- Metrics (gauge, rate, counter, and histogram).
- Service checks.
- Agent metadata and other events emitted from the `/intake/` endpoint.

Datadog Agent also emits Application Performance Monitoring data, which it sends to Datadog. Cribl Stream does not currently support ingesting this APM data.

On the system(s) that you want to monitor, you'll need to install Datadog Agent and configure it to send data to Cribl Stream. Cribl Stream can parse, filter, and enrich that data, and then send it to any supported Destination, including a Cribl Stream Datadog Destination. (By default, Datadog Agent sends data only to Datadog.)

For inbound log data, this Source supports gzip -compression when the `Content-Encoding: gzip` connection header is set. For other data types, it assumes that all inbound data is compressed using `deflate`.

Configure Datadog to use Datadog API v1

This Source communicates with the Datadog API. Although v2 is the latest version of this API, this Source uses v1, which Datadog still supports.

To configure your Datadog Agent to work with this Source, ensure that in the `datadog.yaml` file, `use_v2_api.series` is set to `false`. Otherwise, when Datadog Agent sends metrics, Cribl Stream will not receive them, and `API Key invalid, dropping transaction` errors will appear in the Datadog Agent logs.

Potential Cribl Stream support for Datadog API v2 is being tracked as **CRIBL-18281** in Known Issues.

Configure Cribl Stream to Ingest Datadog Agent Output

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for Datadog Agent data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address.

This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Max active requests: Maximum number of active requests per worker process. Use `0` for unlimited.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

Extract metrics: Toggle to `Yes` to extract each incoming metric to multiple events, one per data point. This works well when sending metrics to a `statsd`-type output. If sending metrics to DatadogHQ or any destination that accepts arbitrary JSON, leave toggled to `No` (the default).

Forward API key validation requests: Toggle to `Yes` to send key validation requests from Datadog Agent to the Datadog API. If toggled to `No` (the default), Stream handles key validation requests by always responding that the key is valid.

Reject unauthorized certificates: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Defaults to `Yes`. Available when **Forward API key validation requests** is toggled to `Yes`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must

establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__agent_api_key`
- `__agent_event_type`
- `__final`
- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.
- `__inputId`
- `__srcIpPort` – See details below.
- `_time`

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Datadog Agent sending data to this Source.

When any proxies (including load balancers) lie between the Datadog Agent and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Sending Datadog Agent Data to Cribl Stream

Before you begin this section, you should have Datadog Agent running on one or more hosts.

To enable Datadog Agent to send data to Cribl Stream, you'll set the following environment variables:

- `DD_DD_URL`: The URL or IP address and port of your Datadog Agent Source in Cribl Stream.
- `DD_LOGS_CONFIG_LOGS_DD_URL`: The same value as above, assuming log collection is enabled on Datadog Agent.
- `DD_LOGS_CONFIG_USE_HTTP`: Set to `true`. Cribl Stream ingests Datadog Agent logs over HTTP only; ingesting logs over TCP is not supported.

Set these environment variables in one of two ways: (1) through a `docker run` command, or (2) by editing the `datadog.yaml` configuration file that your Datadog Agent uses.

Using the `docker run` Command

Here's an example `docker run` that sets the environment variables described above, along with others required for Datadog Agent but not relevant to Cribl Stream. Replace the example values with values appropriate for your environment.

```
docker run --rm --name dd-agent
  -e DD_API_KEY=6d1ephx1w55p978i6d1ephx1w55p978i \
  -e DD_SKIP_SSL_VALIDATION=true \
  -e DD_DD_URL="http://0.0.0.0:8080" \
  -e DD_LOGS_ENABLED=true \
  -e DD_LOGS_CONFIG_LOGS_DD_URL="0.0.0.0:8080" \
  -e DD_LOGS_CONFIG_USE_HTTP=true \
  -e DD_LOGS_CONFIG_LOGS_NO_SSL=true \
  -e DD_LOGS_CONFIG_CONTAINER_COLLECT_ALL=true \
  -e DD_DOGSTATSD_NON_LOCAL_TRAFFIC="true" \
  gcr.io/datadoghq/agent:7
```

Using a Config File

Instead of using environment variables, you can set the Cribl Stream-related values in your Datadog Agent's `datadog.yaml` config file.

See the documentation links in the example config file that Datadog maintains online; and, the docs that describe filesystem locations relevant to getting Datadog Agent to configure itself with the desired `datadog.yaml` file.

Managing What Data Goes Where

The different kinds of information that Datadog Agents emit - logs, metrics, service checks, agent metadata, and APM data - are not completely independent when you send them to Cribl Stream Datadog Agent Source. The reference to "bundling" near the top of this page introduced this situation in simplified form. The table below explains the relevant constraints for each type of information that Datadog Agents emit, along with the Datadog environment variables that control them.

Type(s) of Information	Dependencies and/or Limitations	Environment Variable
Logs	Independent of other types.	`DD_LOGS_CONFIG_DD_URL`
Metrics, Events, Service Checks, and Metadata	Always sent together.	`DD_DD_URL`
APM Data	Can only be sent to Datadog, for example, `https://trace.agent.datadoghq.com`. Cannot be sent to Cribl Stream even when you **are** sending other types there.	`DD_APM_DD_URL`

Managing API Keys

Suppose your data flow runs from Datadog Agents, to Cribl Stream Datadog Agent Sources, to Cribl Stream Datadog Destinations, to Datadog accounts. You'll need to decide **how many** of each of these elements there are to define the data flow you want. You will also set (or override) **Datadog API keys** to support the desired data flow. For some data flows, you'll need the **General Settings** > **Allow API key from events** toggle in the Cribl Stream Datadog Destination.

Another possibility is that you want data to flow to some Destination other than a Cribl Stream Datadog Destination. If that's the case, try adapting the examples below to your use case. Please connect with us on the `Cribl Community` Slack if you have questions.

Data Flow Examples

The examples which follow start simple and become more complex in terms of desired data flow, and, consequently, of Cribl Stream configuration.

One Agent to One Account

- You're running one Datadog Agent on one host.
- You want the output of the Agent sent to a single Datadog account.
- You only need one API key.
- You configure that single API key on your Cribl Stream Datadog Destination.

Many Agents to One Account

- You're running Datadog Agents on a fleet of hosts.

- You want to consolidate all the output of the Agents into a single Datadog account.
- You only need one API key. This is no different from the simpler one-to-one scenario above.
- You configure that single API key on your Cribl Stream Datadog Destination.
- No matter which host the data originates from, your Cribl Stream Datadog Destination sends it to Datadog using that single API key.

Many Agents to Many Accounts

- You're running Datadog Agents on a fleet of hosts.
- You want the output of the Agents from some hosts to flow into one Datadog account, and the output from other hosts to flow into a different Datadog account.
    - This may need to scale up to multiple accounts, if, for example, you are managing data from several different customers, or from several different organizations within your company.
- You need one API key **for each** Datadog account.
- In the Cribl Stream Datadog Destination, toggle **General Settings** > **Allow API key from events** to `Yes`.
- Here's what happens:
    - Datadog Agent always sends an API key when it communicates with the Cribl Stream Datadog Agent Source. Agents within different subgroups of hosts will send different API keys, as described above.
    - Cribl Stream Datadog Agent Source passes the API key from the Agent to the Cribl Stream Datadog Destination as an internal field.
    - Cribl Stream Datadog Destination uses that API key to direct its output to the correct Datadog account. If need be, you can configure the Destination to override the passed-in API key with a different one. This comes in handy when you know that your Agent(s) are using invalid API keys. You can even override **all** passed-in API keys.

Verifying that Data is Flowing

Once you have configured your Datadog Agent(s) as described above, and they have begun sending data:

- Try viewing the incoming data in the **Live Data** tab in your Cribl Stream Datadog Agent Source.
- If you have a Cribl Stream Datadog Destination set up, connect your Cribl Stream Datadog Agent Source to it via a **QuickConnect Passthru**, and verify that the same data shows up in the Destination's **Live Data** tab.
    - Another possibility is that you want your Cribl Stream Datadog Agent Source to connect to some Destination other than a Cribl Stream Datadog Destination. That's beyond the scope of this example, but verifying data flow should be similar.

- If the Cribl Stream Datadog Destination is configured to send data to a Datadog instance, verify that the same data shows up there, in the appropriate form, according to the transformations you've configured in Cribl Stream.
- If you have a many-to-many data flow as described above, verify that output is being correctly split among the possible Datadog accounts at the end of the data flow.

Assuming that data is behaving as expected, you can proceed to the best part, namely adding one or more Pipelines between Datadog Agent Source and Datadog Destination, to transform the data however you wish. Given the varied nature of what Datadog Agents collect, there should be ample opportunities to make the data leaner and more usable.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.14. Elasticsearch API Source

Cribl Stream supports receiving data over HTTP/S using the Elasticsearch Bulk API.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

For examples of receiving data from popular senders via this API, see Configuring Elastic Beats below.

Configure Cribl Stream to Receive Elasticsearch Bulk API Data over HTTP(S)

Cribl Stream ships with an Elasticsearch API Source preconfigured to listen on Port 9200. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Enabled**: Toggle to `Yes` to enable the Source.
    - **Input ID**: Enter a unique name to identify this Syslog Source definition. The default Source is prefilled with the value `in_elastic`. which can't be changed via the UI. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP on which to listen for Elasticsearch data. (For example, `localhost` or `0.0.0.0`.)
    - **Port**: Enter the port number to listen on.
    - **Elasticsearch API endpoint** (for Bulk API): Absolute path on which to listen for Elasticsearch API requests. Defaults to `/`. Cribl Stream automatically appends `_bulk`, so (for example) `/myPath`

becomes `/myPath/_bulk`. Requests could then be made to either `/myPath/_bulk` or `/myPath/<myIndexName>/_bulk`. Other entries are faked as success.

3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

In the **Authentication type** drop-down, select one of the following options:

- **None**: Don't use authentication.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials. Click **Generate** if you need a new password.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or select **Create** to configure a new secret.
- **Auth tokens**: Use HTTP token authentication. Click **Add Token** and, in the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header. Click **Generate** if you need a new token. Click **Add Token** to display additional rows to specify more tokens.

See also Periodic Logging for information on how auth tokens affect product logging.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Enable proxy mode: If you toggle this to `Yes`, see Proxy Mode below for the resulting options.

Extra HTTP Headers: Name-value pairs to pass as additional HTTP headers. By default, Cribl Stream's responses to HTTP requests include the `X-elastic-product` header, with an `Elasticsearch` value. (This is required by certain clients, including some Elastic Beats.)

API Version: To upstream Elastic Beats, this Cribl Stream Source will appear as an Elasticsearch instance matching the version that you set in this drop-down:

- `6.8.4` – Retained for backward compatibility.
- `8.3.2` – This default entry matches Elasticsearch's current `8.3.x` versions.
- `Custom` – Opens an HTTP response object in the **Custom API Version** editor. This object replicates what an Elasticsearch server would send in its HTTP responses to a client. You can edit the `version : number`, and any other fields, as required to satisfy the Elastic Beat sending data to this Source. (This `Custom` option supports future Elasticsearch releases, as long as Elasticsearch keeps the same response-object structure.)

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Proxy Mode

Enabling proxy mode allows Cribl Stream to proxy non–Bulk API requests to a downstream Elasticsearch server. This can be useful when integrating with Elasticsearch API senders like Elastic Endgame agents, which send requests that Cribl Stream does not natively support. Sliding **Enable proxy mode** to `Yes` exposes the following controls.

Proxy URL: URL of the Elasticsearch server that will proxy non-bulk requests, for example: `http://elastic:9200`.

Reject unauthorized certificates: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Defaults to `Yes`.

Remove headers: Enter any headers that you want removed from proxied requests. Press `Tab` or `Return` to separate header names.

Proxy request timeout: How long, in seconds, to wait for a proxy request to complete before aborting it. Defaults to `60` seconds; minimum timeout is `1` second.

To understand how **Proxy request timeout** interacts with the `X-Forwarded-For` header, see Overriding `__srcIpPort` with Client IP/Port.

Authentication method: Select one of the following options.

- **None**: Don't use authentication.
- **Manual**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Secret**: This option exposes a **Credentials secret** drop-down, in which you can select a stored secret that references the credentials described above. A **Create** link is available to store a new, reusable secret.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Field Normalization

The Elasticsearch API input normalizes the following fields:

- `@timestamp` becomes `_time` at millisecond resolution.
- `host` is set to `host.name`.
- Original object `host` is stored in `__host`.

The Elasticsearch Destination does the reverse, and it also recognizes the presence of `__host`.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.
- `__host`
- `__id`
- `__index`
- `__inputId`
- `__pipeline` - If present in the Elasticsearch `event.action` field of the event. See also how to override the pipeline attribute.
- `__srcIpPort` – See details below.
- `__type`

Overriding the Pipeline Attribute in the Elasticsearch and Elastic Cloud Destinations

The Elasticsearch Source will record the pipeline attribute received in a variable named `__pipeline`, if pipeline was presented in the Source event. If you want to forward the pipeline from the Source event to an Elasticsearch or Elastic Cloud Destination, set up the **Elastic pipeline** in one of the following ways.

This expression will use the value of `__pipeline` or default to `'myPipeline'` if `__pipeline` is missing:

```
__pipeline || 'myPipeline'
```

An alternative is to pass the pipeline if present, or otherwise omit it:

```
__pipeline ? __pipeline : undefined
```

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the Elasticsearch client sending data to this Source.

When any proxies (including load balancers) lie between the Elasticsearch client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Configuring Elastic Beats

Beats are open-source data shippers that act as agents, sending data to Elasticsearch (or to other services, in this case Cribl Stream). The Beats most popular with Cribl users are Filebeat and Winlogbeat.

To set up a Beat to send data to Cribl Stream, edit the Beat's YAML configuration file: `filebeat.yml` for Filebeat, `winlogbeat.yml` for Winlogbeat, and so on. In the config file, you'll specify your Cribl Stream Elasticsearch Source endpoint as the Beat's Elasticsearch output. To the Beat, Cribl Stream will appear as an instance of Elasticsearch.

If you're using HTTP token authentication (which is disabled by default, both on-prem and on Cribl.Cloud): First, set the token. Then add the following to the Beat config file under `output.elasticsearch.headers`, substituting your token for `myToken42`:

```
output.elasticsearch:
  headers:
    Authorization: "myToken42"
```

Configuring an Elastic Agent

An Elastic Agent is single agent for logs, metrics, security data, and threat prevention that sends data to Elasticsearch (or to other services, in this case Cribl Stream).

When you are sending from an Elastic Agent to Cribl Stream, the `elastic-agent.yml` file doesn't pay any attention to the settings for `output.elasticsarch.allow_older_versions: true`. As a result, the Elasticsearch API Source will not get any data.

To set it up correctly, go to the **Advanced Settings** tab, and change the **API Version** to `Custom`. In the **Custom API Version** editor, edit the `version : number` to match the version of the Elastic Agent you are using. This should allow the data to start flowing to the Source.

Periodic Logging

Cribl Stream logs metrics about incoming requests and ingested events once per minute.

If one or more auth tokens are configured and enabled, Cribl Stream logs requests and events for each enabled auth token individually. Since the tokens themselves are redacted for security, Cribl Stream logs the initial text of the token description to help you identify which token a given log is for.

If no auth token is configured and enabled, Cribl Stream simply logs overall statistics about incoming requests and ingested events.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker process.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.15. HTTP/S (Bulk API) Source

Cribl Stream supports receiving data over HTTP/S from Cribl Bulk API, Splunk HEC, and Elastic Bulk API endpoints.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

Configure Cribl Stream to Receive Data over HTTP(S)

Cribl Stream ships with an HTTP Source preconfigured to listen on Port 10080, and on several default endpoints. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `http`, which can't be changed via the UI. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP on which to listen for HTTP(S) data. (For example, `localhost` or `0.0.0.0`.)
    - **Port**: Enter the port number to listen on.
3. Under **Authentication**, enter the **Auth tokens**:
    - **Auth tokens**: Shared secrets to be provided by any client (`Authorization: <token>`). Click **Generate** to create a new secret. If empty, unauthenticated access **will be permitted**.
    - **Description**: Optionally, enter a description.

- **Fields**: Fields to add to events referencing this token. Each field is a **Name/Value** pair, where **Value** is a JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.) For details, see Authentication Fields.

4. Next, you can configure the following **Optional Settings**:
   - **Cribl HTTP event API**: Base path on which to listen for Cribl HTTP API requests. To construct the actual endpoint, Cribl Stream will append `/_bulk` to this path. For example, with the default value of `/cribl`, your senders should send events to a `/cribl/_bulk` path. Use an empty string to disable.
   - **Elastic API endpoint** (for Bulk API): Base path on which to listen for Elasticsearch API requests. For details, see Elastic API Endpiont below.
   - **Splunk HEC endpoint**: Absolute path on which to listen for Splunk HTTP Event Collector (HEC) API requests. Use an empty string to disable. Default entry is `/services/collector`. See Splunk HEC Details below.
   - **Splunk HEC Acks**: Whether to enable Splunk HEC acknowledgements. Defaults to `No`.
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Elastic API Endpoint

Currently, the only supported option is the default `/elastic`, to which Cribl Stream will append `/_bulk`. So, your senders should send events to an `/elastic/_bulk` path. Other entries are faked as success. Use an empty string to disable.

Cribl generally recommends that you use the dedicated Elasticsearch API Source instead of this endpoint. The Elastic API implementation here is provided for backward compatibility, and for users who want to ingest multiple inputs on one HTTP/S port.

Splunk HEC Details

This Splunk HEC implementation is an **event** (such as, not **raw**) endpoint.

For details, see Splunk's documentation. To send data to it from a HEC client, use either `/services/collector` or `/services/collector/event`. (See the examples below.)

Cribl generally recommends that you use the dedicated Splunk HEC Source instead of this endpoint. The Splunk HEC implementation here is provided for backward compatibility, and for users who want to ingest multiple inputs on one HTTP/S port.

Authentication Fields

By default, fields specified here will override fields of the same name in incoming events. However, you can customize this behavior to allow event fields to take precedence. For example, to allow the event's `index` field to take precedence, you could use this expression: `` `event.index || 'defaultIndex'` ``.

Fields add context to events based on the token used. This can be useful for tagging events with metadata such as source or environment, enhancing security by avoiding direct use of authorization values in Routes and Pipelines.

See also Periodic Logging for information on how auth tokens affect product logging.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so forth. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so forth. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; and so forth.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

> The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection`

header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.
- `__inputId`
- `__srcIpPort` – See details below.
- `__host` (Elastic In)
- `__id` (Elastic In)
- `__index` (Elastic In)
- `__type` (Elastic In)

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the client sending data to this Source.

When any proxies (including load balancers) lie between the HTTP client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original HTTP client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Format and Endpoint

Cribl Stream expects HTTP(S) events to be formatted as one JSON record per event. Here are two event records:

Sample Event Format

```
{"_time":1541280341, "_raw":"this is a sample event ", "host":"myHost", "source":"my
{"_time":1541280341, "host":"myOtherHost", "source":"myOtherSource", "_raw": "{\"mes
```

Note 1: Events can be sent as separate POSTs, but Cribl **highly** recommends combining multiple events in newline-delimited groups, and POSTing them together.

