proceed as follows:

1. Connect to the Leader Node.
2. `cd $CRIBL_INSTALL/groups/default/local/cribl`
   `$CRIBL_INSTALL` refers to the directory where Stream is running. Example: `/opt/cribl`
3. `mkdir collectors`
4. `cd collectors`
5. `mkdir quote_generator`
6. `cd quote_generator`
7. `cp ../../../../default/cribl/collectors/script/* .`

Building the Collector in a distributed environment works the same as in single-instance environment with exception of a few differences:

1. You must add the files to a Worker–Group directory, as described above.
2. You must commit and deploy changes to the Workers.

Given the extra steps, we recommend that you first build the Collector in a standalone environment, before deploying it to a distributed environment.

15.1.2. Amazon

15.1.2.1. Amazon Data Firehose Source

Cribl Stream supports receiving data from Amazon Data Firehose delivery streams via the **HTTP endpoint** destination option.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

AWS Configuration

Configuring the endpoint and port settings for integrating Cribl with Amazon Data Firehose varies depending on whether you're using Cribl.Cloud or a non-Cribl.Cloud deployment.

- **Cribl.Cloud**:
  - Configure the AWS destination **HTTP endpoint URL** to your Cribl.Cloud endpoint `https://default.main.<your-org-id>.cribl.cloud` on port `443`. Replace `<your-org-id>` with your actual organization ID.
  - Configure the Cribl Stream Amazon Data Firehose Source to listen on port `10443` internally.
- **Non-Cribl.Cloud**:
  - Configure the AWS destination **HTTP endpoint URL** to the public URL of your Cribl Stream instance.
  - Configure the Cribl Stream Amazon Data Firehose Source to either listen on port `443` with elevated privileges or use a reverse proxy to forward traffic from port `443` to a non-privileged port, like `10443`.

Configure Cribl Stream to Receive Data over HTTP(S) from Amazon Data Firehose

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
   - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.

    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Address to bind on. Defaults to `0.0.0.0` (all addresses).
    - **Port**: Enter the port number to listen on. In Cribl.Cloud, use port `10443`, as this is where the data is processed internally.
3. Under **Authentication**, enter the **Auth tokens**:
    - **Auth tokens**: Shared secrets to be provided by any client (Authorization: <token>). Click **Generate** to create a new secret. If empty, unauthenticated access **will be permitted**.
4. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `No`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields for this Source:

- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.
- `__inputId`
- `__raw`
- `__srcIpPort` – See details below.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Amazon Data Firehose client sending data to this Source.

When any proxies (including load balancers) lie between the Amazon Data Firehose client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Limitations

If you set the optional `IntervalInSeconds` and/or `SizeInMBs` parameters in the Amazon Data Firehose `BufferingHints` API, beware of selecting extreme values (toward the ends of the API's supported ranges). These can send more bytes than Cribl Stream can buffer, causing Cribl Stream to send HTTP 500 error responses to Amazon Data Firehose.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.2.2. Amazon Kinesis Data Streams Source

Cribl Stream supports receiving data records from Amazon Kinesis Data Streams.

Type: **Pull** | TLS Support: **YES** (secure API) | Event Breaker Support: **No** | Uses Key-Value Store

Configure Cribl Stream to Receive Data from Amazon Kinesis Data Streams

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Kinesis Stream Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Stream name**: Enter the name of the Kinesis Data Stream (not ARN) to read data from.
    - **Region**: Select the AWS region where your Kinesis Data Stream is located. If your region isn't listed, you can manually enter it. Additionally, you can specify the service endpoint in the **Endpoint** field under Advanced Settings.
3. Next, you can configure the following **Optional Settings**:
    - **Shard iterator start**: Location from which a newly created Source should start reading any shard, including shards that are added later. Defaults to `Earliest Record`.
    - **Record data format**: Format of data inside the Kinesis Stream records. Gzip compression is automatically detected. For details, see Record Data Format Options.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, AssumeRole, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Record Data Format Options

In **Record data format**, options include:

- Cribl (the default): Use this option if Cribl Stream wrote data to Kinesis in this format. This is a type of NDJSON.
- Newline JSON: Use if the records contain newline-delimited JSON (NDJSON) events – for example, Kubernetes logs ingested through Kinesis. This is a good choice if you don't know the records' format.
- CloudWatch Logs: Use if you've configured CloudWatch to send logs to Kinesis.
- **Event per line**: NDJSON can use this format when it fails to parse lines as valid JSON.

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method:

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC – for example, those running in a private cloud.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key.

IAM Role Authentication

When using an IAM role to authenticate with Kinesis Streams, the IAM policy statements must include the following Actions:

- `kinesis:GetRecords`
- `kinesis:GetShardIterator`
- `kinesis:ListShards`

For details, see AWS' Actions, resources, and condition keys for Amazon Kinesis Data Streams documentation.

Manual Authentication

The **Manual** option exposes these additional fields:

Access key: Enter your AWS access key. If not present, will fall back to `env.AWS_ACCESS_KEY_ID`, or to the metadata endpoint for IAM role credentials.

Secret key: Enter your AWS secret key. If not present, will fall back to `env.AWS_SECRET_ACCESS_KEY`, or to the metadata endpoint for IAM credentials.

Secret Authentication

The **Secret** option exposes this additional field:

Secret key pair: Use the drop-down to select a secret key pair that you've configured in Cribl Stream's internal secrets manager or (if enabled) an external KMS. Follow the **Create** link if you need to configure a key pair.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for Kinesis Streams: Whether to use Assume Role credentials to access Kinesis Streams. Defaults to `No`.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Shard selection expression: A JavaScript expression to be called with each `shardId` for the stream. The shard will be processed if the expression evaluates to a truthy value. Defaults to `true`. Avoid trying to use this expression to distribute data evenly across Worker Processes – the preferred way to do that is to use round robin load balancing.

Service Period: Time interval (in minutes) between consecutive service calls that check for configuration updates and perform maintenance. Defaults to `1` minute. This differs from polling frequency, which determines how often the Source fetches new data. Adjust the service period to balance the need for quick configuration updates (use a shorter interval) with the frequency of maintenance tasks (use a longer interval for less frequent tasks).

Endpoint: Kinesis stream service endpoint. If empty, the endpoint will be automatically constructed from the region.

Signature version: Signature version to use for signing Kinesis Stream requests. Defaults to `v4`.

Verify KPL checksums: Enable this setting to verify Kinesis Producer Library (KPL) event checksums. This setting is not available when Cribl Stream is deployed in FIPS mode.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority – self-signed certificates, for example. Defaults to `Yes`.

Avoid duplicate records: If toggled to `Yes`, this Source will always start streaming at the next available record in the sequence. (This can cause data loss after a Worker Node's unexpected shutdown or restart.) With the default `No`, the Source will reread the last two batches of events at startup. (This prevents data loss, but can ingest duplicate events.)

Records limit per call: In v.4.0.4 and later, sets the maximum number of records ingested, per shard, in each getRecords call. You can acclerate data collection by increasing the default/minimum `5000` limit, to as high as `10000` records.

Total records limit: In v.4.0.4 and later, sets the maximum number of records, across all shards, to pull down at once per Worker Process. Default/minimum value is `20000` records. Beware of very high values that could excessively consume Workers' memory.

Shard Load Balancing: The load-balancing algorithm to use for spreading out shards across Workers and Worker Processes. Options include:

- Consistent Hashing (default)
- Round Robin

For the Round Robin option, both the Leader and the Worker Groups must be on Cribl Stream 4.1 or later.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Field for this Source:

- `__checksum`
- `__encryptionType`
- `__final`
- `__inputID`
- `__isKPL`
- `__partitionKey`
- `__sequenceNumber`

Apart from the internal fields, one important non-internal field that this Source adds is `_raw`.

Principles for Configuration Decisions

To get the best results, apply these principles when configuring the Source and Amazon Kinesis Data Streams itself:

The number of shards should be a multiple of the number of Worker Processes in the Worker Group. A ratio of one shard to one Worker Process yields the fastest possible processing.

Distributing data evenly across Worker Processes yields the best performance. To achieve this, choose **Advanced Settings > Shard Load Balancing > Round Robin**. This helps avoid the situation where some Worker Processes are overburdened while others sit idle. Avoid trying to use the **Advanced Settings > Shard selection expression** for this purpose.

How the Source and Kinesis Interact

The Leader Node for the Kinesis Streams Source stores shard state on disk, so that the Source can pick up where it left off across restarts. The state file is located in the `$CRIBL_HOME/state/` directory. The path format looks like this:

```
.../state/kvstore/<group-id>/input_kinesis_<input-id>_<stream-name>/state.json
```

For example:

```
state/kvstore/default/input_kinesis_kinesisIn_just-a-test/state.json
```

Worker Processes become Kinesis Consumers and get a list of available shards from Kinesis. They then contact the Leader Node to request the sequence numbers that the Leader has stored for those shards. Each sequence number references a specific record.

Every five minutes, each Worker Process takes the latest sequence numbers for the shards it is responsible for, and forwards those sequence numbers to the Leader Node, enabling the Leader Node to update the state that it is storing. The Leader Node persists the `shardId` > `sequenceNumber` mapping to disk using a key-value store where the keys are Shard IDs and the values are sequence numbers.

In situations where Worker Processes must reload state (by retrieving it from the key-value store on the Leader Node), each Worker Process will resume reading the same shard it was reading before, provided that neither the number of shards nor the number of Worker Processes have changed.

Polling Frequency

The polling frequency for the Kinesis Streams Source is adaptive. By default, if the Source has caught up to the latest records, it sets a delay of `1` second. If it has not caught up, it immediately requests the next batch of records without waiting. This ensures efficient data consumption without unnecessary delays.

Setting Shard iterator start

Under certain circumstances, the Leader Node will not have any sequence numbers for a given shard and the Worker Process will be reading from that shard for the first time. (These conditions include when the shard is newly added to the Kinesis stream and/or when the Source is newly created.)

When this happens, the Worker Process then does what is specified in **Optional Settings** > **Shard iterator start**:

- When **Shard iterator start** is set to `Earliest record`, the Worker starts reading from the beginning.
- When it is set to `Latest record`, the Worker Process resumes reading the shard from the point where Cribl Stream previously left off.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.2.3. Amazon S3 Source

Cribl Stream supports receiving data from Amazon S3 buckets. The Amazon S3 Source can receive data using either of these methods:

- S3 Bucket event notifications through Amazon Simple Queue Service (SQS)
- Amazon Security Lake event subscriptions

These two notifications use the same method of sending data objects to a queue, but the underlying data format from these two methods differ. Cribl Stream supports both data structures.

Type: **Pull** | TLS Support: **YES** (secure API) | Event Breaker Support: **YES**

Cribl Stream running on Linux (only) can use this Source to read Parquet files, identified by a `.parquet`, `.parq`, or `.pqt` filename extension.

For configuration examples, see our Amazon S3 Better Practices and Using S3 Storage and Replay guides.

S3 Setup Strategy

The source S3 bucket must be configured to send `s3:ObjectCreated:*` events to an SQS queue, either directly (easiest) or via SNS (Amazon Simple Notification Service). See the event notification configuration guidelines below.

SQS messages will be deleted after they're read, unless an error occurs, in which case Cribl Stream will retry. This means that although Cribl Stream will ignore files not matching the **Filename Filter**, their SQS events/notifications will still be read, and then deleted from the queue (along with those from files that match).

These ignored files will no longer be available to other S3 Sources targeting the same SQS queue. If you still need to process these files, we suggest one of these alternatives:

- Using a different, dedicated SQS queue. (Preferred and recommended.)
- Applying a broad filter on a single Source, and then using pre-processing Pipelines an/or Route filters for further processing.

Compression

Cribl Stream can ingest compressed S3 files if they meet one of the following conditions:

- Compressed with the `x-gzip` MIME type.

- Ends with the `.gz`, `.tgz`, `.tar.gz`, `.tgz`, or `.tar` extension.
- Can be uncompressed using the `zlib.gunzip` algorithm.

Storage Class Compatibility

Cribl Stream does **not** support data preview, collection, or replay from S3 Glacier or S3 Deep Glacier storage classes, whose stated retrieval lags (variously minutes to 48 hours) cannot guarantee data availability when the Collector needs it.

Cribl Stream **does** support data preview, collection, and replay from S3 Glacier Instant Retrieval when you're using the S3 Intelligent-Tiering storage class.

Configure Cribl Stream to Receive Data from Amazon S3

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this S3 Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Queue**: The name, URL, or Amazon Resource Name (ARN) of the SQS queue to read events from. When specifying a non-AWS URL, you must use the format: `{url}/<queueName>`. (For example: `https://host:port/<queueName>`.) This value must be a JavaScript expression (which can evaluate to a constant), enclosed in single quotes, double quotes, or backticks.
3. Next, you can configure the following **Optional Settings**:
    - **Filename filter**: Regex matching file names to download and process. Defaults to `.*`, to match all characters. This regex will be evaluated against the S3 key's full path.
    - **Region**: AWS Region where the S3 bucket and SQS queue are located. Required, unless the **Queue** entry is a URL or ARN that includes a Region.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. In the **Authentication** settings, select one of the following options from the menu:

Option	Description
Auto	This default option uses the AWS SDK for JavaScript to check for credentials in a specific order by priority. It first checks for IAM Roles for Amazon EC2, then a shared credentials file, then environmental variables, and so forth. See Authentication Settings for more information.
Manual	If not running on AWS, select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, such as those running a private cloud. See Authentication Settings for more information.
Secret	If not running on AWS, select this option to supply a stored secret that references an AWS access key and secret key. See Authentication Settings for more information.

5. If needed, configure the **AssumeRole** settings. You can use these settings to access resources in a different region than Cribl Stream. You can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. See Assume Role Settings for more information.
6. Optionally, refer to the following sections for the remaining settings:
    - Processing Settings
    - Advanced Settings
    - Connected Destinations
7. Select **Save**, then **Commit & Deploy**.
8. Verify that data is flowing correctly to Cribl Stream by viewing the **Live Data** feed from the Source.

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, such as those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

The values for **Access key** and **Secret key** can be a constant or a JavaScript expression (such as `${C.env.MY_VAR}`). Enclose values containing special characters (like, `/`) or using environment variables in single quotes or backticks.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select a secret key pair that you've configured in Cribl Stream's internal secrets manager or (if enabled) an external KMS. Follow the **Create** link if you need to configure a key pair.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for S3: Whether to use Assume Role credentials to access S3. Defaults to `Yes`.

Enable for SQS: Whether to use Assume Role credentials when accessing SQS. Defaults to `No`.

AWS account ID: SQS queue owner's AWS account ID. Leave empty if the SQS queue is in the same AWS account.

AssumeRole ARN: Enter the ARN of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

Enabled: Defaults to `No`. Toggle to `Yes` to enable the custom command.

Command: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).

Arguments: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

This section defines event breaking rulesets that will be applied, in order.

Event Breaker Rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Checkpoint Settings

Enable checkpointing: When toggled to `No` (the default) Cribl Stream will always start processing a file from the beginning. Toggle to `Yes` if, after an error or restart occurs, you want Cribl Stream to resume processing a given file from the point where it was interrupted, as explained below. When turned on, the following additional setting becomes available:

- **Retries**: The number of times you want Cribl Stream to retry processing a file after an error or restart occurs. If **Skip file on error** is enabled, this setting is ignored.

Other Settings

Endpoint: S3 service endpoint. If empty, defaults to AWS's region-specific endpoint. Otherwise, used to point to an S3-compatible endpoint. To access the AWS S3 endpoints, use the path-style URL format. You don't need to specify the bucket name in the URL, because Cribl Stream will automatically add it to the URL path. For details, see AWS' Path-Style Requests topic.

Signature version: Signature version to use for signing SQS requests. Defaults to `v4`.

Max messages: The maximum number of messages that SQS should return in a poll request. Amazon SQS never returns more messages than this value. (However, fewer messages might be returned.) Acceptable values: 1 to 10. Defaults to `1`.

Visibility timeout seconds: The duration (in seconds) that the received messages are hidden from subsequent retrieve requests, after being retrieved by a ReceiveMessage request. Defaults to `600`.

Cribl Stream will automatically extend this timeout until the initial request's files have been processed – notably, in the case of large files that require additional processing time.

Num receivers: The number of receiver processes to run. The higher the number, the better the throughput, at the expense of CPU overhead. Defaults to `1`.

Poll timeout (secs): How long to wait for events before polling again. Minimum `1` second; default `10`; maximum `20`. Short durations increase the number - and thus the cost – of requests sent to AWS. (The UI will show a warning for intervals shorter than `5` seconds.) Long durations increase the time the Source takes to react to configuration changes and system restarts.

Socket timeout: Socket inactivity timeout (in seconds). Increase this value if retrievals time out during backpressure. Defaults to `300` seconds.

Max Parquet chunk size (MB): Maximum size for each Parquet chunk. Defaults to `5` MB. Valid range is `1` to `100` MB. Cribl Stream stores chunks in the location specified by the `CRIBL_TMP_DIR` environment variable. It removes the chunks immediately after reading them.

Parquet chunk download timeout (seconds): The maximum time to wait for a Parquet file's chunk to be downloaded. If a required chunk cannot be downloaded within this time limit, processing will end. Defaults to `600` seconds. Valid range is `1` second to `3600` seconds (1 hour).

Skip file on error: Toggle to `Yes` to skip files that trigger a processing error (for example, corrupted files). Defaults to `No`, which enables retries after a processing error.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Encoding: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Checkpointing

When Workers restart, checkpointing can prevent the Source from losing data or collecting duplicate events. Among the situations where this works well:

- When Cribl Stream pushes a new configuration: the Leader pushes the configuration to the Workers, and restarts them.

- When a Worker has gotten into a bad state, and you want to restart it.

Checkpointing allows Cribl Stream to resume processing a file at the point where an error or restart occurred, minimizing the number of duplicate events sent downstream in the event of an interruption. To accomplish this, Cribl Stream keeps track of how many events have been processed for a given file. Resuming processing after an interruption, the Source skips the first *N* events it has seen and starts processing from event *N*+1.

The Source manages checkpoint information in memory, but writes it out to disk periodically (once per second, and on Worker shutdown) so that the information can survive a Worker restart. Cribl Stream keeps checkpoint information at the Worker Process level and does not share it between Worker Processes or Worker Nodes.

Checkpointing is a feature to keep in mind when you do disaster recovery (DR) planning.

Caveats to using checkpointing include: Whenever Worker Node state is destroyed (that is, when a Worker ceases to exist), checkpoint information will be lost. In Cribl.Cloud deployments, this can happen during upgrades. Also, because checkpoints are not written to disk on **every** event, the checkpoints written to disk will lag behind those that the S3 Source manages in memory. If the Worker Process stops abruptly without a clean shutdown, checkpoints not yet written to disk will be lost. When processing resumes, the Source will start from just after the last checkpoint written to disk, producing duplicate events corresponding to the lost checkpoints.

Located in the UI at **Advanced Settings** > **Checkpoint Settings** > **Enable checkpointing**, this feature is turned off by default.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__final`
- `__inputId`
- `__source`
- `_time`

How to Configure S3 to Send Event Notifications to SQS

1. Create a Standard SQS Queue. Note its ARN.
2. Replace its access policy with one similar to the examples below. To do so, select the queue; and then, in the **Permissions** tab, click: **Edit Policy Document (Advanced)**. (These examples differ only at line 9, showing public access to the SQS queue versus S3-only access to the queue.)
3. In the Amazon S3 console, add a notification configuration to publish events of the `s3:ObjectCreated:*` type to the SQS queue.

Permissive SQS access policy | Restrictive SQS access policy

```
{
 "Version": "2012-10-17",
 "Id": "example-ID",
 "Statement": [
  {
   "Sid": "<SID name>",
   "Effect": "Allow",
   "Principal": {
    "AWS":"*"
   },
   "Action": [
    "SQS:SendMessage"
   ],
   "Resource": "example-SQS-queue-ARN",
   "Condition": {
      "ArnLike": { "aws:SourceArn": "arn:aws:s3:*:*:example-bucket-name" }
   }
  }
 ]
}
```

S3 and SQS Permissions

The following permissions are required on the S3 bucket:

- `s3:GetObject`
- `s3:ListBucket`

The following permissions are required on the SQS queue:

- `sqs:ReceiveMessage`
- `sqs:DeleteMessage`
- `sqs:ChangeMessageVisibility`
- `sqs:GetQueueAttributes`
- `sqs:GetQueueUrl`

To collect encrypted data, such as CloudTrail logs, you'll need to add access to the KMS resources in your KMS Key Policy. Add the IAM user or role to the **Principal** section of your Key Policy and provide the `kms:Decrypt` **Action**. See Amazon's documentation on Key Policies for more information, including how to view and change your policy.

Temporary Access via SSO Provider

You can use Okta or SAML to provide access to S3 buckets using temporary security credentials.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

How Cribl Stream Pulls Data

Workers poll message from SQS. The call will return messages if they are available, or will time out after 1 second if no messages are available.

Each Worker gets its share of the load from S3. By default, S3 returns a maximum of 1 message in a single poll request. You can change this default in **Max messages**.

Best Practices

Beyond these basics, also see our Amazon S3 Better Practices and Using S3 Storage and Replay guides:

- When Cribl Stream instances are deployed on AWS, use IAM Roles whenever possible.
  - Not only is this safer, but it also makes the configuration simpler to maintain.
- Although optional, we highly recommend that you use a **Filename Filter**.

    - This will ensure that Cribl Stream ingests only files of interest.
    - Ingesting only what's strictly needed improves latency, processing power, and data quality.
- If higher throughput is needed, increase **Advanced Settings** > **Number of Receivers** and/or **Max messages**. However, do note:
    - These are set at `1` by default. As a result, **each** Worker Process, in **each** Cribl Stream Worker Node, will run one receiver consuming one message (that is, S3 file) at a time.
    - Total S3 objects processed at a time per Worker Node = Worker Processes x Number of Receivers x Max Messages
    - Increased throughput implies additional CPU utilization.
- When ingesting large files, tune up the **Visibility Timeout**, or consider using smaller objects.
    - The default value of `600s` works well in most cases, and while you certainly can increase it, we suggest that you also consider using smaller S3 objects.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Source Integrations: S3 short course. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

VPC Endpoints

VPC endpoints for SQS and for S3 might need to be set up in your account. Check with your administrator for details.

Connectivity Issues

If you're having connectivity issues, but having no problems with the CLI, see if the AWS CLI proxy is in use. Check with your administrator for details.

Common Issues

"Inaccessible host: 'sqs.us-east-1.amazonaws.com'. This service may not be available..."

Full Error Text: `"message":"Inaccessible host: 'sqs.us-east-1.amazonaws.com'. This service may not be available in the 'us-east-1' region.","stack":"UnknownEndpoint: Inaccessible host: 'sqs.us-east-1.amazonaws.com'. This service may not be available in the 'us-east-1' region.`

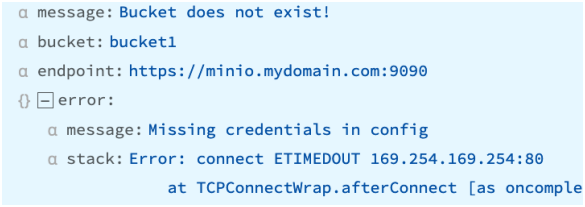
If this is persistent rather than intermittent then it could be caused by TLS negotiation failures. For example, AWS SQS currently does not support TLS 1.3. If intermittent then a network-related issue could be occurring such as DNS-related problems.

"Missing credentials in config" or "stack:Error: connect ETIMEDOUT 169.254.169.254:80"

Can occur when **Authentication** is set to **Auto**, but no IAM role is attached.

Recommendation

Change to Manual Authentication; attach an IAM role; or if using IMDv2, switch to IMDv1 (if possible).



Missing credentials in config

"Bucket does not exist - self signed certificate"

Example Error Text:

```
message: Bucket does not exist - self signed certificate
stack: Error: self signed certificate
    at TLSSocket.onConnectSecure (node:_tls_wrap_1535:34)
    at TLSSocket.emit (node:events:513:28)
    at TLSSocket.emit (node:events:489:12)
    at TLSSocket._fini... Show more
tmpPath: /opt/cribl/s3_bucket/cribl/2023/03/28/CriblOut-XTNGh5.0.json.tmp
```

Can occur when:

- the Destination uses a self-signed cert that has not yet been trusted by Cribl Stream.
- the user does not have appropriate permissions to view the bucket.
- the authentication token generated by your computer has a timestamp that is out of sync with the server's time, resulting in an authentication failure.

Recommendation

Disable **Advanced Settings** > **Reject unauthorized certificates** or; get the sender's cert and add it to the `NODE_EXTRA_CA_CERTS` path for validation; or verify that the user has appropriate permissions.

15.1.2.4. Amazon Security Lake Source

Cribl Stream supports receiving data from Amazon Security Lake. Amazon Security Lake aggregates, normalizes, and stores security-related data from an AWS system. It outputs data using the Open Cybersecurity Schema Framework (OCSF). It's important not to confuse it with Amazon Security Hub, which is a different product.

Type: **Pull** | TLS Support: **YES** (secure API) | Event Breaker Support: **YES**

Cribl Stream running on Linux (only) can use this Source to read Parquet files, identified by a `.parquet`, `.parq`, or `.pqt` filename extension.

You can use the Amazon Security Lake Source in Cribl Stream to:

- Transform, trim, or shape incoming data from Amazon Security Lake and then send it to a downstream Destination, such as your preferred security analytics tool.
- Collect security data from multiple AWS cloud environments, different regions, or different services in the Amazon ecosystem.

Relationship Between Amazon Security Lake and S3

The Amazon Security Lake Source functions nearly identically to the Amazon S3 Source. If needed, you can refer to the Amazon S3 Source documentation for more in-depth coverage of additional best practices and troubleshooting workarounds.

Because they are similar, you can use both the Amazon S3 Source and the Amazon Security Lake Source interchangeably as needed. Consider using both Sources together if your organization uses these different tools for different purposes and it is easier to manage them as separate and distinct data flows.

Both the Amazon Security Lake Source and the Amazon S3 Source can receive data using either of these methods:

- Amazon Security Lake event subscriptions
- S3 Bucket event notifications through Amazon Simple Queue Service (SQS)

These two notifications use the same method of sending data objects to a queue, but the underlying data format from these two methods differ. Cribl Stream supports both data structures. However, the Amazon Security Lake Source does not currently support pulling data from HTTPS endpoints.

You can customize the data template by configuring the default input transformer associated with Amazon Security Lake. However, changing the way Amazon Security Lake represents data could cause issues with the ability for Cribl Stream to consume data from Amazon Security Lake. Only advanced AWS administrators should change the default input transformer.

How the Amazon Security Lake Source Handles Data

When Amazon Security Lake collects security data, it pushes the data object (a parquet file) to a queue located in an S3 bucket. Amazon Security Lake then sends an event notification or a subscriber notification to Cribl Stream. The notification contains the object location data in the S3 bucket. Cribl Stream pulls the data object and deserializes it for further data processing.

Amazon Security Lake uses Amazon S3 as its backend service. For that reason, see the Amazon S3 Source documentation for additional information about how the Amazon Security Lake Source handles data, including SQS messages.

Configure an Amazon Security Lake Source

In Cribl Stream, to set up an Amazon Security Lake Source:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this S3 Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Queue**: The name, URL, or Amazon Resource Name (ARN) of the SQS queue to read events from. When specifying a non-AWS URL, you must use the format: `{url}/<queueName>`. (For example: `https://host:port/<queueName>`.) This value must be a JavaScript expression (which can evaluate to a constant), enclosed in single quotes, double quotes, or backticks.
3. Next, you can configure the following **Optional Settings**:

- **Filename filter**: Regex matching file names to download and process. Defaults to `.*`, to match all characters. This regex will be evaluated against the S3 key's full path.
- **Region**: AWS Region where the S3 bucket and SQS queue are located. Required, unless the **Queue** entry is a URL or ARN that includes a Region.
- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. In the **Authentication** settings, select one of the following options from the menu:

Option	Description
Auto	This default option uses the AWS SDK for JavaScript to check for credentials in a specific order by priority. It first checks for IAM Roles for Amazon EC2, then a shared credentials file, then environmental variables, and so forth. See Authentication Settings for more information.
Manual	If not running on AWS, select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, such as those running a private cloud. See Authentication Settings for more information.
Secret	If not running on AWS, select this option to supply a stored secret that references an AWS access key and secret key. See Authentication Settings for more information.

5. If needed, configure the **AssumeRole** settings. You can use these settings to access resources in a different region than Cribl Stream. You can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. See Assume Role Settings for more information.
6. Optionally, refer to the following sections for the remaining settings:
   - Processing Settings
   - Advanced Settings
   - Connected Destinations
7. Select **Save**, then **Commit & Deploy**.
8. Verify that data is flowing correctly to Cribl Stream by viewing the **Live Data** feed from the Source.

Authentication Settings

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, such as those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

The values for **Access key** and **Secret key** can be a constant or a JavaScript expression (such as `${C.env.MY_VAR}`). Enclose values containing special characters (like, `/`) or using environment variables in single quotes or backticks.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select a secret key pair that you've configured in Cribl Stream's internal secrets manager or (if enabled) an external KMS. Follow the **Create** link if you need to configure a key pair.

Assume Role Settings

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for S3: Whether to use Assume Role credentials to access S3. Defaults to `Yes`.

Enable for SQS: Whether to use Assume Role credentials when accessing SQS. Defaults to `No`.

AWS account ID: SQS queue owner's AWS account ID. Leave empty if the SQS queue is in the same AWS account.

AssumeRole ARN: Enter the ARN of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

Enabled: Defaults to `No`. Toggle to `Yes` to enable the custom command.

Command: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).

Arguments: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

This section defines event breaking rulesets that will be applied, in order.

Event Breaker Rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Checkpoint Settings

Enable checkpointing: When toggled to `No` (the default) Cribl Stream will always start processing a file from the beginning. Toggle to `Yes` if, after an error or restart occurs, you want Cribl Stream to resume processing a given file from the point where it was interrupted, as explained below. When turned on, the following additional setting becomes available:

- **Retries**: The number of times you want Cribl Stream to retry processing a file after an error or restart occurs. If **Skip file on error** is enabled, this setting is ignored.

Other Settings

Endpoint: S3 service endpoint. If empty, defaults to AWS's region-specific endpoint. Otherwise, used to point to an S3-compatible endpoint. To access the AWS S3 endpoints, use the path-style URL format. You don't need to specify the bucket name in the URL, because Cribl Stream will automatically add it to the URL path. For details, see AWS' Path-Style Requests topic.

Signature version: Signature version to use for signing SQS requests. Defaults to `v4`.

Max messages: The maximum number of messages that SQS should return in a poll request. Amazon SQS never returns more messages than this value. (However, fewer messages might be returned.) Acceptable values: 1 to 10. Defaults to `1`.

Visibility timeout seconds: The duration (in seconds) that the received messages are hidden from subsequent retrieve requests, after being retrieved by a ReceiveMessage request. Defaults to `600`.

Cribl Stream will automatically extend this timeout until the initial request's files have been processed – notably, in the case of large files that require additional processing time.

Num receivers: The number of receiver processes to run. The higher the number, the better the throughput, at the expense of CPU overhead. Defaults to `1`.

Poll timeout (secs): How long to wait for events before polling again. Minimum `1` second; default `10`; maximum `20`. Short durations increase the number - and thus the cost – of requests sent to AWS. (The UI will show a warning for intervals shorter than `5` seconds.) Long durations increase the time the Source takes to react to configuration changes and system restarts.

Socket timeout: Socket inactivity timeout (in seconds). Increase this value if retrievals time out during backpressure. Defaults to `300` seconds.

Max Parquet chunk size (MB): Maximum size for each Parquet chunk. Defaults to `5` MB. Valid range is `1` to `100` MB. Cribl Stream stores chunks in the location specified by the `CRIBL_TMP_DIR` environment variable. It removes the chunks immediately after reading them.

Parquet chunk download timeout (seconds): The maximum time to wait for a Parquet file's chunk to be downloaded. If a required chunk cannot be downloaded within this time limit, processing will end. Defaults to `600` seconds. Valid range is `1` second to `3600` seconds (1 hour).

Skip file on error: Toggle to `Yes` to skip files that trigger a processing error (for example, corrupted files). Defaults to `No`, which enables retries after a processing error.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Encoding: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Checkpointing

When Workers restart, checkpointing can prevent the Source from losing data or collecting duplicate events. Among the situations where this works well:

- When Cribl Stream pushes a new configuration: the Leader pushes the configuration to the Workers, and restarts them.
- When a Worker has gotten into a bad state, and you want to restart it.

Checkpointing allows Cribl Stream to resume processing a file at the point where an error or restart occurred, minimizing the number of duplicate events sent downstream in the event of an interruption. To accomplish this, Cribl Stream keeps track of how many events have been processed for a given file. Resuming processing after an interruption, the Source skips the first *N* events it has seen and starts processing from event *N*+1.

The Source manages checkpoint information in memory, but writes it out to disk periodically (once per second, and on Worker shutdown) so that the information can survive a Worker restart. Cribl Stream keeps checkpoint information at the Worker Process level and does not share it between Worker Processes or Worker Nodes.