Note 2: If an HTTP(S) source is routed to a Splunk destination, fields within the JSON payload are mapped to Splunk fields. Fields that do not have corresponding (native) Splunk fields become index-time fields. For example, let's assume we have a HTTP(S) event like this:

```
{"_time":1541280341, "host":"myHost", "source":"mySource", "_raw":"this is a sample event ", "fieldA":"valueA"}
```

Here, `_time`, `host` and `source` become their corresponding fields in Splunk. The value of `_raw` becomes the actual body of the event, and `fieldA` becomes an index-time field. (`fieldA::valueA`).

Examples

Cribl Stream

The examples in this section demonstrate sending HTTP data into a Cribl Stream binary that you manage on-prem, or on a VM. To set up these examples:

1. Configure Cribl to listen on port `10080` for HTTP (default). Set `authToken` to `myToken42`.
2. Send a payload to your Cribl Stream receiver.

Cribl Endpoint – Single Event

Cribl Single Event Example:

```
curl -k http://<myCriblHost>:10080/cribl/_bulk -H 'Authorization: myToken42' -d '{"_
```

Cribl Endpoint – Multiple Events

Cribl Endpoint - Multiple Events

```
curl -k http://<myCriblHost>:10080/cribl/_bulk -H 'Authorization: myToken42' -d $'{"
```

Splunk HEC Event Endpoint

Splunk HEC Event Endpoint

```
curl -k http://<myCriblHost>:10080/services/collector/event -H 'Authorization: myTok
```

```
curl -k http://<myCriblHost>:10080/services/collector -H 'Authorization: myToken42' -
```

For Splunk HEC, the token specification can be either `Splunk <token>` or `<token>`.

Cribl.Cloud – Single Event

1. Generate and copy a token in your Cribl.Cloud instance's HTTP Source > **General Settings**.
2. From the command line, use `https`, your Cribl.Cloud portal's **Ingest Address** and port, and the token's value. You can find the **Ingest Address** on the top nav's **Network Settings** page, under the **Data Sources** tab.

Cribl.Cloud – Single Event

```
curl -k https://default.main.<Your-Org-ID>.cribl.cloud:10080/cribl/_bulk -H 'Authori
```

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to `<group-name>.main` when sending to other Worker Groups.

Periodic Logging

Cribl Stream logs metrics about incoming requests and ingested events once per minute.

If one or more auth tokens are configured and enabled, Cribl Stream logs requests and events for each enabled auth token individually. Since the tokens themselves are redacted for security, Cribl Stream logs the initial text of the token description to help you identify which token a given log is for.

If no auth token is configured and enabled, Cribl Stream simply logs overall statistics about incoming requests and ingested events.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker process.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.16. Raw HTTP/S Source

Cribl Stream supports receiving raw HTTP data. The Raw HTTP Source listens on a specific port, captures every HTTP request to that port, and creates a corresponding event that it pushes to its configured Event Breakers.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

This Source supports gzip-compressed inbound data when the `Content-Encoding: gzip` connection header is set.

Configure Cribl Stream to Receive Raw HTTP Data

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Raw HTTP Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the address to bind on. Defaults to `0.0.0.0` (all addresses).
    - **Port**: Enter the port number to listen on.
3. Under **Authentication**, enter the **Auth tokens**:
    - **Auth tokens**: Shared secrets to be provided by any client. Click **Generate** to create a new secret. If empty, permits open access.
    - **Description**: Optionally, enter a description.
    - **Fields**: Fields to add to events referencing this token. Each field is a **Name/Value** pair, where **Value** is a JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.) For details, see Authentication Fields.
4. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Authentication Fields

By default, fields specified here will override fields of the same name in incoming events. However, you can customize this behavior to allow event fields to take precedence. For example, to allow the event's `index` field to take precedence, you could use this expression: `` `event.index || 'defaultIndex'` ``.

Fields add context to events based on the token used. This can be useful for tagging events with metadata such as source or environment, enhancing security by avoiding direct use of authorization values in Routes and Pipelines.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Health check endpoint: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:

- `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
- `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.

Allowed URI paths: List of URI paths accepted by this input. Supports wildcards, for example, `/api/v*/hook`. Defaults to `*`, which allows all paths.

Allowed HTTP methods: List of HTTP methods accepted by this input. Supports wildcards, for example, `P*, GET`. Defaults to `*`, which allows all methods.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

Activity log sample rate: Determines how often request activity is logged at the `info` level. The default `100` value logs every 100th value; a `1` value would log every request; a `10` value would log every 10th request; etc.

Max requests per socket: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.

Request timeout (seconds): How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the **Keep-alive timeout**, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use longer timeouts to reduce the number of connections created, which mitigates the associated cost.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection` header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields for this Source:

- `__channel`
- `__headers` – Automatically includes any headers sent with request.
- `__inputId`
- `__srcIpPort` – See details below.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the HTTP client sending data to this Source.

When any proxies (including load balancers) lie between the HTTP client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Dropping request because token invalid",“authToken”: “Bas...Njc=”

The specified token is invalid. Note that the above message is logged only at the debug level.

15.1.17. Metrics Source

Cribl Stream supports receiving metrics in these wire formats/protocols: StatsD, StatsD Extended, and Graphite. Automatic protocol detection happens on the first line received over a TCP connection or a UDP packet. Lines not matching the detected protocol are dropped.

Type: **Push** | TLS Support: **No** | Event Breaker Support: **No**

Cribl Edge Workers support System Metrics only when running on Linux, not on Windows.

Configure Cribl Stream to Receive Metrics

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
    - **UDP port**: Enter the UDP port number to listen on. Not required if listening on TCP.For detail, see UDP Port Considerations.
    - **TCP port**: Enter the TCP port number to listen on. Not required if listening on UDP.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

UDP Port Considerations

Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This results from restrictions of the UDP protocol. To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP senders. Cribl also recommends tuning the OS UDP buffer size.

TLS Settings (TCP Only)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

If you do not see the **Max buffer size** setting, it is because you enabled the Persistent Queue. The Persistent Queue provides its own configurable internal buffer, and **Max buffer size** is not applicable in that case.

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Enable Proxy Protocol: Toggle to `Yes` if the connection is proxied by a device that supports Proxy Protocol v1 or v2.

IP allowlist regex: Regex matching IP addresses that are allowed to send data. Defaults to `.*` (i.e., all IPs.)

**Max buffer size (events) **: Maximum number of events to buffer when downstream is blocking. Defaults to `1000`.

UDP socket buffer size (bytes): Optionally, set the SO_RCVBUF socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Min: `256`. Max: `4294967295`.

It may also be necessary to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__srcIpPort`
- `__metricsInType`

Metric Event Schema and Destination Support

Metric data is read into the following event schema:

```
_metric - the metric name
_metric_type - the type of the metric (gauge, counter, timer)
_value - the value of the metric
_time - metric_time or Date.now()/1000
dim1 - value of dimension1
dim2 - value of dimension2
....
```

Cribl Stream places sufficient information into a field called `__criblMetric` to enable these events to be properly serialized out to any metric outputs (independent of the input type).

The following Destinations natively support the `__criblMetric` field:

- Splunk
- Splunk HEC
- InfluxDB
- Statsd
- Statsd Extended
- Graphite

Data Format/Protocol Examples

StatsD

Format: `MetricName:value|type`

StatsD Example

```
metric1:100|g
metric2:200|ms
metric.dot.3:300.16|c
```

See the StatsD repo.

StatsD Extended

Format: `MetricName:value|type|#dim=value,dim2=value`

StatsD Extended Example

```
metric1:100|g|#dim1:val1,dim2:val2,dim3:val3
metric2:200|ms|#dim1:val1,dim2:val2,dim3:val3
metric.dot.3:300.16|c|#dim1:val1,dim2:val2,dim3:val3
```

Graphite

Format: `MetricName[;dim1=val1[;dim2=val2]] value time`

Graphite Example with Dimensions

```
metric1;dim1=val1;dim2=val2 100 9999
metric2;dim1=val1;dim2=val2 200 9999
metric.dot.3;dim1=val1;dim2=val2 300.16 9999.16
```

Graphite Example without Dimensions

```
metric1 100 9999
metric2 200 9999
metric.dot.3 300.16 9999.16
```

See the Graphite (also known as Carbon) plaintext protocol.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.18. Model Driven Telemetry Source

Cribl Stream supports receiving network device metrics and events via Model Driven Telemetry (MDT).

Type: **Push** | TLS Support: **Yes** | Event Breaker Support: **No**

For observability of network devices, MDT compares favorably with the older SNMP-based approach because:

- MDT's messaging granularity is much finer than SNMP's.
- MDT's push-based model reduces load on network devices, while SNMP's pull-based model queues requests on devices.
- MDT's extensive ecosystem of data modules enables devices to collect many more kinds of data than they could with SNMP tools.

Prerequisites

When you configure MDT on a network device you choose among a variety of options and techniques. For this Source (in Cribl Stream version 4.5), you must configure your upstream sending device to use the following:

- MDT in dial-out mode.
- gRPC for the data transport mechanism.
- YANG models for data representation.
- Self-describing, also known as Key/Value Protocol Buffers (protobufs) for data encoding.

Configure Cribl Stream to Receive Model Driven Telemetry Data

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources**. Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.

- **Description**: Optionally, enter a description.
- **Address**: Enter the hostname/IP to listen to. Defaults to `0.0.0.0`.
- **Port**: Enter the port number to listen on. Defaults to port `57000`.

3. Under **Authentication**, enter the **Auth tokens**:
   - **Auth tokens**: Shared secrets to be provided by any client. Click **Generate** to create a new secret. If empty, permits open access.
   - **Description**: Optionally, enter a description.
   - **Fields**: Fields to add to events referencing this token. Each field is a **Name/Value** pair, where **Value** is a JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.) For details, see Authentication Fields.
4. Next, you can configure the following **Optional Settings**:
   - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter:

`worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB of disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Cribl Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of `KB`, `MB`, and so forth. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so forth. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`. This setting helps ensure events the best chance of delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Worker startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Max active connections: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set `0` for unlimited connections.

Shutdown timeout: Time to allow the server to shut down gracefully before forcing shutdown. Defaults to `5000` milliseconds (5 seconds).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of data from this Source via the Routing table.

Select **QuickConnect** to send data from this Source to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__srcIpPort`

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.19. NetFlow Source

Cribl Stream supports receiving NetFlow v5 and v9 data via UDP.

Type: **Push** | TLS Support: **No** | Event Breaker Support: **No**

This Source ingests NetFlow records similarly to how it ingests events from other upstream senders: fields are broken out, and each record includes a message header. If you prefer to render NetFlow data as metrics, use a pre-processing Pipeline or a Route.

If you want to associate a Community ID with a network flow that passes through this Source, connect the Source to a Route containing a Function that supports expression evaluation; then, in the Function, use the C.Net.communityIDv1() method. You can even generate different CommunityIDs for different use cases within the same network flow – to do this, use multiple `communityIDv1()` methods, with the optional `seed` parameter.

Configure Cribl Stream to Receive NetFlow Data

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this NetFlow Source definition.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen for NetFlow data. For example: `localhost`, `0.0.0.0`, or `::`.
    - **Port**: Enter the port number.
    - **Enable pass-through:** Enable this setting to allow Cribl Stream to forward events to a NetFlow Destination. If enabled, Cribl Stream generates an additional event containing `__netflowRaw`, which directly routes the raw NetFlow packet data to a downstream NetFlow Destination. These additional events do not count against any ingest quotas.
3. Next, you can configure the following **Optional Settings**:

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

From the top nav, click **Manage**, then select a **Worker Group** to configure. Next, you have two options:

Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This results from restrictions of the UDP protocol.

To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP sender. Cribl also recommends tuning the OS UDP buffer size.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

For more about PQ modes, see Always On versus Smart Mode.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per

Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Cribl Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (that is, all IPs).

IP denylist regex: Regex matching IP addresses whose messages you want this Source to ignore. Defaults to `^$` (that is, every specific IP address in the list). This takes precedence over the allowlist.

UDP socket buffer size (bytes): Optionally, set the `SO_RCVBUF` socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Minimum: `256`. Maximum: `4294967295`.

It may also be necessary to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Template cache minutes (minutes): This setting only affects v9 flow records. Use this setting to specify the length of time (in minutes) that Cribl Stream caches NetFlow v9 templates before discarding them. For example, setting the duration to `30` means Cribl Stream will cache templates for 30 minutes. If flow records are not refreshed by a new event, the templates are discarded.

The template cache minutes setting helps optimize the performance and reliability of NetFlow v9 data processing. This setting manages memory usage and ensures that outdated templates do not persist indefinitely. As you tune your NetFlow source, the goal is to balance system performance against memory use. Monitor your network and adjust this setting to find the right balance between template availability and system data overload. Some considerations when tuning your system:

- If your network's data patterns change often, consider using a shorter cache duration. Conversely, if the data records are stable and change less frequently, try using a longer duration.
- Monitor the status of this Source across your Worker/Edge nodes. If you notice Cribl Stream discards FlowSets, it may mean the cache duration is too short. Try increasing the cache duration and then observer whether there is a performance improvement. Alternatively, adjust your NetFlow exporters to send templates more frequently.
- If your system is using too much memory, it may mean that your cache duration is too long, especially if you have a lot of NetFlow exporters sending data to a single Source.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

What Fields to Expect

The NetFlow Source does minimal processing of the incoming UDP messages to remain consistent with the internal Cribl event model. For each UDP message received on the socket, you can expect an event with the following fields. We have organized these fields into categories to make them easier to grasp; the categories are our own, and not from the NetFlow specifications. The field definitions are mostly copied from Cisco NetFlow documentation.

The fields for NetFlow v5 and v9 data are different.

Fields for NetFlow v9

For NetFlow v9, Cisco-registered fields map to their most natural representation in Cribl. Specifically:

- IPv4 addresses are represented as dotted octet strings.
- IPv6 as colon-separated octet strings.
- MAC addresses also as colon-separated strings.
- Numbers that are six bytes or less are represented as numbers.
- Numbers that are greater than six bytes are represented as strings.
- Registered field attribute names are the camelCase versions of the SCREAMING_CASE names in the Cisco whitepaper.

Cribl Stream collects and offers unregistered fields in an array of records consisting of their type codes and byte buffers. Cribl Stream can accept and handle additional Internet Protocol Flow Information Export (IPFIX) codes. However, Cribl Stream does not decode those values. You can add Pipeline functions to change how these fields are processed by default.

Not all NetFlow v9 fields will appear on all events. Only those specified by the template for that specific data record. These fields are available for NetFlow v9:

- `inBytes`: The number of incoming Bytes.
- `inPkts`: The number of incoming packets.
- `flows`: The number of flows that were aggregated.
- `protocol`: The IP protocol.
- `srcTos`: The type of service setting when entering the incoming interface.
- `tcpFlags`: The accumulation of all the TCP flags seen in this flow.

- `l4SrcPort`: The TCP/UDP source port number.
- `ipv4SrcAddr`: The IPv4 source address.
- `srcMask`: The number of contiguous bits in the source subnet mask.
- `inputSnmp`: The input interface index.
- `l4DstPort`: The TCP/UDP destination port number.
- `ipv4DstAddr`: The IPv4 destination address.
- `dstMask`: The number of contiguous bits in the destination subnet mask.
- `outputSnmp`: The output interface index.
- `ipv4NextHop`: The IPv4 address of the next-hop router.
- `srcAs`: The source BGP autonomous system number. The length may be and defaults to 2.
- `dstAs`: The destination BGP autonomous system number. The length may be and defaults to 2.
- `bgpIpv4NextHop`: The IPv4 address of the next-hop router in the bgp domain.
- `mulDstPkts`: The number of IP multicast outgoing packets.
- `mulDstBytes`: The number of IP multicast outgoing bytes.
- `lastSwitched`: The system uptime in milliseconds at which the last packet of this flow was switched.
- `firstSwitched`: The system uptime in milliseconds at which the first package of this flow was switched.
- `outBytes`: The number of outgoing bytes.
- `outPkts`: The number of outgoing packets.
- `minPktLngth`: The minimum IP packet length on incoming packets.
- `maxPktLngth`: The maximum IP packet length on incoming packets.
- `ipv6SrcAddr`: The IPv6 source address.
- `ipv6DstAddr`: The IPv6 destination address.
- `ipv6SrcMask`: The number of contiguous bits in the IPv6 source mask.
- `ipv6DstMask`: The number of contiguous bits in the IPv6 destination mask.
- `ipv6FlowLabel`: The IPv6 flow label as per the RFC 2460 definition.
- `icmpType`: The ICMP packet type, reported as type * 256 + code.
- `mulIgmpType`: The IGMP packet type.
- `samplingInterval`: The rate at which packets are sampled; a value of 100 indicates that 1% of packets are sampled.
- `samplingAlgorithm`: The platform sampling algorithm; 1 is deterministic, 2 is random.
- `flowActiveTimeout`: Timeout value in seconds for active flow entries in the NetFlow cache.
- `flowInactiveTimeout`: Timeout value in seconds for inactive flow entries in the NetFlow cache.

- `engineType`: The type of flow switching engine; 0 is RP, 1 is VIP/Linecard.
- `engineId`: The ID number of the flow switching engine.
- `totalBytesExp`: The number of bytes exported by the observation domain.
- `totalPktsExp`: The number of packets exported by the observation domain.
- `totalFlowsExp`: The number of flows exported by the observation domain.
- `ipv4SrcPrefix`: The IPv4 source address prefix, specific for Catalyst architecture.
- `ipv4DstPrefix`: The IPv4 destination address prefix, specific for Catalyst architecture.
- `mplsTopLabelType`: The MPLS top label type; 0 is unknown, 1 is TE midpoint, 2 is AToM, 3 is VPN, 4 is BGP, and 5 is LDP.
- `mplsTopLabelIpAddr`: The IPv4 address of the forwarding equivalent class corresponding to the MPLS top label.
- `flowSamplerId`: The ID number of the flow sampler.
- `flowSampleMode`: The type of algorithm used for sample data.
- `flowSamplerRandomInterval`: The packet interval at which to sample.
- `minTtl`: Minimum TTL on incoming packets.
- `maxTtl`: Maximum TTL on incoming packets.
- `ipv4Ident`: The IPv4 identification field.
- `dstTos`: The type of service byte setting when exiting the outgoing interface.
- `inSrcMac`: The incoming source MAC address.
- `outDstMac`: The outgoing destination MAC address.
- `srcVlan`: The virtual LAN ID associated with the ingress interface.
- `dstVlan`: The virtual LAN ID associated with the egree interface.
- `ipProtocolVersion`: The IP version. The default is assumed to be 4 if unspecified.
- `direction`: The flow direction; 0 is ingress, 1 is egress.
- `ipv6NextHop`: The IPv6 address of the next-hop router.
- `bgpIpv6NextHop`: The IPv6 address of the next-hop router in the bgp domain.
- `ipv6OptionHeaders`: The IPv6 option headers found in the flow.
- `mplsLabel1`: The MPLS label at position 1 in the stack.
- `mplsLabel2`: The MPLS label at position 2 in the stack.
- `mplsLabel3`: The MPLS label at position 3 in the stack.
- `mplsLabel4`: The MPLS label at position 4 in the stack.
- `mplsLabel5`: The MPLS label at position 5 in the stack.