Checkpointing is a feature to keep in mind when you do disaster recovery (DR) planning.

Caveats to using checkpointing include: Whenever Worker Node state is destroyed (that is, when a Worker ceases to exist), checkpoint information will be lost. In Cribl.Cloud deployments, this can happen during upgrades. Also, because checkpoints are not written to disk on **every** event, the checkpoints written to disk will lag behind those that the S3 Source manages in memory. If the Worker Process stops abruptly without a clean shutdown, checkpoints not yet written to disk will be lost. When processing resumes, the Source will start from just after the last checkpoint written to disk, producing duplicate events corresponding to the lost checkpoints.

Located in the UI at **Advanced Settings** > **Checkpoint Settings** > **Enable checkpointing**, this feature is turned off by default.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__final`
- `__inputId`
- `__source`
- `_time`

Troubleshooting

Navigate to and open the Amazon Security Lake Source, then use the Source's **Job Inspector** tab to see the results of recent collection runs.

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

For More Information

The Amazon Security Lake Source functions nearly identically to the Amazon S3 Source. If needed, you can refer to the Amazon S3 Source documentation for information about:

- How to configure S3 to send event notifications to SQS.
- How Cribl Stream pulls data.
- Best practices.

15.1.2.5. Amazon SQS Source

Cribl Stream supports receiving events from Amazon Simple Queuing Service.

Type: **Pull** | TLS Support: **YES** (secure API) | Event Breaker Support: **No**

Configure Cribl Stream to Receive Data from Amazon SQS

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - ***Input ID**: Enter a unique name to identify this SQS Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Queue**: The name, URL, or ARN of the SQS queue to read events from. This value must be a JavaScript expression (which can evaluate to a constant), enclosed in single quotes, double quotes, or backticks. To specify a non-AWS URL, use the format: `'{url}/<queueName>'`. (For example, `':port/<myQueueName>'`.)
    - **Queue type**: The queue type used (or created). Defaults to `Standard`. `FIFO` (First In, First Out) is the other option.
3. Next, you can configure the following **Optional Settings**:
    - **Create queue**: If toggled to `Yes`, Cribl Stream will create the queue if it does not exist.
    - **Region**: AWS Region where the SQS queue is located. Required, unless the **Queue** entry is a URL or ARN that includes a Region.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, AssumeRole, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select a secret key pair that you've configured in Cribl Stream's internal secrets manager or (if enabled) an external KMS. Follow the **Create** link if you need to configure a key pair.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for SQS: Whether to use Assume Role credentials to access SQS. Defaults to `No`.

AWS account ID: SQS queue owner's AWS account ID. Leave empty if SQS queue is in same AWS account.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the external ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Endpoint: SQS service endpoint. If empty, the endpoint will be automatically constructed from the AWS Region.

Signature version: Signature version to use for signing SQS requests. Defaults to `v4`; `v2` is also available.

Max messages: The maximum number of messages that SQS should return in a poll request. Amazon SQS never returns more messages than this value. (However, fewer messages might be returned.) Acceptable values: `1` to `10`. Defaults to `10`.

Visibility timeout seconds: The duration (in seconds) that the received messages are hidden from subsequent retrieve requests, after they're retrieved by a `ReceiveMessage` request. Defaults to `600`.

Num receivers: The number of receiver processes to run. The higher the number, the better the throughput, at the expense of CPU overhead. Defaults to `3`.

Poll timeout (secs): How long to wait for events before polling again. Minimum `1` second; default `10`; maximum `20`. Short durations increase the number - and thus the cost – of requests sent to AWS. (The UI will show a warning for intervals shorter than `5` seconds.) Long durations increase the time the Source takes to react to configuration changes and system restarts.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to reject certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`, the restrictive option.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__final`

- `__inputId`
- `__raw`
- `__receivedTs`
- `__sqsMessageId`
- `__sqsReceiptHandle`
- `_time`

SQS Permissions

The following permissions are needed on the SQS queue:

- `sqs:ReceiveMessage`
- `sqs:DeleteMessage`
- `sqs:GetQueueAttributes`
- `sqs:GetQueueUrl`
- `sqs:CreateQueue` (optional, if and only if you want Cribl Stream to create the queue)

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

VPC endpoints for SQS might need to be set up in your account. Check with your administrator for details.

Common Issues

“Inaccessible host: ‘sqs.us-east-1.amazonaws.com’. This service may not be available…”

Full Error Text: `"message":"Inaccessible host: 'sqs.us-east-1.amazonaws.com'. This service may not be available in the 'us-east-1' region.","stack":"UnknownEndpoint: Inaccessible host: 'sqs.us-east-1.amazonaws.com'. This service may not be available in the 'us-east-1' region.`

If this is persistent rather than intermittent then it could be caused by TLS negotiation failures. For example, AWS SQS currently does not support TLS 1.3. If intermittent then a network-related issue could be occurring such as DNS-related problems.

How Cribl Stream Pulls Data

Workers poll messages from SQS. The call will return a message if one is available, or will time out after 1 second if no messages are available.

Each Worker gets its share of the load from SQS, and it receives a notification of a file newly added to an S3 bucket. By default, SQS returns a maximum of 10 messages in a single poll request.

15.1.3. Azure

15.1.3.1. Azure Blob Storage Source

Cribl Stream supports receiving data from Azure Blob Storage buckets. Cribl Stream uses Azure Event Grid to receive notifications, via a queue, when new blobs are added to a storage account.

Type: **Pull** | TLS Support: **YES** (secure API) | Event Breaker Support: **YES** Available in: Cribl Stream (LogStream) 2.4.4 and above.

Cribl Stream running on Linux (only) can use this Source to read Parquet files, identified by a `.parquet`, `.parq`, or `.pqt` filename extension.

For configuration examples, see Resources below.

Restrictions

Cribl Stream supports data ingestion from Azure's **hot** and **cool** access tiers, but not from the **archive** tier – whose stated retrieval lag, up to several hours, cannot guarantee data availability.

This Source supports block blobs, but not append blobs, which can change after they are initially created and the create message is sent. Consider using a Cribl Stream Azure Event Hubs Source if you need to ingest changeable Azure data.

Configure Cribl Stream to Receive Data from Azure Blob Storage

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Azure Blob Storage Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.

- **Queue**: The queue name from which to read Blob notifications. Value must be a JavaScript expression (which can evaluate to a constant value), enclosed in quotes or backticks. Can be evaluated only at init time. For example, referencing a Global Variable: `myQueue-${C.vars.myVar}`.

3. Under **Authentication**, select an **Authentication method** from the dropdown:
   - **Manual**: Use this default option to enter your Azure Storage connection string directly. Exposes a **Connection string** field for this purpose. (If left blank, Cribl Stream will fall back to `env.AZURE_STORAGE_CONNECTION_STRING`.)
   - **Secret**: This option exposes a **Connection string (text secret)** drop-down, in which you can select a stored secret that references an Azure Storage connection string. The secret can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need a new secret. For details, see Connection String Format.
   - **Client secret**: This option allows you to use the Azure service principal's client secret to authenticate, and exposes Azure service principal settings.
   - **Certificate**: This option allows you to use a certificate registered with the Azure service principal to authenticate, and exposes Azure service principal settings.
4. Next, you can configure the following **Optional Settings**:
   - **Filename filter**: Regex matching file names to download and process. Defaults to `.*`, to match all characters.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Connection String Format

Manual and **Secret** authentication methods use an Azure Storage connection string in this format:

```
DefaultEndpointsProtocol=[http|https];AccountName=<your-account-name>;AccountKey=<yo
```

A fictitious example, using Microsoft's recommended HTTPS option, is:

```
DefaultEndpointsProtocol=https;AccountName=storagesample;AccountKey=12345678...32;En
```

Service Principal Settings

Client secret and **Certificate** authentication methods expose the following additional settings:

- **Storage account name**: Enter the name of your Azure Storage Account.
- **Tenant ID**: Enter the service principal's tenant ID.
- **Client ID**: Enter the service principal's client ID.
- **Client secret (text secret)** (with **Client secret** method selected): Select a text secret containing the client secret, or create a new one.
- **Certificate** (with **Certificate** method selected): Select the certificate you registered as credentials for your app in the Azure portal, or create a new one.

Processing Settings

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

Enabled: Defaults to `No`. Toggle to `Yes` to enable the custom command.

Command: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).

Arguments: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

This section defines event breaking rulesets that will be applied, in order.

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Pipelines. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Max messages: The maximum number of messages to return in a poll request. Azure queues never return more messages than this value (although they might return fewer messages). Acceptable values: `1` to `32`.

Visibility timeout (secs): The duration (in seconds) that the received messages are hidden from subsequent retrieve requests, after being retrieved by a `ReceiveMessage` request. Defaults to `600` seconds. Maximum allowed value is `604800` seconds (7 days).

Cribl Stream will automatically extend this timeout until the initial request's files have been processed – notably, in the case of large files that require additional processing time.

Num receivers: The number of receiver processes to run. The higher the number, the better the throughput, at the expense of CPU overhead. Defaults to `1`.

Service period (secs): The interval (in seconds) at which pollers should be validated, and restarted if exited. Defaults to `5` seconds.

Skip file on error: Toggle to `Yes` to skip files that trigger a processing error (for example, corrupted files). Defaults to `No`, which enables retries after a processing error.

Max Parquet chunk size (MB): Maximum size for each Parquet chunk. Defaults to `5` MB. Valid range is `1` to `100` MB. Cribl Stream stores chunks in the location specified by the `CRIBL_TMP_DIR` environment variable. It removes the chunks immediately after reading them.

Parquet chunk download timeout (seconds): The maximum time to wait for a Parquet file's chunk to be downloaded. If a required chunk cannot not be downloaded within this time limit, processing will end. Defaults to `600` seconds. Valid range is `1` second to `3600` seconds (1 hour).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__accountName`
- `__final`
- `__inputId`
- `__source`
- `__topic`
- `_time`

The remainder of this topic covers required Azure-side configuration.

Configuring Azure Blob Notifications

This Source needs to receive Azure Event Grid notifications, via a queue, when new blobs are added to a storage account. This queue approach enables Cribl Stream to manage backpressure conditions and retries upon errors.

You will therefore need to enable notifications in the Azure portal. The basic flow is:

File upload → Blob container → Blob Created notification → Azure Queue Storage queue

To configure notifications from the Blob storage account in the Azure backend, there are three major steps, outlined below:

1. Create an Event Grid system topic.

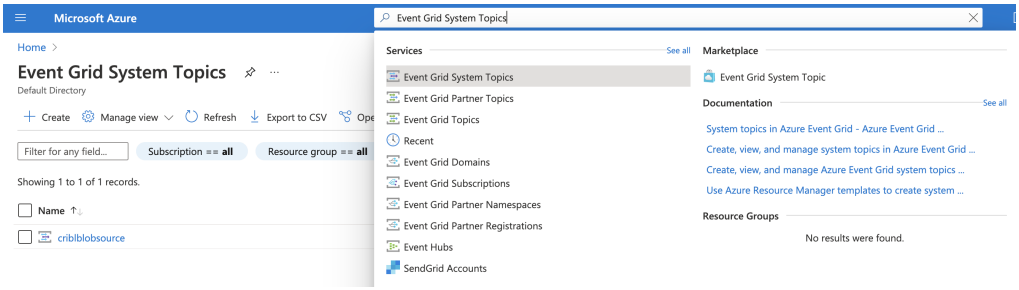
2. Create a queue.

3. Configure the generation of storage account notifications when new blobs are uploaded to the queue.

Azure's UI will change over time. Please fall back to Microsoft's Azure Event Grid documentation for up-to-date instructions and screenshots.

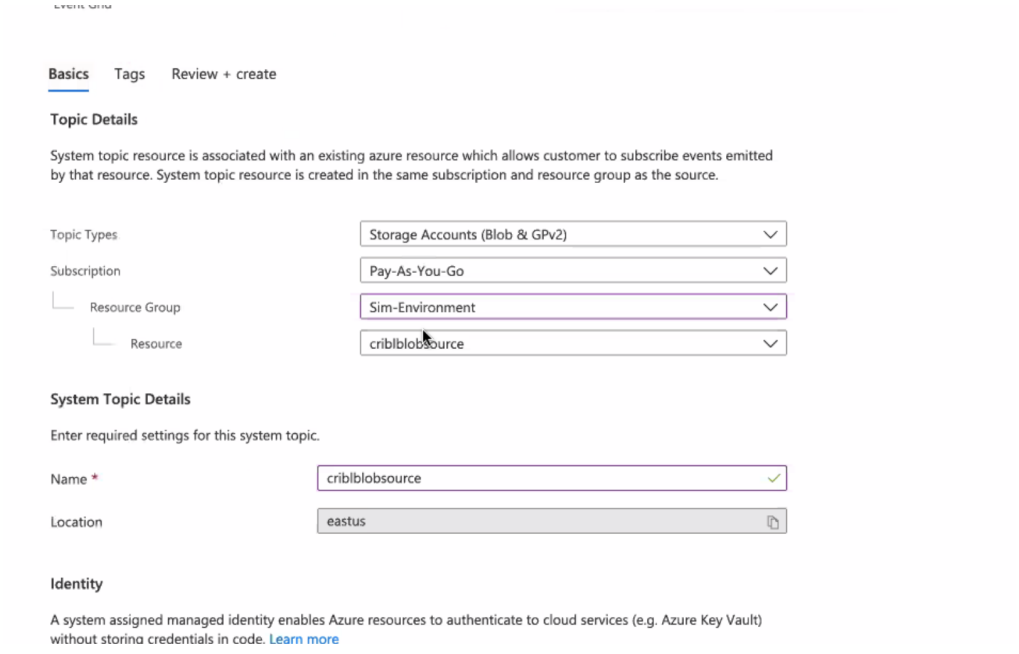
1. Create System Topic

First, you must create a system topic, to which Azure will publish notifications. In the Azure portal, start at **Event Grid System Topics**:



Azure portal > System topics

Select **+Create** to create a new system topic, then set the **Topic Type** to **Storage Account (Blob)**:



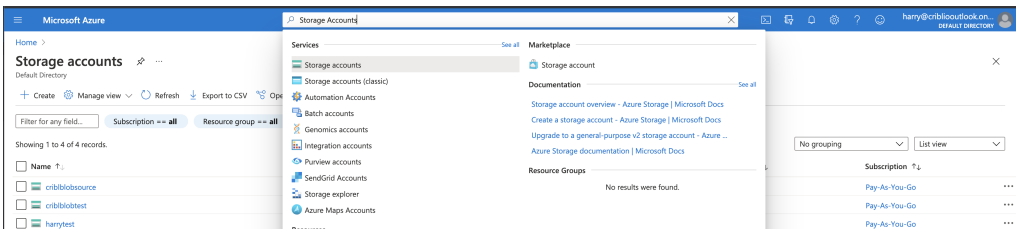
Creating a system topic

In **Subscription > Resource Group > Resource**, reference the storage account where you want to generate notifications.

Give the topic an arbitrary name that is meaningful to you. (In this example, the name is the same as the storage account.)

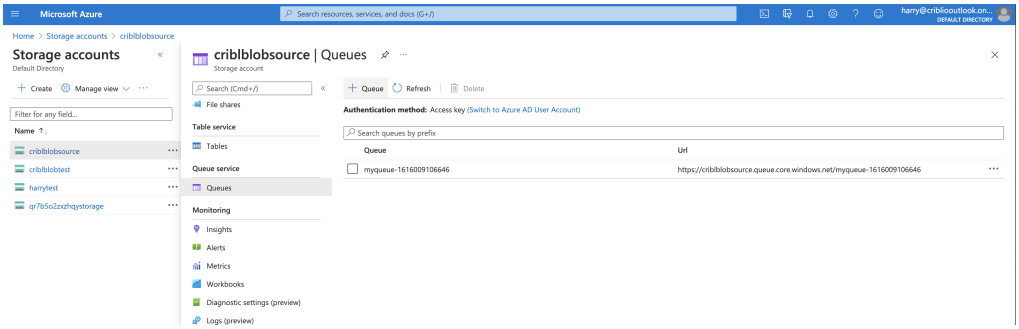
2. Create Storage Queue

Next, navigate to your storage account to create a queue.



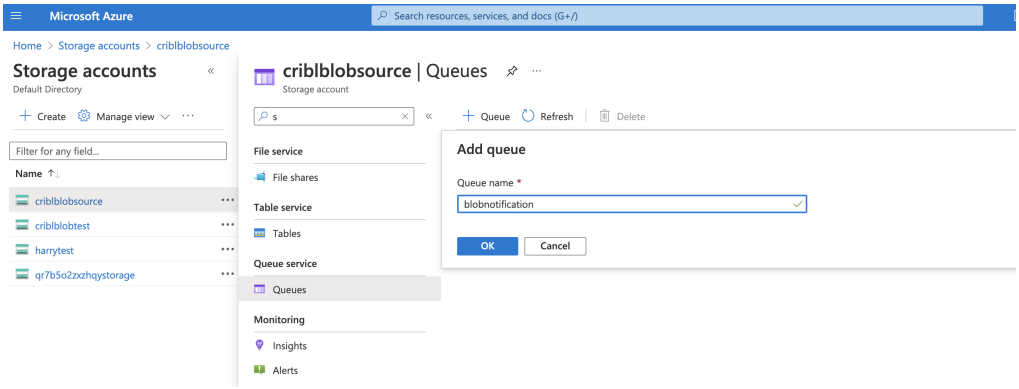
Accessing your storage account

Select the storage account for which you would like to set up notifications. Then, in the submenu, select **Queue service > Queues**:



Accessing queues

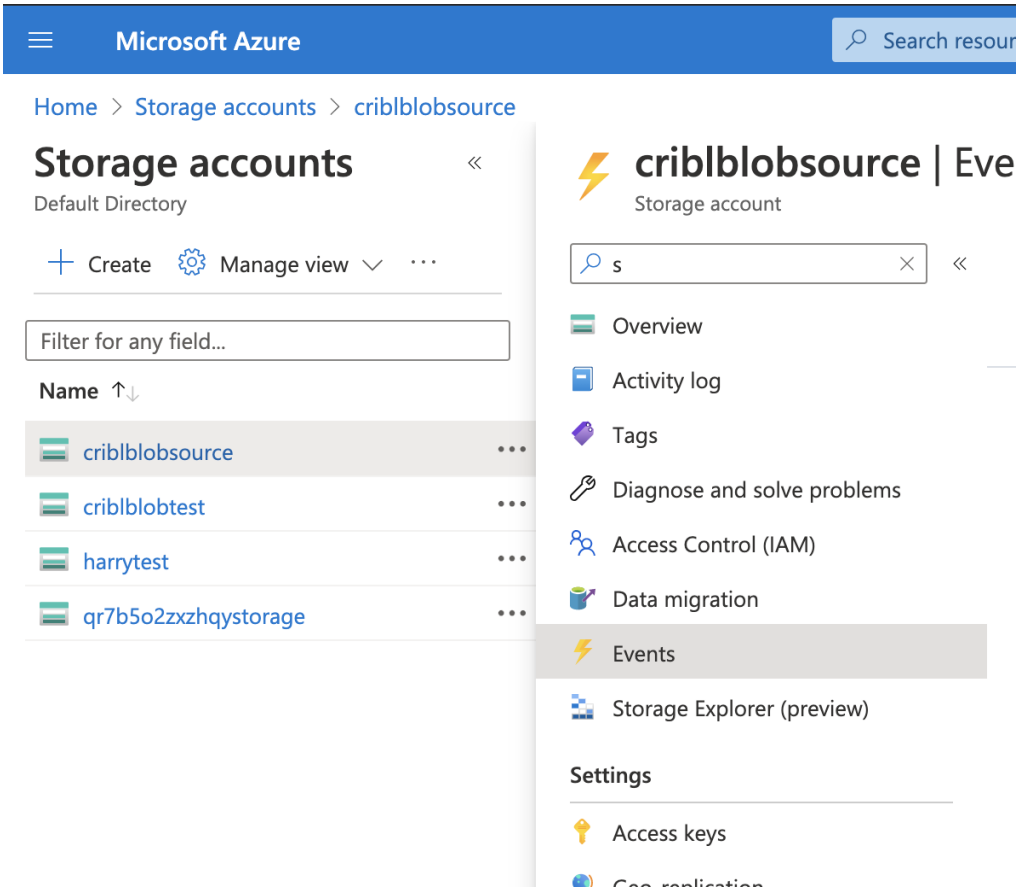
Select **Create queue**, and give the queue a name that is meaningful to you.



Adding a queue

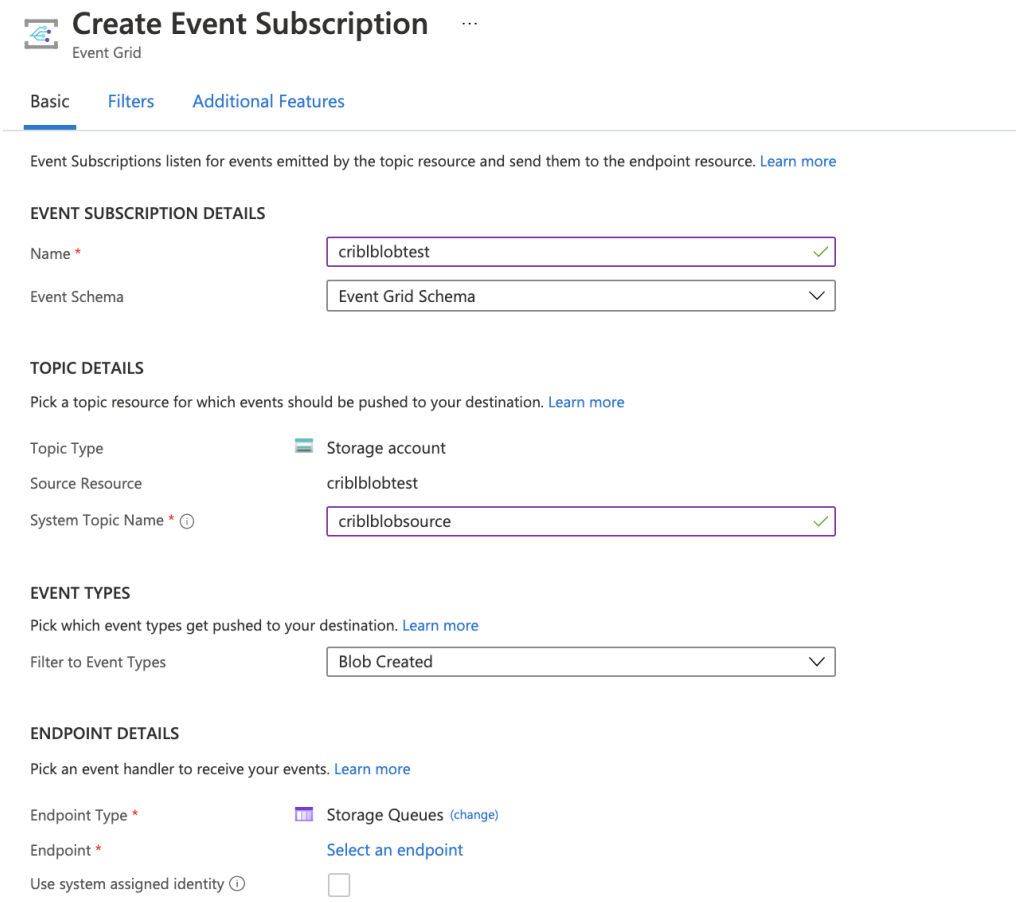
3. Configure Storage Account Notifications

Next, set up the storage account that will publish **Blob Create** notifications to the queue, using the system topic. From the **Storage Accounts** menu, select **Events**:



Accessing your storage account

Then click **+ Event Subscription** to proceed:

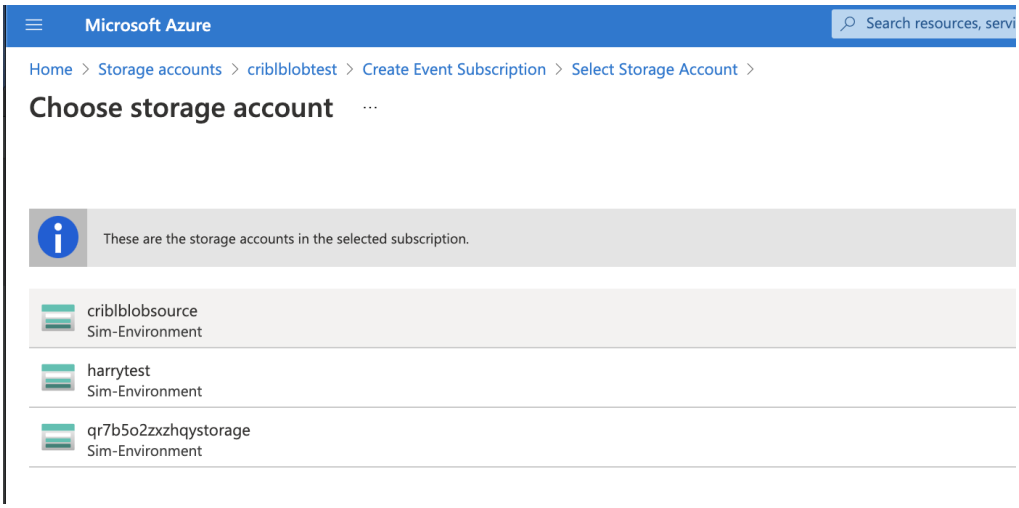


Creating a subscription.

There are a few things to configure here:

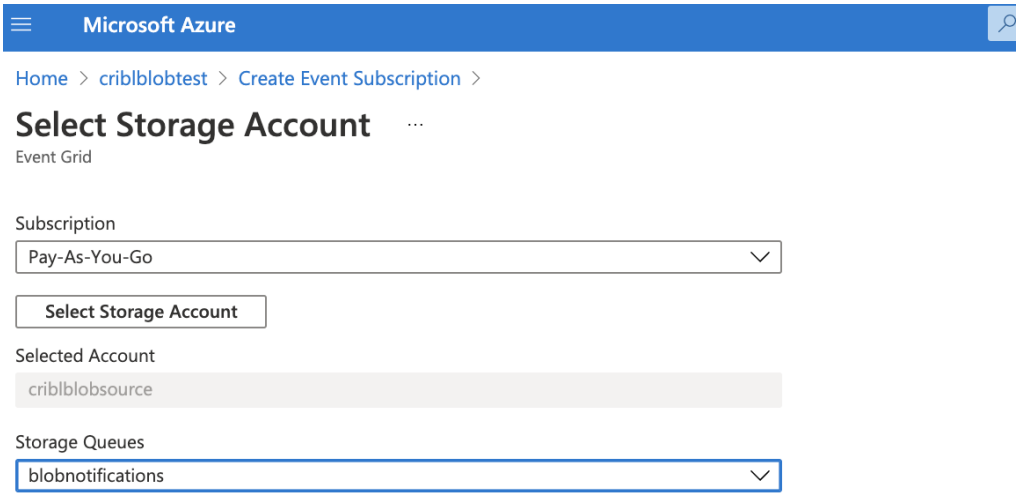
- Enter a **Name** for the subscription.
- In **System Topic Name**, enter the name of the system topic you created in 1. Create System Topic above.
- In **Event Types**, select **Blob Created**, and deselect **Blob Deleted**.
- As the **Endpoint Type**, select **Storage Queues**.
- Click **Select an endpoint**, and click the subscription to use (**Pay-As-You-Go**).

Next, select the storage account on which to add the subscription:



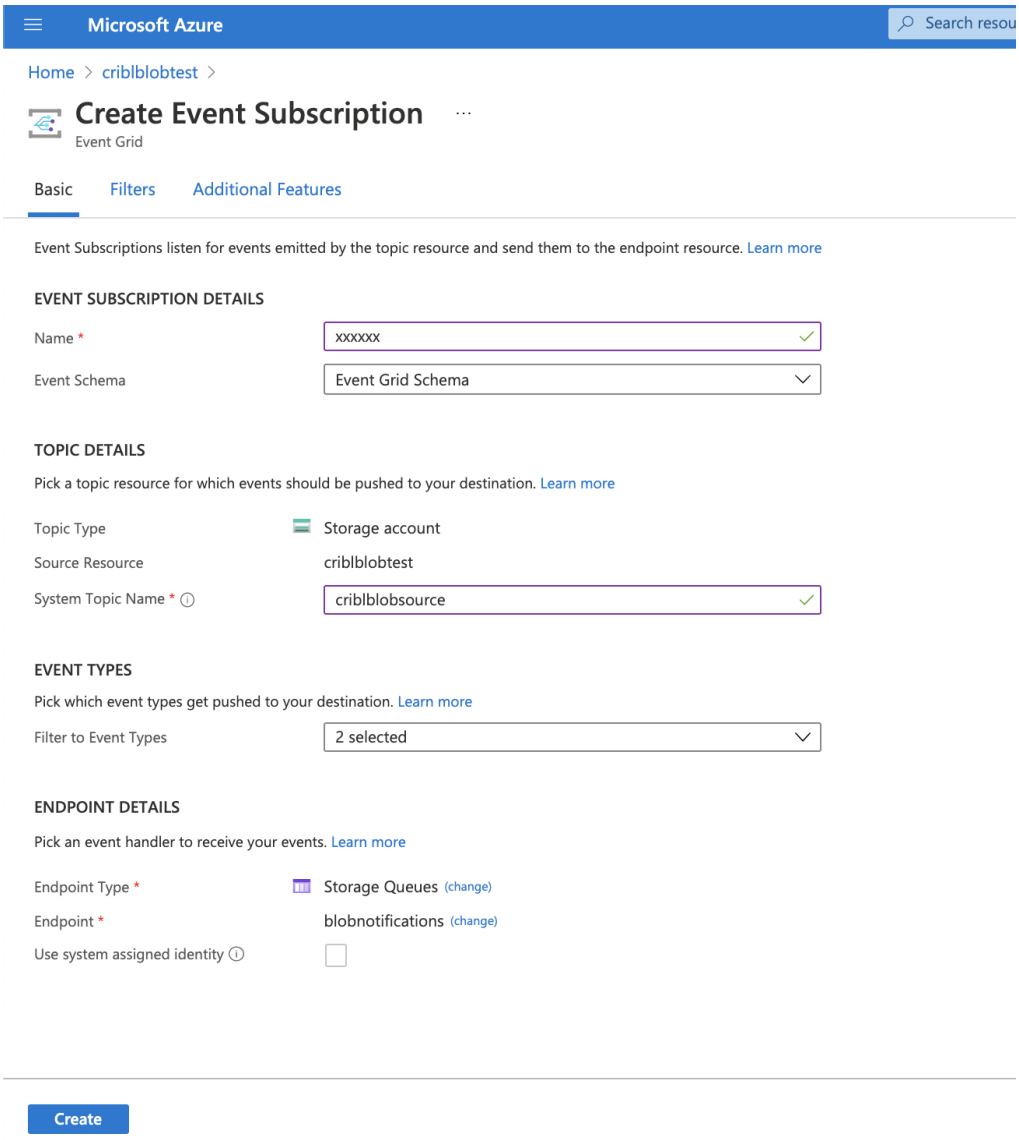
Choosing the storage account

Select the queue you created in Create Storage Queue above, and click **Confirm Selection** to save the settings.



Selecting the storage account

To complete the process, click **Create**.



Creating the subscription

How Cribl Stream Pulls Data

Workers poll messages from Azure Blob Storage using the Azure Event Grid Queue. The call will return a message if one is available, or will time out after 5 seconds if no messages are available.

Each Worker gets its share of the load from Azure Event Grid, and receives a notification of a new file added to an Azure Blob Storage bucket.

By default, the maximum number of messages Azure Event Grid returns in a single poll request is 1 per Worker Process.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Resources

For examples of configuring Cribl Stream to interoperate with Azure services, see these guides:

- SSO with Microsoft Entra ID and OIDC (On-Prem).
- SSO with Microsoft Entra ID and SAML (Cribl.Cloud).
- SSO with Microsoft Entra ID and SAML (On-Prem).

Also see these Packs on the Cribl Packs Dispensary, which provide processing Pipelines to transform and optimize incoming Azure data. You can directly import these Pipelines and adapt them to your needs:

- Microsoft Azure NSG Source to Common Schema.
- Azure NSG Flow Logs.
- Azure NSG Flow Logs to OCSF.
- Azure Audit Logs to OCSF.
- Microsoft Office Activity & Azure Logs.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.3.2. Azure Event Hubs Source

Cribl Stream supports receiving data records from Azure Event Hubs.

Type: **Pull** | TLS Support: **YES** (secure API) | Event Breaker Support: **No**

Azure Event Hubs uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Stream must receive events directly from senders. You might need to adjust your firewall rules to allow this traffic.

For configuration examples, see Resources below.

Configure Cribl Stream to Receive Data from Azure Event Hubs

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Brokers**: List of Event Hubs Kafka brokers to connect to – for example, `yourdomain.servicebus.windows.net:9093`. Get the hostname from the host portion of the primary or secondary connection string in Shared Access Policies. If omitted, the port will default to `9093`.
    - **Event Hub name**: The name of the Event Hub (a.k.a. Kafka Topic) to subscribe to.
3. Next, you can configure the following **Optional Settings**:
    - **Filename filter**: Regex matching file names to download and process. Defaults to `.*`, to match all characters.
    - **Group ID**: The name of the consumer group that includes this Cribl Stream instance. Defaults to `Cribl`.
    - **From beginning**: Whether to start reading from the earliest available data. Relevant only during initial subscription. Defaults to `Yes`.

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the TLS, Authentication, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

To prevent excessive Kafka rebalancing and reduced throughput, each **Group ID** that you specify here should be subscribed to only one Kafka Topic – that is, only to the single Topic you specify in **Event Hub name**. This has a few implications:

- The **Group ID** should be something other than `$Default`, especially if Event Hubs are stored In shared accounts, where the `$Default` group might be subscribed to other Topics.
- The **Group ID** should also be unique for each of your Azure Event Hubs, Kafka, and Confluent Cloud Sources.
- You should configure a **separate** Azure Event Hubs Source for each Group:Topic pair whose events you want to subscribe to.

For details, see Controlling Rebalancing.

TLS Settings (Client Side)

Enabled: Defaults to `Yes`.

Validate server certs: Whether to reject connections to servers without signed certificates. Defaults to `Yes`.

Authentication Settings

Enabled: With the default `Yes` setting, this section's remaining settings are displayed, and all are required settings.

SASL mechanism: SASL (Simple Authentication and Security Layer) authentication mechanism to use with Kafka brokers. Defaults to `PLAIN`, which exposes Basic Authentication options that rely on Azure Event Hubs connection strings. Select `OAUTHBEARER` to enable OAuth Authentication via a different set of options.

Basic Authentication

Selecting the `PLAIN` SASL mechanism provides the options listed in this section.

Username: The username for authentication. For Event Hubs, this should always be `$ConnectionString`.

Authentication method: Use the buttons to select one of these options:

- **Manual**: Use this default option to enter your Event Hubs connection string's primary or secondary key from the Event Hubs workspace. Exposes a **Password** field for this purpose.
- **Secret**: This option exposes a **Password (text secret)** drop-down, in which you can select a stored secret that references an Event Hubs connection string. The secret can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need a new secret.

Connection String Format

Either authentication method above uses an Azure Event Hubs connection string in this format:

```
Endpoint=sb://<FQDN>/;SharedAccessKeyName=<your-shared-access-key-name>;SharedAccessKey=<your-shared-access-key-value>
```

A fictitious example is:

```
Endpoint=sb://dummynamespace.servicebus.windows.net/;SharedAccessKeyName=DummyAccessKeyN
```

OAuth Authentication

Selecting the `OAUTHBEARER` SASL mechanism provides the options listed in this section.

Microsoft Entra ID authentication endpoint: Specifies the Microsoft Entra ID endpoint from which to acquire authentication tokens. Defaults to `https://login.microsoftonline.com`. You can instead select `https://login.microsoftonline.us` or `https://login.partner.microsoftonline.cn`.

Client ID: Enter the `client_id` to pass in the OAuth request parameter.

Tenant identifier: Enter your Microsoft Entra ID subscription's directory ID (tenant ID).

Scope: Enter the scope to pass in the OAuth request parameter. This will be of the form: `https://<Event-Hubs-Namespace-Host-name>/.default`. (For example, for an Event Hubs Namespace > Host name: `goatyoga.servicebus.windows.net`, **Scope**: `https://goatyoga.servicebus.windows.net/.default`.)

Authentication method: Use the buttons to select one of these options:

- **Manual**: This default option exposes a **Client secret** field, in which to directly enter the `client_secret` to pass in the OAuth request parameter.
- **Secret**: Exposes a **Client secret (text secret)** drop-down, in which you can select a stored secret that references the `client_secret`. A **Create** link is available to define a new secret.

- **Certificate**: Exposes a **Certificate name** drop-down, in which you can select a stored certificate. A **Create** link is available to define a new cert.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Max retries: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2-20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For

example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Use these settings to fine-tune Cribl Stream's integration with Event Hubs Kafka brokers. For details, see Azure Event Hubs' recommended configuration documentation. If you are unfamiliar with these parameters, contact Cribl Support to understand the implications of changing the defaults.

Heartbeat interval (ms): Expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. (Corresponds to `heartbeat.interval.ms` in the Kafka domain.) Value must be lower than `sessionTimeout`, and typically should not exceed 1/3 of the `sessionTimeout` value. Defaults to `3000` ms (3 seconds).

Session timeout (ms): Timeout used to detect client failures when using Kafka's group management facilities. (Corresponds to `session.timeout.ms` in the Kafka domain.) If the client sends the broker no heartbeats before this timeout expires, the broker will remove this client from the group, and will initiate a rebalance. Value must be lower than `rebalanceTimeout`. Defaults to `30000` ms (30 seconds).

Rebalance timeout (ms): Maximum allowed time for each worker to join the group after a rebalance has begun. (Corresponds to `rebalance.timeout.ms` in the Kafka domain.) If this timeout is exceeded, the coordinator broker will remove the worker from the group. Defaults to `60000` ms (1 minute).

Connection timeout (ms): Maximum time to wait for a successful connection. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour).

Request timeout (ms): Maximum time to wait for a successful request. Defaults to `60000` ms (1 minute).

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Stream initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Source from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Source to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Offset commit interval (ms): How often, in milliseconds, to commit offsets. If both this field and the **Offset commit threshold** are empty, Cribl Stream will commit offsets after each batch. If both fields are set, Cribl Stream will commit offsets when either condition is met.

Offset commit threshold: The number of events that will trigger an offset commit. If both this field and the **Offset commit interval** are empty, Cribl Stream will commit offsets after each batch. If both fields are set, Cribl Stream will commit offsets when either condition is met.

Max bytes per partition: The maximum amount of data that the server will return per partition. Must equal or exceed the maximum message size the server allows. (Otherwise, the producer will be unable to send messages larger than the consumer can fetch.) If not specified, defaults to `1048576`.

Max bytes: Maximum amount of bytes to accumulate in the response. The default is `10485760 (10 MB)`.

Maximum number of errors per socket: Maximum number of consecutive request errors that can occur on a single socket connection before the connection is discarded and reestablished. This mitigates issues with idle connections, particularly those used for sending heartbeats, thereby reducing the number of rebalances in a consumer group. Default is `0`, which disables this feature. Accepts values `1-100`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Minimize duplicates: Optionally, toggle to `Yes` to start only one consumer for each topic partition. This reduces duplicates.

If you observe an excessive number of group rebalances, and/or you observe consumers not regularly pulling messages, try increasing the values of **Heartbeat interval**, **Session timeout**, and **Rebalance timeout**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__topicIn` (indicates the Kafka topic that the event came from)
- `__partition`
- `__schemaId` (when using Azure Schema Registry)
- `__key` (when using Schema Registry)
- `__headers` (when using Schema Registry)
- `__keySchemaIdIn` (when using Schema Registry)
- `__valueSchemaIdIn` (when using Schema Registry)

How Cribl Stream Pulls Data

Azure Event Hubs treat all the Worker Nodes as members of a Consumer Group, and each Worker gets its share of the load from Azure Event Hubs. This is the same process as normal Kafka. By default, Workers will poll every 5 seconds. In the case of Leader failure, Worker Nodes will continue to receive data as normal.

Randomized Partition Assignment

In Cribl Stream v.4.8.2 and newer, partition assignment is randomized. The Worker Processes selected to consume data during partition assignment are selected randomly, reducing the possibility of uneven load distribution when there are fewer partitions than Worker Processes. Note that *random* assignment is not the same as *balanced* assignment, and even distribution of work is not guaranteed.

Controlling Rebalancing

When you configure multiple Sources that subscribe to different topics, but all belong to the same consumer group, a state change affecting any Source in this consumer group will affect all the other Sources. Examples of state changes include: deploying new configs, adding or removing Worker Processes, or Worker Processes crashing.

Here's an example – three Sources, three different topics, all in one consumer group:

- `Source_1 - Topic_1 - ConsumerGroup1`
- `Source_2 - Topic_2 - ConsumerGroup1`
- `Source_3 - Topic_3 - ConsumerGroup1`

Imagine that Source 1 undergoes a state change event, such as a Worker Process crash. Source 2 and Source 3 will rebalance – stopping data flow until the rebalance completes.

Shared Worker Group Mitigation

If Sources that share a consumer group all deploy as part of the same Worker Group, changes will have smaller side effects than when Sources are spread across different Worker Groups. (Conversely, imagine a configuration where deploying new configs for Worker Group 1 caused rebalancing of topics in worker Worker Group 2. This spillover would be especially undesirable.)

Bottom Line

Changes to any member of a consumer group affect all other members of that consumer group. To prevent this undesired behavior, make sure to use a unique **Group ID** for each Kafka, Confluent Cloud, and Azure Event Hubs Source.

Resources

For examples of configuring Cribl Stream to interoperate with Azure services, see these guides:

- Azure Event Hubs Integrations.
- SSO with Microsoft Entra ID and OIDC (On-Prem).
- SSO with Microsoft Entra ID and SAML (Cribl.Cloud).
- SSO with Microsoft Entra ID and SAML (On-Prem).

Also see these Packs on the Cribl Packs Dispensary, which provide processing Pipelines to transform and optimize incoming Azure data. You can directly import these Pipelines and adapt them to your needs:

- Microsoft Azure NSG Source to Common Schema.
- Azure NSG Flow Logs.
- Azure NSG Flow Logs to OCSF.
- Azure Audit Logs to OCSF.
- Microsoft Office Activity & Azure Logs.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

KafkaJSProtocolError: Not authorized to access topics: [Topic authorization failed]

The username does not have read permissions for the specified topic.

15.1.4. Google Cloud

15.1.4.1. Google Cloud Pub/Sub Source

Cribl Stream supports receiving data records from Google Cloud Pub/Sub, a managed real-time messaging service for sending and receiving messages between applications.

Type: **Pull** | TLS Support: **YES** (secure API) | Event Breaker Support: **No**

Prerequisites

When working with Google Cloud Pub/Sub, you need to know:

- The project where your credentials originated.
- The project that contains any topic and subscription you want to work with.

If the desired topic and subscription reside in the same project where your credentials originated, describe them using either short names **or** fully-qualified names.

If the desired topic and subscription reside in a different project than the one where your credentials originated, you **must** describe them using fully-qualified names.

Here's an example of a fully-qualified topic name: `projects/my-project-id/topics/my-topic-id`.

The short name for the same topic would be: `my-topic-id`.

Configure Cribl Stream to Receive Data from Pub/Sub

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.

- **Input ID**: Enter a unique name to identify this Pub/Sub Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
- **Description**: Optionally, enter a description.
- **Topic ID**: ID of the Pub/Sub topic from which to receive events.
- **Subscription ID**: ID of the subscription to use when receiving events.

3. Next, you can configure the following **Optional Settings**:
   - **Create topic**: If toggled to `Yes`, Cribl Stream will create the topic on Pub/Sub if it does not exist.
   - **Create subscription**: If set to `Yes` (the default), Cribl Stream will create the subscription on Pub/Sub if it does not exist.
   - **Ordered delivery**: If toggled to `Yes`, Cribl Stream will receive events in the order that they were added to the queue. For ordered delivery to work correctly, ensure that both the process receiving events and the subscription from which messages are read have ordered delivery enabled.
   - **Region**: Region to retrieve messages from. Select `default` to allow Google to auto-select the nearest region. (If you've enabled **Ordered delivery**, the selected region must be allowed by message storage policy.)
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication method** drop-down to select a Google authentication method:

- **Auto**: This option uses the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to provide the location of a credential JSON file. The environment variable can also be set directly in JSON format. When this option is set, Cribl Stream will first check whether the `GOOGLE_APPLICATION_CREDENTIALS` environment variable exists and properly set with valid credentials. If this environmental variable is missing or incorrect, @ß{product} checks for credentials in two additional fallback locations, as described in the official Google Cloud documentation: How Application Default Credentials works. In addition to using the `GOOGLE_APPLICATION_CREDENTIALS` environment variable, you can use credentials attached to your Google Cloud instance.
- **Manual**: With this default option, you use the **Service account credentials** field to enter the contents of your service account credentials file (a set of JSON keys), as downloaded from Google Cloud. To insert the file itself, click the upload button at this field's upper right. As an alternative, you can use environment variables, as outlined here.

- **Secret**: Use the drop-down to select a key pair that you've configured in Cribl Stream's internal secrets manager or (if enabled) an external KMS.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Max backlog: When the Destination exerts backpressure, this setting limits the number of events that Cribl Stream will queue for processing before it stops retrieving further events. Defaults to `1000` events.

Number of concurrent streams: How many streams to pull messages from at one time. Doubling the value doubles the number of messages this Source pulls from the topic (if available), while consuming more CPU and memory. Defaults to `5`.

Request timeout (ms): Pull request timeout, in milliseconds. Defaults to `60000` ms (i.e., 1 minute).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__messageId` – ID of the message from Google.
- `__projectId` – ID of the Google project from which the data was received.
- `__publishTime` – Time at which the event was originally published to the Pub/Sub topic.
- `__subscriptionIn` – The subscription from which the event was received.
- `__topicIn` – The topic from which the event was received.

Google Cloud Roles and Permissions

Your Google Cloud service account should have at least the following roles on subscriptions:

- `roles/pubsub.subscriber`
- `roles/pubsub.viewer` or `roles/viewer`

As an alternative, you can rely on the following discrete permissions, which are included in the above roles:

- `pubsub.snapshots.seek`
- `pubsub.subscriptions.consume`
- `pubsub.topics.attachSubscription`

To enable Cribl Stream's **Create topic** and/or **Create subscription** options, your service account should have one of the following (or higher) roles:

- `roles/pubsub.editor`
- `roles/editor`

Either `editor` role confers multiple permissions, including those from the lower `viewer`, `subscriber`, and `publisher` roles. For additional details, see the Google Cloud Access Control topic.

How Cribl Stream Pulls Data

Pub/Sub treats all the Worker Nodes as members of a Consumer Group, and each Worker gets its share of the load from Pub/Sub. This is the same process as normal Kafka. By default, Workers will poll every 1 minute. In the case of Leader failure, Worker Nodes will continue to receive data as normal.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.5. Kafka

15.1.5.1. Kafka Source

Cribl Stream supports receiving data records from a Kafka cluster. This Source automatically detects compressed data in `Gzip`, `Snappy`, or `LZ4` format, and automatically decompresses the data upon ingesting it.

Type: **Pull** | TLS Support: **YES** | Event Breaker Support: **No**

Kafka uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Stream must receive events directly from senders. You might need to adjust your firewall rules to allow this traffic.

Configure Cribl Stream to Receive Data from Kafka Topics

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Brokers**: List of Kafka brokers to use, for example, `localhost:9092`.
    - **Topics**: Enter the name(s) of topics to subscribe to. Press `Enter/Return` between multiple entries.

    To optimize performance and prevent excessive rebalancing, Cribl recommends subscribing each Kafka Source to only one topic. To subscribe to multiple topics, consider creating a dedicated Kafka Source for each one.

    For the same reason, the **Group ID** (below) should be unique for each of your Kafka, Confluent Cloud, and Azure Event Hubs Sources. For details, see Controlling Rebalancing.
3. Next, you can configure the following **Optional Settings**:

- **Group ID**: The name of the consumer group to which this Cribl Stream instance belongs.
- **From beginning**: Whether to start reading from the earliest available data. Relevant only during initial subscription. Defaults to `Yes`.
- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the TLS, Authentication, Schema Registry, Processing, Retries, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Client Side)

Enabled: defaults to `No`. When toggled to `Yes`:

Autofill?: This setting is experimental.

Validate client certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `No`.

Server name (SNI): Leave this field blank. See Connecting to Kafka below.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Authentication

This section documents the SASL (Simple Authentication and Security Layer) authentication settings to use when connecting to brokers. Using TLS is highly recommended.

Enabled: Defaults to `No`. When toggled to `Yes`:

SASL mechanism: Use this drop-down to select the SASL authentication mechanism to use. The mechanism you select determines the controls displayed below.

PLAIN, SCRAM-256, or SCRAM-512

With any of these authentication mechanisms, select one of the following buttons:

Manual: Displays **Username** and **Password** fields to enter your Kafka credentials directly.

Secret: This option exposes a **Credentials secret** drop-down in which you can select a stored text secret that references your Kafka credentials. A **Create** link is available to store a new, reusable secret.

GSSAPI/Kerberos

Kerberos authentication is not supported for Cribl-managed Workers in Cribl.Cloud, but it is enabled for customer-managed (hybrid or on-prem) Worker Groups, whether the Leader is based in Cribl.Cloud or on-prem.

Selecting Kerberos as the authentication mechanism displays the following options:

Keytab location: Enter the location of the keytab file for the authentication principal.

Principal: Enter the authentication principal, for example: `kafka_user@example.com`.

Broker service class: Enter the Kerberos service class for Kafka brokers, for example: `kafka`.

You will also need to set up your environment and configure the Cribl Stream host for use with Kerberos. For details, see Kafka Authentication with Kerberos.

Schema Registry

This section governs Kafka Schema Registry authentication for Avro-encoded data with a schema stored in the Confluent Schema Registry.

Enabled: Defaults to `No`. When toggled to `Yes`, displays the following controls:

Schema registry URL: URL for access to the Confluent Schema Registry (for example, `http://<hostname>:8081`).

Connection timeout (ms): Specifies the maximum time allowed for establishing a successful connection to the schema registry. Defaults to 30000 ms (30 seconds). Valid range is 1000 ms - 60000 ms (or 1 sec to 60 sec).

Request timeout (ms): Maximum time to wait for a successful request from the schema registry. Defaults to 60000 ms (or 1 minute).

Retry Limit: Max number of times to retry requests to the schema registry before dropping the outgoing message. Defaults to 1; enter 0 to not retry at all.

Authentication enabled: Toggle to `Yes` if your schema registry requires authentication.

- **Credentials secret**: Select or **Create** a stored text secret containing the username and password provided by your schema registry administrator.

TLS enabled: When toggled to `Yes`, displays the following TLS settings for the Schema Registry.

These have the same format as the TLS Settings (Client Side) above.

- **Validate server certs**: Require client to reject any connection that is not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `No`.
- **Server name (SNI)**: Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.
- **Minimum TLS version**: Optionally, select the minimum TLS version to use when connecting.
- **Maximum TLS version**: Optionally, select the maximum TLS version to use when connecting.
- **Certificate name**: The name of the predefined certificate.
- **CA certificate path**: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.
- **Private key path (mutual auth)**: Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.
- **Certificate path (mutual auth)**: Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.
- **Passphrase**: Passphrase to use to decrypt private key.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Max retries: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2–20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Use these settings to fine-tune Cribl Stream's integration with Kafka topics. If you are unfamiliar with these parameters, contact Cribl Support to understand the implications of changing the defaults.

Heartbeat interval (ms): Expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Value must be lower than `sessionTimeout`, and typically should not exceed 1/3 of the `sessionTimeout` value. Defaults to `3000` ms (3 seconds). For details, see the Kafka documentation.

Session timeout (ms): Timeout used to detect client failures when using Kafka's group management facilities. If the client sends the broker no heartbeats before this timeout expires, the broker will remove this client from the group, and will initiate a rebalance. Value must be between the broker's configured `group.min.session.timeout.ms` and `group.max.session.timeout.ms`. Defaults to `30000` ms (30 seconds). For details, see the Kafka documentation.

Rebalance timeout (ms): Maximum allowed time for each worker to join the group after a rebalance has begun. If the timeout is exceeded, the coordinator broker will remove the worker from the group. Defaults to `60000` ms (1 minute). For details, see the Kafka documentation.

Connection timeout (ms): Maximum time to wait for a successful connection. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour). For details, see the Kafka documentation.

Request timeout (ms): Maximum time to wait for a successful request. Defaults to `60000` ms (1 minute). For details, see the Kafka documentation.

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Stream initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Source from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Source to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Offset commit interval (ms): How often, in milliseconds, to commit offsets. If both this field and the **Offset commit threshold** are empty, Cribl Stream will commit offsets after each batch. If both fields are set, Cribl Stream will commit offsets when either condition is met.

Offset commit threshold: The number of events that will trigger an offset commit. If both this field and the **Offset commit interval** are empty, Cribl Stream will commit offsets after each batch. If both fields are set,

Cribl Stream will commit offsets when either condition is met.

Max bytes per partition: The maximum amount of data that the server will return per partition. Must equal or exceed the maximum message size the server allows. (Otherwise, the producer will be unable to send messages larger than the consumer can fetch.) If not specified, defaults to `1048576`.

Max bytes: Maximum amount of bytes to accumulate in the response. The default is `10485760 (10 MB)`.

Maximum number of errors per socket: Maximum number of consecutive request errors that can occur on a single socket connection before the connection is discarded and reestablished. This mitigates issues with idle connections, particularly those used for sending heartbeats, thereby reducing the number of rebalances in a consumer group. Default is `0`, which disables this feature. Accepts values `1-100`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

If you observe an excessive number of group rebalances, and/or you observe consumers not regularly pulling messages, try increasing the values of **Heartbeat interval**, **Session timeout**, and **Rebalance timeout**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Connecting to Kafka

Leave the TLS Settings > Server name (SNI) field blank

In Cribl Stream's Kafka-based Sources and Destinations (including this one), the Kafka library that Cribl Stream uses manages SNI (Server Name Indication) without any input from Cribl Stream. Therefore, you should leave the **TLS Settings** > **Server name (SNI)** field blank.

Setting this field in the Cribl Stream UI can cause traffic to be routed to the wrong brokers, because it interferes with the Kafka library's operation.

Connecting to a Kafka cluster entails working with hostnames for **brokers** and **bootstrap servers**.

Brokers are servers that comprise the storage layer in a Kafka cluster. Bootstrap servers handle the initial connection to the Kafka cluster, and then return the list of brokers. A broker list can run into the hundreds. Every Kafka cluster has a `bootstrap.servers` property, defined as either a single `hostname:port` K-V pair, or a list of them. If Cribl Stream tries to connect via one bootstrap server and that fails, Cribl Stream then tries another one on the list.

In the **General Settings** > **Brokers** list, you can enter either the hostnames of brokers that your Kafka server has been configured to use, or, the hostnames of one or more bootstrap servers. If Kafka returns a list of brokers that's longer than the list you entered, Cribl Stream keeps the full list internally. Cribl Stream neither saves the list nor makes it available in the UI. The connection process simply starts at the beginning whenever the Source or Destination is started.

Here's an overview of the connection process:

1. From the **General Settings** > **Brokers** list – where each broker is listed as a hostname and port – Cribl Stream takes a hostname and resolves it to an IP address.
2. Cribl Stream makes a connection to that IP address. Notwithstanding the fact that Cribl Stream resolved **one** particular hostname to that IP address, there may be **many** services running at that IP address – each with its own distinct hostname.
3. Cribl Stream establishes TLS security for the connection.

Although SNI is managed by the Kafka library rather than in the Cribl Stream UI, you might want to know how it fits into the connection process. The purpose of the SNI is to specify one hostname – that is, service – among many that might be running on a given IP address within a Kafka cluster. Excluding the other services is one way that TLS makes the connection more secure.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__final`
- `__headers` (when present in the record)
- `__inputId`
- `__key` (when using Schema Registry)
- `__keySchemaIdIn` (when using Schema Registry)
- `__origTime`
- `__partition`

- `__raw`
- `__schemaId` (when using Schema Registry)
- `__topicIn` (indicates the Kafka topic that the event came from; see `__topicOut` in our Kafka Destination documentation)
- `__valueSchemaIdIn` (when using Schema Registry)
- `_raw`
- `_time`

How Cribl Stream Pulls Data

Kafka treats all the Worker Nodes as members of a Consumer Group, and Kafka manages each Node's data load. By default, Workers will poll every 5 seconds. In the case of Leader failure, Worker Nodes will continue to receive data as normal.

How Cribl Stream Handles the `_time` Field

Events that the Kafka Source emits always contain a `_time` field, and sometimes also an `__origTime` field. Here's how Cribl Stream determines what to send:

- If the incoming Kafka message contains no `_time` field, the message's timestamp becomes the value of the emitted event's `_time` field.
- If the incoming Kafka message contains a `_time` field whose value is a timestamp in UNIX epoch time, that timestamp becomes the value of the emitted event's `_time` field.
- If the incoming Kafka message contains a `_time` field whose value is **not** a timestamp in UNIX epoch time (such as an ISO or UTC timestamp), that becomes the value of the emitted event's `__origTime` field, **and** the message's timestamp becomes the value of the emitted event's `_time` field.

Randomized Partition Assignment

In Cribl Stream v.4.8.2 and newer, partition assignment is randomized. The Worker Processes selected to consume data during partition assignment are selected randomly, reducing the possibility of uneven load distribution when there are fewer partitions than Worker Processes. Note that *random* assignment is not the same as *balanced* assignment, and even distribution of work is not guaranteed.

Controlling Rebalancing

When you configure multiple Sources that subscribe to different topics, but all belong to the same consumer group, a state change affecting any Source in this consumer group will affect all the other Sources. Examples of state changes include: deploying new configs, adding or removing Worker Processes, or Worker Processes crashing.

Here's an example – three Sources, three different topics, all in one consumer group:

- `Source_1 - Topic_1 - ConsumerGroup1`
- `Source_2 - Topic_2 - ConsumerGroup1`
- `Source_3 - Topic_3 - ConsumerGroup1`

Imagine that Source 1 undergoes a state change event, such as a Worker Process crash. Source 2 and Source 3 will rebalance – stopping data flow until the rebalance completes.

Shared Worker Group Mitigation

If Sources that share a consumer group all deploy as part of the same Worker Group, changes will have smaller side effects than when Sources are spread across different Worker Groups. (Conversely, imagine a configuration where deploying new configs for Worker Group 1 caused rebalancing of topics in worker Worker Group 2. This spillover would be especially undesirable.)

Bottom Line

Changes to any member of a consumer group affect all other members of that consumer group. To prevent this undesired behavior, make sure to use a unique **Group ID** for each Kafka, Confluent Cloud, and Azure Event Hubs Source.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

KafkaJSProtocolError: Not authorized to access topics: [Topic authorization failed]

The username does not have read permissions for the specified topic.

15.1.5.2. Confluent Cloud Source

Cribl Stream supports receiving Kafka topics from the Confluent Cloud managed Kafka platform. As of Cribl Stream v.3.3, this Source automatically detects compressed data in `Gzip`, `Snappy`, or `LZ4` format.

Your Confluent Cloud permissions should include `Consumer Group: Read`.

Type: **Pull** | TLS Support: **YES** | Event Breaker Support: **No**

Confluent Cloud uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Stream must receive events directly from senders. You might need to adjust your firewall rules to allow this traffic.

Ingest Kafka Topics from Confluent Cloud

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Bootstrap servers**: List of Confluent Cloud bootstrap servers to use, for example, `myAccount.confluent.cloud:9092`.
    - **Topics**: Enter the name(s) of topics to subscribe to. Press `Enter/Return` between multiple entries.

    To optimize performance and prevent excessive rebalancing, Cribl recommends subscribing each Confluent Cloud Source to only one topic. To subscribe to multiple topics, consider creating a dedicated Confluent Cloud Source for each one.

    For the same reason, the **Group ID** (below) should be unique for each of your Confluent Cloud, Kafka, and Azure Event Hubs Sources. For details, see Controlling Rebalancing.
3. Next, you can configure the following **Optional Settings**:
    - **Group ID**: The name of the consumer group to which this Cribl Stream instance belongs.

- **From beginning**: Whether to start reading from the earliest available data. Relevant only during initial subscription. Defaults to `Yes`.
- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the TLS, Authentication, Schema Registry, Processing, Retries, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Client Side)

Enabled: defaults to `No`. When toggled to `Yes`:

Autofill?: This setting is experimental.

Validate client certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `Yes`.

Server name (SNI): Leave this field blank. See Connecting to Kafka below.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Authentication

This section documents the SASL (Simple Authentication and Security Layer) authentication settings to use when connecting to bootstrap servers. Using TLS is highly recommended.

Enabled: Defaults to `No`. When toggled to `Yes`:

- **SASL mechanism**: Select the SASL (Simple Authentication and Security Layer) authentication mechanism to use. Defaults to `PLAIN`. `SCRAM-SHA-256`, `SCRAM-SHA-512`, and `GSSAPI/Kerberos` are also available. The mechanism you select determines the controls displayed below.

PLAIN, SCRAM-256, or SCRAM-512

With any of these SASL mechanisms, select one of the following buttons:

Manual: Displays **API key** and **Secret** fields to enter your Kafka credentials directly.

Secret: This option exposes a **Credentials secret** drop-down in which you can select a stored text secret that references your Kafka credentials. A **Create** link is available to store a new, reusable secret.

GSSAPI/Kerberos

Kerberos authentication is not supported for Cribl-managed Workers in Cribl.Cloud, but it is enabled for on-prem Worker Groups, whether the Leader is based in Cribl.Cloud or on-prem.

Selecting Kerberos as the authentication mechanism displays the following options:

Keytab location: Enter the location of the keytab file for the authentication principal.

Principal: Enter the authentication principal, for example: `kafka_user@example.com`.

Broker service class: Enter the Kerberos service class for Kafka brokers, for example: `kafka`.

You will also need to set up your environment and configure the Cribl Stream host for use with Kerberos. See Kafka Authentication with Kerberos for further detail.

Schema Registry

This section governs Confluent Schema Registry Authentication for Avro-encoded data with a schema stored in the Confluent Schema Registry.

Enabled: defaults to `No`. When toggled to `Yes`, displays the following controls:

Schema registry URL: URL for access to the Confluent Schema Registry (for example, `http://<hostname>:8081`).

Connection timeout (ms): Specifies the maximum time allowed for establishing a successful connection to the schema registry. Defaults to 30000 ms (30 seconds). Valid range is 1000 ms - 60000 ms (or 1 sec to 60 sec).

Request timeout (ms): Maximum time to wait for a successful request from the schema registry. Defaults to 60000 ms (or 1 minute).

Retry Limit: Max number of times to retry requests to the schema registry before dropping the outgoing message. Defaults to 1; enter 0 to not retry at all.

Authentication enabled: Toggle to `Yes` if your schema registry requires authentication.

- **Credentials secret**: Select or **Create** a stored text secret containing the username and password provided by your schema registry administrator.

TLS enabled: defaults to `No`. When toggled to `Yes`, displays the following TLS settings for the Schema Registry (in the same format as the TLS Settings (Client Side) above):

- **Validate server certs**: Require client to reject any connection that is not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `No`.
- **Server name (SNI)**: Leave this field blank. See About Kafka and TLS below.
- **Minimum TLS version**: Optionally, select the minimum TLS version to use when connecting.
- **Maximum TLS version**: Optionally, select the maximum TLS version to use when connecting.
- **Certificate name**: The name of the predefined certificate.
- **CA certificate path**: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.
- **Private key path (mutual auth)**: Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.
- **Certificate path (mutual auth)**: Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.
- **Passphrase**: Passphrase to use to decrypt private key.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Max retries: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2`–`20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Use these settings to fine-tune Cribl Stream's integration with Kafka topics. If you are unfamiliar with these parameters, contact Cribl Support to understand the implications of changing the defaults.

Heartbeat interval (ms): Expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Value must be lower than `sessionTimeout`, and typically should not exceed 1/3 of the `sessionTimeout` value. Defaults to `3000` ms (3 seconds). For details, see the Kafka documentation.

Session timeout (ms): Timeout used to detect client failures when using Kafka's group management facilities. If the client sends the broker no heartbeats before this timeout expires, the broker will remove this client from the group, and will initiate a rebalance. Value must be between the broker's configured `group.min.session.timeout.ms` and `group.max.session.timeout.ms`. Defaults to `30000` ms (30 seconds). For details, see the Kafka documentation.

Rebalance timeout (ms): Maximum allowed time for each worker to join the group after a rebalance has begun. If the timeout is exceeded, the coordinator broker will remove the worker from the group. Defaults to `60000` ms (1 minute). For details, see the Kafka documentation.

Connection timeout (ms): Maximum time to wait for a successful connection. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour). For details, see the Kafka documentation.

Request timeout (ms): Maximum time to wait for a successful request. Defaults to `60000` ms (1 minute). For details, see the Kafka documentation.

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Stream initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Source from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Source to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Offset commit interval (ms): How often, in milliseconds, to commit offsets. If both this field and the **Offset commit threshold** are empty, Cribl Stream will commit offsets after each batch. If both fields are set, Cribl Stream will commit offsets when either condition is met.

Offset commit threshold: The number of events that will trigger an offset commit. If both this field and the **Offset commit interval** are empty, Cribl Stream will commit offsets after each batch. If both fields are set, Cribl Stream will commit offsets when either condition is met.

Max bytes per partition: The maximum amount of data that the server will return per partition. Must equal or exceed the maximum message size the server allows. (Otherwise, the producer will be unable to send messages larger than the consumer can fetch.) If not specified, defaults to `1048576`.

Max bytes: Maximum amount of bytes to accumulate in the response. The default is `10485760 (10 MB)`.