- `mplsLabel6`: The MPLS label at position 6 in the stack.
- `mplsLabel7`: The MPLS label at position 7 in the stack.
- `mplsLabel8`: The MPLS label at position 8 in the stack.
- `mplsLabel9`: The MPLS label at position 9 in the stack.
- `mplsLabel10`: The MPLS label at position 10 in the stack.
- `inDstMac`: The incoming destination MAC address.
- `outSrcMac`: The outgoing source MAC address.
- `ifName`: The shortened interface name.
- `ifDesc`: The full interface name.
- `samplerName`: The name of the flow sampler.
- `inPermanentBytes`: The running byte counter for a permanent flow.
- `inPermanentPkts`: The running packet counter for a permanent flow.
- `fragmentOffset`: The fragment-offset value from fragmented IP packets.
- `forwardingStatus`: The forwarding status.
- `mplsPalRd`: The MPLS pal route distinguisher.
- `mplsPrefixLen`: The number of consecutive bits in the MPLS prefix length.
- `srcTrafficIndex`: The BGP policy accounting source traffic index.
- `dstTrafficIndex`: The BGP policy accounting destination traffic index.
- `applicationDescription`: The application description.
- `applicationTag`: The application tag.
- `applicationName`: The name associated with a classification.
- `postIpDiffServeCodePoint`: The value of a differentiated services code point encoded in the differentiated services field, after modification.
- `replicationFactor`: The multicast replication factor.
- `layer2PacketSectionOffset`: The layer 2 packet section offset, potentially a generic offset.
- `layer2PacketSectionSize`: The layer 2 packet section size, potentially a generic size.
- `layer2PacketSectionData`: The layer 2 packet section data.

Option Data Records for NetFlow v9

Options data records report aggregate metadata about the Exporters. Like data records, they can include any or all of the previous fields. Additionally, they also have a `scopes` field with a value containing an array of records with a `type` field. The valid types are:

- `system`
- `interface`
- `line-card`
- `cache`
- `template`

Option data records also have a `value` field, which is a natural number. The JavaScript type is either a number or a string, depending on the size of the value.

Fields for NetFlow v5

General

- `_time`: The UNIX timestamp (in seconds) at which the message was received by Cribl Stream.
- `source`: A string in the form `udp|<remote IP address>|<remote port>`, indicating the remote sender.
- `host`: The hostname of the machine running Cribl Stream that ingested this event.
- `inputInt`: SNMP index of input interface; always set to zero.
- `outputInt`: SNMP index of output interface.
- `protocol`: IP protocol type (for example, TCP = 6; UDP = 17) of the observed network flow.
- `tcpFlags`: Cumulative logical OR of TCP flags in the observed network flow.
- `tos`: IP type of service; switch sets it to the ToS of the first packet of the flow.
- `icmpType`: Type of the ICMP message. Only present if the protocol is ICMP.
- `icmpCode`: Code of the ICMP message. Only present if the protocol is ICMP.

Because this Source reads input data directly from bytes in a compact format, there is nothing suitable to put in a `_raw` field, and the Source does not add a `_raw` field to events.

Flow Source and Destination

- `srcAddr`: Source IP address; in case of destination-only flows, set to zero.
- `dstAddr`: Destination IP address.
- `nextHop`: IP address of next hop router.
- `srcPort`: TCP/UDP source port number.

- `dstPort`: TCP/UDP destination port number. If this is an ICMP flow, this field is a combination of ICMP type and ICMP code, which are broken out separately as `icmpType` and `icmpCode` fields.
- `srcMask`: Source address prefix mask bits.
- `dstMask`: Destination address prefix mask bits.
- `srcAs`: Autonomous system number of the source, either origin or peer.
- `dstAs`: Autonomous system number of the destination, either origin or peer.

Flow Statistics

- `packets`: Packets in the flow.
- `octets`: Total number of Layer 3 bytes in the packets of the flow.
- `startTime`: System uptime, in milliseconds, at the start of the flow.
- `endTime`: System uptime, in milliseconds, at the time the last packet of the flow was received.
- `durationMs`: `endTime` minus `startTime`.

Header

The following are subfields within the `header` field:

- `count`: Number of flows exported in this flow frame (protocol data unit, or PDU).
- `sysUptimeMs`: Current time in milliseconds since the export device booted.
- `unixSecs`: Current seconds since 0000 UTC 1970.
- `unixNsecs`: Residual nanoseconds since 0000 UTC 1970.
- `flowSequence`: Sequence counter of total flows seen.
- `engineType`: Type of flow switching engine.
- `engineId`: ID number of the flow switching engine.
- `samplingMode`: The first two bits of what Cisco NetFlow documentation calls `SAMPLING_INTERVAL`. These bits specify a sampling mode.
- `samplingInterval`: The remaining 14 bits of what Cisco NetFlow documentation calls `SAMPLING_INTERVAL`. These bits specify a sampling interval.
- `version`: NetFlow export format version number.

Also, the internal fields listed below will be present.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These “meta” fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields accessible for this Source:

- `__netflowRaw` : Directly routes the raw NetFlow packet data to a downstream NetFlow Destination.

Considerations for Working with NetFlow Data FlowSets

For both NetFlow v5 and v9, Cribl Stream:

- Can forward NetFlow packets to other NetFlow destinations. However, it cannot modify the the contents of the incoming packet. In other words, Cribl Stream forwards the packets verbatim as they came in.
- Only routes NetFlow packets from upstream exporters and cannot generate its own NetFlow packets.
- Cannot forward non-NetFlow input data to NetFlow Destinations.
- Can forward NetFlow packets to non-NetFlow Destinations, such as Splunk, Syslog, S3, and others. To send NetFlow flow records to other non-NetFlow Destinations, use the other events generated on the NetFlow Source that do not include the `__netflowRaw` field. NetFlow Destinations discard those events.

Cribl Stream emits:

- Decoded Cribl events downstream for each data record and options data record.
- When you enable pass-through mode: an undecoded Cribl event for the entire packet.

High Availability and Disaster Recovery for NetFlow v9

NetFlow v9 Template Records are sent every 20 packets or every 30 minutes. Cribl Stream uses a key-value store to share these records across Worker Nodes in a Worker Group, ensuring availability for processing FlowSets.

- **Template Sharing**: Records are shared across Worker Nodes with a minimal delay, ensuring timely processing. The brief interval between receiving and sharing Template Records is designed to be negligible, given the low rate of Template Record changes.
- **Worker Coordination**: The key-value store allows uninterrupted processing during Worker Node failures.
- **Disaster Recovery**: Replication in the key-value store ensures Template Records are preserved, enabling seamless recovery.

UDP Tuning

Incoming UDP traffic is put into a buffer by the Linux kernel. Cribl will drain from that buffer as resources are available. At lower throughput levels, and with plenty of available processes, this isn't an issue. As you scale up, however, the default size of that buffer may be too small.

You can check the current buffer size with:

```
$ sysctl net.core.rmem_max
```

A typical value of about 200 KB is far too small for an even moderately busy syslog server. You can check the health of UDP with the following command. Check the `packet receive errors` line.

```
$ netstat -su
```

If `packet receive errors` is more than zero, you have lost events, which is a particularly serious problem if the number of errors is increasing rapidly. This means you need to increase your `net.core.rmem_max` setting (see earlier).

You can update the live settings, but you'll also need to change the boot-time setting so next time you reboot everything is ready to roll.

Live change, setting to 25 MB:

```
$ sysctl -w net.core.rmem_max=26214400
net.core.rmem_max = 26214400
$ sysctl -w net.core.rmem_default=26214400
net.core.rmem_default = 26214400
```

For the permanent settings change, add the following lines to `/etc/sysctl.conf`:

```
net.core.rmem_max=26214400
net.core.rmem_default=26214400
```

We recommend you track a few things related to UDP receiving:

- The `netstat -su` command, watching for errors.

- The **Status** tab in the UDP (Raw) Source. In particular, watch for dropped messages. They could indicate you need a bigger buffer under **Advanced Settings** (default: 1000 events). They could also indicate your Worker is encountering pressure further down the Pipeline.
- Especially if you increase your kernel receive buffer as above, watch your Worker processes' memory usage.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Data Collisions

When Cribl Stream receives a NetFlow v9 template, it identifies the template using three values:

- Template ID
- Source ID, which is unique to the upstream exporting device
- IP address of the upstream exporting device

Cribl Stream uses these three values to prevent data collisions. However, data collisions may occur under these two conditions:

- Your system has a heterogeneous variety of upstream exporter devices, AND
- The Exporter IP addresses are rewritten (such as by a proxy server) before they are sent downstream to Cribl Stream.

In that situation, it is possible for two exporter devices with the same IP address to send packets simultaneously and cause a collision. The workaround is to create unique IP addresses for the exporters or use the original IP addresses.

15.1.20. OpenTelemetry (OTel) Source

Cribl Stream supports receiving trace, metric, and log events from OTLP-compliant senders. Cribl Stream supports log events beginning in v.4.7.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

Supported and Unsupported Input Data

In Cribl Stream 4.0.3 and later, the Open Telemetry Source supports receiving compressed inbound data (with DEFLATE or gzip compression), as well as uncompressed data.

In Cribl Stream 4.1 and later, this Source supports receiving telemetry data over either of the transports that the OpenTelemetry Protocol (OTLP) describes: gRPC or HTTP. OTLP defines Protocol buffer (Protobuf) schemas for its payloads (requests and responses). With the HTTP transport, this Source supports Binary Protobuf payload encoding, but currently does not support JSON Protobuf.

The OpenTelemetry Project's Data Sources documentation provides these hierarchical definitions of Cribl Stream's supported trace and metric event types:

- A **trace** tracks the progression of a single request.
  - Each trace is a tree of **spans**.
  - A span object represents the work being done by the individual services, or components, involved in a request as that request flows through a system.
- A **metric** provides aggreggated statistical information.
  - A metric contains individual measurements called **data points**.
- A **log** provides a recording of an event.
  - See the OTLP Logs Function topic for an explanation of OTLP logs structure.

Breaking Changes Between OTLP 0.19.0 and 1.3.1

With version 0.19.0, the OTLP Protobuf spec introduced breaking changes in its field names. This means that if you created Routes or Pipelines that work with OTLP version 0.10.0, they may break when you use them with OTLP 1.3.1.

To use Routes or Pipelines created before Cribl Stream 4.7 with OTLP 1.3.1, you must check their filters and logic for any use of obsolete field names, and modify them accordingly,

Configure an OTel Source

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Unique ID for this Source. For example, `OTel042`.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen on. Defaults to `0.0.0.0` (all addresses, IPv4 format).
    - **Port**: By default, OTel applications send output to port `4317` when using the gRPC protocol, and port `4318` when using HTTP. This setting defaults to `4317` – you must change it if you set **Protocol** (below) to `HTTP`, or you want Cribl Stream to collect data from an OTel application that is using a different port.

Port `4318` is not available on Cribl-managed Worker Groups in Cribl.Cloud.

3. Next, you can configure the following **Optional Settings**:
    - **Protocol**: Use the drop-down to choose the protocol matching the data you will ingest: `gRPC` (the default), or `HTTP`.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Enter the bearer token that must be included in the authorization header.

- **Auth token (text secret)**: Provide an HTTP token referenced by a secret. Select a stored text secret in the resulting drop-down, or click **Create** to configure a new secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: Provide username and password credentials referenced by a secret. Select a stored text secret in the resulting **Credentials secret** drop-down, or click **Create** to configure a new secret.

TLS Settings (Server Side)

In OTel terminology, your Cribl Stream OTel Source will receive OTel data from a **Collector** running on a local **agent**. In Cribl Stream's terminology, the Collector is the **client** and the OTel Source is the **server**. This is why this Source's UI identifies the Source's TLS Settings as "server-side."

For more about this client-server relationship, see the TLS Configuration Example below.

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs (mTLS). Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

> On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.
>
> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Advanced Settings always displays **OTLP version**, **Extract spans**, **Extract metrics**, and **Environment**. When **OTLP version** is set to `1.3.1`, the UI also displays **Extract logs**.

The **Extract spans**, **Extract metrics**, and **Extract logs** settings are unique to OTel. Their default `No` settings allow Cribl Stream to essentially function as a bump on the wire, generating a single event for each incoming OTel event. This can be useful when, for example, you want to send whole OTel events to persistent storage.

- **OTLP version**: The drop-down offers `0.10.0` (default) and `1.3.1`.
- **Extract spans**: Toggle to `Yes` if you want Cribl Stream to generate an individual event for each span. (Recall that traces contain multiple spans.)
- **Extract metrics**: Toggle to `Yes` if you want Cribl Stream to generate an individual event for each data point. (Recall that OTel metric events contain multiple data points.)
- **Extract logs**: Available only when **OTLP version** is set to `1.3.1`. Toggle to `Yes` if you want Cribl Stream to generate an individual event for each log record. Cribl recommends doing this to make it easier to transform and manipulate logs.

- **Environment**: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

When **General Settings** > **Protocol** is set to `gRPC`, the UI displays one additional setting:

- **Max active connections**: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set `0` for unlimited connections.

When **General Settings** > **Protocol** is set to `HTTP`, the UI displays these additional settings:

- **Health check endpoint**: Toggle to `Yes` to enable a health check endpoint specific to this Source, `http(s)://<host>:<port>/cribl_health`. A `200` HTTP response code is returned when the Source is healthy. Otherwise, two errors you could receive are:
  - `ECONNRESET` where the Source failed to initialize due to not having listeners on the port.
  - `503` or `Server is busy, max active connections reached` indicate there are too many connections per Worker Process.
- **Max active requests**: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.
- **Max requests per socket**: The maximum number of requests Cribl Stream should allow on one socket before instructing the client to close the connection. Defaults to `0` (unlimited). See Balancing Connection Reuse Against Request Distribution below.
- **Socket timeout (seconds)**: How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever.
- **Request timeout (seconds)**: How long to wait for an incoming request to complete before aborting it. The default `0` value means wait indefinitely.
- **Keep-alive timeout (seconds)**: After the last response is sent, Cribl Stream will wait this long for additional data before closing the socket connection. Defaults to `5` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).
- **IP allowlist regex**: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).
- **IP denylist regex**: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Balancing Connection Reuse Against Request Distribution

Max requests per socket allows you to limit the number of HTTP requests an upstream client can send on one network connection. Once the limit is reached, Cribl Stream uses HTTP headers to inform the client that it must establish a new connection to send any more requests. (Specifically, Cribl Stream sets the HTTP `Connection`

header to `close`.) After that, if the client disregards what Cribl Stream has asked it to do and tries to send another HTTP request over the existing connection, Cribl Stream will respond with an HTTP status code of `503 Service Unavailable`.

Use this setting to strike a balance between connection reuse by the client, and distribution of requests among one or more Worker Node processes by Cribl Stream:

- When a client sends a sequence of requests on the same connection, that is called connection reuse. Because connection reuse benefits client performance by avoiding the overhead of creating new connections, clients have an incentive to **maximize** connection reuse.
- Meanwhile, a single process on that Worker Node will handle all the requests of a single network connection, for the lifetime of the connection. When receiving a large overall set of data, Cribl Stream performs better when the workload is distributed across multiple Worker Node processes. In that situation, it makes sense to **limit** connection reuse.

There is no one-size-fits-all solution, because of variation in the size of the payload a client sends with a request and in the number of requests a client wants to send in one sequence. Start by estimating how long connections will stay open. To do this, multiply the typical time that requests take to process (based on payload size) times the number of requests the client typically wants to send.

If the result is 60 seconds or longer, set **Max requests per socket** to force the client to create a new connection sooner. This way, more data can be spread over more Worker Node processes within a given unit of time.

For example: Suppose a client tries to send thousands of requests over a very few connections that stay open for hours on end. By setting a relatively low **Max requests per socket**, you can ensure that the same work is done over more, shorter-lived connections distributed between more Worker Node processes, yielding better performance from Cribl Stream.

A final point to consider is that one Cribl Stream Source can receive requests from more than one client, making it more complicated to determine an optimal value for **Max requests per socket**.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

TLS Configuration Example

Here's a simple example for using TLS to secure the communication between an OpenTelemetry client and your Cribl Stream OTel Source.

1. Choose or generate a certificate and key. If you need to generate a certificate/key pair, you can adapt the following OpenSSL command:

   ```
   openssl req -nodes -new -x509 -newkey rsa:2048 -keyout myKey.pem -out myCert.pem
   ```

   This example command will generate both a self-signed cert named `myCert.pem` (certified for 420 days), and an unencrypted, 2048-bit RSA private key named `myKey.pem`.

2. Configure the **TLS Settings (Server Side)**. Toggle **Enabled** to `Yes`, then:
   - Enter the appropriate values in the **Certificate name**, **Private key path**, and **Certificate path** fields. A **Create** link is available if you need a new certificate, and **Certificate name** also works as a drop-down to allow you to choose from any existing certificates.
   - Leave the **CA certificate path** field empty.
   - Leave **Authenticate client (mutual auth)** toggled to `No`.

3. Configure the OTel client. See the OTel Collector TLS Configuration Settings README for an explanation of the relevant settings. The config file might be named `otel-config.yaml`, `otel-local-config.yaml`, or just `config.yaml`, depending on your environment. This YAML file will have an `exporters` section, which you must edit to include an `otlp` sub-section, as follows:
   - Add an `endpoint` whose value is the IP address of either (a) the Cribl Stream Worker Node on which your OTel Source is running, or (b) the IP address of the load balancer for the relevant Worker Group. In the example snippet below, this is the `<Cribl_IP_address>`. Specify the port on which Cribl Stream's OTel Source is listening; port `4317` is the default.
   - Set `tls` > `insecure` to `false`. This matches your setting **TLS Settings (Server Side)** > **Enabled** to `Yes` on the Cribl Stream OTel Source.
   - Set `tls` > `insecure_skip_verify` to `true`. This matches your setting **TLS Settings (Server Side)** > **Authenticate client (mutual auth)** to `No` on the Cribl Stream OTel Source. Setting `insecure_skip_verify` to `true` is also required if you're using a self-signed certificate.

   Here's how the section you edited should look:

   ```
   exporters:
     otlp:
       endpoint: "https://<Cribl_IP_address>:4317"
       tls:
         insecure: false
         insecure_skip_verify: true
   ```

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

When your upstream sender is the OpenTelemetry Collector and its logs show the error `Exporting failed. Will retry the request after interval`, try increasing the duration specified in **Advanced Settings** > **Keep-alive timeout (seconds)**. Choose a duration that aligns with your OpenTelemetry Collector configuration, such that the OpenTelemetry Collector has enough time to send its events before the keep-alive timeout elapses.

15.1.21. SNMP Trap Source

Cribl Stream supports receiving data from SNMP Traps.

Type: **Push** | TLS Support: **NO** | Event Breaker Support: **No**

Configure Cribl Stream to Receive SNMP Traps

Cribl Stream, except in Cribl.Cloud, ships with an SNMP Trap Source preconfigured to listen on port `9162`. You can clone or directly modify this Source to further configure it, and then enable it.

In Cribl Stream, configure SNMP Traps:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Source definition. The default Source is prefilled with the value `in_snmp_trap`. which can't be changed via the UI. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Address to bind on. Defaults to `0.0.0.0` (all addresses).
    - **UDP Port**: Port on which to receive SNMP traps. Defaults to `162`.

      Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This results from restrictions of the UDP protocol.

      To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP senders. Cribl also recommends tuning the OS UDP buffer size.
3. Next, you can configure the following **Optional Settings**:

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication Settings

SNMPv3 authentication provides secure access to devices through optional user authentication and decryption of incoming data packets. Cribl Stream lets you choose any of the following levels of security:

- User name checking without authentication.
- User authentication without privacy.
- User authentication with privacy.

SNMPv3 authentication: Toggle to `Yes` to enable SNMPv3 authentication and reveal authentication parameters. Defaults to `No`.

Allow unmatched traps: Toggle to `Yes` to pass through traps that don't match any of the configured users. Cribl Stream will not attempt to authenticate or decrypt these traps. When toggled to `No` (default), Cribl Stream drops traps without a correctly configured user name.

v3 Name: Enter the SNMPv3 user name (required). Multiple users are supported.