Maximum number of errors per socket: Maximum number of consecutive request errors that can occur on a single socket connection before the connection is discarded and reestablished. This mitigates issues with idle connections, particularly those used for sending heartbeats, thereby reducing the number of rebalances in a consumer group. Default is `0`, which disables this feature. Accepts values `1-100`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

If you observe an excessive number of group rebalances, and/or you observe consumers not regularly pulling messages, try increasing the values of **Heartbeat interval**, **Session timeout**, and **Rebalance timeout**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Connecting to Kafka

Leave the TLS Settings > Server name (SNI) field blank

In Cribl Stream's Kafka-based Sources and Destinations (including this one), the Kafka library that Cribl Stream uses manages SNI (Server Name Indication) without any input from Cribl Stream. Therefore, you should leave the **TLS Settings** > **Server name (SNI)** field blank.

Setting this field in the Cribl Stream UI can cause traffic to be routed to the wrong brokers, because it interferes with the Kafka library's operation. This is especially important for Confluent Cloud Dedicated clusters, which rely on SNI – as managed by the Kafka library – for routing.

Connecting to a Kafka cluster involves using hostnames for two key components: bootstrap servers and brokers.

Brokers are servers that comprise the storage layer in a Kafka cluster. Bootstrap servers handle the initial connection to the Kafka cluster, and then return the list of brokers. A broker list can run into the hundreds. Every Kafka cluster has a `bootstrap.servers` property, defined as either a single `hostname:port` K-V pair, or a list of them. If Cribl Stream tries to connect via one bootstrap server and that fails, Cribl Stream then tries another one on the list.

In the **General Settings** > **Bootstrap servers** list, you can enter either the hostnames of brokers that your Kafka server has been configured to use, or, the hostnames of one or more bootstrap servers. If Kafka returns a list of brokers that's longer than the list you entered, Cribl Stream keeps the full list internally. Cribl Stream neither saves the list nor makes it available in the UI. The connection process simply starts at the beginning whenever the Source or Destination is started.

Here's an overview of the connection process:

1. From the **General Settings** > **Bootstrap servers** list – where each broker is listed as a hostname and port – Cribl Stream takes a hostname and resolves it to an IP address.
2. Cribl Stream makes a connection to that IP address. Notwithstanding the fact that Cribl Stream resolved **one** particular hostname to that IP address, there may be **many** services running at that IP address – each with its own distinct hostname.
3. Cribl Stream establishes TLS security for the connection.

Although SNI is managed by the Kafka library rather than in the Cribl Stream UI, you might want to know how it fits into the connection process. The purpose of the SNI is to specify one hostname – that is, service – among many that might be running on a given IP address within a Kafka cluster. Excluding the other services is one way that TLS makes the connection more secure.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__topicIn` (indicates the Confluent Cloud topic that the event came from; see `__topicOut` in our [Confluent Cloud Destination](destinations-Confluent Cloud) documentation)
- `__partition`
- `__schemaId` (when using Schema Registry)

How Cribl Stream Pulls Data

Confluent Cloud treats all the Worker Nodes as members of a Consumer Group, and Confluent Cloud manages each Node's data load. By default, Workers will poll every 5 seconds. In the case of Leader failure, Worker Nodes will continue to receive data as normal.

How Cribl Stream Handles the `_time` Field

Events that the Kafka Source emits always contain a `_time` field, and sometimes also an `__origTime` field. Here's how Cribl Stream determines what to send:

- If the incoming Kafka message contains no `_time` field, the message's timestamp becomes the value of the emitted event's `_time` field.
- If the incoming Kafka message contains a `_time` field whose value is a timestamp in UNIX epoch time, that timestamp becomes the value of the emitted event's `_time` field.
- If the incoming Kafka message contains a `_time` field whose value is **not** a timestamp in UNIX epoch time (for example, an ISO or UTC timestamp), that becomes the value of the emitted event's `__origTime` field, **and** the message's timestamp becomes the value of the emitted event's `_time` field.

Randomized Partition Assignment

In Cribl Stream v.4.8.2 and newer, partition assignment is randomized. The Worker Processes selected to consume data during partition assignment are selected randomly, reducing the possibility of uneven load distribution when there are fewer partitions than Worker Processes. Note that *random* assignment is not the same as *balanced* assignment, and even distribution of work is not guaranteed.

Controlling Rebalancing

When you configure multiple Sources that subscribe to different topics, but all belong to the same consumer group, a state change affecting any Source in this consumer group will affect all the other Sources. Examples of state changes include: deploying new configs, adding or removing Worker Processes, or Worker Processes crashing.

Here's an example – three Sources, three different topics, all in one consumer group:

- `Source_1 - Topic_1 - ConsumerGroup1`
- `Source_2 - Topic_2 - ConsumerGroup1`
- `Source_3 - Topic_3 - ConsumerGroup1`

Imagine that Source 1 undergoes a state change event, such as a Worker Process crash. Source 2 and Source 3 will rebalance – stopping data flow until the rebalance completes.

Shared Worker Group Mitigation

If Sources that share a consumer group all deploy as part of the same Worker Group, changes will have smaller side effects than when Sources are spread across different Worker Groups. (Conversely, imagine a configuration where deploying new configs for Worker Group 1 caused rebalancing of topics in worker Worker Group 2. This spillover would be especially undesirable.)

Bottom Line

Changes to any member of a consumer group affect all other members of that consumer group. To prevent this undesired behavior, make sure to use a unique **Group ID** for each Kafka, Confluent Cloud, and Azure Event Hubs Source.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

KafkaJSProtocolError: Not authorized to access topics: [Topic authorization failed]

The username does not have read permissions for the specified topic.

15.1.5.3. Amazon MSK Source

Cribl Stream supports receiving data records from an Amazon Managed Streaming for Apache Kafka (MSK) cluster. This Source automatically detects compressed data in `Gzip`, `Snappy`, or `LZ4` format.

Type: **Pull** | TLS Support: **YES** | Event Breaker Support: **No**

Kafka uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Stream must receive events directly from senders. You might need to adjust your firewall rules to allow this traffic.

Configure Cribl Stream to Receive Data from Kafka Topics

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Brokers**: List of Kafka brokers to connect to, for example, `kafkaBrokerHost:9092`. Specify hostname and port – for example, `mykafkabroker:9092` – or just hostname, in which case Stream will assign port 9092.
    - **Topics**: Enter the name(s) of topics to subscribe to. Press `Enter/Return` between multiple entries.
    - **Region**: Select the name of the AWS Region where your Amazon MSK cluster is located.

To optimize performance and prevent excessive rebalancing, Cribl recommends subscribing each Kafka Source to only one topic. To subscribe to multiple topics, consider creating a dedicated Kafka Source for each one.

For the same reason, the **Group ID** (below) should be unique for each of your Kafka, Confluent Cloud, and Azure Event Hubs Sources. For details, see Controlling Rebalancing.

3. Next, you can configure the following **Optional Settings**:
    - **Group ID**: The name of the consumer group to which this Cribl Stream instance belongs.
    - **From beginning**: Toggle this off if you want Cribl Stream, upon subscribing to a topic for the first time, to read new messages only. Otherwise Cribl Stream will read all messages available on the server, starting from the oldest.
    - **Tags**: Optionally, add tags that you can use for filtering and grouping in Cribl Stream's UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.
4. Optionally, you can adjust the TLS, Authentication, Assume Role, Processing, Retries, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Client Side)

For Amazon MSK Sources and Destinations:

- IAM is the only type of authentication that Cribl Stream supports.
- Because IAM auth requires TLS, TLS is automatically enabled.

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `Yes`.

Server name (SNI): Leave this field blank. See Connecting to Kafka below.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, such as those running in a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Stream's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for MSK: Toggle on to use Assume Role credentials to access MSK.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID in order to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Max retries: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2`–`20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Use these settings to fine-tune Cribl Stream's integration with Kafka topics. If you are unfamiliar with these parameters, contact Cribl Support to understand the implications of changing the defaults.

Heartbeat interval (ms): Expected time between heartbeats to the consumer coordinator when using Kafka's group management facilities. Value must be lower than `sessionTimeout`, and typically should not exceed 1/3 of the `sessionTimeout` value. Defaults to `3000` ms (3 seconds). For details, see the Kafka documentation.

Session timeout (ms): Timeout used to detect client failures when using Kafka's group management facilities. If the client sends the broker no heartbeats before this timeout expires, the broker will remove this client from the group, and will initiate a rebalance. Value must be between the broker's configured `group.min.session.timeout.ms` and `group.max.session.timeout.ms`. Defaults to `30000` ms (30 seconds). For details, see the Kafka documentation.

Rebalance timeout (ms): Maximum allowed time for each Worker to join the Group after a rebalance has begun. If the timeout is exceeded, the coordinator broker will remove the Worker from the Group. Defaults to `60000` ms (1 minute). For details, see the Kafka documentation.

Connection timeout (ms): Maximum time to wait for a connection to complete successfully. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour). For details, see the Kafka documentation.

Request timeout (ms): Maximum time to wait for Kafka to respond to a request. Defaults to `60000` ms (1 minute). For details, see the Kafka documentation.

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Stream initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Source from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Source to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Offset commit interval (ms): How often, in milliseconds, to commit offsets. If both this field and the **Offset commit threshold** are empty, Cribl Stream will commit offsets after each batch. If both fields are set, Cribl Stream will commit offsets when either condition is met.

Offset commit threshold: How many events are needed to trigger an offset commit. If both this field and the **Offset commit interval** are empty, Cribl Stream will commit offsets after each batch. If both fields are set, Cribl Stream will commit offsets when either condition is met.

Max bytes per partition: Maximum amount of data that Kafka will return per partition, per fetch request. Must equal or exceed the maximum message size (maxBytesPerPartition) that Kafka is configured to allow. Otherwise, Cribl Stream can get stuck trying to retrieve messages. Defaults to `1048576 (1 MB)`.

Max bytes: Maximum number of bytes that Kafka will return per fetch request. Defaults to `10485760 (10 MB)`.

Maximum number of errors per socket: Maximum number of consecutive request errors that can occur on a single socket connection before the connection is discarded and reestablished. This mitigates issues with idle connections, particularly those used for sending heartbeats, thereby reducing the number of rebalances in a consumer group. Default is `0`, which disables this feature. Accepts values `1-100`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

If you observe an excessive number of group rebalances, and/or you observe consumers not regularly pulling messages, try increasing the values of **Heartbeat interval**, **Session timeout**, and **Rebalance timeout**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Connecting to Kafka

Leave the TLS Settings > Server name (SNI) field blank

In Cribl Stream's Kafka-based Sources and Destinations (including this one), the Kafka library that Cribl Stream uses manages SNI (Server Name Indication) without any input from Cribl Stream. Therefore, you should leave the **TLS Settings** > **Server name (SNI)** field blank.

Setting this field in the Cribl Stream UI can cause traffic to be routed to the wrong brokers, because it interferes with the Kafka library's operation.

Connecting to a Kafka cluster entails working with hostnames for **brokers** and **bootstrap servers**.

Brokers are servers that comprise the storage layer in a Kafka cluster. Bootstrap servers handle the initial connection to the Kafka cluster, and then return the list of brokers. A broker list can run into the hundreds. Every Kafka cluster has a `bootstrap.servers` property, defined as either a single `hostname:port` K-V pair, or a list of them. If Cribl Stream tries to connect via one bootstrap server and that fails, Cribl Stream then tries another one on the list.

In the **General Settings** > **Brokers** list, you can enter either the hostnames of brokers that your Kafka server has been configured to use, or, the hostnames of one or more bootstrap servers. If Kafka returns a list of brokers that's longer than the list you entered, Cribl Stream keeps the full list internally. Cribl Stream neither saves the list nor makes it available in the UI. The connection process simply starts at the beginning whenever the Source or Destination is started.

Here's an overview of the connection process:

1. From the **General Settings** > **Brokers** list – where each broker is listed as a hostname and port – Cribl Stream takes a hostname and resolves it to an IP address.

2. Cribl Stream makes a connection to that IP address. Notwithstanding the fact that Cribl Stream resolved **one** particular hostname to that IP address, there may be **many** services running at that IP address – each with its own distinct hostname.
3. Cribl Stream establishes TLS security for the connection.

Although SNI is managed by the Kafka library rather than in the Cribl Stream UI, you might want to know how it fits into the connection process. The purpose of the SNI is to specify one hostname – that is, service – among many that might be running on a given IP address within a Kafka cluster. Excluding the other services is one way that TLS makes the connection more secure.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__topicIn` (indicates the Kafka topic that the event came from; see `__topicOut` in our Kafka Destination documentation)
- `__partition`
- `__schemaId` (when using Schema Registry)
- `__key` (when using Schema Registry)
- `__headers` (when using Schema Registry)
- `__keySchemaIdIn` (when using Schema Registry)
- `__valueSchemaIdIn` (when using Schema Registry)

How Cribl Stream Pulls Data

Kafka treats all the Worker Nodes as members of a Consumer Group, and Kafka manages each Node's data load. By default, Workers will poll every 5 seconds. In the case of Leader failure, Worker Nodes will continue to receive data as normal.

How Cribl Stream Handles the `_time` Field

Events that the Kafka Source emits always contain a `_time` field, and sometimes also an `__origTime` field. Here's how Cribl Stream determines what to send:

- If the incoming Kafka message contains no `_time` field, the message's timestamp becomes the value of the emitted event's `_time` field.
- If the incoming Kafka message contains a `_time` field whose value is a timestamp in UNIX epoch time, that timestamp becomes the value of the emitted event's `_time` field.
- If the incoming Kafka message contains a `_time` field whose value is **not** a timestamp in UNIX epoch time (for example, an ISO or UTC timestamp), that becomes the value of the emitted event's `__origTime` field, **and** the message's timestamp becomes the value of the emitted event's `_time` field.

Randomized Partition Assignment

In Cribl Stream v.4.8.2 and newer, partition assignment is randomized. The Worker Processes selected to consume data during partition assignment are selected randomly, reducing the possibility of uneven load distribution when there are fewer partitions than Worker Processes. Note that *random* assignment is not the same as *balanced* assignment, and even distribution of work is not guaranteed.

Controlling Rebalancing

When you configure multiple Sources that subscribe to different topics but all belong to the same consumer group, a state change affecting any Source in this consumer group will affect all the other Sources. Examples of state changes include: deploying new configs, adding or removing Worker Processes, and Worker Processes crashing.

Here's an example – three Sources, three different topics, all in one consumer group:

- `Source_1 - Topic_1 - ConsumerGroup1`
- `Source_2 - Topic_2 - ConsumerGroup1`
- `Source_3 - Topic_3 - ConsumerGroup1`

Imagine that Source 1 undergoes a state change event, such as a Worker Process crash. Source 2 and Source 3 will rebalance – stopping data flow until the rebalance completes.

Shared Worker Group Mitigation

If Sources that share a consumer group all deploy as part of the same Worker Group, changes will have smaller side effects than when Sources are spread across different Worker Groups. (Conversely, imagine a configuration where deploying new configs for Worker Group 1 caused rebalancing of topics in Worker Worker Group 2. This spillover would be especially undesirable.)

Bottom Line

Changes to any member of a consumer group affect all other members of that consumer group. To prevent this undesired behavior, make sure to use a unique **Group ID** for each Kafka, Confluent Cloud, Amazon MSK, and Azure Event Hubs Source.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

KafkaJSProtocolError: Not authorized to access topics: [Topic authorization failed]

The username does not have read permissions for the specified topic.

15.1.6. Office 365

15.1.6.1. Office 365 Activity Source

Cribl Stream supports receiving data from the Office 365 Management Activity API. This facilitates analyzing actions and events on Microsoft Entra ID, Exchange, and SharePoint, along with global auditing and Data Loss Prevention data.

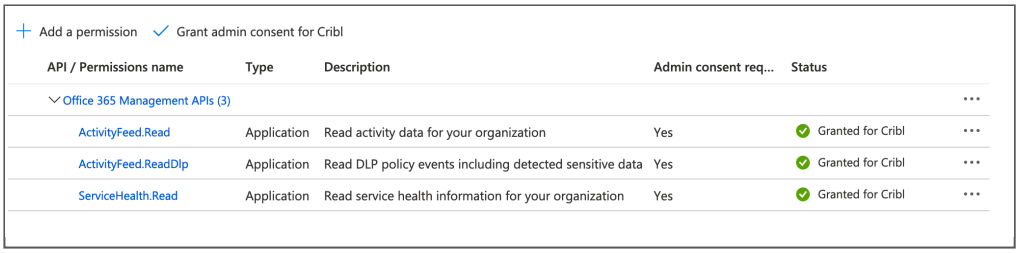
Type: **Pull** | TLS Support: **YES** | Event Breaker Support: **YES**

TLS is enabled via the HTTPS protocol on this Source's underlying REST API.

Microsoft Entra ID Permissions

In Microsoft Entra ID (formerly Azure Active Directory), the application representing your Cribl Stream instance must be granted the following permissions to pull data. Each permission's **Type** must be `Application` – `Delegated` is not sufficient:

- `ActivityFeed.Read` – Required for all Content Types except `DLP.All`.
- `ActivityFeed.ReadDlp` – Required for the `DLP.All` Content Type.



Registered application permissions

Office 365 Subscriptions

Cribl Stream does not support starting/stopping Office 365 subscriptions. You can start subscriptions either via another Office 365 API client, or simply via `curl` commands. We document the `curl` command method below in Starting Content Subscriptions.

Configure Cribl Stream to Receive Data from the Activity API

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Tenant ID**: Enter the Office 365 Azure tenant ID.
    - **App ID**: Enter the Office 365 Azure application ID.
    - **Subscription Plan**: See Subscription Plan below.
3. Under **Authentication**, select the **Authentication method** from the dropdown:
    - **Manual**: This default option provides a **Client secret** field, where you directly enter the required Office 365 Azure client secret.
    - **Secret**: This option instead exposes a **Client secret (text secret)** drop-down, from which you select a stored text secret to authenticate with. Click **Create** to configure a new secret.
4. Next, you can configure the following **Optional Settings**:
    - **Publisher identifier**: Use in API requests as described here. If not defined, defaults to Microsoft Office 365 tenant ID.
    - **Content Types**: See the Content Types section below.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Processing, Retries, and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Subscription Plan

Select the Office 365 subscription plan for your organization. Options include:

- **Office 365 Enterprise**
- **Office 365 GCC**
- **Office 365 GCC High**
- **Office 365 DoD**

Content Types

Here, you can configure polling independently for the following types of audit data from the Office 365 Management Activity API:

- **Active Directory**
- **Exchange**
- **SharePoint**
- **General**: All workloads not included in the above content types
- **DLP.All**: Data Loss Prevention events only, for all workloads

For each of these content types, the **Content Types** table provides the following controls:

Interval Description: This column is informational only.

Interval: Optionally, override the default polling interval. See About Polling Intervals below.

Log Level: Set the verbosity level to one of `debug`, `info` (the default), `warn`, or `error`.

Enabled: Toggle this to `Yes` for each service that you want to poll.

About Polling Intervals

To poll the Office 365 Management Activity API, Cribl Stream uses the **Interval** field's value to establish the search date range and the cron schedule (for example: `*/${interval} * * * *`).

Therefore, intervals set in minutes must divide evenly into 60 minutes to create a predictable schedule. Dividing 60 by intervals like `1`, `2`, `3`, `4`, `5`, `6`, `10`, `12`, `15`, `20`, or `60` itself yields an integer, so you can enter any of these values.

Cribl Stream will reject intervals like `23`, `42`, or `45`, or `75` – which would yield non-integer results, meaning unpredictable schedules.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Retries

Retry type: The algorithm to use when performing HTTP retries. Options include `Backoff` (the default), `Static`, and `Disabled`.

Initial retry interval (ms): Time interval between failed request and first retry (kickoff). Maximum allowed value is 20,000 ms (1/3 minute). A value of `0` means retry immediately until reaching the retry limit in **Max retries**.

Max retries: Maximum number of times to retry a failed HTTP request. Defaults to `5`. Maximum: `20`. A value of `0` means don't retry at all.

Backoff multiplier: Base for exponential backoff. A value of `2` (default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, etc.

Retry HTTP codes: List of HTTP codes that trigger a retry. Leave empty to use the defaults (`429` and `503`). Cribl Stream does not retry codes in the `200` series.

Honor Retry-After header: When toggled to `Yes` (the default) and the `retry-after` header is present, Cribl Stream honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. Cribl Stream always ignores `retry-after` headers that specify a delay longer than 20 seconds.

- Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).
- When toggled to `No`, Cribl Stream ignores all `retry-after` headers.

Retry Connection Timeout: Toggle to `Yes` to automatically retry a single connection attempt after a timeout (`ETIMEDOUT`) to ensure data continuity.

Retry Connection Reset: Toggle to `Yes` to automatically retry a connection after a peer reset (`ECONNRESET`) to maintain data flow.

Advanced Settings

Ingestion lag (minutes): How far back into the past the Office 365 Activity API should look for events to retrieve. This is necessary because there can be a lag of 60 to 90 minutes (or longer) before Office 365 events become available via the API. The default value of `0` means don't look back. When it's very important to avoid missing events, consider running multiple overlapping jobs, as described below.

Request timeout (secs): The maximum time period for an HTTP request to complete before Cribl Stream treats it as timed out. Defaults to `300` (i.e., 5 minutes). Enter `0` to disable timeout metering.

Job timeout: Maximum time the job is allowed to run (for example, `30`, `45s`, or `15m`). Units are seconds, if not specified. Enter `0` for unlimited time. Defaults to `0`.

Time to live: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__collectible`
- `__final`
- `__inputId`
- `__isBroken`
- `__source`

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Starting Content Subscriptions

Content subscriptions (a different concept from the O365 subscription plans) are required in order for Cribl Stream to be able to begin retrieving O365 data. There is a separate subscription required for each Content Type. If you are using an existing Azure-registered application ID that already has subscriptions started, then you can ignore this section. But if you are:

- Using a newly registered application ID, and therefore never had any subscriptions started, or
- Reusing an application ID that had subscriptions started, but are currently stopped

...then you will need to use this procedure to manually start the necessary subscriptions. Follow either of the two methods below, using (respectively) PowerShell or `curl`.

Using PowerShell

This sample PowerShell script will enable all subscriptions for you. Update the appropriate variables as required:

```
# Create app of type Web app / API in Microsoft Entra ID, generate a Client Secret, a
# Get the tenant GUID from Properties | Directory ID under the Microsoft Entra ID se
$AppID = "<APP_ID>"
$ClientSecret = "<CLIENT_SECRET>"
$TenantID = "<TENANT_ID>"
$loginURL = "https://login.microsoftonline.com/"

# For $resource, use one of these endpoint values based on your subscription plan:
# * Enterprise - manage.office.com
# * GCC - manage-gcc.office.com
# * GCC High - manage.office365.us
# * DoD - manage.protection.apps.mil
$resource = "https://manage.office.com"

$body = @{grant_type="client_credentials";resource=$resource;client_id=$AppID;client_
$oauth = Invoke-RestMethod -Method Post -Uri $loginURL/$TenantID/oauth2/token?api-ve
$headerParams = @{'Authorization'="$($oauth.token_type) $($oauth.access_token)"}

Invoke-WebRequest -Headers $headerParams -Uri "$resource/api/v1.0/$TenantID/activity/

Invoke-WebRequest -Method Post -Headers $headerParams -Uri "$resource/api/v1.0/$Tenan
Invoke-WebRequest -Method Post -Headers $headerParams -Uri "$resource/api/v1.0/$Tenan
Invoke-WebRequest -Method Post -Headers $headerParams -Uri "$resource/api/v1.0/$Tenan
Invoke-WebRequest -Method Post -Headers $headerParams -Uri "$resource/api/v1.0/$Tenan
Invoke-WebRequest -Method Post -Headers $headerParams -Uri "$resource/api/v1.0/$Tenan
```

Using curl

This is a two-step process. The first command obtains an auth token, which is used in the second command to actually start the subscription. To execute these commands, you'll need the same information (i.e., client secret, application ID, and tenant ID) that you already require to configure this Source in Cribl Stream's GUI. Replace those three variables as appropriate in the commands below.

1. `curl -d "client_secret=<client secret>&resource=https://manage.office.com&client_id=<app id>&grant_type=client_credentials" -X POST https://login.windows.net/<tenant id>/oauth2/token`
2. `curl -d "" -H "Authorization: Bearer <access token>" -X POST https://manage.office.com/api/v1.0/<tenant id>/activity/feed/subscriptions/start?contentType=<content_type_name>`

Here is an example of each command executed and expected output:

Example Command #1

```
$ curl -d
"client_secret=abcdefghijklmnopqrstuvwxyz12345678&resource=https://manage.office.com&cli
ffff-ffff-ffff-aaaaaaaaaaaa&grant_type=client_credentials" -X POST
https://login.windows.net/12345678-aaaa-4233-cccc-160c6c30154a/oauth2/token
```

Output:

```
{"token_type":"Bearer","expires_in":"3599","ext_expires_in":"3599","expires_on":"1622089
JWT here...MRDvw"}
```

Example Command #2

```
$ curl -d "" -H "Authorization: Bearer eyJ0...long JWT here...MRDvw" -X POST
"https://manage.office.com/api/v1.0/12345678-aaaa-4233-cccc-
160c6c30154a/activity/feed/subscriptions/start?contentType=Audit.AzureActiveDirectory"
```

Output:

```
{"contentType":"Audit.AzureActiveDirectory","status":"enabled","webhook":null}
```

Note there is no output when executing this second command with a `stop` operation.

You'll need to execute the second command for each Content Type whose logs you wish to collect. Use the exact strings below to specify Content Types in that command:

- `Audit.AzureActiveDirectory`
- `Audit.Exchange`
- `Audit.SharePoint`
- `Audit.General`
- `DLP.All`

How Cribl Stream Pulls Data

The Office 365 Activity Source retrieves data using Cribl Stream scheduled Collection jobs, which include Discover and Collection phases. The Discover phase task returns the URL of the content to collect.

In the Source's **General Settings** > **Content Types** > **Interval** column, you configure the polling schedule for each Content Type independently. Each Content Type that you enable gets its own separate scheduled job.

The job scheduler spreads the Collection tasks across all available Workers. The collected content is paginated, so the collection phase might include multiple calls to fetch data.

Viewing Scheduled Jobs

Once you've configured and saved the Source, you can view the Collection jobs' results by reopening the Source's config modal and clicking its **Job Inspector** tab.

You can also view these jobs (among scheduled jobs for other Collectors and Sources) in the **Monitoring** > **System** > **Job Inspector** > **Currently Scheduled** tab.

Mitigating Stuck-Job Problems

Occasionally, a scheduled job fails, but continues running for hours or even days, until someone intervenes and cancels it. If left alone, such a "stuck", "orphaned," or "zombie" job will never complete. This can cause missing events in downstream receivers, along with `HTTP timeout` or similar errors in Cribl Stream's logs.

To keep stuck jobs from running excessively long:

- First, try setting **Advanced** > **Timeout (secs)** to a duration shorter than the default of `300` seconds (5 minutes).

- If adjusting **Timeout (secs)** does not fix the problem, try the global setting **Job Timeout** – whose default of `0` allows a job to run indefinitely – to a desired maximum duration. You'll find **Job Timeout** among the task manifest and buffering limits.

Using these settings in tandem works like this:

- **Timeout (secs)** limits the time that Cribl Stream will wait for an HTTP request to complete.
- Then, if a job gets stuck and keeps running beyond that limit, **Job Timeout** can catch and terminate the job, because it monitors the overall time the job has been running.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Multiple Overlapping Jobs

You can schedule multiple Collection jobs where each job uses a different ingestion lag, for example, three different jobs with **Ingestion lag** set to `120` (two hours), `720` (twelve hours), and `5760` (four days), respectively.

Although this approach will collect data over partially overlapping time ranges – meaning that you'll have duplicate events – it can improve the chances that you'll catch "straggler" events affected by the known lag times in the Office 365 Management Activity API.

See Also

The Community-contributed Microsoft Office Activity & Azure Logs Pack provides sample Pipelines to parse and streamline ingested Office 365 and EntraID/Azure AD data. You can import these and adapt them to your own needs.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.6.2. Office 365 Message Trace Source

Cribl Stream supports receiving Office 365 Message Trace data. This mail-flow metadata can be used to detect and report on malicious activity including bulk emails, spoofed-domain emails, and data exfiltration.

Type: **Pull** | TLS Support: **YES** | Event Breaker Support: **YES**

TLS is enabled via the HTTPS protocol on this Source's underlying REST API.

Office 365 Setup

At a minimum, your Office 365 service account should include a role with `Message Tracking` and `View-Only Recipients` permissions, assigned to the Office 365 user that will integrate with Cribl Stream. Assign these permissions in the Exchange admin center (https://admin.exchange.microsoft.com).

Modern Authentication (OAuth 2.0) Setup

If you plan to use OAuth, OAuth Secret, or OAuth Certificate authentication, your Office 365 setup must include at least one role with the corresponding required permissions:

1. In the Microsoft Azure portal, create a Microsoft Entra ID App Registration. For details, see the Microsoft Azure documentation.
2. Assign the application at least one Azure AD role that will enable it to access the Reporting Web Service:
    - Global Reader
    - Global Administrator
    - Exchange Administrator

Make sure that at least one role includes the `ReportingWebService.Read.All` permission. For detailed steps, see Microsoft's Assign Azure AD Roles to Users topic.

Configure Cribl Stream to Receive Office 365 Message Trace Data

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.

- To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.

2. In the **New Source** modal, configure the following under **General Settings**:
   - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
   - **Description**: Optionally, enter a description.
   - **Report URL**: Enter the URL to use when retrieving report data. Defaults to: `https://reports.office365.com/ecp/reportingwebservice/reporting.svc/MessageTrac`
   - **Poll interval**: How often (in minutes) to run the report. Must divide evenly into 60 minutes to create a predictable schedule, or Save will fail. See About Polling Intervals below.
3. Under **Authentication**, select the **Authentication method** from the dropdown:
   - In the **Authentication** section, use the buttons to select an **Authentication method**: Basic, Basic (credentials secret), OAuth, OAuth (text secret), or OAuth Certificate. The default is **OAuth**. All OAuth options rely on the OAuth 2.0 protocol.
4. Next, you can configure the following **Optional Settings**:
   - Use the **Date range start** and **Date range end** settings to specify the time window for data collection. These settings help compensate for delays and gaps in Message Trace data. Use relative time formats for ongoing data collection and exact epoch values to backfill specific time gaps.
   - **Date range start**: Backward offset for the head of the search date range. Supports relative time format like `-3h@h` or exact epoch values like `1720536960`.
   - **Date range end**: Backward offset for the tail of the search date range. Supports relative time format like `-2h@h` or exact epoch values like `1720533360`.
   - **Log level**: For data collection's runtime log, set the verbosity level to one of `debug`, `info`, `warn`, or `error`. (If not selected, defaults to `info`.)
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Processing, Retries, and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Basic Authentication

Selecting **Basic** exposes **Username** and **Password** fields, where you directly enter the HTTP Basic credentials to use on Message Trace API calls.

Basic Secret Authentication

Selecting **Basic (credentials secret)** exposes a **Credentials secret** drop-down, where you select an existing stored secret that references your credentials on the Message Trace API. You can use the adjacent **Create**

button to store a new, reusable secret.

OAuth Authentication

The default **OAuth** authentication method exposes the following fields, all required:

- **Client secret**: Directly enter the `client_secret` to pass in the OAuth request parameter.
- **Tenant identifier**: Directory ID (tenant identifier) in Microsoft Entra ID.
- **Client ID**: The `client_id` to pass in the OAuth request parameter.
- **Resource**: Resource parameter to pass in the OAuth request parameter. Defaults to: `https://outlook.office365.com`.

OAuth Secret Authentication

Selecting **OAuth (text secret)** exposes three of the same controls as the default OAuth method, but – as you'd expect – you instead enter the **Client secret** by reference:

- **Client secret**: Use the drop-down to select an existing stored `client_secret` to pass in the OAuth request parameter. You can use the adjacent **Create** button to store a new, reusable secret.
- **Tenant identifier**: Directory ID (tenant identifier) in Microsoft Entra ID.
- **Client ID**: The `client_id` to pass in the OAuth request parameter.
- **Resource**: Resource parameter to pass in the OAuth request parameter. Defaults to: `https://outlook.office365.com`.

OAuth Certificate Authentication

Selecting **OAuth (certificate)** exposes two of the same controls as the above OAuth methods (**Tenant identifier** and **Client ID**). But this authentication method – available in Cribl Stream 4.1.3 and later – foregrounds controls to define the certificate you're using to authenticate. Treat all fields here as required, except for the optional **Passphrase**:

- **Certificate name**: Use the drop-down to select an existing certificate to pass in the OAuth request parameter. You can use the adjacent **Create** button to store a new, reusable cert.
- **Private key path**: Path to the private key to use. The key should be in PEM format. Can reference `$ENV_VARS`.
- **Passphrase**: If your private key requires a passphrase to decrypt it, enter that passphrase here.
- **Certificate path**: Path to the certificate to use. The cert should be in PEM format. Can reference `$ENV_VARS`.
- **Tenant identifier**: Directory ID (tenant identifier) in Microsoft Entra ID.
- **Client ID**: The `client_id` to pass in the OAuth request parameter.

- **Resource**: Resource parameter to pass in the OAuth request parameter. Defaults to: `https://outlook.office365.com`.
- **Subscription Plan**: Select the Office 365 subscription plan for your organization. Options include:
  - **Office 365 Enterprise**
  - **Office 365 GCC**
  - **Office 365 GCC High**
  - **Office 365 DoD**

About Polling Intervals

To poll the Office 365 Message Trace API, Cribl Stream uses the **Poll interval** field's value to establish the cron schedule. For example, `*/${interval} * * * *`.

Because the interval is set in minutes, it must divide evenly into 60 minutes to create a predictable schedule. Dividing 60 by intervals like `1`, `2`, `3`, `4`, `5`, `6`, `10`, `12`, `15`, `20`, or `60` itself yields an integer, so you can enter any of these values.

Cribl Stream will reject intervals like `23`, `42`, or `45`, or `75` – which would yield non-integer results, meaning unpredictable schedules.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Retries

Retry type: The algorithm to use when performing HTTP retries. Options include `Backoff` (the default), `Static`, and `Disabled`.

Initial retry interval (ms): Time interval between failed request and first retry (kickoff). Maximum allowed value is 20,000 ms (1/3 minute). A value of `0` means retry immediately until reaching the retry limit in **Max retries**.

Max retries: Maximum number of times to retry a failed HTTP request. Defaults to `5`. Maximum: `20`. A value of `0` means don't retry at all.

Backoff multiplier: Base for exponential backoff. A value of `2` (default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.

Retry HTTP codes: List of HTTP codes that trigger a retry. Leave empty to use the defaults (`429` and `503`). Cribl Stream does not retry codes in the `200` series.

Honor Retry-After header: When toggled to `Yes` (the default) and the `retry-after` header is present, Cribl Stream honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. Cribl Stream always ignores `retry-after` headers that specify a delay longer than 20 seconds.

- Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).
- When toggled to `No`, Cribl Stream ignores all `retry-after` headers.

Retry Connection Timeout: Toggle to `Yes` to automatically retry a single connection attempt after a timeout (`ETIMEDOUT`) to ensure data continuity.

Retry Connection Reset: Toggle to `Yes` to automatically retry a connection after a peer reset (`ECONNRESET`) to maintain data flow.

Advanced Settings

Request timeout (secs): Maximum time to wait for an individual Message Trace API request to complete. Defaults to `300` seconds (5 minutes). Enter `0` to disable metering, allowing unlimited response time. Because there is a single request to the Message Trace API per page of data, this timeout is applied at the page (request) level.

Job timeout: Maximum time a job is allowed to run. Defaults to `0`, for unlimited time. Units are seconds if not specified. Sample entries: `30`, `45s`, `15m`.

Time to live: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.

Disable time filter: Disables Collector event time filtering when a date range is specified in General Settings. Toggle to `No` to allow filtering.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__final`
- `__inputId`
- `__isBroken`
- `__source`

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

How Cribl Stream Pulls Data

The Office 365 Message Trace Source uses a scheduled REST Collector. It runs one collection task every **Poll interval**, and a single Worker will process the collection. The data is paginated, so the Worker might make multiple calls to fetch the data.

Viewing Scheduled Jobs

This Source executes Cribl Stream's scheduled collection jobs. Once you've configured and saved the Source, you can view those jobs' results by reopening the Source's config modal and clicking its **Job Inspector** tab.

Each content type that you enabled gets its own separate scheduled job.

You can also view these jobs (among scheduled jobs for other Collectors and Sources) in the **Monitoring** > **System** > **Job Inspector** > **Currently Scheduled** tab.

Mitigating Stuck-Job Problems

Occasionally, a scheduled job fails, but continues running for hours or even days, until someone intervenes and cancels it. If left alone, such a "stuck", "orphaned," or "zombie" job will never complete. This can cause missing events in downstream receivers, along with `HTTP timeout` or similar errors in Cribl Stream's logs.

To keep stuck jobs from running excessively long:

- First, try setting **Advanced** > **Timeout (secs)** to a duration shorter than the default of `600` seconds (10 minutes).
- If adjusting **Timeout (secs)** does not fix the problem, try setting **Advanced** > **Job Timeout** – whose default of `0` allows a job to run indefinitely – to a desired maximum duration.

Using these settings in tandem works like this:

- **Timeout (secs)** limits the time that Cribl Stream will wait for an HTTP request to complete.
- Then, if a job gets stuck and keeps running beyond that limit, **Job Timeout** can catch and terminate the job, because it monitors the overall time the job has been running.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

See Also

The Community-contributed Microsoft Office Activity & Azure Logs Pack provides sample Pipelines to parse and streamline ingested Office 365 and EntraID/Azure AD data. You can import these and adapt them to your own needs.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.6.3. Office 365 Services Source

Cribl Stream supports receiving data from the Microsoft Graph service communications API. This facilitates analyzing the status and history of service incidents on multiple Microsoft cloud services, along with associated incident and Message Center communications. For details, see Microsoft's Overview of the Graph API.

Type: **Pull** | TLS Support: **YES** | Event Breaker Support: **YES**

TLS is enabled via the HTTPS protocol on this Source's underlying REST API.

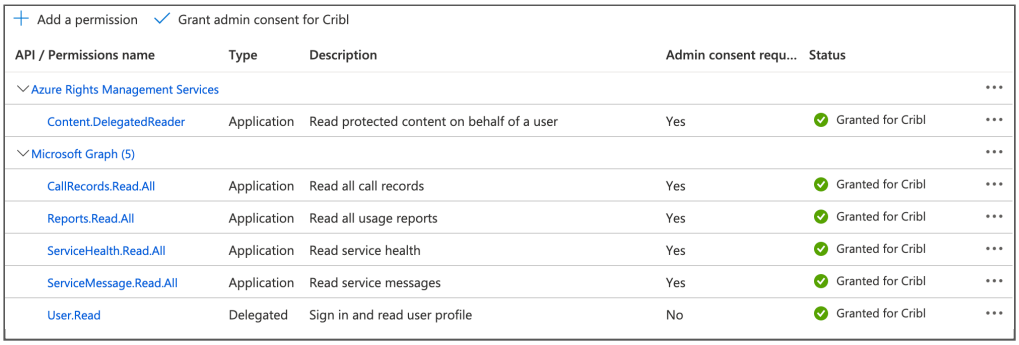
Microsoft has retired its prior Office 365 Service Communications API, forcing a switch to the Graph API mentioned above. Due to a limitation in this new API, Cribl Stream (LogStream) 3.3 and above can no longer collect the **Historical Status** content type that was available in this Source through LogStream 3.2.2.

For more about the Microsoft Graph API, see our Microsoft Graph API Collection guide.

Microsoft Entra ID Permissions

In Microsoft Entra ID (formerly Azure Active Directory), the application representing your Cribl Stream instance must be granted the following permissions to pull data. (The permission **Type** for both must be `Application` – `Delegated` is not sufficient:)

- `ServiceHealth.Read.All`
- `ServiceMessage.Read.All`



Add a permission | Grant admin consent for Cribl

API / Permissions name	Type	Description	Admin consent requ...	Status
Azure Rights Management Services				
Content.DelegatedReader	Application	Read protected content on behalf of a user	Yes	Granted for Cribl
Microsoft Graph (5)				
CallRecords.Read.All	Application	Read all call records	Yes	Granted for Cribl
Reports.Read.All	Application	Read all usage reports	Yes	Granted for Cribl
ServiceHealth.Read.All	Application	Read service health	Yes	Granted for Cribl
ServiceMessage.Read.All	Application	Read service messages	Yes	Granted for Cribl
User.Read	Delegated	Sign in and read user profile	No	Granted for Cribl

Registered application permissions

Configure Cribl Stream to Receive Data from the Service API

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Office 365 Services definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Tenant ID**: Enter the Office 365 Azure tenant ID.
    - **App ID**: Enter the Office 365 Azure application ID.
3. Under **Authentication**, select the **Authentication method** from the dropdown:
    - **Manual**: This default option provides a **Client secret** field, where you directly enter the required Office 365 Azure client secret.
    - **Secret**: This option instead exposes a **Client secret (text secret)** drop-down, from which you select a stored text secret to authenticate with. Click **Create** to configure a new secret.
4. Next, you can configure the following **Optional Settings**:
    - **Subscription Plan**: See Subscription Plan below.
    - **Content Types**: See the Content Types section below.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Processing, Retries, and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Subscription Plan

Select the Office 365 subscription plan for your organization. Options include:

- **Office 365 Enterprise**
- **Office 365 GCC**
- **Office 365 GCC High**
- **Office 365 DoD**

Content Types

Here, you can configure polling separately for the following types of data from the Office 365 Service Communications API:

- **Current Status**: Get a real-time view of current and ongoing service incidents.
- **Messages**: Find incident and Message Center communications.

As of this revision, this Microsoft API provides data for Office 365, Yammer, Dynamics CRM, and Microsoft Intune cloud services. For each of these content types, this section provides the following controls:

Enabled: Toggle this to `Yes` for each service that you want to poll.

Interval: Optionally, override the default polling interval. See About Polling Intervals below.

Log level: Set the verbosity level to one of `debug`, `info` (the default), `warn`, or `error`.

About Polling Intervals

To poll the Office 365 Service Communications API, Cribl Stream uses the **Interval** field's value to establish the search date range and the cron schedule, for example: `*/${interval} * * * *`

Therefore, intervals set in minutes – those for **Current Status** – must divide evenly into 60 minutes to create a predictable schedule. Dividing 60 by intervals like `1`, `2`, `3`, `4`, `5`, `6`, `10`, `12`, `15`, `20`, or `60` itself yields an integer, so you can enter any of these values.

Cribl Stream will reject intervals like `23`, `42`, or `45`, or `75` – which would yield non-integer results, meaning unpredictable schedules.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Retries

Retry type: The algorithm to use when performing HTTP retries. Options include `Backoff` (the default), `Static`, and `Disabled`.

Initial retry interval (ms): Time interval between failed request and first retry (kickoff). Maximum allowed value is 20,000 ms (1/3 minute). A value of `0` means retry immediately until reaching the retry limit in **Max retries**.

Max retries: Maximum number of times to retry a failed HTTP request. Defaults to `5`. Maximum: `20`. A value of `0` means don't retry at all.

Backoff multiplier: Base for exponential backoff. A value of `2` (default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, etc.

Retry HTTP codes: List of HTTP codes that trigger a retry. Leave empty to use the defaults (`429` and `503`). Cribl Stream does not retry codes in the `200` series.

Honor Retry-After header: When toggled to `Yes` (the default) and the `retry-after` header is present, Cribl Stream honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. Cribl Stream always ignores `retry-after` headers that specify a delay longer than 20 seconds.

- Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).
- When toggled to `No`, Cribl Stream ignores all `retry-after` headers.

Retry Connection Timeout: Toggle to `Yes` to automatically retry a single connection attempt after a timeout (`ETIMEDOUT`) to ensure data continuity.

Retry Connection Reset: Toggle to `Yes` to automatically retry a connection after a peer reset (`ECONNRESET`) to maintain data flow.

Advanced Settings

Request timeout (secs): The maximum time period for an HTTP request to complete before Cribl Stream treats it as timed out. Defaults to `300` (i.e., 5 minutes). Enter `0` to disable timeout metering.

Job timeout: Maximum time the job is allowed to run (for example, `30`, `45s`, or `15m`). Units are seconds, if not specified. Enter `0` for unlimited time. Defaults to `0`.

Time to live: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__final`
- `__inputId`
- `__isBroken`
- `__source`

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

How Cribl Stream Pulls Data

The Office 365 Services Source retrieves data using Cribl Stream scheduled Collection jobs, which include Discover and Collection phases. The Discover phase task returns the URL of the content to collect.

In the Source's **General Settings** > **Content Types** > **Interval** column, you configure the polling schedule for each Content Type independently.

The job scheduler spreads the Collection tasks across all available Workers. The collected content is paginated, so the collection phase might include multiple calls to fetch data.

Viewing Scheduled Jobs

This Source executes Cribl Stream's scheduled collection jobs. Once you've configured and saved the Source, you can view those jobs' results by reopening the Source's config modal and clicking its **Job Inspector** tab.

Each content type that you enabled gets its own separate scheduled job.

You can also view these jobs (among scheduled jobs for other Collectors and Sources) in the **Monitoring** > **System** > **Job Inspector** > **Currently Scheduled** tab.

Mitigating Stuck-Job Problems

Occasionally, a scheduled job fails, but continues running for hours or even days, until someone intervenes and cancels it. If left alone, such a "stuck", "orphaned," or "zombie" job will never complete. This can cause missing events in downstream receivers, along with `HTTP timeout` or similar errors in Cribl Stream's logs.

To keep stuck jobs from running excessively long:

- First, try setting **Advanced** > **Timeout (secs)** to a duration shorter than the default of `300` seconds (5 minutes).
- If adjusting **Timeout (secs)** does not fix the problem, try the global setting **Job Timeout** – whose default of `0` allows a job to run indefinitely – to a desired maximum duration. You'll find **Job Timeout** among the task manifest and buffering limits.

Using these settings in tandem works like this:

- **Timeout (secs)** limits the time that Cribl Stream will wait for an HTTP request to complete.
- Then, if a job gets stuck and keeps running beyond that limit, **Job Timeout** can catch and terminate the job, because it monitors the overall time the job has been running.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

See Also

The Community-contributed Microsoft Office Activity & Azure Logs Pack provides sample Pipelines to parse and streamline ingested Office 365 and EntraID/Azure AD data. You can import these and adapt them to your own needs.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.7. Prometheus

15.1.7.1. Prometheus Scraper Source

Cribl Stream supports receiving batched data from Prometheus targets. This is a pull Source; to ingest Prometheus streaming data, see Prometheus Remote Write.

Type: **Pull** | TLS Support: Configurable | Event Breaker Support: **No**

This Source assumes that incoming data is snappy-compressed. It does not currently support Prometheus metadata.

Configure Cribl Stream to Scrape Prometheus Data

As of version 4.2, we've removed this Source from Cribl Edge. Please use the Edge-specific Prometheus Edge Scraper Source instead.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Discovery type**: Use this drop-down to select a discovery mechanism for targets. See Discovery Type below for the options.

Some **Discovery type** options replace the **Targets** field with additional controls below the **Poll interval** and **Log level** fields – while also adding an **Assume Role** and/or **Target Discovery** left tab to the modal.

3. Next, you can configure the following **Optional Settings**:
    - **Extra dimensions**: Specify the dimensions to include in events. Defaults to `host` and `source`.

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Discovery Type

Use this drop-down to select a discovery mechanism for targets. To manually enter a targets list, use Static (the default). To enable dynamic discovery of endpoints to scrape, select DNS or AWS EC2. Each selection exposes different controls and/or tabs, listed below.

Static Discovery

The `Static` option adds a **General Settings** > **Targets** field, in which you enter a list of specific Prometheus targets from which to pull metrics.

Values can be in URL or `host[:port]` format, for example: `http://localhost:9090/metrics`, `localhost:9090`, or `localhost`.

If you specify only `host[:port]`, the endpoint will resolve to: `http://host[:port]/metrics` – that is, the protocol will be prepended and the `/metrics` path will be appended in all cases, even if you add a path. If you need a nonstandard path, you must enter the full URL (including protocol) with path. For example: `http://localhost:9090/my/custom/path`.

DNS Discovery

The `DNS` option adds a Target Discovery tab to the modal, and adds two extra fields to its **General Settings** tab:

- **DNS names**: Enter a list of DNS names to resolve.
- **Record type**: Select the DNS record type to resolve. Defaults to `SRV` (Service). Other options are `A` or `AAAA`.

AWS EC2 Discovery

The `AWS EC2` option adds Assume Role and Target Discovery tabs to the modal, and adds one extra field to the **Optional Settings** tab:

- **Region**: The AWS region in which to discover EC2 instances with metrics endpoints to scrape.

This option also adds controls in the **Advanced Settings** tab, as described below.

Authentication (Prometheus)

Use the **Authentication method** drop-down to select one of these authentication options for Prometheus:

- **Manual**: In the resulting **Username** and **Password** fields, enter Basic authentication credentials corresponding to your Prometheus targets.
- **Secret**: This option exposes a **Secret** drop-down, in which you can select a stored secret that references your credentials described above. The secret can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. Click **Create** if you need to configure a new secret.

Assume Role

With the AWS EC2 target discovery type, you can configure AssumeRole behavior on AWS.

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

- **Enable for EC2**: Toggle to `Yes` if you want to use `AssumeRole` credentials to access EC2.
- **AssumeRole ARN**: Enter the Amazon Resource Name (ARN) of the role to assume.
- **External ID**: Enter the External ID to use when assuming the role.
- **Duration (seconds)**: Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Target Discovery

Setting the General Settings > Discovery type drop-down to DNS or AWS EC2 exposes this tab. These two discovery types expose different controls here.

Target Discovery for DNS

Setting the Discovery type drop-down to DNS exposes the following **Target Discovery** fields.

Metrics protocol: Select `http` (the default) or `https` as the protocol to use when collecting metrics.

Metrics path: Specify a path to use when collecting metrics from discovered targets. Defaults to `/metrics`.

Target Discovery for AWS

Setting the Discovery type drop-down to AWS EC2 exposes the following **Target Discovery** controls. The first controls is a special case:

- **Authentication method**: Select the **Auto**, **Manual**, or **Secret** button to determine how Cribl Stream will authenticate against AWS. Each selection changes the fields displayed on this tab – see AWS Authentication Options for details.

These remaining controls are displayed for all **Authentication method** selections:

- **Metrics protocol**: Select `http` (the default) or `https` as the protocol to use when collecting metrics.
- **Metrics port**: Specify the port number to append to the metrics URL for discovered targets. Defaults to `9090`.
- **Metrics path**: Specify a path to use when collecting metrics from discovered targets. Defaults to `/metrics`.
- **Use public IP**: The `Yes` default uses the public IP address for discovered targets. Toggle to `No` to use a private IP address.
- **Search filter**: Click **Add filter** to apply filters when searching for EC2 instances. Each filter row provides two columns:
  - **Filter name**: Select standard attributes from the drop-down, or type in custom attributes.
  - **Filter values**: Enter values to match within this row's attribute, Press `Enter` between values. (If you specify no values, the search will return only `running` EC2 instances.)

AWS Authentication Options

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables

> `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. This option displays the same fields as Auto, plus:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. This option displays the same fields as Auto, plus:

- **Secret key pair**: Use the drop-down to select a secret key pair that you've configured in Cribl Stream's internal secrets manager or (if enabled) an external KMS. Click **Create** if you need to configure a key pair.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Reject unauthorized certificates: Whether to accept certificates (such as self-signed certificates, for example) that cannot be verified against a valid Certificate Authority. Defaults to `Yes`.

Job timeout: Maximum time a job is allowed to run. Defaults to `0`, for unlimited time. Units are seconds if not specified. Sample entries: `30`, `45s`, `15m`.

Time to live: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Advanced Settings for AWS

These two additional settings appear only when **Optional Settings** > **Discovery Type** is set to `AWS EC2`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to reject certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`, the restrictive option.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__source`
- `__isBroken`
- `__inputId`
- `__final`
- `__criblMetrics`
- `__channel`
- `__cloneCount`

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

How Cribl Stream Pulls Data

The Prometheus Source retrieves data using Cribl Stream scheduled Collection jobs. You determine the schedule using your **Poll interval** entry.

With the `DNS` or `AWS EC2` **Discovery Type**, these jobs include both Discover and Collection phases. The Discover phase runs on a single Worker, and returns 1 collection task per discovered target.

The job scheduler spreads the Collection tasks across all available Workers.

Viewing Scheduled Jobs

This Source executes Cribl Stream's scheduled collection jobs. Once you've configured and saved the Source, you can view those jobs' results by reopening the Source's config modal and clicking its **Job Inspector** tab.

Each content type that you enabled gets its own separate scheduled job.

You can also view these jobs (among scheduled jobs for other Collectors and Sources) in the **Monitoring** > **System** > **Job Inspector** > **Currently Scheduled** tab.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.7.2. Prometheus Remote Write Source

Cribl Stream supports receiving metric data from Prometheus instances that are configured to send data via the remote write protocol.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source assumes that incoming data is snappy-compressed.

Configure Cribl Stream to Receive Metrics from Prometheus Remote Write Sources

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
    - **Remote Write API endpoint**: Enter the absolute path on which to listen for Prometheus requests. Defaults to `/write`, which will (in this example) expand as: `http://<your-upstream-URL>:<your-port>/write`.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header, or select **Generate** if you need a new token.
- **Auth token (text secret)**: Provide an HTTP token referenced by a secret. Select a stored text secret in the resulting drop-down, or select **Create** to configure a new secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials. Click **Generate** if you need a new password.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `No`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the

Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data.

Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is

healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__criblMetrics`
- `__final`
- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.
- `__inputId`
- `__srcIpPort` – See details below.
- `_time`
- `_value`

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Prometheus Remote Write client sending data to this Source.

When any proxies (including load balancers) lie between the Prometheus Remote Write client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Detecting Metrics' Types

Because Prometheus remote write requests don't specify metrics' types, Cribl Stream applies the following rules to determine the type as we ingest them:

- If the metric's name ends with `_total`, `_sum`, `_count`, or `_bucket`, the type is set to `counter`.

- Otherwise, the metric's type is set to `gauge`.

This is consistent with the type detection practiced by other services implementing the remote write protocol. See, for example, New Relic's and Elastic's documentation.

Note that Cribl Stream supports the `timer` type in addition to `counter` and `gauge`.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.7.3. Grafana Source

Cribl Stream supports receiving metric and log data from Grafana Agent instances via the Prometheus remote write specification. The Grafana Agent uses Prometheus for metrics collection and Grafana Loki for log collection.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source assumes that incoming data is snappy-compressed.

Configure Cribl Stream to Receive Metrics and Logs from Grafana Agent Sources

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
3. Next, you can configure the following **Optional Settings**:
    - **Remote Write API endpoint**: Absolute path on which to listen for Grafana Agent's remote write requests. Defaults to `/api/prom/push`, which will (in this example) expand as: `http://<your-upstream-URL>:<your-port>/api/prom/push`.
    - **Logs API endpoint**: Absolute path on which to listen for Loki logs requests. Defaults to `/loki/api/v1/push`, which will (in this example) expand as: `http://<your-upstream-URL>:<your-port>/loki/api/v1/push`.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

The **Authentication** tab provides separate **Loki** and **Prometheus** sections, enabling you to configure these inputs separately. The two sections provide identical options.

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Enter the bearer token that must be included in the authorization header.
- **Auth token (text secret)**: Provide an HTTP token referenced by a secret. Select a stored text secret in the resulting drop-down, or select **Create** to configure a new secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `No`.

- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.
- `__inputId`
- `__labels` – For log events only – will contain all the labels found in each event's corresponding Loki stream.
- `__srcIpPort` – See details below.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Grafana client sending data to this Source.

When any proxies (including load balancers) lie between the Grafana client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Detecting Metrics' Types

Because Prometheus remote write requests don't specify metrics' types, Cribl Stream applies the following rules to determine the type as we ingest them:

- If the metric's name ends with `_total`, `_sum`, `_count`, or `_bucket`, the type is set to `counter`.

- Otherwise, the metric's type is set to `gauge`.

This is consistent with the type detection practiced by other services implementing the remote write protocol. See, for example, New Relic's and Elastic's documentation.

Note that Cribl Stream supports the `timer` type in addition to `counter` and `gauge`.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.7.4. Loki Source

Cribl Stream supports receiving log data from Grafana Loki via an adaptation of the Protobuf (Protocol Buffers) specification.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source assumes that incoming data is snappy-compressed.

Configure Cribl Stream to Receive Loki Logs Data

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
    - **Logs API endpoint**: Absolute path on which to listen for Loki logs requests. Defaults to `/loki/api/v1/push`, which will (in this example) expand as: `http://<your-upstream-URL>:<your-port>/loki/api/v1/push`.
3. Next, you can configure the following **Optional Settings**: - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication type** drop-down to specify how Loki's Promtail agent will authenticate against Cribl Stream:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header.
- **Auth token (text secret)**: Provide an HTTP token referenced by a secret. Select a stored text secret in the resulting drop-down, or select **Create** to configure a new secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate server certs**: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

> The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection`

header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__final`
- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.
- `__inputId`
- `__labels` – Will contain all the labels found in each event's corresponding Loki stream.
- `__srcIpPort` – See details below.
- `_time`

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Loki client sending data to this Source.

When any proxies (including load balancers) lie between the Loki client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.8. Splunk

15.1.8.1. Splunk HEC Source

Cribl Stream supports receiving data over HTTP/S using the Splunk HEC (HTTP Event Collector).

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

For examples of optimizing incoming Splunk events for downstream services, see our Splunk Stream to Cribl Stream, Splunk to Elasticsearch, and Splunk to Exabeam guides.

Also examine several Splunk Forwarder/UF Packs on the Cribl Packs Dispensary. These provide processing Pipelines to optimize Splunk Windows events and Universal Forwarder internal events. You can directly import these and adapt them to your needs.

Configure Cribl Stream to Receive Data over Splunk HEC

Cribl Stream ships with a Splunk HEC Source preconfigured to listen on Port 8088. You can clone or directly modify this Source to further configure it, and then enable it.

In Cribl Stream, configure Splunk HEC:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Splunk HEC Source definition. The default Source is prefilled with the value `in_splunk_hec`, which can't be changed via the UI. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.

- **Description**: Optionally, enter a description.
- **Address**: Enter the hostname/IP on which to listen for HTTP(S) data. Such as: `localhost` or `0.0.0.0`. Supports IPv4 and IPv6 addresses.
- **Port**: Enter the port number.
- **Splunk HEC endpoint**: Absolute path on which to listen for the Splunk HTTP Event Collector API requests. Defaults to `/services/collector`.

This single endpoint supports JSON events via `/event`, health checks via `/health`, raw events via `/raw`, and Splunk S2S events via `/s2s`. See the Splunk REST API endpoints documentation and the examples below. The Source will automatically detect where to forward the request.

3. Next, you can configure the following **Optional Settings**:
   - **Allowed Indexes**: List the values allowed in the HEC event index field. Allows wildcards. Leave blank to skip validation.
   - **Splunk HEC acks**: Whether to enable Splunk HEC acknowledgments. Defaults to `No`. See Working with HEC Acks below to learn about context and limitations.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing, Auth tokens and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Working with HEC Acks

Cribl Stream sends a `200` or similar HTTP response code when it receives an event.

Some senders also send **ack requests**, which differ from events. This type of request asks Cribl Stream to acknowledge delivery of an array of event IDs. (A sender might **require** HEC acks to be enabled. Cribl does not maintain a comprehensive list of senders that require acks – please refer to your sender's documentation.)

How Cribl Stream responds depends on **Optional Settings** > **Splunk HEC acks**:

- When **Splunk HEC acks** is turned on, Cribl Stream will respond to an ack request with an acknowledgement affirming that Cribl Stream received each of the events whose IDs were listed in the array.
- When **Splunk HEC acks** is turned off, Cribl Stream will respond to an ack request with a `400` error and text saying that `ACK` is disabled.

It makes sense to turn **Splunk HEC acks** on for senders that keep TCP connections open while waiting for an ack, because this behavior can exhaust available file descriptors.

There is a caveat to how HEC acks work in Cribl Stream: The ack response simply cites whatever event IDs appeared in the ack request, regardless of whether or not those events were ever received or processed by Cribl Stream. In that sense, what Cribl Stream sends is a "fake ack:" unlike acknowledgements in some other systems, the ack in itself is meaningless. It mainly serves to spare a sender from keeping TCP connections open needlessly.

To determine whether Cribl Stream successfully ingested an event, pay no attention to acks. Instead, verify that the sender received a `200` or similar HTTP response from the Splunk HEC source.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as, the system's CA). Defaults to `No`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so forth. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so forth. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Event Breakers

This section defines event breaking rulesets that will be applied, in order, on the `/raw` endpoint.

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maximum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to determine field's value (can be a constant).

Fields specified on the **Fields** tab will normally override fields of the same name in events. But you can specify that fields in events should override these fields' values.

In particular, where incoming events have no `index` field, this Source adds one with the literal value `default`. You can override this value by using **Add Field** to specify an `index` field, and then setting its **Value** to an expression of the following form: `index == 'default' ? 'myIndex' : index`

Fields here are evaluated and applied **after** any fields specified in the Auth Tokens section.

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Auth Tokens

Provides the authentication token required to access this Source's data. Ensure the token is valid and has the necessary permissions for data retrieval.

Not providing a token allows **unauthenticated access**.

If you exclusively use secret tokens for your Splunk HEC Source, be aware that Cribl Stream versions older than 4.8.2 will not recognize them. This can lead to unintended consequences, such as unsecured data ingestion. To ensure compatibility and security, configure both regular HEC tokens and secret tokens, especially in environments with mixed versions.

Authentication method: Choose between manually entering a **Token** or selecting a stored **Secret**. If you opt for manual entry, type the token directly or **Generate** a new one. For added security, use the secrets store to select a stored **Token (text secret)** or **Create** a new one.

Enable token: Controls the status of the specified authentication token. When set to `Yes`, the specified auth token is active and can be used for client access. If it's set to `No`, the token is disabled, causing it to be skipped and ignored during initialization. This means that any client attempting to use a disabled token will not be granted access.

Disabling a token can be helpful when you need to temporarily stop receiving data from a particular service or application. Disabling a token prevents the service or application from sending data to your endpoint without having to completely delete the token.

See also Periodic Logging for information on how auth tokens affect product logging.

Description: Optional (but recommended), the description for this token. Although this field is optional, the token description becomes the display name for the token. You can select this display name to expand or collapse the token details.

Allowed indexes: Optionally, specify which indexes are permissible for events ingested using this token. Supports multiple index values and wildcards.

Fields: Fields to add to events referencing this token. Each field is a **Name/Value** pair.

Fields specified on the **Auth Tokens** tab will normally override fields of the same name in events. But you can specify that fields in events should override these fields' values.

> In particular, where incoming events have no `index` field, this Source adds one with the literal value `default`. You can override this value by using **Add Field** to specify an `index` field, and then setting its **Value** to an expression of the following form: `index == 'default' ? 'myIndex' : index`
>
> Fields here are evaluated and applied **before** any fields specified in the Fields section.

Advanced Settings

Use Universal Forwarder time zone (S2S only): Leave the default toggle set to `Yes` to have Event Breakers determine the time zone for events based on Universal Forwarder–provided metadata when the time zone can't be inferred from the raw event.

Drop control fields: When set to `Yes`, this setting drops Splunk control fields such as `crcSalt` and `savedPort`. Defaults to `Yes`. Toggle to `No` if you want to retain these fields and store the data in the `__ctrlFields` internal field.

Extract metrics (S2S only): Toggle to `Yes` if you're using Splunk's S2S protocol. When enabled, Cribl will identify and handle Splunk metric events, ensuring that metric events generated by Splunk are processed and forwarded as metrics.

Emit per-token request metrics: Toggle to `Yes` to emit per-token `<prefix>.http.perToken` and summary `<prefix>.http.summary` request metrics. This enables Periodic Logging.

CORS allowed origins: If you need to enable cross-origin resource sharing with Splunk senders, use this field to specify the HTTP origins to which Cribl Stream should send `Access-Control-Allow-*` headers. You can enter multiple domains and use wildcards. This and its companion **CORS allowed headers** option should seldom be needed – see Working with CORS Headers below. Both options are available in Cribl Stream 4.1.2 and later.

CORS allowed headers: List HTTP headers that Cribl Stream will send in a CORS preflight response to your configured (above) **CORS allowed origins** as `Access-Control-Allow-Headers`. Enter `*` to allow all headers.

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.

- `__hecToken`
- `__inputId`
- `__ctrlFields`
- `__s2sVersion` – value can be either `v3` or `v4`. This field is present only when the Source is receiving S2S-encoded payloads.
- `__srcIpPort` – See details below.
- `__TZ`

Universal Forwarder Time Zone

The `__TZ` field uses the universal forwarder time zone to mitigate cases where incoming events have timestamp strings but no time zone information. Event Breakers use the `__TZ` field to derive time zone information, enabling them to set the `_time` field correctly. See Using the UF Time Zone for additional information.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Splunk HEC client sending data to this Source.

When any proxies (including load balancers) lie between the Splunk HEC client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Working with CORS Headers

The **CORS allowed origins** and **CORS allowed headers** settings are needed **only** when you want JavaScript code running in a web browser to send events to the Splunk HEC Source. In this (uncommon) scenario, the code in question sends a preflight request that includes CORS (Cross-Origin Resource Sharing) headers, and the Splunk HEC Source includes CORS headers in its response.

If the settings (and thus the CORS headers in the response) are correct, the browser will allow the code in question to complete requests to the Splunk HEC Source – that is, allow the code to read the Source's

responses. (These settings are optional because for some web applications it's sufficient to send requests **without** reading responses.)

The CORS header dance begins when the web browser sends a request with a header stating its origin. What happens next depends on how you've configured the CORS header settings, as explained in the tables below. (For these examples, we'll assume an origin of `https://mycoolwebapp:3001`.)