You must configure at least one user to enable SNMPv3 authentication. If desired, you can enter separate user credentials for each SNMPv3 user. The authentication protocol, authentication key, privacy protocol, and privacy key can be unique for each user.

For authentication to succeed, the user name and authentication protocol and key must match in the Source and the sending device configuration.

For decryption to succeed, the user name, authentication protocol and key, and the privacy protocol and key must match in the Source and the sending device configuration.

Authentication protocol: Select the authentication protocol required for your use case. If you select `None`, Cribl Stream will only check the user name without authenticating the user or decrypting the data. Otherwise, Cribl Stream uses the authentication protocol you specify and the key you provide to authenticate the user.

Options include:

- `None`
- `MD5`

- `SHA1`
- `SHA224`
- `SHA256`
- `SHA384`
- `SHA512`

v3 authentication key: Enter the authentication key.

Choosing an authentication protocol also allows you to select an optional privacy protocol to decrypt incoming packets.

Cribl Stream logs authentication failures at the `debug` level.

Privacy protocol: Select the privacy protocol required for your use case. If you select `None`, Cribl Stream authenticates the user without decrypting the incoming data. Otherwise, Cribl Stream uses the privacy protocol you specify and the key you provide to decrypt the data.

Options include:

- `None`
- `AES128`
- `AES256b (Blumenthal)`
- `AES2556r (Reeder)`

For every successfully decrypted trap, Cribl Stream adds `__didDecrypt: true` to the Event. Cribl Stream logs decryption failures at the `debug` level.

v3 privacy key: Enter the privacy key.

Add user: Click to add a new set of user credentials for SNMPv3 authentication.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

> The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

> If you do not see the **Max buffer size** setting, it is because you enabled the Persistent Queue. The Persistent Queue provides its own configurable internal buffer, and **Max buffer size** is not applicable in that case.

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

> In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Include varbind types: Toggle on to include varbind types in the `varbinds` field on each event. This is required for the SNMP Trap Serialize Function to serialize compliant events into SNMP traps before sending them to an SNMP Trap Destination. The field is parsed to an array of objects like, `[{oid: string, value: any, type: number}]`. Off by default.

IP allowlist regex: Regex matching IP addresses that are allowed to send data. Defaults to `.*`, that is, all IPs.

Max buffer size (events): Maximum number of events to buffer when downstream is blocking. Defaults to `1000`.

UDP socket buffer size (bytes): Optionally, set the SO_RCVBUF socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Min: `256`. Max: `4294967295`.

It may also be necessary to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Fields for this Source:

- `__didDecrypt`: Set to `true` for every trap that is successfully decrypted.
- `__final`
- `__inputId`
- `__snmpRaw`: Buffer containing Raw SNMP packet
- `__snmpVersion`: Acceptable values are `0`, `2` , or `3`. These respectively indicate SNMP v1, v2c, and v3.
- `__srcIpPort` : In this particular Source, this field uses a pipe (|) symbol to separate the source IP address and the port, in this format: `event.__srcIpPort = ${rInfo.address}|${rInfo.port};`
- `_time`

Considerations for Working with SNMP Trap Data

- It's possible to work with SNMP metadata (that is, we'll decode the packet). Options include dropping, routing, and so on.
- SNMP packets can be forwarded to other SNMP destinations. However, the contents of the incoming packet **cannot** be modified – that is, we'll forward the packets verbatim as they came in.
- SNMP packets can be forwarded to non-SNMP destinations (for example, Splunk, Syslog, S3, and so on).
- Non-SNMP input data **cannot** be sent to SNMP destinations.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.22. Syslog Source

The Syslog Source receives syslog data (UDP/TCP) from various devices. Syslog messages are parsed into structured fields or stored in a raw format if unrecognized. For high-volume scenarios, TCP load balancing distributes data, optimizing performance and minimizing CPU strain.

Compatible RFCs:

- Supports structured syslog data defined by RFC 3164 and RFC 5424, which can include timestamps, facility codes, severities, and message content for detailed analysis.
- Processes message-length prefixes specified in RFC 5425 and RFC 6587, ensuring complete and accurate data transmission.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

For details on how to replace your syslog server with Cribl Stream, and for configuration examples, see these resources:

- Syslog Best Practices.
- Syslog to Cribl Stream Reference Architecture.
- Palo Alto Syslog to Cribl.Cloud.
- CEF/LEEF Syslog Pack.
- Exabeam Pack for Palo Alto Networks NGFW.

Configure Cribl Stream to Receive Data over Syslog

Cribl Stream ships with a Syslog Source preconfigured to listen for both UDP and TCP traffic on Port 9514. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.

2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Syslog Source definition. The default Source is prefilled with the value `in_syslog_default`. which can't be changed via the UI. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP on which to listen for data. For example, `localhost` or `0.0.0.0`. For details, see IP Address Considerations.
    - **UDP port**: Enter the UDP port number to listen on. Not required if listening on TCP. The maximum supported inbound UDP message size is 16,384 bytes. For details, see UDP Port Considerations.
    - **TCP port**: Enter the TCP port number to listen on. Not required if listening on UDP.
3. Next, you can configure the following **Optional Settings**:
    - **Fields to keep**: List of fields from source data to retain and pass through. Supports wildcards. Defaults to `*` wildcard, meaning keep all fields. Fields **not** specified here (by wildcard or specific name) will be removed from the event.
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

IP Address Considerations

Cribl recommends that you change the **Address** setting from its default `0.0.0.0` only if you know precisely why you're doing so. There are very few use cases where changing this broad default makes sense. All your Worker Nodes in each Worker Group receive this config, and no two Nodes should have the same IPs, other than `0.0.0.0` or `127.0.0.1`. The `0.0.0.0` tells the system to listen to all interfaces and addresses. A `127.0.0.1` entry means listen **only** on `localhost`.

UDP Port Considerations

Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This is due to the UDP protocol's restrictions. To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP senders. Cribl also recommends tuning the OS UDP buffer size.

Listening on Port 514

For Syslog devices that are hardcoded to send to port 514, you can listen on this port on Cribl.Cloud, which otherwise is normally available only with privileged access. To do this, enable the built-in

> `in_syslog_default` Syslog Source, which forwards traffic from port 514 to 10514.
>
> Note that traffic on port 514 is unencrypted. This means that using this port may result in collecting fake or undesirable data. Enable the `in_syslog_default` Source only if you are aware of this risk.

TLS Settings (TCP Only)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

If you do not see the **Max buffer size** setting, it is because you enabled the Persistent Queue. The Persistent Queue provides its own configurable internal buffer, and **Max buffer size** is not applicable in that case.

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

On this tab, you can enrich fields with added fields, and attach a pre-processing Pipeline to condition inbound syslog data.

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Enable Proxy Protocol: Toggle to `Yes` if the connection is proxied by a device that supports Proxy Protocol v1 or v2.

Single msg per UDP: Enable this to treat received UDP packet data as a full syslog message. With the `No` default, Cribl Stream will treat newlines within the packet as event delimiters.

Allow non-standard app name: Toggle to `Yes` to allow hyphens to appear in an RFC 3164–formatted Syslog message's `TAG` section. For details, see TAG Section Processing.

Enable TCP load balancing: Toggle to `Yes` if you want the Source to load balance traffic across all Worker Processes, as explained below. (This setting is available only in Cribl Stream deployed in Distributed mode.)

IP allowlist regex: Regex matching IP addresses that are permitted to send data. Defaults to `.*` (that is, all IPs).

Max buffer size (events): Maximum number of events to buffer when downstream is blocking. The buffer is only in memory. (This setting is applicable only to UDP syslog.) Events dropped because they exceed this buffer are logged as dropped in `stats` messages.

UDP socket buffer size (bytes): Optionally, set the SO_RCVBUF socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Min: `256`. Max: `4294967295`.

It may also be necessary to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Default timezone: Timezone to assign to timestamps that omit timezone info. Accept the default `Local` value, or use the drop-down list to select a specific timezone by city name or GMT/UTC offset.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

TCP Load Balancing

This feature is available only for Cribl Stream deployments that are in Distributed mode.

When the Syslog Source receives a high volume of data over TCP, a single Worker Process can place excessive CPU load on its Cribl Stream Worker Node, while remaining Worker Processes on the same node mostly sit idle. This undesirable condition is called "TCP pinning" because the high volume of traffic "pins" a single TCP connection.

To alleviate TCP pinning, try toggling **Advanced Settings** > **Enable TCP load balancing** on. The Syslog Source will then load balance traffic across all Worker Processes.

When TCP load balancing is enabled, the Worker Node forks a special Worker Process dedicated to load balancing; creates sockets for communication between the load balancer and the regular Worker Processes; and, makes TCP load balancing metrics available.

The Load Balancing Process

The Worker Node forks a new, special **load balancer** Worker Process that distributes incoming syslog data among the other Worker Processes. For customer-managed (hybrid or on-prem) Worker Groups, consider

reducing the Process count by 1, if possible. This will leave a core free to run the load balancer process.

If you want to verify that the load balancer Worker Process exists, teleport into the relevant Worker and in the **Worker Processes** tab you will see a Worker Process with `LB` in its name.

To view logs from the Leader UI, navigate to **Monitoring** > **Logs** > `<Worker Node ID>` > **Load Balancer**.

Worker Process Socket Files

The load balancer Worker Process sends data to the regular Worker Processes over inter-process communication (IPC) sockets. This means that in the `state` directory, there is a socket file for each load balancer Worker Process and each Worker Process.

By default, the socket files are linked to `state`, from the Cribl `tmp` directory. For customer-managed (hybrid or on-prem) Stream Worker Groups, you can specify a directory other than `tmp` for these links. Cribl recommends that you do **not** use this option, but if you find it necessary, navigate to **Group Settings** > **General Settings** > **Sockets** to configure as desired.

TCP Load Balancing Metrics

Metrics specific to TCP load balancing become available.

- `lb.bytes_out` – Total bytes processed by the load balancer Worker Process, by Source.
- `lb.writable_sockets` – Total unblocked Worker Process sockets, by Source.
- `lb.blocked_sockets` – Total blocked Worker Process sockets, by Source.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

TAG Section Processing

Cribl Stream will try to parse `appname` out of a syslog message's `TAG` section, even when the message is not RFC 5424–formatted.

This practice means that the `TAG` section can contain any alphanumeric character or an underscore (`_`). When the **Allow–non-standard app name** option is enabled, Cribl Stream will also process hyphens that appear in an RFC 3164–formatted Syslog message's `TAG` section. If Cribl Stream encounters a hyphenated `appname`, it will continue processing to find `procid`. (This setting has no effect on RFC 5424–formatted messages.)

If the `TAG` section contains any non-alphanumeric character, Cribl Stream will treat that character as the termination of the `TAG` section, and as the starting character of the `CONTENT` section.

`CONTENT` Section Processing

Cribl Stream will try to parse `procid` from the beginning of the `CONTENT` section if this section is directly after the `TAG` section, and if it either follows a `:` or is surrounded by `[]`. This process occurs regardless of the **Allow–non-standard app name** setting.

What Fields to Expect

To create fields, the Syslog Source requires messages to comply with RFC 3164 or RFC 5424. If messages sent to the Source comply with neither of these RFCs, you'll see the following fields:

- `_raw`: Contains the whole message, but no other fields broken out.
- `_time`: Contains the time the message was received by Cribl Stream.
- `__srcIpPort <udp|tcp>:<port>`: See Internal Fields.
- `__syslogFail`: See Internal Fields.
- `host`: IP address of the device sending the incoming message.

If messages sent to the Source comply with either RFC 3164 or RFC 5424, fields that the RFC deems guaranteed will always be there, but fields deemed optional might or might not be. Once Cribl Stream parses the required fields and any optional fields, what remains is the actual message.

To see this in real life, install the `cribl-syslog-input` Pack and preview the `RFC5424-RFC3164.log` sample file.

RFC Name for Field	Cribl Name for Field	Guaranteed?	Notes
`PRI`	`facility`, `facilityName`, `severity`, `severityName`	Yes	`PRI` is a bitwise representation of Facility and Severity, which is how Cribl Stream can derive values for all four of its fields.
`TIMESTAMP`	`_time`	Yes	This field's format differs depending on which RFC the messages adhere to. Cribl Stream converts it to UNIX epoch time.
`HOSTNAME`	`host`	Yes	

RFC Name for Field	Cribl Name for Field	Guaranteed?	Notes
APP-NAME	appname	No	
PROCID	procid	No	
MSGID	msgid	No	
STRUCTURED-DATA	structuredData	No	
MSG	message	Yes	

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but are accessible and Functions can use them to make processing decisions.

Fields for this Source:

- `__inputId`
- `__srcIpPort <udp|tcp>:<port>`: Identifies the port of the sending socket.
- `__syslogFail`: `true` for data that fails RFC 3164/5424 validation as syslog format.

`stats` Log Message

In Cribl Stream 4.2.2 and later, `stats` log messages report the number of events received, buffered, or dropped for exceeding the maximum Cribl buffer size. By default, these messages are logged every 60 seconds. These values also appear in **Sources** > **Syslog** > <Source_name> > **Status**, in the **UDP** row.

UDP Tuning

This section applies only to UDP-based syslog ingest with on-prem or hybrid Cribl Stream Worker Groups or Cribl Edge Fleets. It does not apply to TCP-based syslog, nor to Cribl-managed Stream Workers in Cribl.Cloud, where Cribl will manage UDP tuning for you.

Incoming UDP traffic is put into a buffer by the Linux kernel. Cribl will drain from that buffer as resources are available. At lower throughput levels, and with plenty of available processes, this isn't an issue. As you scale up, however, the default size of that buffer is very likely too small.

Monitoring Buffer Size and Packet Errors

You can check the current buffer size with the following command:

```
$ sysctl net.core.rmem_max
```

A typical value of about 200 KB is far too small for an even moderately busy syslog server.

You can check the health of UDP with the following command. Check the `packet receive errors` line.

```
$ netstat -su
```

If `packet receive errors` is more than zero, you have lost events, which is a particularly serious problem if the number of errors is increasing rapidly. This means you need to increase your `net.core.rmem_max` setting (covered earlier in this section).

Commands to Update Settings

You can update the live settings. But you'll also need to change the boot-time setting, so that next time you reboot, everything is ready to roll.

Live change, setting to 25 MB:

```
$ sysctl -w net.core.rmem_max=26214400
net.core.rmem_max = 26214400
$ sysctl -w net.core.rmem_default=26214400
net.core.rmem_default = 26214400
```

For the permanent settings change, add the following lines to `/etc/sysctl.conf`:

```
net.core.rmem_max=26214400
net.core.rmem_default=26214400
```

We recommend that you track a few things related to UDP receiving:

- The `netstat -su` command, watching for errors.
- The **Status** tab in the Syslog Source. In particular, watch for dropped messages. They could indicate you need a bigger buffer under **Advanced Settings** (default: 1000 events). They could also indicate your

Worker is encountering pressure further down the Pipeline.

- Especially if you increase your kernel receive buffer as above, watch your Worker processes' memory usage.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Source Integrations: Syslog short course. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to review a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

15.1.23. TCP JSON Source

Cribl Stream can receive newline-delimited JSON data over TCP.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No**

Configure Cribl Stream to Receive TCP JSON Data

Cribl Stream ships with a TCP JSON Source preconfigured to listen on Port 10070. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name. The default Source is prefilled with the value `in_tcp_json`, which can't be changed via the UI. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for TCP JSON data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter the port number to listen on.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Use this default option to enter the shared secret that clients must provide in the `authToken` header field. Exposes an **Auth token** field for this purpose. (If left blank, unauthenticated access will be permitted.) A **Generate** link is available if you need a new secret.
    - **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the `authToken` header field value described above. The secret can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need a new secret.
4. Next, you can configure the following **Optional Settings**:

- **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the TLS, Persistent Queue Settings, Processing and Advanced settings, or Connected Destinations outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Cribl Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so forth. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so forth. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event, using Eval-like functionality.

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Enable proxy protocol: Toggle to `Yes` if the connection is proxied by a device that supports proxy protocol v1 or v2.

Enable load balancing (Cribl Stream only): Toggle to `Yes` to distribute the data from incoming TCP connections across multiple Worker Processes. This improves performance compared to the default of having all data from an incoming connection processed on a single Worker Process.

- This spins up an extra Worker Process (named `wLB` in **Settings** > **Processes**) on the Worker Node, which handles splitting data from incoming TCP connections across all other Worker Processes.
- When enabled, the option to include common fields in the JSON header is not supported. This means fields specified under `fields` in the JSON header are not automatically added to all events.

Load balancing is available only in Cribl Stream Distributed deployments.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (such as, all IPs).

Max active connections: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set to `0` for unlimited connections.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the configuration will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and Functions can use them to make processing decisions.

Field for this Source:

- `__inputId`
- `__srcIpPort`

Format

Cribl Stream expects TCP JSON events in newline-delimited JSON format:

1. A header line. Can be empty – for example, `{}`. If **authToken** is enabled (see above) it should be included here as a field called `authToken`. When `authToken` is **not** set, the header line is **optional**. In this case, the first line will be treated as an event if does not look like a header record.

In addition, if events need to contain common fields, they can be included here under `fields`. In the example below, `region` and `AZ` will be automatically added to all events.

2. A JSON event/record per line.

Sample TCP JSON Events

```
{"authToken":"myToken42", "fields": {"region": "us-east-1", "AZ":"az1"}}

{"_raw":"this is a sample event ", "host":"myHost", "source":"mySource", "fieldA":"v
{"host":"myOtherHost", "source":"myOtherSource", "_raw": "{\"message\":\"Something i
```

TCP JSON Field Mapping to Splunk

If a TCP JSON Source is routed to a Splunk destination, fields within the JSON payload are mapped to Splunk fields. Fields that do not have corresponding (native) Splunk fields become index-time fields. For example, let's assume we have a TCP JSON event as below:

```
{"_time":1541280341, "host":"myHost", "source":"mySource", "_raw":"this is a sample event ", "fieldA":"valueA"}
```

Here, `_time`, `host`, and `source` become their corresponding fields in Splunk. The value of `_raw` becomes the actual body of the event, and `fieldA` becomes an index-time field (`fieldA::`valueA``).

Examples

Testing TCP JSON In

This first example simply tests that data is flowing in through the Source:

1. Configure Cribl Stream to listen on port `10001` for TCP JSON. Set `authToken` to `myToken42`.
2. Create a file called `test.json` with the payload above.
3. Send it over to your Cribl Stream host: `cat test.json | nc <myCriblHost> 10001`

Cribl Stream to Cribl.Cloud

This second example demonstrates using TCP JSON to send data from one Cribl Stream instance to a downstream Cribl.Cloud instance. We assume that the downstream Cloud instance uses Cribl.Cloud's **default** TCP JSON Source configuration.

So all the configuration happens on the upstream instance's TCP JSON Destination. Replace the `<Your-Org-ID>` placeholder with the Org ID from your Cribl.Cloud portal.

TCP JSON Destination Configuration

On the upstream Cribl Stream instance's Destination, set the following field values to match the target Cloud instance's defaults:

General Settings

Address: `default.main.<Your-Org-ID>.cribl.cloud` – you can simply copy/paste your Cribl.Cloud portal's **Ingest Endpoint** here. With a Cribl.Cloud Enterprise plan, generalize the `default.main` substring in this URL to `<group-name>.main` when sending to other Worker Groups.

Port: `10070`

TLS Settings (Client Side)

Enabled: `Yes`

Validate server certs: `Yes`

Periodic Logging

Cribl Stream logs metrics about incoming requests and ingested events once per minute.

These logs are stored in the `metrics.log` file. To view them in the UI, open the Source's **Logs** tab and choose **Worker Process X Metrics** from the drop-down, where **X** is the desired Worker Process.

This kind of periodic logging helps you determine whether a Source is in fact still healthy even when no data is coming in.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.24. TCP (Raw) Source

Cribl Stream supports receiving of data over TCP. (See examples and header options below.)

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **YES**

Configure Cribl Stream to Receive TCP Data

Cribl Stream ships with a TCP Source preconfigured to listen on Port 10060. You can clone or directly modify this Source to further configure it, and then enable it.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. Configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this TCP Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter hostname/IP to listen for raw TCP data. For example, `localhost` or `0.0.0.0`.
    - **Port**: Enter port number.
    - **Enable Header**: Toggle to `Yes` to indicate that client will pass a header record with every new connection. The header can contain an `authToken`, and an object with a list of fields and values to add to every event. These fields can be used to simplify Event Breaker selection, routing, and so forth. Header format: `{ "authToken" : "myToken", "fields": { "field1": "value1", "field2": "value2" }}`.
    - **Shared secret (authToken)**: Shared secret to be provided by any client (in `authToken` header field). Click **Generate** to create a new secret. If empty, unauthenticated access will be permitted.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the TLS Settings, Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Server Side)

Enabled defaults to `No`. When toggled to `Yes`:

Certificate name: Name of the predefined certificate.

Private key path: Server path containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`.

Passphrase: Passphrase to use to decrypt private key.

Certificate path: Server path containing certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

CA certificate path: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`.

Authenticate client (mutual auth): Require clients to present their certificates. Used to perform mutual authentication using SSL certs. Defaults to `No`. When toggled to `Yes`:

- **Validate client certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.
- **Common Name**: Regex that a peer certificate's subject attribute must match in order to connect. Defaults to `.*`. Matches on the substring after `CN=`. As needed, escape regex tokens to match literal characters. (For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.) If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.

Minimum TLS version: Optionally, select the minimum TLS version to accept from connections.

Maximum TLS version: Optionally, select the maximum TLS version to accept from connections.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so forth. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so forth. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings. **Queue file path**: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

> You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Custom Command

In this section, you can pass the data from this input to an external command for processing before the data continues downstream.

Enabled: Defaults to `No`. When toggled to `Yes`:

Command: Enter the command that will consume the data (via `stdin`) and will process its output (via `stdout`).

Arguments: Click **Add Argument** to add each argument for the command. You can drag arguments vertically to resequence them.

Event Breakers

Event Breaker rulesets: A list of event breaking rulesets that will be applied to the input data stream before the data is sent through the Routes. Defaults to `System Default Rule`.

Event Breaker buffer timeout: How long (in milliseconds) the Event Breaker will wait for new data to be sent to a specific channel, before flushing out the data stream, as-is, to the Routes. Minimum `10` ms, default `10000` (10 sec), maxiumum `43200000` (12 hours).

Fields

In this section, you can add Fields to each event using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Enable Proxy Protocol: Toggle to `Yes` if the connection is proxied by a device that supports Proxy Protocol v1 or v2. When this setting is enabled, the `__srcIpPort` internal field will show the original source IP address and port. When it is disabled, the `__srcIpPort` field will show the IP address and port of the proxy that forwarded the connection.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (i.e,. all IPs).

Max active connections: Maximum number of active connections allowed per Worker Process. Defaults to `1000`. Set a lower value if connection storms are causing the Source to hang. Set `0` for unlimited connections.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields accessible for this Source:

- `__inputId`
- `__srcIpPort`
- `__channel`

TCP Source Examples

Every new TCP connection may contain an **optional** header line, with an `authToken` and a list of fields and values to add to every event. To use the Cribl Stream Cloud sample, copy the `<token_value>` out of your Cribl Stream Cloud TCP Source.

Sample test.raw (on-prem) | Sample test.raw (Cribl.Cloud)

```
{"authToken":"myToken42", "fields": {"region": "us-east-1", "AZ":"az1"}}

this is event number 1
this is event number 2
```

Enabling the Example – Cribl Stream

1. Configure Cribl Stream to listen on port `7777` for raw TCP. Set `authToken` to `myToken42`.
2. Create a file called `test.raw`, with the payload above.
3. Send it over to your Cribl Stream host, using this command: `cat test.raw | nc <myCriblHost> 7777`

Enabling the Example – Cribl.Cloud

Use netcat with `--ssl` and `--ssl-verify`:

Command-line test

```
cat test.raw | nc --ssl --ssl-verify default.main.<Your-Org-ID>.cribl.cloud 10060
```

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to `<group-name>.main` when sending to other Worker Groups.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.25. UDP (Raw) Source

Cribl Stream supports receiving raw, unparsed data via UDP.

Type: **Push** | TLS Support: **NO** | Event Breaker Support: **NO**

Configure Cribl Stream to Receive Raw UDP Data

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the **New Source** modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this raw UDP Source definition.
    - **Description**: Optionally, enter a description.
    - **Address**: Enter the hostname/IP to listen for raw UDP data. For example: `localhost`, `0.0.0.0`, or `::`.
    - **Port**: Enter the port number.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Sources in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Persistent Queue Settings, Processing, and Advanced settings, or Connected Destinations outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Sending large numbers of UDP events per second can cause Cribl.Cloud to drop some of the data. This results from restrictions of the UDP protocol.

To minimize the risk of data loss, deploy a customer-managed (hybrid) Stream Worker Group with Worker Nodes as close as possible to the UDP sender. Cribl also recommends tuning the OS UDP buffer size.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

If you do not see the **Max buffer size** setting, it is because you enabled the Persistent Queue. The Persistent Queue provides its own configurable internal buffer, and **Max buffer size** is not applicable in that case.

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, etc. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data.

Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

In this section, you can add Fields to each event using Eval-like functionality.

- **Name**: Field name.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Single msg per UDP: Toggle to `Yes` if each UDP message should be treated as an independent event. Leave set to the default `No` if the message should be broken on newlines to create multiple events.

Ingest raw bytes: Toggle to `Yes` to add a `__rawBytes` field to each event containing an array of the bytes received as the UDP message.

IP allowlist regex: Regex matching IP addresses that are allowed to establish a connection. Defaults to `.*` (i.e, all IPs).

Max buffer size (events): Maximum number of events to buffer when downstream is blocking. The buffer is only in memory.

UDP socket buffer size (bytes): Optionally, set the SO_RCVBUF socket option for the UDP socket. This value tells the operating system how many bytes can be buffered in the kernel before events are dropped. Leave blank to use the OS default. Min: `256`. Max: `4294967295`.

It may also be necessary to increase the size of the buffer available to the `SO_RCVBUF` socket option. Consult the documentation for your operating system for a specific procedure.

Setting this value will affect OS memory utilization.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

What Fields to Expect

The Raw UDP Source does minimal processing of the incoming UDP messages to remain consistent with the internal Cribl event model. For each UDP message received on the socket, you can expect an event with the following fields:

- `_raw`: Contains the UTF-8 representation of the entire message received (if **Single msg per UDP** is set to `Yes`), or of the given line that was split out of the message.
- `_time`: The UNIX timestamp (in seconds) at which the message was received by Cribl Stream.
- `source`: A string in the form `udp:<remote IP address>:<remote port>`, indicating the remote sender.
- `host`: The hostname of the machine running Cribl Stream that ingested this event.

Also, the internal fields listed below will be present.

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields accessible for this Source:

- `__inputId`
- `__srcIpPort`
- `__rawBytes`: When **Ingest raw bytes** is set to `Yes`, this field will be an array containing the bytes of the UDP message.

UDP Tuning

Incoming UDP traffic is put into a buffer by the Linux kernel. Cribl will drain from that buffer as resources are available. At lower throughput levels, and with plenty of available processes, this isn't an issue. As you scale up, however, the default size of that buffer may be too small.

You can check the current buffer size with:

```
$ sysctl net.core.rmem_max
```

A typical value of about 200 KB is far too small for an even moderately busy syslog server. You can check the health of UDP with the following command. Check the `packet receive errors` line.

```
$ netstat -su
```

If `packet receive errors` is more than zero, you have lost events, which is a particularly serious problem if the number of errors is increasing rapidly. This means you need to increase your `net.core.rmem_max` setting (see earlier).

You can update the live settings, but you'll also need to change the boot-time setting so next time you reboot everything is ready to roll.

Live change, setting to 25 MB:

```
$ sysctl -w net.core.rmem_max=26214400
net.core.rmem_max = 26214400
$ sysctl -w net.core.rmem_default=26214400
net.core.rmem_default = 26214400
```

For the permanent settings change, add the following lines to `/etc/sysctl.conf`:

```
net.core.rmem_max=26214400
net.core.rmem_default=26214400
```

We recommend you track a few things related to UDP receiving:

- The `netstat -su` command, watching for errors.
- The **Status** tab in the UDP (Raw) Source. In particular, watch for dropped messages. They could indicate you need a bigger buffer under **Advanced Settings** (default: 1000 events). They could also indicate your Worker is encountering pressure further down the Pipeline.
- Especially if you increase your kernel receive buffer as above, watch your Worker processes' memory usage.

Troubleshooting

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

15.1.26. Windows Event Forwarder Source

Cribl Stream supports receiving Windows events from the Windows Event Forwarding (WEF) mechanism built into modern versions of Microsoft Windows (including Windows 10, Windows Server 2012, and more-recent releases).

The integration between WEF and Cribl works by generating events on Windows systems, which are collected by Windows Event Collectors (WECs). These events are then forwarded to Cribl using WEF, secured by either mutual TLS or Kerberos authentication. Cribl receives the events through the Windows Event Forwarder Source, processes them according to configured pipelines, and sends the processed events to designated Destinations.

Type: **Push** | TLS Support: **YES** | Event Breaker Support: **No** | Uses Key-Value Store

Prerequisites

- WEF is set up and enabled.
- WEF client(s) are pointed to WECs.
- You've configured either client certificate or Kerberos authentication.

On Cribl Edge, Kerberos authentication for this Source is supported only for Edge Nodes running on x86_64 Linux.

Configure Cribl Stream to Receive Windows Events

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Source** and select the Source you want from the list, choosing either **Select Existing**.
    - To configure via the Routes, select **Data** > **Sources** (Stream) or **More** > **Sources** (Edge). Select the Source you want. Next, select **Add Source**.
2. In the Source modal, configure the following under **General Settings**:
    - **Input ID**: A unique name that identifies this Windows Event Forwarder Source.
    - **Address**: The hostname/IP on which to listen for Windows events data. Example: `localhost` or `0.0.0.0`.

- **Port**: The port number. The default, `5986`, is the port used by Windows Event Collector for HTTPS-based subscriptions.
- **Authentication method**: The method for accepting incoming client connections, either `Client certificate` or `Kerberos`.

Kerberos authentication is not supported for Cribl-managed Workers in Cribl.Cloud, but it is enabled for customer-managed Worker Groups, whether on-prem or hybrid.

- For **Client Certificate**:
  - **Certificate name**: Choose the certificate you created.
  - **Private key path**: Server path containing the private key (in PEM format) to use. For Cribl.Cloud, the default path is `/opt/criblcerts/criblcloud.key` for a Cribl-managed Worker Group in Cribl.Cloud. Path can reference `$ENV_VARS`.
  - **Passphrase**: Passphrase to use to decrypt private key.
  - **Certificate path**: Server path containing certificates (in PEM format) to use. For Cribl.Cloud, the default path is `/opt/criblcerts/criblcloud.crt` for a Cribl-managed Worker Group in Cribl.Cloud. Path can reference `$ENV_VARS`.
  - **CA certificate path**: Server path containing CA certificates (in PEM format) to use. Path can reference `$ENV_VARS`. If multiple certificates are present in a `.pem`, the first certificate in the chain should be the issuing CA certificate. If the first certificate is not the issuing CA, use the **CA fingerprint override** setting to specify the expected SHA1 fingerprint. This should match the order of traversing the chain from the host to the root CA cert.

The CA certificate that generated the Cribl Stream server certificate must match the root CA that signed all client certificates that will be forwarding Windows events to this Source. If the issuing CA is an intermediate CA, this CA must also match on the server and all client certs.

  - **Common Name**: Regex that a peer certificate's subject attribute must be able to connect. Defaults to `.*`.
    - Matches on the substring after `CN=`.
    - As needed, escape regular expression (regex) tokens to match literal characters. For example, to match the subject `CN=worker.cribl.local`, you would enter: `worker\.cribl\.local`.
    - If the subject attribute contains Subject Alternative Name (SAN) entries, the Source will check the regex against all of those but ignore the Common Name (CN) entry (if any). If the certificate has no SAN extension, the Source will check the regex against the single name in the CN.
  - Optionally, select the **Minimum TLS version** and **Maximum TLS version** to accept from connections.

        - **Verify certificate via OCSP**: If toggled to `Yes`, Cribl Stream will use an OCSP (Online Certificate Status Protocol) service to check that client certificates presented in incoming requests have not been revoked. Exposes the **Strict validation** toggle.
        - **Strict validation**: If enabled, Cribl Stream will fail checks on **any** OCSP error. Otherwise, Cribl Stream will fail checks only when a certificate is revoked, and will ignore other errors (such as `OCSP server is unavailable` errors).
    - For **Kerberos**: Provide the SPN and keytab file location that you set in Keytab file.
        - **Service Principal Name**: The Service Principal Name (SPN) in this format: `HTTP/<fully qualified domain name>@REALM`. This identifies the service in the Kerberos realm. The service pricipal name is case-sensitive, and must be exactly in the form used to export the keytab.
        - **Keytab location**: The path to the keytab file containing the service principal credentials. Cribl Stream uses `/etc/krb5.keytab` by default. This file contains the keys used for Kerberos authentication.
    - Optionally, add **Tags** that you can use to filter and group Destinations in Cribl Stream's **Manage Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
3. **Subscriptions** define which logs to collect and how to filter them. You need to add at least one subscription. For comprehensive details on subscription settings and the query builder, refer to the subscriptions section.
4. Optionally, configure any Persistent Queue, Processing, and Advanced settings outlined in the below sections.
5. Click **Save**, then **Commit & Deploy**.

Subscriptions

Subscriptions control which events are collected from Windows endpoints and sent to the Cribl Stream Windows Event Forwarder Source. They filter the types of events to monitor, like security logs or application logs.

Due to the way subscription bookmarks are stored, Leader CPU usage is directly impacted by the number of subscriptions created for the Source and the number of clients receiving each subscription. To optimize performance, prefer to minimize the number of subscriptions by combining them where possible.

You can tailor your event collection to focus on the data that matters most to your organization's security and monitoring needs. This helps reduce noise, save storage space, and ensure critical events are captured and analyzed.

Select **Add Subscription** and fill out the following fields to define at least one new, required subscription.

Name: A friendly name for the subscription, which is only used to help you identify it.

Version: A read-only field that automatically updates whenever you save changes to the subscription. This version number reflects the specific configuration of the subscription and helps ensure that clients correctly interpret and process the subscription data.

Format: You can choose `Raw` to receive only XML data about the subscribed events, or `RenderedText` to additionally include amplifying information generated by the client about the event's contents.

Heartbeat: The maximum allowable time, in seconds, before the client will check in with Cribl Stream even if it has no new events to send.

Batch timeout: The maximum time, in seconds, that the client should batch new events before sending them to Cribl Stream.

Windows Event Collector defines two delivery modes of "Event Delivery Optimization":

- The "Minimize Bandwidth" mode corresponds to a **Heartbeat** and **Batch timeout** of 6 hours (21,600 seconds).
- The "Minimize Latency" mode corresponds to a **Heartbeat** of 1 hour (3,600 seconds) and a **Batch timeout** of 30 seconds.

Locale: The language code to use for the events sent by the client, in RFC-3066 format (for example, `en-US`). The language code uses ISO 639, and the country code uses ISO 3166. Defaults to `en-US` when left blank.

Read existing events: Controls whether the client should send historical events when it first connects. The behavior of **Read existing events** is influenced by the **Use bookmarks** setting. See the table below for a complete overview.

Use bookmarks: Keeps track of which events it has received.

Setting	Behavior
Read Existing Events = `No`	Only new events generated after it receives the subscription are sent.
Read Existing Events = `Yes` & **Use Bookmarks** = `No`	All historical events are sent on the initial subscription and each time a client *forcibly* renews its subscription (for example, after group policy update), all events matching the query will be sent. Restarting Cribl Stream or restarting the client will not cause all events to be re-sent.

Setting	Behavior
Read Existing Events = `Yes` & **Use Bookmarks** = `Yes`	Historical events are sent on the initial subscription, but only new events (later than the saved bookmark) are sent on subsequent (even forced) subscription renewals.

Important Considerations

- **Subscription Changes**: If you change and save a subscription, the saved bookmarks are no longer valid (they are tied to a specific subscription version), and all events matching the updated subscription will be sent.
- **Leader and Worker Node Interactions**: Worker Nodes continue to accept new events even when the Leader is down. They sync with the Leader when it's back up. However, bookmarks stored in memory can be lost if a Worker Node restarts while the Leader is down.
- **Client Balancing and Bookmarks**: If a client balances to a different Worker Node while the Leader is down, it might receive a stale bookmark. Bookmarks are only sent to the client when it requests a subscription, not when it delivers events. This typically happens on the `Refresh=XX` interval from the GPO.
    - If the Leader is down when a client requests a subscription, it will receive the last known bookmark from the Worker Node, which could be outdated.
    - If a Worker Node restarts while the Leader is down, the client might not receive any bookmark at all, potentially leading to duplicate events.

Compression: Sets whether Windows clients compress the events sent to Cribl Stream, using the Streaming Lossless Data Compression (SLDC) algorithm. Defaults to `Yes`.

Queries: See the explanation in Configuring Queries below.

Query builder mode: See the explanation in Configuring Queries below.

Targets: Set the DNS names of the clients that should receive this subscription. This field supports wildcard matching.

Fields: Use this setting to add fields exclusively to the events that WEF delivers **for the subscription you are defining**, using Eval-like functionality. To add fields to all incoming events regardless of subscription, use **Processing Settings** > **Fields** instead:

Optionally, you can create the field such that its **Value** is the value of a subscription metadata element. (See the available subscription metadata elements listed below.)

To do this, specify a **Value** of `__subscription.<metadata_element>`. The Source will then find the metadata element you specified in the special object `__subscription` and set the value to that.

For example, if you wanted all events for the subscription to be tagged with its **Locale**, you could set the **Name** to `Locale` (or any arbitrary name) and **Value** to `__subscription.locale`.

- **Name**: Field name.
- **Value**: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Subscription Metadata Elements

Metadata Element	Type	Corresponding UI Setting
`version`	string	**Version**
`subscriptionName`	string	**Name**
`contentFormat`	`Raw` or `RenderedText`	**Format**
`readExistingEvents`	boolean	**Read existing events**
`heartbeatInterval`	number	**Heartbeat**
`batchTimeout`	number	**Batch timeout**
`sendBookmarks`	boolean	**Use bookmarks**
`compress`	boolean	**Compression**
`queries`	array	see About the Query builder mode below

Change Subscriptions

If you change a subscription that is in use, Windows Event Forwarder will discover the new subscription ID. Once the `Refresh=XX` interval has elapsed, if any events were sent to the now-invalid previous subscription ID, Windows will resend them to the new one (assuming that these events remain valid under the updated subscription parameters). The Receiver Refuses to Accept Delivery of Events warnings you'll see in this scenario are normal.