CORS allowed origins value	What Splunk HEC Source does	Does Browser then allow code to read response?
`*`	Send `Access-Control-Allow-Origin: *` header.	Yes
Multiple wildcard values	If origin value matches any wildcard, send `Access-Control-Allow-Origin: https://mycoolwebapp:3001` header.	Yes
Nothing (not configured)	Send neither an `Access-Control-Allow-Origin` nor an `Access-Control-Allow-Headers` header.	No

The web browser's request might also include an `Access-Control-Request-Headers` header that lists one or more headers that it wants to use in a subsequent `POST` request (that is, the "actual" as opposed to preflight request). The Splunk HEC Source can then respond with an `Access-Control-Allow-Headers` header **if and only if** it's also sending the `Access-Control-Allow-Origin` header.

CORS allowed headers value	What Splunk HEC Source does	Does Browser then allow code to read response?
`*`	Send `Access-Control-Allow-Headers` header with the same list the client sent.	Yes
Multiple wildcard values	If any headers from the client's list match wildcards, send `Access-Control-Allow-Headers` header listing the matching headers.	Yes
Nothing (not configured)	Do not send an `Access-Control-Allow-Headers` header.	Probably not

Format and Endpoint Examples

Splunk HEC to Cribl Stream

- Configure Cribl Stream to listen on port `8088` with an auth token of `myToken42`.
- Send a payload to your Cribl Stream receiver.

Note: Token specification can be either `Splunk <token>` or `<token>`.

Splunk HEC - JSON Event Examples | Splunk HEC - Raw Event Example | Splunk HEC - Health Event Example

```
curl -k http://<myCriblHost>:8088/services/collector/event -H 'Authorization: myT

curl -k http://<myCriblHost>:8088/services/collector -H 'Authorization: myToken42

# Multiple Events
curl -k http://<myCriblHost>:8088/services/collector -H 'Authorization: myToken42

# Metrics Events
curl -k http://<myCriblHost>:8088/services/collector/event -H 'Authorization: myT

curl -k http://<myCriblHost>:8088/services/collector/event -H 'Authorization: myT

# Send the auth token as a query parameter, with no additional configuration
curl -k "http://<myCriblHost>:8088/services/collector/event?token=mToken42" -d '{
```

Splunk HEC to Cribl.Cloud

- Navigate to Cribl.Cloud's Splunk HEC Source > **Auth Tokens** tab.
- Copy your token out of the **Token** field.
- From the command line, use `https`, your Cribl.Cloud portal's **Ingest Address** and port, and the token's value. You can find the **Ingest Address** on the top nav's **Network Settings** page, under the **Data Sources** tab.

Splunk HEC > Cribl Cloud endpoint

```
curl -k "https://default.main.<Your-Org-ID>.cribl.cloud:8088/services/collector" \
    -H "Authorization: <token_value>" \
    -d '{"event": "Goats are better than ponies."}{"event": "Goats are better climbe
```

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to

`<group-name>.<workspaceID>` when sending to other Worker Groups and/or Workspaces.

Periodic Logging

Cribl Stream emits metrics about incoming requests when **Advanced Settings > Emit per-token request metrics** is enabled. These metrics can be routed to a Destination by enabling the Cribl Metrics Source. There are two categories of metrics: per-token metrics provide details for each configured token, while summary metrics aggregate data across all tokens. If no tokens are configured, only summary metrics will be emitted.

Per-token metric names will be prefixed by `<basePrefix>.http.perToken.`, where `<basePrefix>` is the configured base prefix for the Cribl Metrics Source. The available metric names are listed below, excluding the prefix. As these are counter-type metrics, they will not be emitted if the value is zero.

- `bytesReceived`
- `numRequests`
- `numEvents`
- `numErrors` *Note: this is cumulative of specific error types below as well as a catch-all for other types*
- `numParserErrors`
- `numToDisabledToken`

The summary metric names will be prefixed by `<basePrefix>.http.summary.` where `<basePrefix>` is the configured base prefix for the Cribl Metrics Source. The available metric names are listed below, excluding the prefix. As these are counter-type metrics, they will not be emitted if the value is zero.

- `bytesReceived`
- `numRequests`
- `numEvents`
- `numErrors` *Note: this is cumulative of specific error types below as well as a catch-all for other types*
- `numParserErrors`
- `numToDisabledToken`
- `numAuthFailures`
- `numToWrongUrl`
- `numAckReqs`
- `numReqsAcked`

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

"Malformed HEC event"

The event is missing both `event` and `fields` fields.

"Invalid token"

Auth token(s) are defined, but the token specified in the HEC request doesn't match any defined tokens, therefore it's invalid.

"Invalid index"

The Splunk HEC Source's **Allowed Indexes** field is configured with specific indexes, but the client's HTTP request didn't specify any of them.

"{"text":"Server is busy","code":9,"invalid-event-number":0}"

"Server is busy" is the equivalent of a 503 HTTP response code. The most likely cause is the **Max active requests** setting in the HEC input's Advanced Settings is insufficient to service the number of simultaneous HEC requests. Increase the value and monitor your clients to see if the 503 response is eliminated.

This is not logged in Cribl Stream, but would be found in the response payload sent to your HEC client.

"Could not find parser for URL path" and "Dropping request because parser not found"

These errors can occur if there is a trailing slash in the URL path. For example, posting to `services/collector/` instead of `services/collector` can trigger these messages. Ensure that the URL

path is correct by closely examining the reported `urlPath`.

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.8.2. Splunk Search Source

Cribl Stream supports receiving Splunk search data from Splunk Search.

Type: **Pull** | TLS Support: **Yes** | Event Breaker Support: **YES**

Configure Cribl Stream to Receive Splunk Search Data

In Cribl Stream, configure Splunk Search Data:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Splunk Search Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Cron schedule**: Enter a cron expression to define the schedule on which to run this job. Defaults to one run every 15 minutes. The **Estimated Schedule** below this field shows the next few collection runs, as examples of the cron interval you've scheduled. You enter the **Cron schedule** expression in UTC time, but the **Estimated Schedule** examples are displayed in local time.
3. Under **Search**, configure the following:
    - **Search**: Enter the Splunk query. For example: `index=myAppLogs level=error channel=myApp OR | mstats avg(myStat) as myStat WHERE index=myStatsIndex`.
    - **Search head**: Enter the search head base URL. The default is `https://localhost:8089`.
    - **Earliest**: You can enter the earliest time boundary for the search. This maybe be an exact or relative time. For example: `2022-01-14T12:00:00Z` or `-16m@m`.
    - **Latest**: You can enter the latest time boundary for the search. This maybe be an exact or relative time. For example: `2022-01-14T12:00:00Z` or `-16m@m`.
4. Next, you can configure the following **Optional Settings**:

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Under **Authentication**, select the **Authentication type** from the dropdown:
   - **None**: Don't use authentication. Compatible with REST servers like AWS, where you embed a secret directly in the request URL.
   - **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
   - **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or click **Create** to configure a new secret.
   - **Bearer Token**: Provide the `token` value configured and generated in Splunk.
   - **Bearer Token (text secret)**: Provide the Bearer Token referenced by a secret. Select a stored text secret in the resulting **Token (text secret)** drop-down, or click **Create** to configure a new secret.
6. Optionally, you can adjust the Processing, Retries, and Advanced settings outlined in the sections below.
7. Select **Save**, then **Commit & Deploy**.

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to the `Splunk Search Ruleset.`

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Retries

Retry type: The algorithm to use when performing HTTP retries. Options include `Backoff` (the default), `Static`, and `Disabled`.

Initial retry interval (ms): Time interval between failed request and first retry (kickoff). Maximum allowed value is 20,000 ms (1/3 minute). A value of `0` means retry immediately until reaching the retry limit in **Max retries**.

Max retries: Maximum number of times to retry a failed HTTP request. Defaults to `5`. Maximum: `20`. A value of `0` means don't retry at all.

Backoff multiplier: Base for exponential backoff. A value of `2` (default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, etc.

Retry HTTP codes: List of HTTP codes that trigger a retry. Leave empty to use the defaults (`429` and `503`). Cribl Stream does not retry codes in the `200` series.

Honor Retry-After header: When toggled to `Yes` (the default) and the `retry-after` header is present, Cribl Stream honors any `retry-after` header that specifies a delay, up to a maximum of 20 seconds. Cribl Stream always ignores `retry-after` headers that specify a delay longer than 20 seconds.

- Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).
- When toggled to `No`, Cribl Stream ignores all `retry-after` headers.

Retry Connection Timeout: Toggle to `Yes` to automatically retry a single connection attempt after a timeout (`ETIMEDOUT`) to ensure data continuity.

Retry Connection Reset: Toggle to `Yes` to automatically retry a connection after a peer reset (`ECONNRESET`) to maintain data flow.

Advanced Settings

Reject unauthorized certificates: Whether to accept certificates (such as self-signed certificates, for example) that cannot be verified against a valid Certificate Authority. Defaults to `Yes`.

Search endpoint: Rest API used to conduct a search. Defaults to `services/search/jobs/export`.

Output mode: Format of the returned output. Defaults to JSON format.To parse the returned JSON, add the Cribl event breaker which parses newline delimited events in the Event Breakers tab.

Events returned from Splunk search can also be returned in the more compact CSV format. To use CSV format, set the **Output mode** to CSV and specify the CSV event breaker in the Event Breakers tab.

Endpoint parameters: Optional HTTP request parameters to append to the request URL. These refine or narrow the request. Click **Add Parameter** to add parameters as key-value pairs:

- **Name**: Field name.
- **Value**: JavaScript expression to compute the field's value (can be a constant).

Endpoint headers:: Click **Add Header** to (optionally) add request headers to send to the endpoint, as key-value pairs:

- **Name**: Header name.
- **Value**: JavaScript expression to compute the header's value, normally enclosed in backticks (for example, `` `${earliest}` ``). Can also be a constant, enclosed in single quotes (`'earliest'`). Values without delimiters (for example, `earliest`) are evaluated as strings.

Log level: Set the verbosity level for the data collection's runtime log.

Job timeout: Maximum time a job is allowed to run. Defaults to `0`, for unlimited time. Units are seconds if not specified. Sample entries: `30`, `45s`, `15m`.

Time to live: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.

Request Timeout (secs): Here, you can set a maximum time period (in seconds) for an HTTP request to complete before Cribl Stream treats it as timed out. Defaults to `0`, which disables timeout metering.

Encoding: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__outputMode`

How Cribl Stream Pulls Data

This Collector-based Source will gather data from the specified **Search head** URL repeatedly, on the interval specified in the **Cron schedule** field. A single Worker executes each collection job.

If the Leader goes down, search jobs in progress will complete, but future scheduled searches will not run until the Leader relaunches.

Mitigating Stuck-Job Problems

Occasionally, a scheduled job fails, but continues running for hours or even days, until someone intervenes and cancels it. If left alone, such a "stuck", "orphaned," or "zombie" job will never complete. This can cause missing events in downstream receivers, along with `HTTP timeout` or similar errors in Cribl Stream's logs.

To keep stuck jobs from running excessively long:

- First, try setting **Advanced** > **Request Timeout (secs)** – whose default of `0` means "wait forever" – to a desired maximum duration.
- If adjusting **Timeout (secs)** does not fix the problem, try setting **Advanced** > **Job Timeout** – whose default of `0` allows a job to run indefinitely – to a desired maximum duration.

Using these settings in tandem works like this:

- **Timeout (secs)** limits the time that Cribl Stream will wait for an HTTP request to complete.
- Then, if a job gets stuck and keeps running beyond that limit, **Job Timeout** can catch and terminate the job, because it monitors the overall time the job has been running.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.8.3. Splunk TCP Source

Cribl Stream supports receiving Splunk data from Universal or Heavy Forwarders.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

For examples of optimizing incoming Splunk events for downstream services, see our Splunk Stream to Cribl Stream, Splunk to Elasticsearch, and Splunk to Exabeam guides.

Also examine several Splunk Forwarder/UF Packs on the Cribl Packs Dispensary. These provide processing Pipelines to optimize Splunk Windows events and Universal Forwarder internal events. You can directly import these and adapt them to your needs.

Configure Cribl Stream to Receive Splunk TCP Data

Cribl Stream ships with a Splunk TCP Source preconfigured to listen on Port 9997. You can clone or directly modify this Source to further configure it, and then enable it.

In Cribl Stream, configure Splunk TCP:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `in_splunk_tcp`, which can't be changed via the UI. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for Splunk data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter port number.
3. Next, you can configure the following **Optional Settings**:

    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing, Auth tokens and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so forth. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so forth. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

As of Cribl Stream 4.1, Source-side PQ's default **Mode** changed from `Smart` to `Always on`. This option more reliably ensures events' delivery, and the change does not affect existing Sources' configurations. However:

- If you create Stream Sources programmatically, and you want to enforce the previous `Smart` mode, you'll need to update your existing code.
- If you enable `Always on`, this can reduce data throughput. As a trade-off for data durability, you might need to either accept slower throughput, or provision more machines/faster disks.
- You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule.`

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Auth Tokens

Add Token : Click to add authorization tokens. Each token's section provides the fields listed below. If no tokens are specified, unauthenticated access **will be permitted**.

Token: Shared secrets to be provided by any Splunk forwarder (`Authorization: <token>`). Click **Generate** to create a new secret.

Description: Optional description for this token.

Advanced Settings

Enable Proxy Protocol: Toggle to `Yes` if the connection is proxied by a device that supports Proxy Protocol v1 or v2.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (such as, all IPs).

Max active connections: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set `0` for unlimited connections.

Max S2S version: The highest version of the Splunk-to-Splunk protocol to expose during handshake. Defaults to `v4`; `v3` is also available.

Use Universal Forwarder time zone: Displayed (and enabled by default) only when **Max S2S version** is set to `v4`. Provides Event Breakers with a `__TZ` field, which derives events' time zone from UF-provided metadata. See Using the UF Time Zone and Configuring a Splunk Forwarder, below.

Drop control fields: When set to `Yes`, this setting drops Splunk control fields such as `crcSalt` and `savedPort`. Defaults to `Yes`. Toggle to `No` if you want to retain these fields and store the data in the `__ctrlFields` internal field.

Extract metrics: Toggle to `Yes` if you're using Splunk's S2S protocol. When enabled, Cribl will identify and handle Splunk metric events, ensuring that metric events generated by Splunk are processed and forwarded as metrics.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

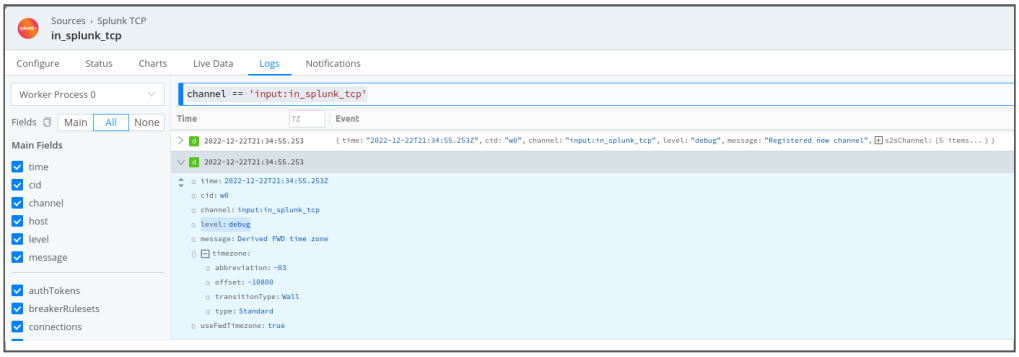
Using the UF Time Zone

Under Advanced Settings, the **Use Universal Forwarder time zone** toggle mitigates cases where incoming events have timestamp strings but no time zone information. For example:

```
12-15-2022 14:57:22.080 WARN TcpOutputFd [1607 TcpOutEloop] - Connect to 172.17.0.1:9
```

This gap can be problematic, especially if the originating Universal Forwarder is in a different time zone from the processing Worker Node.

The `__TZ` field is the solution. Event Breakers use the `__TZ` field to derive time zone information, enabling them to set the `_time` field correctly. Derived time zone information will appear in Cribl Stream's own logs as shown below:



Time zone information in logs

Setting the Log Level for Connection Messages

When a Splunk forwarder connects to Cribl Stream, Cribl Stream logs the following message at the `debug` level: `Connection with forwarder has been established successfully.`

To see this message, set the `:forwarders` level to `debug`.

Each message contains details specific to the forwarder, such as the protocol, Splunk version, or remote host, to name a few.

In some situations, logging each incoming connection can produce many messages, which can make it hard to find other messages.

You can adjust the level of these connection messages. To do so, follow these steps:

1. Select **Settings** > **Global Settings** > **Logging** > **Levels**.
2. Search for the channel that logs the connection messages. It will have a name in the form `input:<source-id>:forwarders`. For example: `input:in_splunk_tcp:forwarders`.
3. Set the channel to the log level you prefer, such as `debug` or `silly`.
4. Click **Save** to save your setting.
5. Commit and deploy the change.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__ctrlFields`
- `__s2sVersion` – value can be either `v3` or `v4`
- `__source`
- `__srcIpPort`
- `__TZ` – see above

Configuring a Splunk Forwarder

To configure a Splunk forwarder (UF, HF) use the following sample outputs.conf stanzas:

outputs.conf (on-prem) | outputs.conf (Cribl Cloud)

```
[tcpout]
disabled = false
defaultGroup = cribl, <optional_clone_target_group>, ...
enableOldS2SProtocol = true

[tcpout:cribl]
server = [<cribl_ip>|<cribl_host>]:<port>, [<cribl_ip>|<cribl_host>]:<port>, ...
compressed = false
sendCookedData = true
# As of Splunk 6.5, using forceTimebasedAutoLB is no longer recommended. Ensure t
# forceTimebasedAutoLB = false
```

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to `<group-name>.main` when sending to other Worker Groups.

If your use case requires compression, use useClientSSLCompression vs compressed on forwarder to compress the data stream.

Preventing Data Loss with v3

If you set **Max S2S version** to `v3` and are using Splunk 9.1.0 or later, Cribl recommends that you use the `enableOldS2SProtocol = true` setting shown above to avoid data loss. If you are working with `v3` and a Splunk version earlier than 9.1.0, you should use `negotiateProtocolLevel = 0`. Depending on your environment, enabling `negotiateProtocolLevel` with a non-`0` value could cause Cribl Stream to not accept data from the forwarder.

If you set **Max S2S version** to `v4`, these settings are not necessary. The Splunk receiver will detect which version is in use and automatically use the correct handler.

See Internal Fields for information on the `__s2sVersion` field.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Splunk Forwarder Performance Issues

If you encounter performance issues with a Splunk Forwarder, Cribl recommends increasing the number of parallel ingestion Pipelines or increasing forwarder throughput. You can experiment with either or both of these settings.

To increase the number of parallel ingestion Pipelines, adjust the setting for `parallelIngestionPipelines` in `server.conf`. Experiment with values ranging from `2-4`.

To adjust forwarder throughput, increase the `maxKBps` value in `limits.conf`. The default value is `256`. A value of `0` removes all throttling from the forwarder.

"Connection rejected" with a `reason` of "Too many connections"

The maximum number of active Splunk TCP connections has been exceeded per Worker Process. The default is 1000.

Recommendation

In the Splunk TCP input's Advanced Settings configuration, increase the Max Active Connections value, set it to 0 for unlimited, and/or increase the # of Worker Processes the Worker Node(s) are using.

15.1.9. Internal

15.1.9.1. Cribl Internal Source

The Cribl Internal Source enables you to capture and send Cribl Stream's own internal **logs** and **metrics** through Routes and Pipelines.

Type: **Internal** | TLS Support: **N/A** | Event Breaker Support: **No**

Scope and Purpose

In Distributed mode, this Source's CriblLogs option can process internal logs only from Worker Processes. (Logs on the Leader remain on the Leader, because the Leader Node is not part of any processing path.)

In both Distributed and Single-instance mode, this Source's CriblLogs option omits API Process logs, meaning that it omits telemetry/license-validation traffic. You can, however, use a Script Collector to check for API Server (or Worker Group) events.

This Source's CriblMetrics option offers Cribl's most up-to-date and precise view of event throughput and transformation, aggregated every 2 seconds at the Worker Process level. The CriblLogs option is less granular – tracking logs that are written once per minute – so CriblLogs might fail to reflect Worker Process crashes or restarts.

In Cribl.Cloud, on Cribl-managed Worker Groups in Cribl.Cloud, the CriblLogs internal Source contains only logs related to Sources and Destinations.

Configure Cribl Internal Logs/Metrics as a Data Source

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing **Select Existing**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Next, select either the default `CriblLogs` or `CriblMetrics` to open the configuration modal.

3. Configure the **General Settings** for your selected Source.
    - For Cribl Logs, configure the following:
        - **Enabled**: This duplicates the parent page's **Enabled** toggle. Keep it at `Yes` to enable Cribl logs as a Source.
        - **Input ID**: This is prefilled with the default value `CriblLogs`, which cannot be changed via the UI.
        - **Description**: Optionally, enter a description.
    - For Cribl Metrics, configure the following:
        - **Enabled**: This duplicates the parent page's **Enabled** toggle. Keep it at `Yes` to enable Cribl metrics as a Source.
        - **Input ID**: This is prefilled with the default value `CriblLogs`, which cannot be changed via the UI.
        - **Description**: Optionally, enter a description.
4. Next, you can configure the following **Optional Settings** for your selected Source:
    - For Cribl Logs, configure the following:
        - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
    - For Cribl Metrics, configure the following:
        - **Metric name prefix**: Enter an optional prefix that will be applied to metrics provided by Cribl Stream. The prefix defaults to `cribl.logstream.`
        - **Full fidelity**: Toggle this to `No` to exclude granular metrics that can cause high CPU load. For details, see Full Fidelity below. .
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

If Cribl Stream detects `source` or `host` fields in metrics, it copies their values into new dimensions with added `event_` prefixes (for example, `event_source`). This preserves the original fields' values if they're overwritten in downstream services. For details, see Duplicated Fields/Dimensions.

You can disable metric collection for these and other fields by specifying them in **Settings** > **Global** > **System** > **General Settings** > **Limits** > **Metrics** > **Disable field metrics**.

5. Optionally, configure any Processing and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Full Fidelity

When you toggle **Full fidelity** to `No`, the following metrics will be dropped:

- `cribl.logstream.host.(in_bytes,in_events,out_bytes,out_events)`
- `cribl.logstream.index.(in_bytes,in_events,out_bytes,out_events)`
- `cribl.logstream.source.(in_bytes,in_events,out_bytes,out_events)`
- `cribl.logstream.sourcetype.(in_bytes,in_events,out_bytes,out_events)`

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality. For example, here you could specify adding an `index` field.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Reporting Metrics Less Frequently

By default, Cribl Stream generates internal metrics every 2 seconds. To consume metrics at longer intervals, you can use or adapt the `cribl_metrics_rollup` Pipeline that ships with Cribl Stream.

Attach this Pipeline to your **Cribl Internal** Source as a pre-processing Pipeline. The Pipeline's **Rollup Metrics** Function has a default **Time Window** of 30 seconds, which you can adjust to a different granularity as needed. This provides a second lever to reduce granularity, in addition to the Full fidelity toggle described above.

Omitting `sourcetype`

You can easily drop the `sourcetype` attribute from metrics events, leaving only `event_sourcetype`. This will prevent duplicate `sourcetype` events from being routed to Destinations.

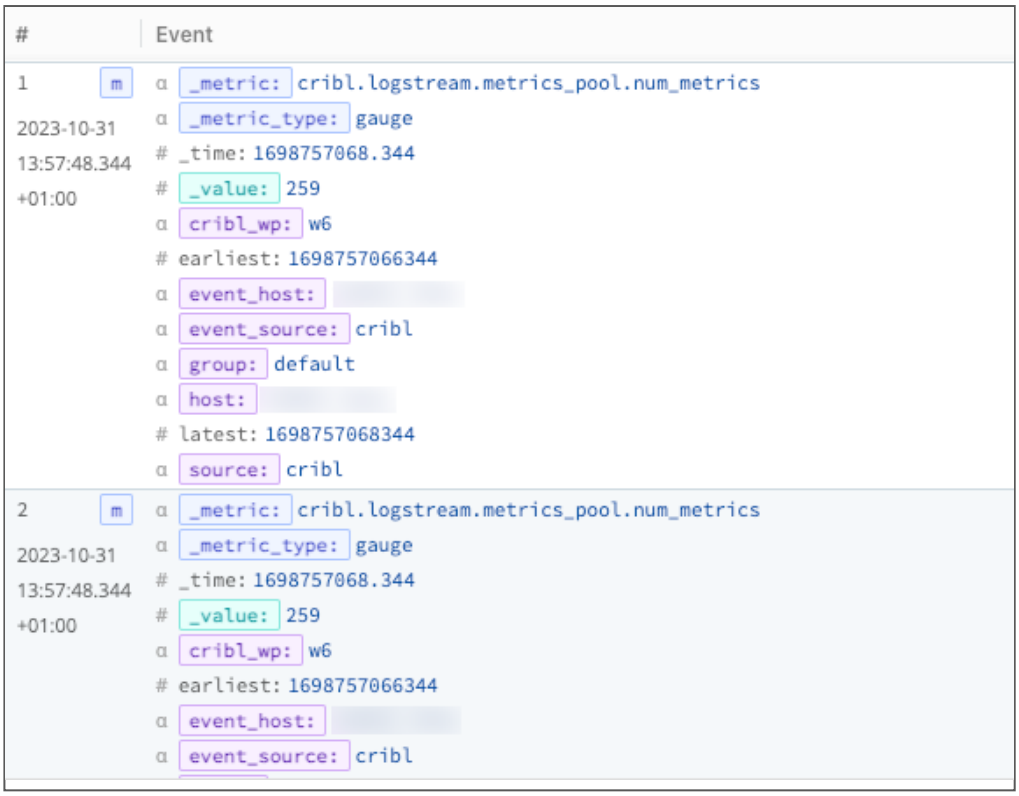
To do this: In the same `cribl_metrics_rollup` pre-processing Pipeline (or a clone) that you attach to your Source, enable the final Eval Function, which applies this **Filter** expression to remove the `sourcetype` field: `_metric && _metric.startsWith('cribl.logstream.sourcetype.')`

Duplicated Fields/Dimensions

The CriblMetrics Source operates on metrics that Worker Nodes report to their Leader Nodes. Typically included are `source` and `host` fields.

Sending metrics from this Source to Splunk is one common use case. Because Splunk might overwrite these two fields, the Source copies their values into new dimensions with added `event_` prefixes: `event_source` and `event_host`. This way, if Splunk does overwrite `source` and/or `host`, their original values remain intact in the new dimensions with `event_` prefixes.

Here's an example of how the added dimensions look in the **Live Capture** window:



Doubled fields

If you are not sending to a downstream service that overwrites `source` or `host` fields, you can use an appropriate Function to drop the added dimensions. You also have the option to suppress these fields entirely by specifying them in **Settings** > **Global** > **System** > **General Settings** > **Limits** > **Metrics** > **Disable field metrics**.

Internal Fields

The following fields will be added to all events/metrics:

- `source`: set to `cribl`.
- `host`: set to the hostname of the Cribl instance.

Use these fields to guide these events/metrics through Cribl Routes.

All Cribl internal fields are subject to change and modification. Cribl provides them to assist with analytics and diagnostics, but does not guarantee that they will remain available.

15.1.9.2. Cribl HTTP Source

The Cribl HTTP Source receives data from a Cribl HTTP Destination connected to the same Leader. Relaying data between a Cribl HTTP Destination and Cribl HTTP Source pair prevents double-billing: You'll be charged no additional charges or credits after initial ingest to the first Worker Group.

It's common to send data from Cribl Edge to a Cribl Stream Worker Group using this kind of pairing.

Type: **Internal** | TLS Support: **YES** | Event Breaker Support: **No**

For guidance on when to choose this Source versus the Cribl TCP Source, see Interoperation Protocols.

Within Cribl Stream, the Cribl HTTP Source is available only in Distributed deployments.
In single-instance mode, or for testing, you can use the Raw HTTP/S Source instead. However, this substitution will not facilitate sending all internal fields, as described below.

How It Works

You can use the Cribl HTTP Source to transfer data between Worker Nodes and Workers. If the Cribl HTTP Source receives data from its Cribl HTTP Destination counterpart on another Worker, you're billed for ingress only once – when Cribl first receives the data. All data subsequently relayed to other Workers via a Cribl HTTP Destination/Source pair is not charged.

This use case is common in hybrid Cribl.Cloud deployments, where a customer-managed (hybrid) Worker Node sends data to a Worker in Cribl.Cloud for additional processing and routing to Destinations. However, the Cribl HTTP Destination/Source pair can similarly reduce your metered data ingress in other scenarios, such as on-prem Edge to on-prem Stream.

As one usage example, assume that you want to send data from one Node deployed on-prem, to another that is deployed in Cribl.Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl.Cloud.
- Create an on-prem Cribl HTTP Destination.
- Create a Cribl HTTP Source, on the target Stream Worker Group or Edge Fleet in Cribl.Cloud.
- For an on-prem Node configure a File System Collector to send data to the Cribl HTTP Destination, and from there to the Cribl HTTP Source in Cribl.Cloud.
- On Cribl-managed Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl HTTP Destination and the Cribl HTTP Source it's sending data to, or enabled on both. Otherwise, no data will flow. On Cribl.Cloud instances, the Cribl HTTP Source ships with TLS enabled by default.

Configuration Requirements

The key points about configuring this architecture are:

- The Cribl HTTP Destination must be on a Node that is connected to the same Leader as the Cribl HTTP Source(s).
- The Destination's **Cribl endpoint** field must point to the **Address** and **Port** you've configured on its peer Cribl HTTP Source(s).
- Cribl 3.5.4 was a breakpoint in Cribl HTTP Leader/Worker communications. Nodes running the Cribl HTTP Source on Cribl 3.5.4 and later can send data only to Nodes running v.3.5.4 and later. Nodes running the Cribl HTTP Source on Cribl 3.5.3 and earlier can send data only to Nodes running v.3.5.3 and earlier.

Configure the Cribl HTTP Source

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: Enter a unique name to identify this Cribl HTTP Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the address to bind on. Defaults to `0.0.0.0` (all addresses).
    - **Port**: Enter the port number to listen on, for example, `10200`.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use for filtering and grouping in the Cribl Stream UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.
4. Optionally, configure any TLS settings, Persistent Queue, Processing, Advanced settings and Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled Defaults to `No`. When toggled to `Yes`, exposes this section's remaining fields.

Certificate name: Select a predefined certificate from the drop-down. A **Create** button is available to create a new certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`, exposes these two additional fields:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `No`.
- **Common name**: Regex matching subject common names in peer certificates allowed to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

Enable Persistent Queue defaults to `No`. When toggled to `Yes`:

Mode: Choose a mode from the drop-down:

- With `Smart` mode, PQ will write events to the filesystem only when it detects backpressure from the processing engine.
- With `Always On` mode, PQ will always write events directly to the queue before forwarding them to the processing engine.

Max buffer size: Maximum number of events to hold in-memory before dumping them to disk.

Commit frequency: Number of events to send before committing that Stream has read them.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space the queue is allowed to consume. Once this limit is reached, Cribl Stream stops queueing and applies the fallback **Queue-full behavior**. Enter a numeral with units of KB, MB, etc.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Stream will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`; `Gzip` is also available.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

The Cribl HTTP Source (and the Cribl TCP Source) treat internal fields differently than other Sources do. That's because of the difference in the way that incoming data originates.

Other Sources ingest data that's not coming from Cribl Edge or Stream, meaning that no Cribl internal fields can be present in that data when it arrives at the Source, and the Source is free to add internal fields without clobbering (overwriting) anything that existed already.

By contrast, the Cribl HTTP Source and the Cribl TCP Source ingest data that's coming from a Cribl HTTP or Cribl TCP Destination. That data **can** contain internal fields when it arrives at the Source. This means that if the Source adds internal fields, those could potentially clobber what existed before.

To avoid this problem, the Cribl HTTP Source and the Cribl TCP Source add a unique `__forwardedAttrs` (i.e., "forwarded attributes") field. The nested structure of the `__forwardedAttrs` field contains any of the following fields that are present in the arriving data:

Internal Fields
`__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.
`__inputId`
`__outputId`
`__srcIpPort` – See details below.

Other Fields
`cribl_breaker`
`cribl_pipe`

These fields are **copied** into `__forwardedAttrs`, not moved there. As the data (apart from `__forwardedAttrs`) moves through the Source and any Pipelines, the values of these fields can be overwritten. But the copies of these fields in `__forwardedAttrs` remain unchanged, so you can retrieve them as necessary.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the HTTP client sending data to this Source.

When any proxies (including load balancers) lie between the HTTP client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Troubleshooting

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.9.3. Cribl TCP Source

The Cribl TCP Source receives data from a Cribl TCP Destination connected to the same Leader. Relaying data between a Cribl TCP Destination and Cribl TCP Source pair prevents double-billing: You'll be charged no additional charges or credits after initial ingest to the first Worker Group.