About Query Builder Mode

This setting produces the `queries` array in one of two different forms, depending on whether you select its **Simple** button or its **Raw XML** button.

Simple produces an array whose elements each contain `path`, a string that corresponds to **Queries** > **Path**, and `queryExpression`, a string that corresponds to **Queries** > **Query expression**.

Raw XML produces an array whose elements each contain only the `xmlQuery` metadata element. This is the XML query you specified, in the form of a string, that corresponds to the **XML query** setting.

To access any element in the array, use array indexing. For example:

- `__subscription.queries[0].path` will access the path to the first query in an array created by **Query builder mode** > **Simple**.
- `__subscription.queries[0].xmlQuery` will access the first query in an array created by **Query builder mode** > **Raw XML**.

Configure Queries

Queries determine which events to send from the clients. **At least one query is required.** The format is derived from the XPath implementation used by Windows Event Collector.

WEF subscriptions have a 22 `EventID` limit. To monitor more `EventIDs`, create multiple subscriptions.

You have two **Query builder mode** options: **Simple** or **Raw XML**.

- **Raw XML** allows you to enter your XPath query into the **XML query** field.
- **Simple** allows you to manually build queries. Click **Add Query** to define each new query. A query has the following properties:
    - **Path**: Set this to the `Path` attribute of a `Select` XPath element. See the example below.
    - **Query expression**: Set this to the value inside a `Select` XPath element. See the example below.

With either a **Simple** or **Raw XML** query, you can use the **Targets** field to specify the DNS names of the endpoints that should forward these events. Supports wildcards (for example, `*.mydomain.com`). The default global wildcard (`*`) enables all endpoints.

If you have both **Simple** and **Raw XML** queries defined within a given Subscription, the **Query builder mode** button that you select when saving this Source's configuration determines which query/queries Cribl Stream will send. To send both **Simple** and **Raw XML** queries, use the **Add Subscription** button to define multiple subscriptions.

Example

When creating a subscription in a Windows Event Collector, you can view the generated XML/XPath query. Consider a subscription that returns all events from the Security log that are of severities Critical, Error, or Warning, and that occurred within the last 24 hours. This subscription would generate XML like this:

```
<QueryList>
  <Query Id="0" Path="Security">
    <Select Path="Security">*[System[(Level=1  or Level=2 or Level=3) and TimeCreate
  </Query>
</QueryList>
```

To use this subscription in a Cribl Stream Windows Event Forwarder Source, you would either use the **Raw XML** option and paste the above XML, or use **Simple** mode and set the following query properties:

- **Path**: `Security`
- **Query expression**: `*[System[(Level=1 or Level=2 or Level=3) and TimeCreated[timediff(@SystemTime) <= 86400000]]]`

You do not need to use the `<Query>` element's `Id` or `Path` attributes anywhere in the Cribl Stream subscription config.

Persistent Queue Settings

In this section, you can optionally specify persistent queue storage, using the following controls. This will buffer and preserve incoming events when a downstream Destination is down, or exhibiting backpressure.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the **Enable Persistent Queue** toggle. If enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB disk space allocated per PQ-enabled Source, per Worker Process.

The 1 GB limit is on uncompressed inbound data, and no compression is applied to the queue. This limit is not configurable. For configurable queue size, compression, mode, and other options below, use a hybrid Group.

Enable Persistent Queue: Defaults to `No`. When toggled to `Yes`:

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.

- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Cribl Stream has read them. Defaults to `42`.

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so on. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Source will stop queueing data and block incoming data. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this field's specified path, Cribl Stream will append `/<worker-id>/inputs/<input-id>`.

Compression: Optional codec to compress the persisted data after a file is closed. Defaults to `None`; `Gzip` is also available.

In Cribl Stream 4.1 and later, Source-side PQ's default **Mode** is `Always on`, to best ensure events' delivery. For details on optimizing this selection, see Always On versus Smart Mode.

You can optimize Worker Nodes' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Fields

Use this setting to add fields to **all events coming into the Source**, using Eval-like functionality. (To add fields on a per-subscription basis, use **Subscriptions** > **Fields** instead.)

Name: Field name.

Value: JavaScript expression to compute field's value, enclosed in quotes or backticks. (Can evaluate to a constant.)

Pre-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

Advanced Settings

Allow MachineID mismatch: Set this to `Yes` if you do not want to verify that the events sent by a client match the client's certificate Common Name (Subject CN). If set to `No`, events where the `MachineID` (by default the client's machine name, like `CLIENT1.domainName.com`) do not match the CN will be rejected.

This setting applies only to client certificate authentication. If you use Kerberos authentication, this option will not appear and will be treated as a `No` value.

Show originating IP: Toggle to `Yes` when clients are connecting through a proxy that supports the `X-Forwarded-For` header to keep the client's original IP address on the event instead of the proxy's IP address. This setting affects how the Source handles the `__srcIpPort` field.

Capture request headers: Toggle this to `Yes` to add request headers to events, in the `__headers` field.

Max active requests: Maximum number of active requests allowed for this Source, per Worker Process. Defaults to `256`. Enter `0` for unlimited.

IP allowlist regex: Grants access to requests originating from specific IP addresses that match a defined pattern. Unmatched requests are rejected with a 403 (Forbidden) status code. Defaults to `.*` (allow all).

IP denylist regex: Blocks requests originating from specific IP addresses that match a defined pattern, even if they would be allowed by default. Rejected requests receive a 403 (Forbidden) status code. Defaults to `^$` (allow all).

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Socket timeout (seconds): How long Cribl Stream should wait before assuming that an inactive socket has timed out. The default `0` value means wait forever. For Kerberos authentication, see how to adjust timeouts.

Keep-alive timeout (seconds): After the last response is sent, Cribl Stream how long to wait for additional data before closing the socket connection. Defaults to `90` seconds; minimum is `1` second; maximum is `600` seconds (10 minutes).

The longer the timeout, the more Cribl Stream will reuse connections. The shorter the timeout, the closer Cribl Stream gets to creating a new connection for every request. When request frequency is high, you can use

longer timeouts to reduce the number of connections created, which mitigates the associated cost.

For Kerberos authentication, see how to adjust timeouts.

CA fingerprint override (client certificate only): Use this setting only if the first certificate in the configured CA chain does not match the SHA1 fingerprint that the WEF client expects, such as an intermediate certificate. If that is the case, enter the expected SHA1 fingerprint. The thumbprint specified here must match the `IssuerCA` parameter in the Subscription Manager template.

Timeout Considerations for Kerberos Authentication

If you use Kerberos authentication, there are some trade-offs you should consider when you select settings in **Subscriptions** > **Batch timeout** and **Advanced Settings** > **Keep-alive timeout (seconds)**.

Windows expects socket connections to be long-lived for Kerberos authentication so it can avoid the overhead of performing the two-step Kerberos authentication on each new batch delivery.

Set **Subscriptions** > **Batch timeout**, **Subscriptions** > **Heartbeat**, or both to be less than or equal to **Keep-alive timeout** (or the lowest **Batch timeout** if several subscriptions are used), especially when a load balancer is in front of the Worker Nodes.

Set **Socket timeout** higher than **Batch timeout** (or the lowest **Batch timeout** if several subscriptions are used). This ensures that connections aren't prematurely closed before batches are sent. If the **Socket timeout** has elapsed between event deliveries or heartbeats, Cribl Stream will still handle it gracefully, but incur an additional overhead of two network round trips.

Connected Destinations

Select **Send to Routes** to enable conditional routing, filtering, and cloning of this Source's data via the Routing table.

Select **QuickConnect** to send this Source's data to one or more Destinations via independent, direct connections.

Event Handling

The Windows Event Forwarder Source uses internal fields and a key-value store to manage and process events efficiently. Internal fields are metadata added to events for internal processing and should be treated as read-only to avoid unintended consequences. Key fields include:

- `__final`
- `__headers` – Added only when **Advanced Settings** > **Capture request headers** is set to `Yes`.

- `__inputId`
- `__srcIpPort` – See details below.
- `__subscriptionName`
- `__subscriptionVersion`
- `_raw`
- `_time`

The key-value store uses the `machineId` as keys to store bookmark information when bookmarks are enabled. This ensures that events are processed correctly and efficiently by maintaining the state of event processing.

Together, the key-value store and internal fields work to ensure accurate and efficient event handling. The key-value store maintains the state of event processing, while internal fields provide necessary metadata for internal operations, enabling Cribl Stream to process and route events effectively.

Overriding `__srcIpPort` with Client IP/Port

The `__srcIpPort` field's value contains the IP address and (optionally) port of the WEF client sending data to this Source.

In the WEF Source configuration, there's an option to handle the `X-Forwarded-For` header, which is commonly used by load balancers to pass the original client's IP address. When any proxies (including load balancers) lie between the WEF client and the Source, the last proxy adds an `X-Forwarded-For` header whose value is the IP/port of the original client. With multiple proxies, this header's value will be an array, whose first item is the original client IP/port.

If `X-Forwarded-For` is present, and **Advanced Settings** > **Show originating IP** is set to `No`, the original client IP/port in this header will override the value of `__srcIpPort`.

If **Show originating IP** is set to `Yes`, the `X-Forwarded-For` header's contents will **not** override the `__srcIpPort` value. (Here, the upstream proxy can convey the client IP/port without using this header.)

Troubleshoot

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

High CPU Usage on Leader Node API Process

Problem: Experiencing high CPU usage on your Leader Node's API process is often a symptom of having too many subscriptions (thousands). This can lead to performance issues and instability.

Solutions: First attempt to reduce or consolidate your subscriptions. This can often alleviate the problem without the need for additional configurations. However, since the process of consolidating subscriptions can vary significantly between environments, there is no one-size-fits-all approach.

If you are unable to reduce the number of subscriptions sufficiently, consider enabling Write-Ahead Log (WAL) mode for the key-value store (KV Store). We recommend working with Cribl Support to incorporate the new **KV Store** settings effectively. You can find these settings under **Settings** > **Global Settings** > **General Settings** > **Limits** or in the limits.yml file.

Security Event Log Forwarding Fails

Error: `Error "0x138C" Windows Event Forward plugin can't read any event from the query since the query returns no active channel.`

Solution: Enable the Network Service to read the security logs by configuring access for the Event Log Service.

When configuring a Group Policy Object (GPO) to add NETWORK SERVICE permissions, carefully review existing permissions to prevent unintended removal. Preserve all necessary permissions to avoid application issues.

Cannot Find the Certificate

Error:
`The forwarder is having a problem communicating with subscription manager at address… The WS-Management service cannot find the certificate that was requested.`

For example:

```
The forwarder is having a problem communicating with subscription manager at address

Error code is 2150858882 and Error Message is <f:WSManFault xmlns:f=http://schemas.m
```

Resolution:

- The `NETWORK SERVICE` user does not have permissions to use the private key of the certificate for authentication.
- Add the `NETWORK SERVICE` user to the list of users allowed to use the private key.

Receiver Refuses to Accept Delivery of Events

Warning:
`The receiver refuses to accept delivery of events and requests that the subscription be canceled.`

If you make a change to a subscription that is in use, **and** if the Windows client tries to send events before the `Refresh=XX` interval has elapsed, the result is that these events are sent to the old subscription, which is now invalid because its query is outdated or because other subscription parameters have changed.

The warning message tells the WEF client to stop sending events to the now-invalid old subscription.

Resolution:

Windows Event Forwarder handles this scenario gracefully, and you do not need to take any action to resolve it:

- Once the `Refresh=XX` interval has elapsed, the WEF client will ask for and receive the updated subscription, and from then on should be able to successfully deliver events against that new subscription.
- Any events that were refused under the old/invalid subscription ID will be resent under the new one, assuming that they remain valid according to the new subscription parameters.

Subscription Cannot be Created

Error:
`The subscription <subscription> can not be created. The error code is 5004.`

The error appears in the `Microsoft-Windows-Eventlog-ForwardingPlugin/Operational` log.

Resolution:

1. Apply the `O:BAG:SYD:...` permissions to make the log file readable.
2. Reboot the machine.

Verify that Client and Destination are Joined to a Domain

Error:
`If Kerberos mechanism is used, verify that the client computer and the destination computer are joined to a domain.`

When you are using auto-enroll, the `Eventlog-ForwardingPlugin Operational` logs might display an error of this form.

Resolution:

In your auto-enroll template's **Client-Server Authentication Properties**, make sure the **Subject Name format** is set to **Common name**.

Subscription 22 EventID Limit

Issue: No events are forwarded. Windows Event Forwarding (WEF) subscriptions cannot include more than 22 `EventIDs` in a single filter.

Solution: To monitor more `EventIDs`, create multiple subscriptions, each with a filter containing no more than 22 `EventIDs`.

Resources

For processing Pipelines that you can import and adapt to your needs, examine these resources on the Cribl Packs Dispensary:

- Microsoft Windows Events – Shape events into JSON or Key=Value format, and dramatically reduce event sizes.
- Cribl Edge Windows for Common Schema – Transform Windows events into a Common Schema.
- Exabeam Pack for Windows – Forward specific Windows Event IDs to Exabeam.
- QRadar Pack for Windows Events – Optimize Windows events for delivery to QRadar.

Further Reading

For more context and greater detail, see ATA Learning's WEF tutorial.

For more about WEF subscriptions, including sample subscription queries, see:

15.1.26.1. Client Certificate Authentication For Windows Event Forwarder

This document covers the client certificate authentication setup steps you need to take before configuring a Windows Event Forwarder Source.

1. Set Up WEF

Follow this Microsoft guide for setting up Windows Event Forwarding (WEF) in a traditional Windows environment. Generally, you can follow the guide's "non-domain" section to correctly configure the endpoints/senders.

2. Configure Certificates

After setting up WEF, you need to configure certificates to ensure secure communication. Server certificate configuration varies depending on your deployment type. However, you'll always need to configure a client certificate.

On-prem deployments: Add the server certificate and CA chain to the Worker Group, see importing certificates for details. Add the client certificate to Windows either manually or with certificate auto-enrollment through Group Policy to automatically configure unique device certificates. For specific configuration options, consult with your Windows administrators.

Cribl.Cloud deployment: Upload the CA chain for your client certificate, see importing certificates for details. The actual certificate/key pair in the chain doesn't matter for this purpose. It's solely to satisfy the technical requirement of uploading a chain. Use Cribl's provided certificate and key:

- `/opt/criblcerts/criblcloud.crt`
- `/opt/criblcerts/criblcloud.key`

3. Set Client Certificate Permissions

Set the appropriate permissions for the `NETWORK SERVICE` user to use the private key of the certificate for authentication.

Open the Certificate Manager tool (`certlm.msc`).

- Right-click your client certificate and select **All Tasks** > **Manage Private Keys...**.
- Add the `NETWORK SERVICE` user.

4. Configure the Subscription Manager and Log Forwarding Group Policies

1. On a domain controller, open the Group Policy Management Console (GPMC).
2. Create a new Group Policy Object (GPO) or edit an existing one that is linked to the organizational unit (OU) containing the computers you want to configure.
3. Navigate to **Computer Configuration** > **Policies** > **Administrative Templates** > **Windows Components**. Select **Event Forwarding** to open the Local Group Policy Editor.
4. Select **Configure target Subscription Manager** and use one of the following templates depending on your deployment type, substituting the appropriate values for the placeholders.
   On-Prem:

   ```
   Server=https://<cribl-worker-or-lb>:<wef-source-port>/wsman/SubscriptionManager/
   ```

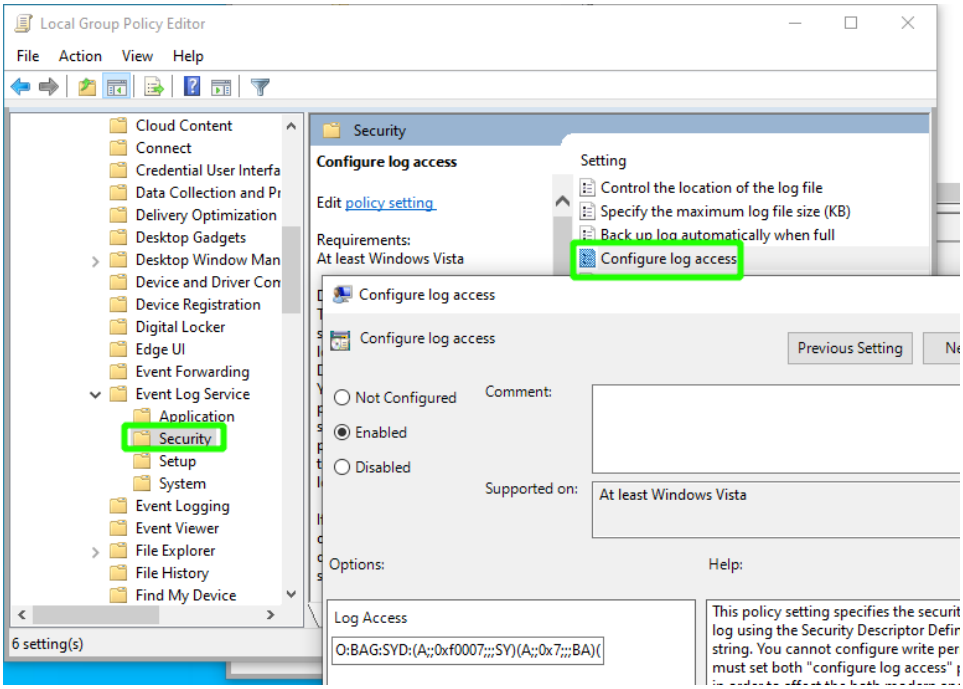
   Cribl.Cloud:

   ```
   https://<group-name>.main.<org-name>.cribl.cloud:<wef-source-port>/wsman/Subscri
   ```

   - The path portion `/wsman/SubscriptionManager/WEC` within the **Subscription Target URL** set using Group Policy Objects (GPOs) is the same as required for a WEC subscription and is strictly case-sensitive. If the capitalization is incorrect, WEF will encounter errors and fail to forward events to Cribl Stream.
   - The `IssuerCA` thumbprint is the SHA1 thumbprint of the issuing certificate, which could be an intermediate certificate. This must match the thumbprint of the first certificate in the certificate chain configured in the WEF Source's CA certificate path or the specified **CA fingerprint override**.
5. When complete, save the policy and apply it to affected endpoints. Link the GPO to the appropriate OU if it is not already linked.
6. To enable the Network Service to read the security logs, you'll need to configure access for the Event Log Service.

   When configuring a Group Policy Object (GPO) to add NETWORK SERVICE permissions, carefully review existing permissions to prevent unintended removal. Preserve all necessary permissions to avoid application issues.

   1. Open the Local Group Policy Editor tool (`gpedit.msc`).
   2. Navigate to **Computer Configuration** > **Policies** > **Administrative Templates** > **Windows Components** > **Event Log Service**. Double-click **Security**, then in the **Settings** pane, select **Configure log access**.



Configuring log access

3. In the resulting modal, under **Options** > **Log Access**, enter the following Log Access configuration:

```
O:BAG:SYD:(A;;0xf0007;;;SY)(A;;0x7;;;BA)(A;;0x1;;;BO)(A;;0x1;;;SO)(A;;0x1;;;S-1-
```

4. Then, reboot your Windows machine to apply this setting. (Source: Microsoft's Security event log forwarding fails... topic.)