It's common to send data from Cribl Edge to a Cribl Stream Worker Group using this kind of pairing.

Type: **Internal** | TLS Support: **YES** | Event Breaker Support: **No**

For guidance on when to choose this Source versus the Cribl HTTP Source, see Interoperation Protocols.

Within Cribl Stream, the Cribl TCP Source is available only in Distributed deployments. In single-instance mode, or for testing, you can use the TCP JSON Source instead. However, this substitution will not facilitate sending all internal fields, as described below.

How It Works

You can use the Cribl TCP Source to transfer data between Worker Nodes and Workers. If the Cribl TCP Source receives data from its Cribl TCP Destination counterpart on another Worker, you're billed for ingress only once – when Cribl first receives the data. All data subsequently transferred to other Workers via a Cribl TCP Destination/Source pair is not charged.

This use case is common in hybrid Cribl.Cloud deployments, where a customer-managed (hybrid) Worker Node sends data to a Worker in Cribl.Cloud for additional processing and routing to Destinations. However, the Cribl TCP Destination/Source pair can similarly reduce your metered data ingress in other scenarios, such as on-prem Cribl Edge to on-prem Cribl Stream.

As one usage example, assume that you want to send data from one Node deployed on-prem, to another that is deployed in Cribl.Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl.Cloud.
- Create an on-prem Cribl TCP Destination.
- Create a Cribl TCP Source, on the target Cribl Stream Worker Group or Cribl Edge Fleet in Cribl.Cloud.
- For an on-prem Node, configure a File System Collector to send data to the Cribl TCP Destination, and from there to the Cribl TCP Source in Cribl.Cloud.
- On Cribl-managed Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl TCP Destination and the Cribl TCP Source it's sending data to, or enabled on both. Otherwise, no data will flow. On Cribl.Cloud instances, the Cribl TCP Source ships with TLS enabled by default.

Configuration Requirements

The key points about configuring this architecture are:

- The Cribl TCP Destination must be on a Node that is connected to the same Leader as the Cribl TCP Source.
- When you configure the Cribl TCP Destination, its **Address** and **Port** values must point to the **Address** and **Port** you've configured on the Cribl TCP Source.
- Cribl 3.5.4 was a breakpoint in Cribl TCP Leader/Worker communications. Nodes running the Cribl TCP Source on Cribl 3.5.4 and later can send data only to Nodes running v.3.5.4 and later. Nodes running the Cribl TCP Source on Cribl 3.5.3 and earlier can send data only to Nodes running v.3.5.3 and earlier.

Configure the Cribl TCP Source

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: Enter a unique name to identify this Cribl TCP Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for TCP JSON data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter the port number to listen on, for example, `10300`.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use for filtering and grouping in the Cribl Stream UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.
4. Optionally, configure any TLS settings, Persistent Queue, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `No`.
- **Common name**: Regex matching subject common names in peer certificates allowed to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

Enable Persistent Queue defaults to `No`. When toggled to `Yes`:

Mode: Choose a mode from the drop-down:

- With `Smart` mode, PQ will write events to the filesystem only when it detects backpressure from the processing engine.
- With `Always On` mode, PQ will always write events directly to the queue before forwarding them to the processing engine.

Max buffer size: Maximum number of events to hold in memory before dumping them to disk. Defaults to `1000`.

Commit frequency: Number of events to send before committing that Cribl Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space the queue is allowed to consume. Once this limit is reached, Cribl Stream stops queueing and applies the fallback **Queue-full behavior**. Enter a numeral with units of KB, MB, and so on.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Stream will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`; `Gzip` is also available.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre–Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Enable proxy protocol: Toggle to `Yes` if the connection is proxied by a device that supports proxy protocol v1 or v2.

Enable load balancing (Cribl Stream only): Toggle to `Yes` to distribute the data from incoming TCP connections across multiple Worker Processes. This improves performance compared to the default of having all data from

an incoming connection processed on a single Worker Process.

- This spins up an extra Worker Process (named `wLB` in **Settings** > **Processes**) on the Worker Node, which handles splitting data from incoming TCP connections across all other Worker Processes.
- When enabled, the option to include common fields in the JSON header is not supported. This means fields specified under `fields` in the JSON header are not automatically added to all events.

Load balancing is available only in Cribl Stream Distributed deployments.

Max active connections: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set to `0` for unlimited connections.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the configuration will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

The Cribl TCP Source (and the Cribl HTTP Source) treat internal fields differently than other Sources do. That's because of the difference in the way that incoming data originates.

Other Sources ingest data that's not coming from Cribl Edge or Cribl Stream, meaning that no Cribl internal fields can be present in that data when it arrives at the Source, and the Source is free to add internal fields without clobbering (overwriting) anything that existed already.

By contrast, the Cribl TCP Source and the Cribl HTTP Source ingest data that's coming from a Cribl TCP or Cribl HTTP Destination. That data **can** contain internal fields when it arrives at the Source. This means that if the Source adds internal fields, those could potentially clobber what existed before.

To avoid this problem, the Cribl TCP Source and the Cribl HTTP Source add a unique `__forwardedAttrs` (that is, "forwarded attributes") field. The nested structure of the `__forwardedAttrs` field contains any of the following fields that are present in the arriving data:

Internal Fields
`__srcIpPort`
`__inputId`
`__outputId`

Other Fields
`cribl_breaker`
`cribl_pipe`

These fields are **copied** into `__forwardedAttrs`, not moved there. As the data (apart from `__forwardedAttrs`) moves through the Source and any Pipelines, the values of these fields can be overwritten. But the copies of these fields in `__forwardedAttrs` remain unchanged, so you can retrieve them as necessary.

Periodic Logging

Cribl Stream logs metrics about incoming requests and ingested events once per minute.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker Process.

This kind of periodic logging helps you determine whether a Source is in fact still healthy even when no data is coming in.

15.1.9.4. Cribl Stream Source (Deprecated)

This Source was deprecated as of Cribl Stream 3.5, and has been removed as of v.4.0. Please instead use the Cribl TCP or the Cribl HTTP Source to enable Worker Nodes to send data to peer Nodes.

The Cribl Stream internal Source is available only in distributed deployments. It is provided to facilitate sending data between Worker Nodes that are connected to the same Leader. You'll find this Source especially valuable in a hybrid Cloud deployment.

This Source can receive data only from a TCP JSON Destination, on a Worker Node that is connected to the same Leader. The following instructions cover configuring such a TCP JSON Destination.

Type: **Internal** | TLS Support: **YES** | Event Breaker Support: **No**

Use New Sources Instead

The replacement Sources, Cribl TCP and the Cribl HTTP, don't rely on IP filtering, for the following reasons:

- Load balancers and/or proxies between the Cribl Destination and Cribl Source can change the IP address, resulting in a bad match and rejected ingest.
- A Lookup table of all IP addresses needed to be sent to each Worker Node/Edge Node from the Leader, which is not scalable.
- The Lookup table of IP addresses required constant communication between the Worker Node/Edge Nodes and the Leader, making this fragile and placing an arbitrary reliance on the Leader that shouldn't be there.

How It Works

You can use the Cribl Stream Source to send data between Workers. In a hybrid Cribl.Cloud deployment, using this Source ensures that you're billed for ingress only once – when the data is originally received. All other data transferred into Workers via the Cribl Stream Source is not charged.

This use case is common in deployments where an on-prem Worker sends data to a Worker in Cribl Cloud, for additional processing and then routing to Destinations.

As one usage example, assume that you want to send data from one Worker Node/Edge Node deployed on-prem, to another that is deployed in Cribl Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl Cloud.
- Create an on-prem TCP JSON Destination.
- Create a "Cribl Stream" Source, on the target Worker Group/Fleet in Cribl Cloud.
- Configure these to send data from the File System Collector to the TCP JSON Destination, and from there to the "Cribl Stream" Source in Cribl Cloud.

The key points about configuring this architecture are:

- The TCP JSON Destination must be on a Worker Node/Edge Node that is connected to the same Leader as the "Cribl Stream" Source.
- The TCP JSON Destination's **Address** and **Port** must match the "Cribl Stream" Source's **Address** and **Port**.

Configuring the Cribl Stream Source

In the **QuickConnect** UI: Click **New Source** or **Add Source**. From the resulting drawer's tiles, select [**System and Internal** >] **Cribl Stream**. Next, click either **Add Destination** or (if displayed) **Select Existing**. The drawer will now provide the following options and fields.

Or, in the **Data Routes** UI: From the top nav of a Cribl Stream instance or Group, select **Data** > **Sources**. From the resulting page's tiles or the **Sources** left nav, select [**System and Internal** >] **Cribl Stream**. Next, click **New Source** to open a **Cribl Stream** > **New Source** modal that provides the following options and fields.

General Settings

Input ID: Enter a unique name to identify this Cribl Stream Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.

Address: Enter hostname/IP to listen for TCP JSON data. For example, `localhost` or `0.0.0.0`.

Port: Enter the port number to listen on.

Authentication Settings

Use the **Authentication method** buttons to select one of these options:

- **Manual**: Use this default option to enter the shared secret that clients must provide in the `authToken` header field. Exposes an **Auth token** field for this purpose. (If left blank, unauthenticated access will be permitted.) A **Generate** link is available if you need a new secret.
- **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the `authToken` header field value described above. The secret can reside in

Cribl Stream's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need a new secret.

Optional Settings

Tags: Optionally, add tags that you can use for filtering and grouping in the Cribl Stream UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `No`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Enable Proxy Protocol: Toggle to `Yes` if the connection is proxied by a device that supports Proxy Protocol v1 or v2.

IP Allowlist Regex: Regex matching IP addresses that are allowed to establish a connection. Although it appears in the **Advanced Settings** UI, this is not a user-configurable setting. Its value is updated automatically to match the IP addresses used in the deployment, and cannot be edited.

Max Active Connections: Maximum number of active connections allowed per Worker Process. Use `0` for unlimited.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Field for this Source:

- `__inputId`
- `__srcIpPort`

15.1.10. System

15.1.10.1. Datagen Source

Cribl Stream supports generating data from datagen files, as detailed in Using Datagens. When a datagen is enabled, each Worker Process uses the specified data generator file to generate events. These events proceed through Routes and Pipelines, or through a QuickConnect configuration, to configured Destinations. Whichever Worker Process generated an event from the file will also send the same event.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **No**

Configure Cribl Stream to Generate Sample Data

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Datagens**: List of datagens. For details, see Datagen Fields below.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use for filtering and grouping in the Cribl Stream UI. Use a tab or hard return between (arbitrary) tag names. These tags aren't added to processed events.
4. Optionally, configure any Processing and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Datagen Fields

To configure the list of datagens, include the following:

- **Data generator file**: Name of the datagen file.

- **Events per second per Worker Node**: Maximum number of events to generate per second, per Worker Node/Edge Node. Defaults to `10`.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`

15.1.10.2. Exec Source

The Exec Source enables you to periodically execute a command and collect its `stdout` output. This is typically used in cases when Cribl Stream cannot accomplish collection with native Collectors or other Sources.

Available in Cribl.Cloud: **No** | Type: **System** | TLS Support: **N/A** | Event Breaker Support: **Yes**

This Source allows you to run **almost anything** on the host system. Make sure you understand the security and other impacts of commands you plan to execute, before proceeding. To disable it on your Worker Nodes, see Disable the Exec Source below.

Especially for monitoring or polling, you'll need to receive the command or script's output periodically. For this reason, the Exec Source lets you specify when the command or script should run, by time interval or by cron-style schedule.

Here are a few examples of what you can run from an Exec Source:

- Database queries.
- Custom commands to poll databases or apps.
- `ping` to check latency.
- `ps -ax` to get a list of running processes.
- `SNMP GET` requests to query an SNMP agent about network entities.
- `netstat -natp` to get lists of sockets and TCP ports, and what they're doing.
- `mtr -c 1 --report --json 8.8.8.8` to run a traceroute on a location (here, `8.8.8.8`), and packaging up a report in JSON format.

Configure an Exec Source

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:

- **Enabled**: Defaults to `Yes`.
- **Input ID**: Enter a unique name to identify this Exec Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
- **Command**: Command to execute; supports Bourne shell syntax.
- **Schedule type**: Use the buttons to select either `Interval` or `Cron`. For details, see Schedule Type below.

3. Next, you can configure the following **Optional Settings**:
   - **Max retries**: Maximum number of retry attempts in the event that the command fails.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Schedule Type

Customize the behavior in the corresponding field below the button.

- **Interval**: Specify how often, in seconds, the command should run. Defaults to `60`.
- **Schedule**: Enter a cron expression. (You enter the cron expression in UTC time, but the resulting **Estimated Schedule** displays in local time.)

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

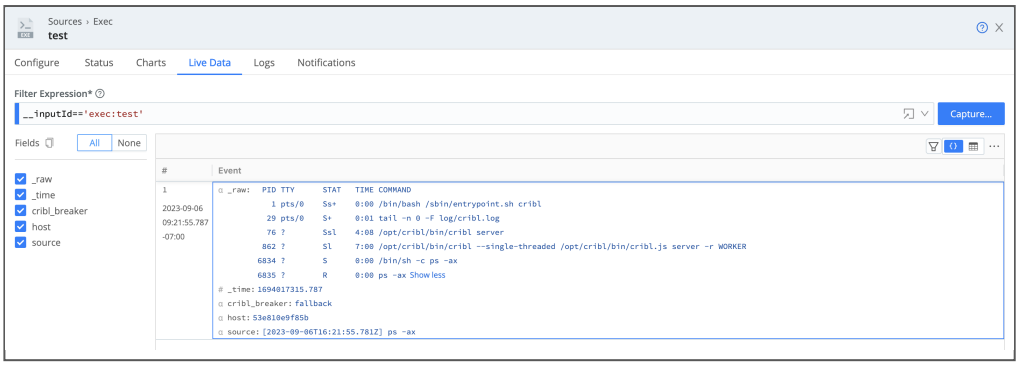
Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses internal fields to assist in forwarding data to a Destination.

You can find the following event fields on the **Live Data** tab of the selected Exec Source, including the hostname and source of the event:

- `_raw`
- `_time`
- `cribl_breaker`
- `host`
- `source`



Event fields

Troubleshooting

If a command isn't running as expected, the **Logs** tab can help you identify issues by displaying the command executed, its elapsed time, and its exit code.

Event fields

Disable the Exec Source on a Node

To disable the Exec Source on a specific Worker Node, set the `CRIBL_NOEXEC` environment variable. This will override any configuration pushed from the Leader Node, ensuring the Exec Source remains disabled on that particular node.

The `CRIBL_NOEXEC` environment variable must be set outside of the Cribl product to disable the Exec Source. This variable cannot be modified within the product's interface.

How to Disable the Exec Source on Different Platforms

To disable the Exec Source, follow the platform-specific instructions below. Once you've set the `CRIBL_NOEXEC` environment variable, the Exec Source will be disabled. To re-enable it, remove or unset the variable.

Disable on Linux Platform

To disable the Exec Source on a Linux system running as a Systemd service, edit the appropriate service definition file:

- Cribl Edge: `/etc/systemd/system/(cribl|cribl-edge).service`
- Cribl Stream: `/etc/systemd/system/cribl.service`

To ensure the `CRIBL_NOEXEC` environment variable is set when the Cribl Edge service starts, add `CRIBL_NOEXEC=1` to the service's configuration. If the service is currently running, a restart is required for the change to take effect.

Disable on Docker

To disable the Exec Source on Docker, modify the `docker run` command (or equivalent) to include the `-e CRIBL_NOEXEC=1` flag.

Disable on Kubernetes/Helm

To disable the Exec Source on Kubernetes, add the `--set env.CRIBL_NOEXEC=1` flag to your `Helm install` command or modify the `values.yml` file to include this setting.

Disable on Windows (For Cribl Edge)

To add the `CRIBL_NOEXEC` environment variable to Cribl Edge on Windows, use the command prompt to execute the following command:

```
setx CRIBL_NOEXEC "1" /M
```

This command sets the environment variable for the current user account. The Cribl Edge service runs under `LocalSystem` user account by default.

15.1.10.3. File Monitor Source

The File Monitor Source generates events from text files, compressed, archived, and (some) binary log files, based on lines and records extracted from the content.

Available in Cribl.Cloud: **No** | Type: **System** | TLS Support: **N/A** | Event Breaker Support: **Yes**

As of v.4.2.x, this Source can process the following file formats:

- **Compressed/archived**: `zip`, `gzip`, `zstd`, and `tar`. Cribl Stream only supports DEFLATE compression for `zip` files.
- **ASCII**: `text`.
- **Non-ASCII binary**.

Binary files are broken into base64-encoded chunks and streamed bypassing Event Breakers. Text files are processed normally through Event Breakers. (Before v.4.2.x, the File Monitor Source could handle only text files.) Also as of v.4.2.x, the File Monitor Source no longer excludes `*.gz` files by default.

File Monitoring and One-Time Ingestion

Cribl Edge offers two options for ingesting file data:

- **File Monitor Source**: This is ideal for ongoing log file monitoring. It can be configured to prioritize processing the latest data in newly discovered files upon startup ("Collect from end"). Subsequently, it automatically monitors and ingests new content as it's added.

To automatically discover and ingest new log files, Cribl Edge requires privileged access for file scanning and reading. For alternative approaches, see Running Edge as an Unprivileged User.

- **One-time File Ingest**: This feature complements the File Monitor by allowing a one-time ingest of any file. It's useful for quickly processing specific files or initial data loads. If **Explore** is enabled, as it might be restricted in some environments for security reasons.

Discovering and Filtering Files to Monitor

To produce its initial list of files to monitor, the File Monitor Source runs a discovery procedure at a configurable **Polling interval**. The Source then applies an **Allowed list** to filter the initial list down into its final form. Then, for each file on the list, the Source compares current state with previously-stored state. This

comparison determines whether the File Monitor Source will actually watch a given file for a given polling interval, or just ignore the file.

In the simplest case, the Source discovers a file for which it has no stored state. This means that the file has just been created, and needs to be monitored. See the Examples for other possibilities, along with a description of the **Status** tab, which displays state information for all files being monitored.

How does the File Monitor Source discover files in the first place? You have the choice of two **Discovery Modes**: **Auto** or **Manual**.

- In **Auto** mode, the Source automatically discovers files that running processes have open for writing. Auto mode collects logs from (the discovered) active files that match the path/allowlist.
  Auto mode is useful to detect which files are being written to. For example, if you enter an allowlist of `*log`, Auto mode will find all the active logs within that directory, no matter what's writing to it, and it will exclude any rotated logs.

Cribl Edge currently supports Auto mode only when running on Linux, not on Windows.

- In **Manual** mode, the Source discovers files based on the specified directory and depth.
  Manual mode is often used to collect logs in a folder where the process that creates them rotates them when they get large. For example, if you specify a path of `/var/log` and an allowlist of `*/messages*`, Manual mode will capture the current `/var/log/messages`, as well as older logs from `/var/log/messages*`.

If you are using a tool like `rsync` to transfer files in chunks, the File Monitor Source might start collecting files before the transfer is complete. To prevent this, configure your tool to transfer files serially. (For example, use: `rsync --append`.)

Configure a File Monitor Source

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
   - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
   - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
   - **Enabled**: Toggle to `Yes` to enable the Source.

- **Input ID**: Enter a unique name to identify this File Monitor Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
- **Description**: Optionally, enter a description.
- **Discovery Mode**: Use the buttons to select one of these options: **Auto** or **Manual**. For details, see Discovery Mode below.

3. Next, you can configure the following **Optional Settings**:
   - **Filename allowlist**: Wildcard syntax, and the exclamation mark (`!`) for negation, are allowed. For example, you can use `!*cribl*access.log` to prevent the Source from discovering Cribl Stream's own log files. The default filters are `*/log/*` and `*log`.
   - **Age duration limit**: Optionally, specify a maximum age of files to monitor. This Source will filter events with timestamps newer than the configured duration. (Where files don't have a parsable timestamp, it will set their events' timestamp to `Now`.) Enter a duration in a format like `30s`, `4h`, `3d`, or `1w`. Defaults to an empty field, which applies no age filters.
   - **Check file modification times**: If toggled to `Yes`, this Source will skip files with modification times older than the configured **Age duration limit**. When you set an **Age duration limit** threshold, the Source will open every file and read through all its contents to seek a timestamp. For best performance, also enable the **Check file modification times** toggle to skip older files.
   - **Collect from end**: If toggled to `Yes`, this Source will prioritize processing the latest data by jumping to the end of newly discovered files on Cribl Stream's startup. This is ideal if you want to focus on new content in existing log files. However, this behavior only applies during the first encounter with a file. For existing files after the initial scan and all subsequent discoveries, Cribl Stream will switch to its normal processing mode, reading from the beginning to capture ongoing updates.
   - **Enable binary files**: If toggled to `Yes`, the Source will report the file as binary and stream it in Base64-encoded chunks. By default, the Source ignores binary (non-text) files such as JPEG images, MP3 audio files, or some binary data files.
   - **Force text format**: If toggled to `Yes`, the Source displays ingested data as text in the event (when the data isn't in a compressed or archived file). This option is helpful if you have files that contain binary mixed with text where the data should be streamed as all text (for example, AuditD logs can contain this type of data).
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Always think through how your **Search path** and **Filename allowlist** settings interact: If you're not careful, you can inadvertently create overlapping monitor groups that deliver duplicates of some files.

> See Using Allowlists Effectively below.

Discovery Mode

The File Monitor Source offers two options:

Auto: Tells the Source to automatically discover files that running processes have open for writing.

Manual: Tells the Source to discover the files within the **Search path** (a directory) that you specify, down to the **Max depth**. You must enter an absolute path (no wildcards) for the **Search path**, as File Monitor searches files in a single directory in Manual mode. The defaults are:

- **Search path** is set to the `/var/log` directory
- **Allowlist** of `*/log/*` and `*log`
- **Max depth** of 4

If you leave the **Max depth** field empty, the Source will search subdirectories, and their subdirectories, and so on, without limit. If you specify `0`, the Source will discover only the top-level files within the **Search path**. For `1`, the Source will discover files one level down.

Both modes allow you to set the **Polling interval**, which otherwise defaults to 10 seconds.

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec.), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Idle timeout: Time, in seconds, before an idle file is closed. Defaults to `300` sec. (5 minutes).

Hash length: How many file header bytes to use in a hash for identifying a file uniquely. Defaults to `256` bytes. For details, see Configuring Hash Lengths.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

This Source defaults to QuickConnect.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are not part of an event, but they are accessible, and Functions can use them to make processing decisions.

For the File Monitor Source, you can use internal fields to enrich events with container and host metadata. The following internal fields are available:

- `__baseFilename`
- `__source` / `source`
- `__raw`
- `__inputId`
- `container_id`

- `container_path`
- `host_path`

Monitoring Renamed Files' State

The File Monitor Source uses a simple scheme to find "backlog" files corresponding to a matching file: Tell it to tail `foo.log`, and it will look for `foo.log.[0-9]` and scrape those, too.

This Source keeps hashes that correspond to the start point within the file, and to the last-read point. This way, if Cribl Stream is stopped, files are rotated, and Cribl Stream is restarted, the File Monitor Source can find the resume point in those backlog files.

Similarly, if you rename the file **within the same backlog scheme** (for example, `foo.log` to `foo.log.0`), the File Monitor Source can resume at the right place. However, if you renamed `foo.log` to `bar.log` (a deviation from the expected naming scheme), this Source could not find its resume point.

Configuring Hash Lengths

For files with identical first lines, configure the hash length to be longer than the first line to ensure that the header includes something unique. It is common for a batch of `CSV` files or `IIS` logs to have identical first lines listing columns that appear in subsequent lines.

If you don't adjust the hash length, all files with headers larger than `256 bytes` will appear to File Monitor as one file. As long as the hash length is greater than the header length, and the subsequent lines include something unique, the File Monitor Source will identify them as different files.

Using Allowlists Effectively

Done properly, file monitoring collects exactly the files you need to see, without duplication. You want to avoid inadvertently creating overlapping monitor groups that deliver duplicates, because this can "run the meter" twice for affected files, potentially causing license issues.

The key is knowing how to craft allowlists.

Crafting Allowlists: Principles

To get the results you want from file monitoring, always apply the following principles.

Write allowlists to explicitly include the full path of files you want to collect.

The search path itself is **not** excluded from the match. For example, if you want to collect the file `/var/log/messages` when you've set your search path to `/var/log`, your filename allowlist needs to be either `/var/log/messages`, `/var/*/messages`, or `*/log/messages`.

Exclusions (`!`) also need to address the full file path. For example, if you want to collect everything from `/var/log/*` **except for** `/var/log/apache/*`, your allowlist must include one of the following:

- `!/var/log/apache/*`
- `!*/apache/*`
- `!*/log/apache/*`

Wildcards (`*`) match **any** part of the file path:

- `*log` matches `/var/foo/bar/myfile.log`.
- `*.log` matches anything ending in `.log`.
- `/var/log/*` matches anything in `/var/log`, subject to the **Max Depth** setting.

Put explicit matches (and exclusions) at the beginning of the allowlist, ahead of wildcard matches.

For example, an allowlist of `/var/log/*` followed by `!/var/log/apache/*` will fail to exclude the file `/var/log/apache/foo` because that file matches the first allowlist entry.

In allowlists, order matters!

Be as specific as possible, whenever possible, to prevent accidental matches.

Each of the following examples shows how to avoid matching unwanted files within the directories that you're monitoring.

To collect `/var/log/boot.log` (and older versions of `boot.log.*`) as well as `/var/log/messages`:

Search path	Filename allowlist
`/var/log`	`/var/log/boot.log`, `/var/log/messages`

To collect everything in `/var/log` while excluding `/var/log/apache/*`:

Search path	Filename allowlist
`/var/log`	`!/var/log/apache/*`, `/var/log/*`

Examples of Allowlists

Below are typical scenarios where good allowlist technique will save you from duplication headaches.

Example: Excluding the System's Own Logs

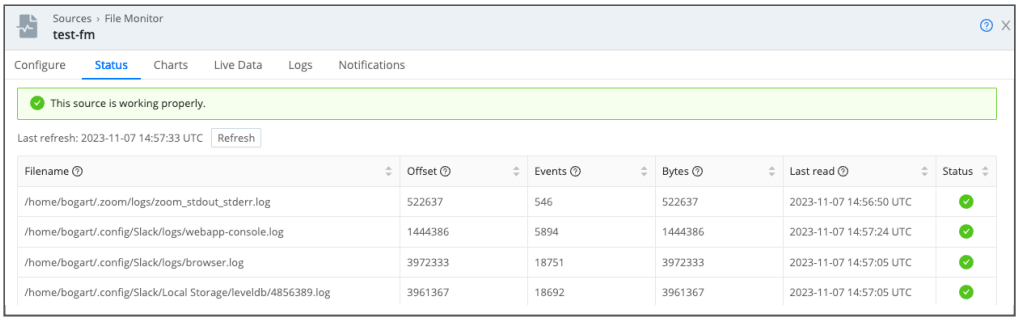
Recall that you'll often create a set of File Monitor Sources, each of which monitors one file. This is **not** the right approach in an example like this one, where **Discovery Mode** is set to **Auto**. Using **Auto** mode in a file monitor along with literally any other file monitor can cause unintended, duplicate collection. Use **Auto** mode carefully!

Here's the example:

Suppose you added a File Monitor Source on a Linux machine, set your **Discovery Mode** to **Auto**, and specified your home directory as the **Search path** (for example, `/home/bogart/`).

You do not want to monitor Cribl Stream's own log files, or any log files generated by Chrome, the web browser you're using. To exclude them, you add `!*cribl*access.log` and `!*chrome*` to your **Allowlist**. You **do** want to monitor any other log files that the Source can discover, so you also add `*log`.

After awhile, the Status tab looks like this:



The Status tab

Example: Fixing Overlapping Monitor Groups

Here's an example of the kind of overlapping monitor groups you should avoid:

Search path	Max depth	Filename allowlist
`/var`	(none)	`*/log/*`
`/var/log/apache`	`0`	`*`

The above configuration would collect all the files in `/var/log/apache/` twice. A better solution would be the following:

Search path	Max depth	Filename allowlist
`/var/log`	(none)	`!*/apache/*`
`/var/log/apache`	`0`	`*`

15.1.10.4. Journal Files Source

The Journal Files Source collects data from systemd's centralized logging, which is called the journald service. This service is a centralized location for all messages logged by different components in a systemd-enabled Linux system. This includes messages from kernel, boot, syslog, or other services. This Source is currently configured to configured to collect data from the `user` journal, as `system` is privileged. This Source is disabled by default.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **No**

The Journal Files Source is available in Cribl.Cloud on customer-managed hybrid Workers, but not on Cribl-managed Workers in Cribl.Cloud.

Discovering and Filtering Journal Files to Monitor

To determine all the names of all journals to read, the Journal Files Source runs a discovery procedure at a configurable **Polling interval**. The Source then applies an **Allowed list** to filter the initial list down into its final form. Then, for each journal on the list, the Source compares current state with previously stored state. This comparison determines whether the Journal Files Source will actually stream a given journal for a given polling interval. The Source then runs the files through the **Filter Rules** which allows you to set additional criteria.

Cribl Stream ships with a single, disabled instance of the Journal Files Source with a default configuration. The search path is configured to point to `$CRIBL_EDGE_FS_ROOT/var/log/journal/$MACHINE_ID` and defaults to streaming the primary `system.journal` it finds there. `$MACHINE_ID` is an environment variable that you can insert into the Source's search path. If you use the environment variable but don't assign a value, the Source will look up the local host `machine id` from `/etc/machine-id` and use that value.

Currently, this Source does not support all of the compression options that the journald service supports. The parser this Source uses to read the files can handle `LZ4` and `ZSTD` compression. When the parser encounters compressed fields it can't unpack, an error message emits in the logs. Below is an example of the error message:

```
Error reading journald event, dropping offset=31678152 evt="Mar 02 21:29:54
goats-xps15 multipassd: undefined"
```

Also, this Source does not support the new `COMPACT` binary file format. The logs will contain an error message when the parser encounters this type of file.

Configure a Journal Files Source

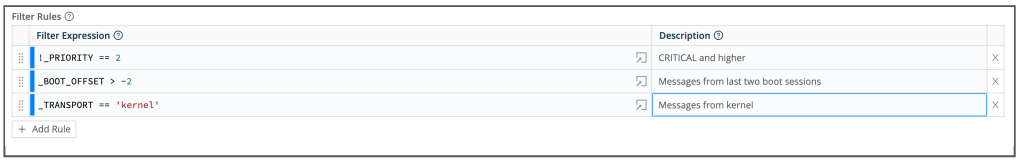
1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: Enter a unique name to identify this Source configuration. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Search path**: Specify the directory to search journals on. Accepts environment variables. The default value for this field varies depending on the product:
    - In Cribl Edge, it defaults to `$CRIBL_EDGE_FS_ROOT/var/log/journal/$MACHINE_ID`.
    - In Cribl Stream, it defaults to `/var/log/journal/$MACHINE_ID`.
    - **Journal allowlist**: The full path of each discovered journal is matched against this wildcard list. Defaults to `system`.
3. Next, you can configure the following **Optional Settings**:
    - **Polling interval**: How often, in seconds, to collect metrics. If not specified, defaults to `10` seconds.
    - **Filter Rules**: Optionally, specify which journal objects to allow. Events are generated if all the rules' expressions evaluate to true, or if no rules are specified.
    - **Filter expression**: JavaScript expression to filter Journal objects. Returns `true` to include it. For details, see Filter Expressions below.
    - **Description**: Optional description of the rule.
    - **Current boot only**: Skip events that are not part of the current boot session.
    - **Age duration limit**: Optionally, specify a maximum age of journal objects to stream. This Source will filter events with timestamps newer than the configured duration. Enter a duration in a format like `30s`, `4h`, `3d`, or `1w`. Defaults to an empty field, which applies no age filters.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Processing and Advanced settings, or Connected Destinations outlined in the sections below.

5. Select **Save**, then **Commit & Deploy**.

Filter Expressions

The default **Filter expression** is `severity <= 4` with a **Description** of `Allow events having 'emergency', 'alert', 'critical', 'error', or 'warning' priority.`

`The screenshot below shows other examples you can use:`



Filter expressions

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings {advanced-tab}

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

In Cribl Edge, this Source defaults to QuickConnect. While, in Cribl Stream, it defaults to Send to Routes.

15.1.10.5. System Metrics Source

Cribl Stream instances can collect metrics from their Linux hosts, and can populate some standard metrics dashboards right out of the box. To see all of the metrics this Source supports, check out Linux System Metrics Details.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **No**

Cribl Edge Workers support this System Metrics Source only when running on Linux. To collect metrics from Windows hosts, use the Windows Metrics Source.

This Source is not available on Cribl-managed Workers in Cribl.Cloud.

Configure Cribl Stream to Collect System Metrics

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Next, select the default `in_system_metrics` to open the configuration modal.
3. Configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: This is prefilled with the default value `in_system_metrics`, which cannot be changed via the UI.
    - **Description**: Optionally, enter a description.
4. Next, you can configure the following **Optional Settings**:
    - **Polling interval**: How often to collect metrics, in seconds. Defaults to `10`.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can configure metrics for Host, Process, Container, or adjust Processing, Advanced settings and Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Host Metrics

Use the buttons to select a level of detail.