7. Check that events are flowing into Cribl Stream now according to the configured subscriptions. On client machines, run `gpupdate /force` to apply the new policy immediately. If events are not flowing, verify all of the following:
   - The clients can reach the Cribl Stream instance through the network to port `5986` (or other configured port) via TLS/HTTP. If clients are connecting to Cribl Stream via a proxy, you may need to set **Show originating IP** to `Yes` (in the Advanced section of the Source configuration). Ensure that the correct outbound firewall port is opened on the client.
   - The certificate chain is correct
   - The endpoints have a valid CRL encompassing the CA cert
   - The CA cert is a trusted root on the clients
   - The server and client certs are issued by the same CA. The `CAPI2` Windows event log might reveal any errors here.
   - Check Cribl Stream for any errors, as well as the `EventForwarding-Plugin` and `Windows Remote Management` event logs on the clients.

Now you can provide client certificate authentication to a Windows Event Forwarder Source.

15.1.26.2. Kerberos Authentication For Windows Event Forwarder

This document covers the Kerberos authentication setup steps you need to take before configuring a Windows Event Forwarder Source.

Kerberos authentication is only supported on x86_64 Linux systems.

Initial Assumptions

To ensure a smooth configuration process, review the following prerequisites:

- The clients that will be sending events are in a Windows domain. In this example, the domain is `contoso.com`, the NETBIOS name is `CONTOSO`, and the domain controller is `DC01.contoso.com`.
- Kerberos KDC is already configured and working on the domain, and WEC with Kerberos authentication already works on the domain.
- You have an x86_64 Worker Node to which you have shell access. This guide assumes a recent Ubuntu distribution.
- The fully qualified domain name (FQDN) of this example Worker Node is `worker1.contoso.com`.
- You are using a Kerberos credential cache of the `DIR` or `FILE` type.

1. Initial Setup for the Worker Node

To set up the Worker Node:

1. Ensure that the Worker Node can resolve the domain controller's FQDN. You can test it with: `ping DC01.contoso.com`.
2. Ensure that the Worker Node's `hostname` is set to the FQDN. If it's not, you can set it with `hostnamectl set-hostname worker1.contoso.com`.
3. Ensure the Worker Node has its clock synchronized with the domain controller.
4. Install the `krb5-user` package and configure Kerberos to correctly identify your domain. Here's an example configuration (`/etc/krb5.conf`).

```
[libdefaults]
default_realm = CONTOSO.COM

[realms]
  CONTOSO.COM = {
    kdc = DC01.contoso.com
    admin_server = DC01.contoso.com
  }

[domain_realm]
  .contoso.com = CONTOSO.COM
  contoso.com = CONTOSO.COM
```

2. Setup for the Domain Controller

Configure the domain controller to support Kerberos authentication for your Worker Node. This involves setting up DNS records and creating a domain user with the necessary permissions and encryption settings. Proper configuration ensures that the Worker Node can securely authenticate and communicate within your network.

To set up the domain controller:

1. Set up forward and reverse DNS for the Worker Node's FQDN (that is, both A and PTR records).
2. Both `nslookup worker1.contoso.com` and `nslookup <worker's IP>` should work.
3. Create a domain user for the Worker Node. This guide assumes the user is called `svc-stream-worker1`.
4. Set the user's password to never expire.
5. Under the user's **Properties** > **Account** tab, set both `This account supports Kerberos AES 128 bit encryption` and `This account supports Kerberos AES 256 bit encryption`.
6. Create a keytab file for the Worker Node. This file will contain the necessary credentials for the Worker Node to authenticate with the domain controller. See the Keytab Export section below for instructions on how to generate the keytab file.

Keytab Export

This section guides you through exporting a keytab file, which is essential for Kerberos authentication. The keytab file contains the necessary credentials for the Worker Node to authenticate with the domain controller. You will generate this file using the `ktpass` command and then transfer it to the Worker Node. This step is

crucial for enabling secure, authenticated communication between your Worker Node and the domain controller.

To export the keytab:

1. Export a keytab file for this user, which will also create the appropriate service principal name (SPN). The keytab will be exported to the root of the user profile running the command.
2. Open an elevated PowerShell prompt on the domain controller.
3. Run the following ktpass command to generate the keytab file: `ktpass /princ http/worker1.contoso.com@CONTOSO.COM /pass <password> /mapuser CONTOSO\svc-stream-worker1 /crypto AES256-SHA1 /ptype KRB5_NT_PRINCIPAL /out worker1.contoso.com.keytab`
    - `ktpass`: This is the command-line utility used to create keytab files for Kerberos authentication.
    - `/princ http/worker1.contoso.com@CONTOSO.COM`: Specifies the principal name. In this case, it is `http/worker1.contoso.com@CONTOSO.COM`. The principal name is a unique identifier for the service.
    - `/pass <password>`: Specifies the password for the user account. Replace `<password>` with the actual password for the `svc-stream-worker1` user.
    - `/mapuser CONTOSO\svc-stream-worker1`: Maps the principal name to the specified domain user account. Here, `CONTOSO\svc-stream-worker1` is the domain user created for the Worker Node.
    - `/crypto AES256-SHA1`: Specifies the encryption type to be used. `AES256-SHA1` is a strong encryption algorithm.
    - `/ptype KRB5_NT_PRINCIPAL`: Specifies the principal type. `KRB5_NT_PRINCIPAL` indicates that the principal is a Kerberos principal.
    - `/out worker1.contoso.com.keytab`: Specifies the output file name for the keytab. The keytab file will be saved as `worker1.contoso.com.keytab`.
4. Note the SPN created here (in this example, `http/worker1.contoso.com@CONTOSO.COM`) as you will need it later. This SPN is case-sensitive.
5. Copy the keytab file to the Cribl Stream Worker Node. Carefully note the file's location on the Worker Node, because you will need it later. The keytab command and output will resemble this example:

```
PS C:\Users\Administrator> ktpass /princ http/wefkerb.weftest.local@WEFTEST.LOCAL /pa
Targeting domain controller: SUP-DC01.weftest.local
Using legacy password setting method

Successfully mapped http/wefkerb.weftest.local@WEFTEST.LOCAL to cribl.
Key created.

Output keytab to wefkerb.weftest.local.keytab:
Keytab version: 0x502
keysize 110 http/wefkerb.weftest.local@WEFTEST.LOCAL ptype 1 (KRB5_NT_PRINCIPAL) vno
```

If you rotate passwords on this user service account, you'll need to export a new keytab file and merge or replace the keytab on each Worker Node. Microsoft describes a general method for this task. The Microsoft method is for a different service, but it explains the general principles. You could also use a tool like `msktutil`.

3. Setup for the Windows Event Forwarding Target

To set up the Windows event forwarding target, you'll need to create group policy objects (GPOs) for the subscription target, the WinRM service, and the NETWORK SERVICE.

Create a GPO for the Subscription Target

Create a Group Policy Object (GPO) to configure the subscription target for Windows Event Forwarding (WEF). This GPO will define the target server and the refresh interval for event subscriptions.

1. Access the UI **Computer Configuration** > **Administrative Templates** > **Windows Components** > **Event Forwarding** > **Configure target Subscription Manager**.
2. Set to `Enabled`.
3. Go to **Subscription Managers** > **Show**.
4. Add `Server=http://worker1.contoso.com:5985/wsman/SubscriptionManager/WEC,Refresh=60` to the list.

Create a GPO for the WinRM Service

Create a Group Policy Object (GPO) to ensure that the Windows Remote Management (WinRM) service is automatically started on client machines. This is a crucial step for enabling remote management and

communication between the clients and the Worker Node. By setting the WinRM service to start automatically, you ensure that the necessary remote management capabilities are always available.

1. Access the UI **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **System Services** > **Windows Remote Management (WS-Management)**.
2. Set **Startup type** to `Automatic`.

Create a GPO for the NETWORK SERVICE

Create a Group Policy Object (GPO) to grant the NETWORK SERVICE account the necessary permissions to read event logs. This is particularly important if you plan to subscribe to the Security event log. Properly configuring these permissions ensures that the `NETWORK SERVICE` account can access and forward the required event logs to the Worker Node.

1. Access the UI **Computer Configuration** > **Policies** > **Windows Settings** > **Security Settings** > **Restricted Groups**.
2. In the right pane, right-click and select **Add Group**.
3. Enter `Event Log Readers` as the group name.
4. Under `Members of this group`, click **Add**.
5. Enter `NETWORK SERVICE` as the member name.

For the change to take effect, you'll have to restart computers after you apply this GPO.

Now you can provide Kerberos authentication to a Windows Event Forwarder Source.

15.1.27. Wiz Source

Cribl Stream supports collecting data from the Wiz cloud security platform. The Wiz Source will communicate with APIs that your organization's Wiz portal exposes: Audit Logs, Configuration Findings (sometimes called Cloud Configuration), Issues, and Vulnerabilities.

Type: **Pull** | TLS Support: **No** | Event Breaker Support: **No**

Prerequisites

Reference the Wiz integration documentation for gathering your Wiz account's unique GraphQL API endpoint URL and authentication information. You'll provide these in the Cribl Stream Wiz Source configuration.

Configuring a Wiz Source

1. From the top nav, click **Manage**, then select a **Worker Group** to configure. Next, you have two options:
    - To configure via the graphical QuickConnect UI, click **Routing** then **QuickConnect**. Next, click **Add Source** and from the resulting drawer's tiles, select **Wiz**. Next, click either **Add Source** or (if displayed) **Select Existing**.
    - To configure via the Routing UI, click **Data** then **Sources**. Select **Wiz** from the list of tiles or the **Sources** left nav. Next, click **Add Source** to open the **Add Source** modal.
2. In the Source modal, configure the following under **General Settings**:
    - **Input ID**: Enter a unique name to identify this Wiz Source definition. If you clone this Source, Cribl Stream will add `-CLONE` to the original **Input ID**.
    - **GraphQL endpoint**: Enter the Wiz GraphQL API endpoint URL. The UI prefills with a URL that you need to update with the appropriate `<region>`, `https://api.<region>.app.wiz.io/graphql`. For example, `https://api.us1.app.wiz.io/graphql`.
    - **Authentication URL**: Select the authentication URL to generate an OAuth token. For details, see Authentication URL below.
    - **Client ID**: Enter the Wiz **Client ID** (53-character string).
    - **Authentication method**: Enter the Wiz **Client secret** (64-character string) password credentials manually or with a secret. When choosing **Secret**, you'll select a stored text secret in the resulting **Client Secret (text secret)** drop-down, or click **Create** to configure a new secret.
    - **Content types**: Toggle **Enable content** to `Yes` for the API types you want to query. For details, see Content Types below.

    - **Tags**: Optionally, add tags that you can use to filter and group Sources in in Cribl Stream's UI. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
3. The remaining options, Processing Settings, Retries, and Advanced Settings, are already configured for Wiz data collection.
4. Click **Save**, then **Commit & Deploy**.
5. Verify that data is making it to Cribl Stream by viewing the **Live Data** feed from the Source.

Authentication URL

If you're using a custom or self-hosted identity provider, enter the specific URL provided by your organization.

Authentication audience: When using a custom **Authentication URL** you can define the audience to use when requesting an OAuth token. This is used to validate that the token is meant for your application. Enter the audience value required by your identity provider. Defaults to `wiz-api`.

Content Types

The **Content types** are:

- **Audit Logs**
- **Configuration Findings**
- **Issues**
- **Vulnerabilities**

The schedule and query are automatically configured for you. See scheduling options for details on how these options work.

Toggle **State tracking** to `Yes` to track state by time, which prevents overlaps between collection jobs where subsequent jobs may return some of the same results as previous jobs. Similarly, it can help prevent gaps in data by allowing the next run to pick up from where the last run ended.

Processing Settings

- **Fields**: You can add Fields to each event, using Eval-like functionality. A field consists of a **Name** and **Value** pair. The **Value** is a JavaScript expression and can be a constant.
- **Pre-Processing**: Select a **Pipeline** to process results before sending to Routes. Optional, and available only when **Send to Routes** is toggled to `Yes`.

Retries

Optionally adjust the default retry settings for failed collect jobs.

- **Retry type**: The algorithm to use when performing HTTP retries. Options include `Backoff` (the default), `Static`, and `Disabled`.
- **Initial retry interval (ms)**: Time interval between failed request and first retry (kickoff). Maximum allowed value is 20,000 ms (1/3 minute). A value of `0` means retry immediately until reaching the retry limit in **Max retries**.
- **Max retries**: Maximum number of times to retry a failed HTTP request. Defaults to `5`. Maximum: `20`. A value of `0` means don't retry at all.
- **Backoff multiplier**: Base for exponential backoff. A value of `2` (default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so forth.
- **Retry HTTP codes**: List of HTTP codes that trigger a retry. Leave empty to use the defaults (`429` and `503`). Cribl Stream does not retry codes in the `200` series.
- **Honor Retry-After header**: When toggled to `Yes` (the default), `retry-after` headers up to a maximum of 20 seconds are processed. Delays longer than 20 seconds are ignored.
  - Cribl Stream will log a warning message with the delay value retrieved from the `retry-after` header (converted to ms).
  - When toggled to `No`, Cribl Stream ignores all `retry-after` headers.
- **Retry Connection Timeout**: Toggle to `Yes` to automatically retry a single connection attempt after a timeout (`ETIMEDOUT`) to ensure data continuity.
- **Retry Connection Reset**: Toggle to `Yes` to automatically retry a connection after a peer reset (`ECONNRESET`) to maintain data flow.

Advanced Settings

Advanced Settings enable you to customize post-processing and administrative options.

- **Request Timeout (seconds)**: The maximum time period for an HTTP request to complete before Cribl Stream treats it as timed out. Defaults to `0`, which disables timeout metering.
- **Time to live**: How long to keep the job's artifacts on disk after job completion. This also affects how long a job is listed in **Job Inspector**. Defaults to `4h`.
- **Environment**: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Connected Destinations

Connected Destinations mimics which method you used to open the Wiz configuration modal in step 1, either the QuickConnect UI or the Routes UI. **Send to Routes** enables conditional routing, filtering, and cloning of this

Source's data via the Routing table. **QuickConnect** allows you to send this Source's data to one or more Destinations via independent, direct connections.

Scheduling

When you enable a **Content type** under **General Settings** the following scheduling options are available:

The Cron schedule configures when collection requests are made.

Job timeout: Maximum time this job will be allowed to run. Units are seconds, if not specified. Sample values: `30`, `45s`, or `15m`. Minimum granularity is 10 seconds, so a `45s` value would round up to a 50-second timeout. Defaults to `0`, meaning unlimited time (no timeout).

Log Level: Level at which to set task logging. More verbose levels are useful for troubleshooting jobs and tasks, but use them sparingly.

The **Earliest time** and **Latest time** defines the time range of events to collect, based on the `_time` field. These fields accept the following syntax:

`[+|-]<time_integer><time_unit>@<snap-to_time_unit>`

To break down this syntax:

Syntax Element	Values Supported
Offset	Specify: `-` for times in the past, `+` for times in the future, or omit with `now`.
<time_integer>	Specify any integer, or omit with `now`.
<time_unit>	Specify the `now` constant, or one of the following abbreviations: `s[econds]`, `m[inutes]`, `h[ours]`, `d[ays]`, `w[eeks]`, `mon[ths]`, `q[uarters]`, `y[ears]`.
@<snap-to_time_unit>	Optionally, you can append the `@` modifier, followed by any of the above `<time_unit>`s, to round down to the nearest instance of that unit. (See the next section for details.)

Cribl Stream validates relative time values using these rules:

- **Earliest** must not be later than **Latest**.
- Values without units get interpreted as seconds. For example, `-1 = -1s`.

Snap-to-Time Syntax

The `@` snap modifier always rounds **down** (backwards) from any specified time. This is true even in relative time expressions with `+` (future) offsets. For example:

- `@d` snaps back to the beginning of today, 12:00 AM (midnight).
- `+128m@h` looks forward 128 minutes, then snaps back to the nearest round hour. (If you specified this in the `Latest` field, and ran the Source at 4:20 PM, collection would end at 6:00 PM. The expression would look forward to 6:28 PM, but snap back to 6:00 PM.)

Other options:

- `@w` or `@w7` to snap back to the beginning of the week – defined here as the preceding Sunday.
- To snap back to other days of a week, use `w1` (Monday) through `w6` (Saturday).
- `@mon` to snap back to the 1st of a month.
- `@q` to snap back to the beginning of the most recent quarter – Jan. 1, Apr. 1, Jul. 1, or Oct. 1.
- `@y` to snap back to Jan. 1.

Working with State Tracking

You can configure the Source to track state, either by time or another arbitrary value. This can help prevent overlaps between jobs, where subsequent runs may return some of the same results as previous runs. Similarly, it can help prevent gaps in data by allowing a run to pick up from where the last run ended.

State update expression: JavaScript expression that defines how to update the state from an event. Use the event's data and the current state to compute the new state.

State merge expression: JavaScript expression that defines which state to keep when merging a task's newly reported state with the previously saved state. Evaluates `prevState` and `newState` variables, resolving to the state to keep.

The default values for these fields are configured to track state by the latest `_time` field found in events gathered in a collection run.

Understanding State Expression Fields

The **State update** and **State merge** expressions control how state is derived from a collection run and how it is merged with existing state, respectively. They're preconfigured to work with the common use case of tracking state by latest `_time`, but you may need to update them for other use cases. To understand what these fields do, let's break down the default values.

State update expression

This expression has a default value of:

```
__timestampExtracted !== false && {latestTime: (state.latestTime || 0) > _time ? sta
```

__timestampExtracted !== false - the `__timestampExtracted` field is set to false if the Event Breaker was unable to parse time for the event. If this is the case, we don't want to update state (the event's `_time` value defaults to `Date.now()` if the Event Breaker was unable to parse out the correct time). If `_timestampExtracted` is `false`, we take advantage of short-circuit evaluation to not update state.

State values must resolve to an object, such as:

```
{ "latestTime": 17122806161 }
```

If the expression does not resolve to an object, Cribl Stream will ignore the result.

{latestTime: (state.latestTime || 0) > _time ? state.latestTime : _time} - compare `state.latestTime` to the event's `_time` value, keeping whichever value is greater.

State merge expression

This expression has a default value of:

```
prevState.latestTime > newState.latestTime ? prevState : newState
```

It compares `prevState` (the state that was previously saved) to `newState` (the state reported from the most recent collection task), keeping the state with the greatest `latestTime` value.

Managing State

Click **Manage State** to view, modify, or delete a state. For more information, see Manage State.

Wiz API Results Limits

The table below shows the results limits for each Wiz API.

API	Limit (results)
Audit Logs	10,000
Cloud Configuration	10,000
Issues	no limit
Vulnerability	no limit

Once your query hits the limit of results for a given Wiz API, the API will send no further results.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Internal Fields

Cribl Stream uses a set of internal fields to assist in data handling. These "meta" fields are **not** part of an event, but they are accessible, and you can use them in Functions to make processing decisions.

Relevant fields for this Source:

- `__collectible` – This object's nested fields contain metadata about each collection job.
- `__collectStats` – This object's nested fields are `method`, `url`, and `elapsedMS`.

Troubleshooting

Navigate to and open the Wiz Source, then use the Source's **Job Inspector** tab to see the results of recent collection runs.

The Source's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they are ingested. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the ingestion process, including any errors or warnings that may have occurred.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify ingestion issues. Analyze the graphs showing events and bytes in/out over time.

Response Errors

The Source treats all non-`200` responses from configured URL endpoints as errors. This includes `1xx`, `3xx`, `4xx`, and `5xx` responses.