- **Basic** enables minimal metrics, averaged or aggregated.
- **All** enables full, detailed metrics, specified for individual CPUs, interfaces, and so on.
- **Custom** displays sub-menus and buttons from which you can choose a level of detail (**Basic**, **All**, **Custom**, or **Disabled**) for each type of event.
- **Disabled** means that no metrics will be generated.

The meaning of **All** and **Disabled** are self-evident. **Basic** and **Custom** have different meanings depending on event type, as follows:

System

Basic level captures load averages, uptime, and CPU count.

Custom toggles **Process** metrics on or off; these are metrics for the numbers of processes in various states.

CPU

Basic level captures active, user, system, idle, iowait percentages over all CPUs.

Custom toggles the following on or off: **Per CPU metrics**, **Detailed metrics** (meaning, for all CPU states), and **CPU time metrics** (meaning raw, monotonic CPU time counters).

Memory

Basic level captures captures total, used, available, `swap_free`, and `swap_total`.

Custom toggles **Detailed metrics** on or off. Detailed means for all memory states.

Network

Basic level captures bytes, packets, errors, connections over all interfaces.

Custom exposes the following:

- The **Interface filter**, which specifies which network interfaces to include or exclude (all are included if the filter is empty).
- **Per interface metrics**, which toggle on or off.
- **Detailed metrics**, which toggle on or off. If on, the **Protocol metrics** toggle appears, allowing you to choose whether to generate metrics for ICMP, ICMPMsg, IP, TCP, UDP, and UDPLite.

Disk

Basic level captures disk used in percent, bytes read and written, and read and write operations, over all mounted disks.

Custom exposes the following:

- The **Device filter**, which specifies which block devices to include or exclude (all are included if the filter is empty). Wildcards and ！(not) operators are supported.
- The **Mountpoint filter**, which specifies which filesystem mountpoints to include or exclude (all are included if the filter is empty). Wildcards and ！(not) operators are supported.
- The **Filesystem type filter**, which specifies which filesystem types to include or exclude (all are included if the filter is empty). Wildcards and ！(not) operators are supported.
- **Per device metrics**, which toggle on or off.
- **Detailed metrics**, which toggle on or off. If on, the **Enable inode metrics** toggle appears, allowing you to choose whether to generate metrics for filesystem inodes.

Process Metrics

With Process Metrics enabled, Cribl Stream captures process-specific metrics from Linux servers and reports them as events. This allows you to monitor specific processes on Cribl.Cloud instances. You can generate events for any process object.

To collect a process metrics event, create a Process Set and add a filter expression. Processes that match the filter are returned as individual events. See Collecting Metrics. Process Sets are separate from aggregate and host-wide metrics.

Process-specific metrics are **not** affected by the **Host Metrics** detail setting.

Adding a Process Set

To add a Process Set:

1. Open the System Metrics Source and access the **Configure** tab.

2. Click the **Process Metrics** menu, then **Add process set**.
3. Configure the details:
    - **Set name**: The name for this process set.
    - **Filter expression**: The JavaScript expression that will filter the processes.
    - **Include children**: When toggled to “Yes”, the processes that match the filter include metrics for child processes.

Filtering Processes

You can filter processes using the field names and values from each process object.

Tip

To see all processes currently running on an Edge Node, click **Explore** in the submenu and open the Processes Tab.

Example filters

This filter looks for Java processes in the sleep state (an interruptible wait) that are using more than 100% of the CPU or more than 25% of memory:

```
cmdline.args[0] == 'java' && status == 'S' && (cpu > 100 || memory_percent > 25)
```

This filter looks for running NGINX web servers that have more than 12 open file descriptors:

```
service == 'nginx' && fds > 12
```

Here are some more Linux processes you could find metrics for:

- `cmdline.args[0].endsWith('/java') && cmdline.args[1] == 'nifi'`
- `exe.path == '/usr/bin/sshd'`
- `uid == 2`
- `cgroup.0 == /user.slice/user-1000.slice/`
- `stat.status == R`
- `stat.starttime > 943517`
- `cpu > 30`
- `memory_percent > 30`
- `stat.num_threads > 10`

The **Filter expression** field expects a specific syntax in order to apply the filter to the processes. These expressions evaluate to either `true` or `false`. See Filters for more information.

Collecting Metrics

Once you have at least one Process Set created and saved, Cribl Stream will begin collecting process metrics at the interval defined in the **Polling interval** field (**General Settings** menu).

To view the status of the Collector and total events collected, click the **Status** tab in the Linux Metrics Source.

To view a live capture of individual metrics gathered from processes that match the Process Set, click the **Live Data** tab. The Process Set that owns each metric is represented by the `__process_set` internal field.

Supported Processes

To view the complete table of supported Linux process metrics, their descriptions, types, and dimensions, see Process-Specific Metrics.

Using Advanced Mode

To test your filter expression against a sample input, click the **Advanced mode** button within the **Filter expression** field. The **Filter expression** modal will open.

Here, you can paste in your filter expression, select a sample JSON input from the drop-down (or enter your own directly in the **Sample input** field), and select a specific event to test against.

The **Advanced mode** window, for process-specific metrics

The **Output** will show you if the filter expression returns any matching processes, based on the filter expressions and JSON input.

Container Metrics

Use the buttons to select a level of detail.

- **Basic** generates the server event and per running container events.
- **All** adds per-device and detailed metrics.
- **Custom** provides controls for customizing which containers to generate metrics from.
- **Disabled** means that no metrics will be generated.

The **Custom** buttons displays additional controls, as follows:

- **Container Filters**: Enter a filter expression to govern which containers to generate metrics from. Leave empty (the default) to generate metrics from all containers.
- **All containers**: Toggle to `Yes` to include stopped and paused containers.
- **Per device metrics**: Toggle to `Yes` to generate separate metrics for each device.
- **Detailed metrics**: Toggle to `Yes` to generate full container metrics.

The **Basic**, **All**, and **Custom** buttons provide the following **Advanced Settings**, which are different from those in the main **Advanced Settings** tab:

- **Docker socket**: Enter the full path(s) for Docker's UNIX domain socket. Defaults to `/var/run/docker.sock` and `/run/docker.sock`.
- **Docker timeout**: Timeout, in seconds, for the Docker API. Defaults to `5`.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

If desired, choose a **Pipeline** from the drop-down if you want to process data from this Source before sending it through the Routes.

Disk Spooling

Enable disk persistence: Whether to save metrics to disk. When set to `Yes`, exposes this section's remaining fields.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`).

Max data size: Maximum disk space the persistent metrics can consume. Once reached, Cribl Stream will delete older data. Example values: `420 MB`, `4 GB`. Default value: `100 MB`.

Max data age: How long to retain data. Once reached, Cribl Stream will delete older data. Example values: `2h`, `4d`. Default value: `24h` (24 hours).

Compression: Optionally compress the data before sending. Defaults to `gzip` compression. Select `none` to send uncompressed data.

Path location: Path to write metrics to. Default value is `$CRIBL_HOME/state/system_metrics`.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Populating Dashboards with System Metrics

Cribl has configured a Prometheus dashboard to display Cribl Stream System Metrics, and shared the dashboard in the Grafana library, which is public. This is a relatively simple dashboard suitable for showing aggregate metrics. Try this dashboard if you prefer **Basic** mode for most of your metrics.

Another useful dashboard is the one that's commonly used with Prometheus and their Node Exporter agent, found here. This dashboard can handle the highly detailed metrics. To use this dashboard, attach the `prometheus_metrics` pre-processing pipeline, and choose **All** mode.

For details on how populate your Grafana Cloud dashboards with system metrics, see System Metrics to Grafana.

15.1.10.6. System State Source

The System State Source collects snapshots of the host system's current state, on a configurable schedule, and sends them out as events to downstream systems for operational and security analytics.

Type: **System** | TLS Support: **N/A** | Event Breaker Support: **No**

Cribl Stream supports configuring only one System State Source per Worker Node and per Worker Group.

This Source is currently unavailable on Cribl-managed Workers in Cribl.Cloud.

Configure Cribl Stream to Collect System State Events

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Select the default `in_system_state` to open the configuration modal.
3. Configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: This is prefilled with the default value `in_system_state`, which cannot be changed via the UI, due to the single-Source restrictions above.
    - **Description**: Optionally, enter a description.
4. Next, you can configure the following **Optional Settings**:
    - **Polling interval**: How often to collect metrics, in seconds. Defaults to `10`. Each run of the state collector generates events with identical `_time` values.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Collector, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.

6. Select **Save**, then **Commit & Deploy**.

Collector Settings

Cribl Stream contains the following System State collectors:

- Host Info
- Disks and File Systems
- DNS
- Firewall
- Hosts File
- Interfaces
- Listening Ports
- Logged-In Users
- Routes
- Services
- Users and Groups

Host Info

With the **Enabled** toggle on (the default), Cribl Stream will create events based on entries collected from the hosts file.

A partial list of Host Info events includes:

- `host`
- `timestamp`
- `cribl.version`
- `cribl.mode`
- `cribl.group`
- `cribl.config_version`
- `os.arch`
- `os.cpu_count`

See the **Explore** > **System State** > **Host Info** UI for a full list of events.

The System State Source provides live system information, with most tabs updating periodically based on the **Polling Interval** configured in the Source. However, the data in the **Host Info** tab is collected once when the Source is started and does not update dynamically.

Disks and File Systems

With the **Enabled** toggle on (the default), Cribl Stream will collect entries on physical disks, partitions, and mounted filesystems. These entries can help you monitor drive status, including available space, percent utilization, inode availability, wait times, and number of blocks free.

This option is available for Windows and Linux Worker Groups, but you must create a different Worker Group for each OS. Follow this procedure:

1. Create a Worker Group for the appropriate OS.
2. Modify the Worker Group by disabling or removing the pre-defined Sources that do not apply to the OS. Remove Windows Event Forwarder or Windows Event Logs and Windows Metrics from Linux Worker Groups, and remove Linux-specific Sources from Windows Worker Groups.
3. Modify the Worker Group mapping to filter by platform – `platform=='win32'` for Windows or `platform=='linux'` for Linux.
4. Deploy Cribl Stream Worker Nodes and verify that the mapping is correct.

If you are using the free version of Cribl Stream, you will only get a single default Worker Group. If you need more than one Worker Group, you'll have to limit your Cribl Stream deployment to one OS or upgrade to Cribl Stream Enterprise.

For each physical disk, Cribl Stream will collect:

- name
- size (in blocks)
- blockSize (in bytes)
- model
- serial
- firmware
- partitions (count)
- interface type

For each partition on a physical disk, Cribl Stream will collect:

- disk (name)
- disk ID (number)
- type (primary or logical)
- label
- offset
- size (in blocks)
- blockSize (in bytes)
- filesystem (mountpoint)

For each mounted filesystem, Cribl Stream will collect:

- mountpoint (path)
- disk (name)
- partition (ID)
- filesystem type
- size (in blocks)
- blockSize (in bytes)
- blocksFree
- inodes
- inodesFree
- flags

DNS

With the **Enabled** toggle on (the default), Cribl Stream will create events for DNS resolvers and search entries. The event field mapping depends on the operating system.

Linux

Cribl Stream emits events with the following fields:

Event Field	Description
`nameServer`	Name server entries from the file.
`search`	Search entries from the file.
`source`	The source of the data used to populate the event.

Windows

Cribl Stream emits events with the following fields:

Event Field	Description
`ifAlias`	Interface alias name (if present).
`ifIndex`	Interface index (if present).
`addressFamily`	IPv4 or IPv6.
`nameServer`	Array of name servers.
`search`	Array of search suffixes .
`source`	The source of the data used to populate the event.

Hosts File

With the **Enabled** toggle on (the default), Cribl Stream will collect entries from the `hosts` file and emit them as events.

Examples of entries in the `hosts` file are:

- `ip`: IP address of the host.
- `hostnames`: list of hostnames per IP address.

Firewall

With the **Enabled** toggle on (the default), Cribl Stream will collect events from host's defined firewall rules.

Chain Policy/References Rule(s) Event Fields

Cribl Stream emits events with the following fields:

- `chain`: Name.
- `policy`: Policy name.
- `pkts`: Total bytes packets processed by the chain.
- `bytes`: Total bytes processed by the chain.
- `references`: Number of chains referencing the current chain.

Chain Rule(s) Event Fields

Cribl Stream emits events with the following fields:

- `chain`: Name.
- `num`: Rule sequence number.
- `pkts`: Number of matched messages processed.
- `bytes`: Cumulative packet size processed (bytes).
- `target`: If the message matches the rule, the specified target is executed.
- `prot`: The specified protocol can be one of `tcp`, `udp`, `udplite`, `icmp`, `icmpv6`, `esp`, `ah`, `sctp`, `mh`, or the special keyword `all`.
- `opt`: Rarely used, this column is used to display IP options.
- `in`: Inbound network interface.
- `out`: Outbound network interface.
- `src`: The source IP address or subnet of the traffic, the latter being anywhere.
- `dest`: The destination IP address or subnet of the traffic, or anywhere.
- `match`: `ctstate`, `state`, `ADDRTYPE` info added to a state field.
- `comment`: Comment defined on the rule.
- `prot_family`: `IPv4` or `IPv6`.

Windows

On Windows, this collector emits events with the following fields:

- `ruleName`: Rule Name.
- `displayName`: Display Name.
- `direction`: Specifies which direction of traffic to match with this rule. The acceptable values for this parameter are `Inbound` or `Outbound`.
- `enabled`: `True` or `False`.
- `action`: Specifies the action to take on traffic that matches this rule. The acceptable values for this parameter are `Allow` or `Block`.
- `group`: Specifies the rule group (if applicable).
- `icmpType`: Specifies the `ICMP` type used.
- `policyStoreSource`: Contains a path to the policy store where the rule originated.
- `profile`: Profile conditions associated with a rule.
- `protocol`: protocols associated with firewall and `IPsec` rules.

- `localPort`: Rules for local-only port mapping.
- `remotePort`: Rules for remote port mapping.

Interfaces

With the **Enabled** toggle on (the default), Cribl Stream will create events for each of the host's network interfaces.

Cribl Stream will create separate events for each entry. All events will have identical timestamp values.

Linux IPV4/IPV6

On Linux, Cribl Stream creates `interface` events with the following fields:

- `ifIndex`: Interface index identification numbers.
- `ifName`: The name of the network interface.
- `flags`: Flags.
- `mtu`: Maximum transmission unit (MTU) in bytes for packets sent on this interface.
- `operstate`: Operational State.
- `linkType`: Physical link type.
- `macAddress`: Media Access Control address.
- `broadcast` Broadcast address.
- `addrInfo`: Array of `{family, ipAddress, mask, prefix}`.

Windows: IPV4/IPV6

On Windows, Cribl Stream creates `interface` events with the following fields:

- `ifIndex`: Interface index identification numbers.
- `interface`: The name of the network interface.
- `mtu`: Maximum transmission unit (MTU) in bytes for packets sent on this interface.
- `flags`: Flags.
- `macAddress`: Media Access Control address.
- `addrInfo`: Array of `{family, ipAddress, mask, prefix}`.

Listening Ports

With the **Enabled** toggle on (the default), Cribl Stream will create events from the list of listening ports and their associated process identifier (pid).

Cribl Stream will create separate events for each entry. All events will have identical timestamp values.

Sample entries include:

- `Protocol Family`: `ipv4` or `ipv6`.
- `Protocol`: `TCP`, `UDP`, or `UNIX`.
- `Socket`: `${addr}:${port}`, or `${path}` for UNIX sockets.
- `Process id`: The process identifier.
- `Program`: The program listening on the port.

Logged-In Users

With the **Enabled** toggle on (the default), Cribl Stream will collect entries from currently logged-in users.

Linux

Cribl Stream emits events with the following fields:

- `uid`: User ID.
- `Last Login date`: Last login date.
- `terminal`: Type of the terminal device.
- `hostname`: Display the hostname of the system, if the user is connected from a remote computer.
- `userName`: Logon name of the user.

Windows

Cribl Stream emits events with the following fields:

- `userName`: Login name of the user.
- `sessionName`: `rdp` (Remote desktop/terminal services login session) or `console` (Direct login session).
- `id`: Session ID.
- `state`: `active` (Active session) or `disc` (Disconnected/inactive session).
- `logonTime`: Date and time the user logged on.
- `source`: Set to `Query User`.

Routes

With the **Enabled** toggle on (the default), Cribl Stream will collect entries from host's network routes and emit them as events.

Sample entries include:

- `address_family`: `ipv4` or `ipv6`.
- `destination`: The destination network or host.
- `prefix`: Emits only from Linux IPv6.
- `flags`: Flags.
- `gateway`: The gateway address.
- `interface`: Interface to which packets for this route will be sent.
- `ifIndex`: Interface ID. Emits only from Windows.
- `mask`: The netmask for the destination net. Emits only from Linux IPv4.
- `metric`: The distance to the target.
- `sequence`: Sequence number in the table.
- `source`: The source of the data used to populate the event.

Services

With the **Enabled** toggle on (the default), Cribl Stream will create events for each configured service (for example `systemd` and `initd`) along with their enabled and running status.

Sample entries include:

- `Name`: Name of the service.
- `Unit Activation Status`: The high-level unit activation state, i.e. generalization of `SUB` for `systemctl`. For `sysV` system value can be `enabled` or `disabled`.
- `Unit Load Status`: Reflects whether the unit definition was properly loaded. (Only `systemctl`).
- `Sub Unit Activation Status`: The low-level unit activation state, values depend on unit type.
- `Description`: Description of the service.

Users and Groups

With the **Enabled** toggle on (the default), Cribl Stream will create events for users and groups.

Linux

On Linux, Cribl Stream creates `user` events with the following fields:

- `username`

- `fullname`
- `loginShell`
- `userHome`
- `userid`
- `primaryGroup` (name of primary group, not group ID)
- `groups` (list of group names)

Cribl Stream also creates `group` events with the following fields:

- `name`
- `groupId`
- `users`

Windows

On Windows, Cribl Stream creates `user` events with the following fields:

- `userName`
- `fullname`
- `description`
- `groups`

Cribl Stream also creates `group` events with the following fields:

- `name`
- `description`
- `users`

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

Select a **Pipeline** (or Pack) from the drop-down to process this Source's data. Required to configure this Source via **Data Routes**; optional to configure via **Collect**/**QuickConnect**.

Disk Spooling

Enable disk spooling: Whether to save metrics to disk. When set to `Yes`, exposes this section's remaining fields.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`).

Max data size: Maximum disk space the persistent metrics can consume. Once reached, Cribl Stream will delete older data. Example values: `420 MB`, `4 GB`. Default value: `100 MB`.

Max data age: How long to retain data. Once reached, Cribl Stream will delete older data. Example values: `2h`, `4d`. Default value: `24h` (24 hours).

Compression: Currently locked to `none`. Cribl plans to add (optional) disk-spooling compression in a future release.

Path location: Path to write metrics to. Default value is `$CRIBL_HOME/state/system_state`.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

15.1.11. AppScope Source

AppScope is an open-source instrumentation utility from Cribl. It offers visibility into any Linux command or application, regardless of runtime, with no code modification. For details about configuring the AppScope CLI, loader, and library, see: https://appscope.dev/docs. Note that AppScope is no longer being actively developed by Cribl.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

Download AppScope

Cribl Stream must download the AppScope package from the Cribl CDN the first time it performs an operation on this Source. This will also update the AppScope package's version, if a newer one is available in the CDN.

If Cribl Stream cannot access the CDN (for example, if you are working on an airgapped instance), you should manually download the binary and place it in `$CRIBL_HOME/state/download/scope`.

Configure Cribl Stream to Receive AppScope Data

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this AppScope Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **UNIX domain socket**: For details, see Unix Domain Socket Fields below.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Use this default option to enter the shared secret clients must provide in the `authToken` header field. Select **Generate** if you need a new auth token. If empty, unauthenticated access will be permitted.

- **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the auth token described above. The secret can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. Click **Create** if you need to configure a new secret.

4. Next, you can configure the following **Optional Settings**:
   - **UNIX socket permissions**: Permissions to set for socket. For the preconfigured `in_appscope` source, defaults to `777`. When creating a new AppScope Source, you should set this to `777`. If empty, falls back to the runtime user's default permissions.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, configure any TLS settings, AppScope Rules, Persistent Queue, Processing, Advanced settings and Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Unix Domain Socket Fields

When set to `Yes`, the **Unix doman socket** field exposes the following two fields to specify a file-backed UNIX domain socket connection to listen on.

- **UNIX socket path**: Path to the UNIX domain socket. Defaults to `$CRIBL_HOME/state/appscope.sock`.
- **UNIX socket permissions**: Permissions to set for this socket, for example, `777`. If empty, Cribl Stream will use the runtime user's default permissions. (Appears under **Optional Settings**)

When **UNIX domain socket** is set to `No`, you instead see the following two fields to specify a network host and port.

- **Address**: Enter the hostname/IP on which to listen for AppScope data. (For example, `localhost`.) Defaults to `0.0.0.0`, meaning all addresses.
- **Port**: Enter the port number to listen on.

By default:

- In Cribl Stream, **UNIX domain socket** is set to `No`, with default network connections (address and port) of `0.0.0.0:10090` for TCP, and `0.0.0.0:10091` for TLS, respectively.
- In Cribl Edge, **UNIX domain socket** is set to `Yes`, with a UNIX socket path of `$CRIBL_HOME/state/appscope.sock`.

TLS Settings (Server Side)

This left tab is displayed only when the Optional Settings > **UNIX domain socket** toggle is set to `No`. It provides the following options.

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

AppScope Rules

The AppScope Rules settings are available:

- In Cribl Stream single-instance – but not Cribl.Cloud – deployments.
- In Cribl Edge, both single-instance and Cloud.

Rules: Click **Add Rule** to include processes to scope, and to link to an AppScope config. Once you have saved the configuration, and committed and deployed your changes, AppScope will instrument any process that

matches a Rule, on any Edge Node in the Fleet.

(When no Rules are defined, you can still scope by PID in the Edge Processes page. Scope by PID only instruments a single process running in one Edge Node.)

- **Process name**: Matches if the string value you enter corresponds to the basename of the scoped process.
- **Process argument**: Matches if the string value you enter appears as a substring anywhere in the scoped process' full command line (including options and arguments).
- **AppScope config**: Select an AppScope config.

Transport override: Enter a URL to override aspects of the transport configuration, such as the hostname, port, or TLS settings. For details, see Transport Override Details.

Transport Override Details

In scenarios like the following, use the **Transport override** option to extend the defaults in AppScope's transport configuration:

- When this Source is set to **TCP** mode, it typically listens on the default address `0.0.0.0`. Scoped clients will need a specific `IP` or `hostname` to connect. In these cases, set **Transport override** URL to a specific IP/hostname (example format: `tcp://my.host.name`). This Source will parse the URL and look for the `hostname` and `port`, then use those values to override what would otherwise be sent to the `scope start` command.
- When this Source is set to **UNIX domain socket**, it listens by default on `$CRIBL_HOME/state/appscope.sock`. The socket is often created on a mounted volume in a container. The path to that socket might be different outside the container, or when mounted into another container. In these cases, set the **Transport override** URL to specify an alternative path (example format: `unix:///some/other/volume/appscope.sock`).

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a

> hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Disk Spooling

For Cribl Search to access the data that arrives at an AppScope Source, **Disk Spooling** must be enabled.

Enable disk persistence: Whether to save metrics to disk. When set to `Yes`, exposes this section's remaining fields.

Bucket time span: The amount of time that data is held in each bucket before it's written to disk. The default is 10 minutes (`10m`).

Max data size: Maximum disk space the persistent metrics can consume. Once reached, Cribl Stream will delete older data. Example values: `420 MB`, `4 GB`. Default value: `100 MB`.

Max data age: How long to retain data. Once reached, Cribl Stream will delete older data. Example values: `2h`, `4d`. Default value: `24h` (24 hours).

Compression: Optionally compress the data before sending. Defaults to `gzip` compression. Select `none` to send uncompressed data.

Path location: Path to write metrics to. Default value is `$CRIBL_HOME/state/appscope.sock`.

Advanced Settings

Enable proxy protocol: Toggle to `Yes` if the connection is proxied by a device that supports Proxy Protocol v1 or v2.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection.

Max active connections: Maximum number of active connections allowed per Worker Process. Defaults to `1000`; enter `0` to allow unlimited connections.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

AppScope with Edge on Kubernetes

When Cribl Edge detects that a `scope`'d process is running inside a Kubernetes container, it reports the Kubernetes metadata as `kube_**` properties. It adds these to the incoming events and metrics, and you can view the combined events and metrics on the AppScope Source's **Live Data** tab.

For Cribl Edge to detect that it's running in a Kubernetes Pod, you must first set the `CRIBL_K8S_POD` environment variable.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__srcIpPort`

Examples

The following examples work only in Cribl Stream. You can vary the scoped commands (`ps -ef` and `curl`) as desired.

Cribl.Cloud – TLS

An `in_appscope_tls` TLS Source is preconfigured for you on Cribl.Cloud, using port `10090`. You can send it AppScope data using this command:

```
./scope run -c <Your-Ingress-Address>:10090 -- ps -ef
```

Cribl Cloud – TCP

An `in_appscope_tcp` TCP Source is preconfigured for you on Cribl.Cloud, using port `10091`. You can send it AppScope data using this command:

```
./scope run -c tcp://<Your-Ingress-Address>:10091 -- curl -so /dev/null \
https://wttr.in/94105
```

Periodic Logging

Cribl Stream logs metrics about incoming requests and ingested events once per minute.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker process.

This kind of periodic logging helps you determine whether a Source is in fact still healthy even when no data is coming in.

15.1.12. CrowdStrike FDR Source

Cribl Stream supports receiving data from the CrowdStrike Falcon Data Replicator (FDR) platform. CrowdStrike data can then be sent to SIEM, threat-hunting, and other security tools and platforms.

Type: **Pull** | TLS Support: **Yes** | Event Breaker Support: **Yes**

This page covers how to configure the Source. Because the FDR platform pulls data from Amazon S3 buckets maintained by CrowdStrike, some of the configuration described here actually involves S3.

For configuration examples that you can import and adapt to your needs, examine these resources on the Cribl Packs Dispensary:

- CrowdStrike FDR Pack.
- Exabeam Pack for CrowdStrike FDR.

Configure a CrowdStrike Source

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Unique ID for this Source. For example, `Endpoint42Investigation`.
    - **Description**: Optionally, enter a description.
    - **Queue**: The name, URL, or ARN of the SQS queue to read notifications from. When a non-AWS URL is specified, format must be: `'{url}/myQueueName'`. For example, `'https://host:port/myQueueName'`. The value must be a JavaScript expression (which can evaluate to a constant value), enclosed in quotes or backticks. The expression can only be evaluated at init time, for example when referencing a Global Variable like this: `https://host:port/myQueue-${C.vars.myVar}`.
3. Next, you can configure the following **Optional Settings**:
    - **Filename filter**: Regex matching file names to download and process. Defaults to: `.*`.
    - **Region**: AWS Region where the S3 bucket and SQS queue are located. Required, unless **Queue** is a URL or ARN that includes a Region.

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Assume Role, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the buttons to select an authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.

- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select a secret key pair that you've configured in Cribl Stream's internal secrets manager or (if enabled) an external KMS. Follow the **Create** link if you need to configure a key pair.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for S3: Whether to use Assume Role credentials to access S3. Defaults to `Yes`.

Enable for SQS: Whether to use Assume Role credentials when accessing SQS (Amazon Simple Queue Service). Defaults to `No`.

AWS account ID: SQS queue owner's AWS account ID. Leave empty if the SQS queue is in the same AWS account.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role.

Processing Settings

Custom Command

In this section, you can pass the data from this input to an external command for processing, before the data continues downstream.

Enabled: Defaults to `No`. Toggle to `Yes` to enable the custom command.

Command: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).

Arguments: Click **Add Argument** to add each argument to the command. You can drag arguments vertically to resequence them.

Event Breakers

In this section, you can apply event breaking rules to convert data streams to discrete events.

Event Breaker rulesets: A list of event breaking rulesets that will be applied, in order, to the input data stream. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute the field's value (can be a constant).

Pre-Processing

Optionally, use the drop-down to select an existing Pipeline to process data from this Source before sending it through the Routes. Otherwise (by default), events will be sent to normal routing and event processing.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

Checkpoint Settings

Enable checkpointing: When toggled to `No` (the default) Cribl Stream will always start processing a file from the beginning. Toggle to `Yes` if, after an error or restart occurs, you want Cribl Stream to resume processing a given file from the point where it was interrupted, as explained below. When turned on, the following additional setting becomes available:

- **Retries**: The number of times you want Cribl Stream to retry processing a file after an error or restart occurs. If **Skip file on error** is enabled, this setting is ignored.

Other Settings

Endpoint: The S3 service endpoint you want CrowdStrike to use. If empty, Cribl Stream will automatically construct the endpoint from the AWS Region. To access the AWS S3 endpoints, use the path-style URL format. You don't need to specify the bucket name in the URL, because Cribl Stream will automatically add it to the URL path. For details, see AWS' Path-Style Requests topic.

Signature version: Signature version to use for signing S3 requests. Defaults to `v4`; `v2` is also available.

Num receivers: The number of receiver processes to run. The higher the number, the better the throughput, at the expense of CPU overhead. Defaults to `1`.

Max messages: The maximum number of messages that SQS should return in a poll request. Amazon SQS never returns more messages than this value. (However, fewer messages might be returned.) Acceptable values: `1` to `10`. Defaults to `1`.

Visibility timeout seconds: After messages are retrieved by a `ReceiveMessage` request, Cribl Stream will hide those messages from subsequent retrieve requests for at least this duration. Default is `21600` seconds (6 hours); maximum allowed threshold is `43200` sec. (12 hours). Set to `0` for no message hiding.

Cribl Stream will automatically extend this timeout until the initial request's files have been processed – notably, for large files that require additional processing time. The generous 6-hour default allows each Worker Process time to decompress, stitch, and read large multi-part files, without duplicate processing.

Poll timeout (secs): How long to wait for events before polling again. Minimum `1` second; default `10`; maximum `20`. Short durations increase the number - and thus the cost – of requests sent to AWS. (The UI will show a warning for intervals shorter than `5` seconds.) Long durations increase the time the Source takes to react to configuration changes and system restarts.

Socket timeout: Socket inactivity timeout (in seconds). Increase this value if retrievals time out during backpressure. Defaults to `300` seconds.

Skip file on error: Toggle to `Yes` to skip files that trigger a processing error. (For example, corrupted files.) Defaults to `No`, which enables retries after a processing error.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to reject certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`, the restrictive option.

Encoding: Character encoding to use when parsing ingested data. If not set, Cribl Stream will default to UTF-8 but might incorrectly interpret multi-byte characters. This option is ignored for Parquet files. UTF-16LE and Latin-1 are also supported.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Checkpointing

When Workers restart, checkpointing can prevent the Source from losing data or collecting duplicate events. Among the situations where this works well:

- When Cribl Stream pushes a new configuration: the Leader pushes the configuration to the Workers, and restarts them.
- When a Worker has gotten into a bad state, and you want to restart it.

Checkpointing allows Cribl Stream to resume processing a file at the point where an error or restart occurred, minimizing the number of duplicate events sent downstream in the event of an interruption. To accomplish this, Cribl Stream keeps track of how many events have been processed for a given file. Resuming processing after an interruption, the Source skips the first *N* events it has seen and starts processing from event *N*+1.

The Source manages checkpoint information in memory, but writes it out to disk periodically (once per second, and on Worker shutdown) so that the information can survive a Worker restart. Cribl Stream keeps checkpoint information at the Worker Process level and does not share it between Worker Processes or Worker Nodes.

Checkpointing is a feature to keep in mind when you do disaster recovery (DR) planning.

Caveats to using checkpointing include: Whenever Worker Node state is destroyed (that is, when a Worker ceases to exist), checkpoint information will be lost. In Cribl.Cloud deployments, this can happen during upgrades. Also, because checkpoints are not written to disk on **every** event, the checkpoints written to disk will lag behind those that the S3 Source manages in memory. If the Worker Process stops abruptly without a clean shutdown, checkpoints not yet written to disk will be lost. When processing resumes, the Source will start from just after the last checkpoint written to disk, producing duplicate events corresponding to the lost checkpoints.

Located in the UI at **Advanced Settings** > **Checkpoint Settings** > **Enable checkpointing**, this feature is turned off by default.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

How Cribl Stream Pulls Data

Worker Processes poll for messages from SQS, using the AWS SDK S3 APIs. Each polling call will return (by default) one message, if any are available. You can change this default using `Max messages`.

If no message is available, the call will time out after one second, and then polling will repeat.
All Worker Processes participate in polling, so as to disribute files' collection and processing evenly across Workers.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.13. Datadog Agent Source

Datadog Agent is open-source software that monitors the host on which it runs. Acting as a DogStatsD server, Datadog Agent also aggregates metrics from other processes or containers on the host.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

Cribl Stream can ingest the following from Datadog Agent, in bundled form:

- Logs.