A few exceptions are treated as non-fatal errors:

- Where a collect job launches multiple tasks, and only a subset of those tasks fail, Cribl Stream places the job in failed status, but treats the error as non-fatal. (Note that Cribl Stream does not retry the failed tasks.)
- Where a collect job receives a `3xx` redirection error code, it follows the error's treatment by the underlying library, and does not necessarily treat the error as fatal.

15.2. Destinations

Destinations are the endpoints where Cribl Stream delivers your data after processing and transformation. Cribl Stream can send data to many different Destinations, including Splunk, Kafka, Kinesis, InfluxDB, Snowflake, Databricks, TCP JSON, and others.

Destinations can write data to either IPv4 or IPv6 addresses.

Destination are grouped into categories that define how they handle unreachable outputs (backpressure events) and their load-balancing capabilities.

Flow of data from Sources into Cribl Stream and then on to Destinations.

Destination Categories

Destinations can be divided into streaming and non-streaming: those that accept events in real time, and those that batch them from a staging directory.

Other than that, each Destination can belong to one of the following (non-exclusive) categories:

- Filesystem-based
- Load-balanced

Streaming and Non-Streaming Destinations

Streaming and non-streaming Destination differ in the way they receive events:

- Streaming Destinations accept events in real time.
- Non-streaming Destinations receive events in batches from a staging directory.

Non-Streaming Destinations

Non-streaming Destinations make use of the staging directory, and have specific behavior regarding batching events into files.

Staging Directory

With non-streaming Destinations, Cribl Stream uses a staging directory in the local filesystem to format and write outputted events before sending them to configured Destinations. After a set of conditions is met, data is compressed and then moved to the final Destination.

To reduce costs when the staging directory is also the final directory, Cribl Stream avoids iterating through all the files within a directory by keeping an inventory of open (in progress) files in the staging directory's root. At startup, Cribl Stream will check for any leftover files in progress from prior sessions, and will ensure that they're moved to their final Destination. The process of moving to the final Destination is delayed after startup (default delay: 30 seconds). Processing of these files is paced at one file per service period (which defaults to 1 second).

In Cribl.Cloud, using a staging directory is only available on customer-managed hybrid Workers.

Batching Conditions

In non-streaming delivery, a file is closed and rolled out when it reaches its configured maximum:

- Size
- Open time
- Idle time

If a new file needs to be open, Cribl Stream will enforce the maximum number of open files by closing files in the order in which they were opened.

Filesystem-based Destinations

Some Destinations are Filesystem-based, which means they receive files on disk from a staging directory and batch them in a queue. When a batch of events is ready for transmission, Cribl Stream closes the file, optionally compresses it, and transmits the file to the downstream service. Filesystem-based Destinations do not support persistent queues.

Load-balanced Destinations

Certain Destinations offer built-in load-balancing capabilities.

Available Destinations

Cribl Stream supports the following Destinations. You can configure proxy servers for all HTTP-based Destinations.

Destination	Protocol	Streaming	Filesystem-Based	Load-Balanced
Amazon S3 Compatible Stores	HTTP/S	Non-streaming		
Amazon CloudWatch Logs	HTTP/S	Streaming		
Data Lakes > Cribl Lake	HTTP/S	Non-Streaming		
Data Lakes > Amazon S3	HTTPS only	Non-Streaming		
Data Lakes > Amazon Security Lake	HTTP/S	Non-Streaming		
Amazon Kinesis Data Streams	HTTP/S	Streaming		
Amazon MSK	TCP	Streaming		
Amazon SQS	HTTP/S	Streaming		
Azure Blob Storage	HTTPS only	Non-Streaming		
Azure Data Explorer	HTTPS only	Streaming or non-streaming		
Azure Event Hubs	TCP	Streaming		
Azure Monitor Logs	HTTPS only	Streaming		
Microsoft Sentinel	HTTP/S	Streaming		
ClickHouse	HTTP/S	Streaming		
Confluent Cloud	TCP	Streaming		
CrowdStrike Falcon LogScale	HTTPS only	Streaming		
CrowdStrike Falcon Next-Gen SIEM	HTTPS only	Streaming		

Destination	Protocol	Streaming	Filesystem-Based	Load-Balanced
Datadog	HTTPS only	Streaming		
Dynatrace HTTP	HTTP/S	Streaming		
Dynatrace OTLP	HTTP/S	Streaming		
Elasticsearch	HTTP/S	Streaming		
Elastic Cloud	HTTPS only	Streaming		
Exabeam	HTTP/S	Non-Streaming		
Filesystem/NFS		Non-Streaming		
Google SecOps	HTTPS only	Streaming		
Google Cloud Logging	HTTPS only	Streaming		
Google Cloud Pub/Sub	HTTPS only	Streaming		
Google Cloud Storage	HTTPS only	Non-Streaming		
Grafana Cloud	HTTP/S	Streaming		
Graphite	TCP or UDP	Streaming		
Honeycomb	HTTPS only	Streaming		
InfluxDB	HTTP/S	Streaming		
Kafka	TCP	Streaming		
Loki	HTTP/S	Streaming		
MinIO	HTTP/S	Non-Streaming		
NetFlow	UDP	Streaming		
New Relic Events	HTTPS only	Streaming		
New Relic Logs & Metrics	HTTPS only	Streaming		
OpenTelemetry (OTel)	gRPC or HTTP/S	Streaming		

Destination	Protocol	Streaming	Filesystem-Based	Load-Balanced
Prometheus	HTTP/S	Streaming		
SentinelOne DataSet	HTTPS only	Streaming		
ServiceNow Cloud Observability	gRPC or HTTP/S	Streaming		
SignalFx	HTTPS only	Streaming		
SNMP Trap	UDP	Streaming		
Splunk HEC	HTTP/S	Streaming		
Splunk Load Balanced	TCP	Streaming		
Splunk Single Instance	TCP	Streaming		
StatsD	TCP or UDP	Streaming		
StatsD Extended	TCP or UDP	Streaming		
Sumo Logic	HTTP/S	Streaming		
Syslog	TCP or UDP	Streaming		(TCP only)
TCP JSON	TCP	Streaming		
Wavefront	HTTPS only	Streaming		
Webhook	HTTP/S	Streaming		

You can adapt the Amazon S3 Compatible Stores Destination to send data to downstream services like Databricks and Snowflake, for which Cribl Stream currently has no preconfigured Destination. For details, please contact Cribl Support.

Internal Destinations

Internal Destinations are special-purpose Destinations that route data within your Cribl Stream deployment, or among Workers across distributed or hybrid Cribl.Cloud deployments. The following internal Destinations are available:

- Default: Specify a default output from among your configured Destinations.
- Output Router: A “meta-Destination.” Configure rules that route data to multiple configured Destinations.
- DevNull: Simply drops events. Preconfigured and active when you install Cribl Stream, so it requires no configuration. Useful for testing.
- Cribl HTTP: Send data among peer Worker Nodes over HTTP. Streaming and load-balanced.
- Cribl TCP: Send data among peer Worker Nodes over TCP. Streaming and load-balanced.
- **SpaceOut**: This experimental Destination is undocumented. Be careful!

Data Delivery to Unreachable Destinations

Cribl Stream attempts to deliver data to all Destinations that are configured to receive it at least once. When a Destination is unreachable, there are three possible behaviors:

- **Block** - Cribl Stream will block incoming events.
- **Drop** - Cribl Stream will drop events addressed to that Destination.
- **Queue** - To prevent data loss, Cribl Stream will write events to a **persistent queue** disk buffer, then forward them when a Destination becomes available. (Available on several streaming Destinations.)

For further information about backpressure (a situation when a Destination receives more data than it can send), see Destination Backpressure Triggers.

You can configure your desired behavior through a Destination’s **Backpressure Behavior** drop-down. Where other options are not displayed, Cribl Stream’s default behavior is **Block**. For details about all the above behaviors and options, see Persistent Queues.

15.2.1. Managing Destinations

For each Destination **type**, you can create multiple definitions, each with different settings, to handle delivering data to different outputs with differing requirements.

Once a Destination definition is created, enabled and set up to receive data, you can verify that data is flowing correctly, and monitor the Destination status to check for issues.

Create a Destination

You can create a new Destination in two ways: by using QuickConnect or Routing.

For configuration settings specific to each Destination, check that Destination's documentation.

Create a Destination with QuickConnect

To create a new Destination via QuickConnect:

1. If you are on a Distributed deployment, first select **Worker Groups** in the sidebar and choose a Worker Group.
2. Select **Routing**, then **QuickConnect**.
3. Select **Add Destination** at right, and select the Destination you want from the list.

For configuration settings specific to each Destination, check that Destination's documentation. After you've set up the Destination, you can verify its data flow.

Create a Destination with Routes

To create a new Destination via Routing:

1. If you are on a Distributed deployment, first select **Worker Groups** in the sidebar and choose a Worker Group.
2. Select **Data**, and then **Destinations**.
3. Select the Destination you want.
4. Select **Add Destination** to open a **New Destination** modal.

For configuration settings specific to each Destination, check that Destination's documentation. After you've set up the Destination, you can verify its data flow.

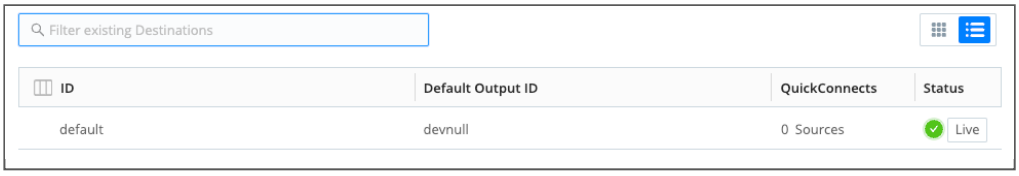
Edit Destination Settings with JSON

To edit any Destination's definition in a JSON text editor, select **Manage as JSON** at the bottom of the Destination modal. You can directly edit multiple values, and you can use the **Import** and **Export** buttons to copy and modify existing Destination configurations as `.json` files.

When JSON configuration contains sensitive information, it is redacted during export.

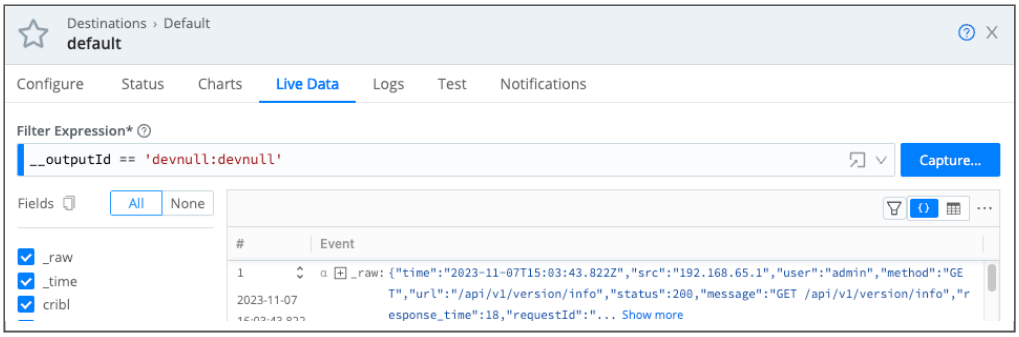
Capture Outgoing Data

To capture data from a single enabled Destination, you can bypass the Preview pane and instead capture directly from the list of Destinations. Select the **Live** button beside the Destination you want to capture.



Destination > Live button

You can also start an immediate capture from within an enabled Destination's config modal, by selecting the modal's **Live Data** tab.



Destination modal > Live Data tab

Verify Data Flow

Use the **Test** tab in the Destination's configuration modal to validate the configuration and connectivity of your Destination. A test sends sample events through the Destination to ensure it is correctly set up and can communicate with the downstream receiver.

You can choose from the available sample events or enter your own events, formatted as a JSON array.

Monitor Destination Status

You can get a quick overview of Destination health status by referring to their status icons.

Additionally, each Destination's configuration modal offers two tabs for monitoring: Status and Charts.

Destination Status Icons

Destination status icons are available on the **Data** > **Destinations** page and for each individual Destination in the list for a specific Destination type.

The icons have the following meanings:

Icon	Meaning
	Healthy. Operating correctly.
	Warning. Experiencing issues. The Destination is not functioning fully. Specific conditions will depend on the Destination type.
	Critical. Experiencing critical issues. Drill down to the Destination's Status tab to find out the details.
	Disabled. The Destination is configured, but not enabled.
	No health metrics available. This may mean that a Destination is enabled, but has not been deployed yet.

You can also find status icons on the Cribl Stream front page on Worker Group tiles. or on any tile indicate that one or more Sources or Destinations in this Worker Group are experiencing issues. Hover over the icon to see more details.

Destination Status Tab

The **Status** tab provides details about the Workers in the group and their status. An icon shows whether the Worker is operating normally.

You can select each Worker's row to see specific information, for example, to identify issues when the Destination displays an error. The specific set of information provided depends on the Destination type. The data represents only process 0 for each Worker Node.

The content of the **Status** tab is loaded live when you open it and only displayed when all the data is ready. With a lot of busy Workers in a group, or Workers located far from the Leader, there may be a delay before you see any information.

The statistics presented are reset when the Worker restarts.

Destination Charts Tab

The **Charts** tab presents a visualization of the recent activity on the Destination. The following data is available:

- Events in
- Thruput in (events per second)
- Bytes in
- Thruput in (bytes per second)
- Blocked status

This data (in contrast with the status tab) is read almost instantly and does not reset when restarting a Worker.

15.2.2. Amazon

15.2.2.1. Amazon CloudWatch Logs Destination

Cribl Stream supports sending data to Amazon CloudWatch Logs. Cribl Stream does **not** have to run on AWS in order to deliver data to CloudWatch Logs.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

IAM Permissions

Ensure your AWS IAM user or role has the following permissions:

- `logs:CreateLogGroup` – Allows the creation of new log groups in CloudWatch Logs.
- `logs:CreateLogStream` – Permits the creation of new log streams within a log group.
- `logs:PutLogEvents` – Enables the insertion of log events into a log stream.

Configure Cribl Stream to Output to Amazon CloudWatch Logs

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this CloudWatch definition.
    - **Description**: Optionally, enter a description.
    - **Log group name**: CloudWatch log group to associate events with.
    - **Log stream prefix**: Prefix for CloudWatch log stream name. This prefix will be used to generate a unique log stream name per Cribl Stream instance. (For example, `myStream_myHost_myOutputId`.)
    - **Region**: AWS region where the CloudWatch Logs group is located.

3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`. When this field is set to `queue`, see Persistent Queue Settings for details.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any Authentication, Assume Role, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior.

Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Stream's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for CloudWatch Logs: Toggle to `Yes` to use Assume Role credentials to access CloudWatch Logs.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Endpoint: CloudWatch Logs service endpoint. If empty, defaults to AWS' Region-specific endpoint. Otherwise, use this field to point to a CloudWatchLogs-compatible endpoint.

To proxy outbound HTTP/S requests, see System Proxy Configuration.

Max queue size: Maximum number of queued batches before blocking. Defaults to `5`.

Max record size (KB, uncompressed): Maximum size of each individual record before compression. For non-compressible data, 1MB (the default) is the maximum recommended size.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

How the Amazon CloudWatch Logs Destination Batches Events

Amazon CloudWatch Logs specifies that a batch of log events in a single request cannot span more than 24 hours.

When the Amazon CloudWatch Logs Destination transmits a batch of events, it notes the most recent event in the batch (by date-time) and drops all events in the batch that are 24 hours older (or more) than the most recent event.

To monitor dropped events, check **Out of Range Dropped Event Count** under **Status**. Alternately, you can monitor a debug log action to flag how many events are being dropped in a batch.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.2.2. Amazon Kinesis Data Streams Destination

Cribl Stream can output events to **Amazon Kinesis Data Streams** records of up to 1MB uncompressed. Cribl Stream does **not** have to run on AWS in order to deliver data to a Kinesis Data Stream.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Meeting the Needs of Different Downstream Receivers

You can use this Destination to send data to different kinds of downstream receivers that have different expectations. In all cases what the Destination sends out are Kinesis Records. This works because the Amazon Kinesis Data Streams Service is flexible about what is actually in a Record, as the two following use cases show.

Sending Multiple Events within One Record

When used to feed data into Amazon Data Firehose, this Destination will start with multiple events as NDJSON, gzip-compress them together into a blob, and send that as a single Kinesis Record. This uses the Kinesis PutRecord API call to send the combined events in a single Record.

Amazon Data Firehose will gunzip-uncompress the Record and split the NDJSON out into individual events again. There are also other downstream receivers besides Amazon Data Firehose that can do the same thing.

This approach requires either:

- **Advanced Settings** > **Compression** set to `Gzip`, **or**
- **Advanced Settings** > **Send batched** toggled on.

Meanwhile, if you want Cribl Stream to be the consumer, on the Kinesis Streams Source, set **Record data format** to `Cribl`. See the format details below.

Sending One Event Per Record

In contrast to the first use case, some downstream receivers require a Kinesis Record to contain exactly one Cribl event. Here, this Destination uses the Kinesis PutRecords API call to send multiple events in a single API call, but where each event has a Record to itself. (Note the difference between `PutRecord` in the previous use case and `PutRecords` in this one.)

This approach requires:

- **Advanced Settings** > **Compression** set to `None`, **and**
- **Advanced Settings** > **Send batched** toggled off.

Meanwhile, if you want Cribl Stream to be the consumer, on the Kinesis Streams Source, set **Record data format** to `Newline JSON`. See the format details below.

Amazon Kinesis Data Streams Permissions

The following permissions are needed to write to an Amazon Kinesis Stream:

- `kinesis:DescribeStream` - Always required.
- `kinesis:PutRecord` - Required for Gzip compression or batching (when **Advanced Settings** > **Compression** is set to `Gzip` or **Advanced Settings** > **Send batched** is toggled on).
- `kinesis:PutRecords` - Required for non-batched mode (when **Advanced Settings** > **Send batched** is toggled off).

Configure Cribl Stream to Output to Amazon Kinesis Data Streams

In Cribl Stream, configure Amazon CloudWatch Kinesis Data Streams:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Kinesis definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Stream name**: Enter the name of the Kinesis Data Stream (not ARN) to which to send events.
    - **Region**: Select the AWS region where your Kinesis Data Stream is located. If your region isn't listed, you can manually enter it. Additionally, you can specify the service endpoint in the **Endpoint** field under Advanced Settings.
3. Next, you can configure the following **Optional Settings**:

- **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`. When this field is set to `queue`, see Persistent Queue Settings for details.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Authentication, Assume Role, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high

as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Authentication

Use the **Authentication Method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

For details, see AWS' Actions, resources, and condition keys for Amazon Kinesis Data Streams documentation.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Stream's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for Kinesis Streams: Toggle to `Yes` to use Assume Role credentials to access Kinesis Streams.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Endpoint: Kinesis Stream service endpoint. If empty, the endpoint will be automatically constructed from the region.

To proxy outbound HTTP/S requests, see System Proxy Configuration.

Signature version: Signature version to use for signing Kinesis stream requests. Defaults to `v4`.

Put request concurrency: Maximum number of ongoing put requests before blocking. Defaults to `5`.

Max record size (KB, uncompressed): Maximum size of each individual record before compression. For non-compressible data, 1MB (the default) is the maximum recommended size.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Compression: Type of compression to use on records being sent downstream. Defaults to `Gzip`, and when set to `None`, displays the following control:

Send batched: Whether to send multiple events batched as a single NDJSON Kinesis record (the default) or send each event as its own Kinesis record, serialized as JSON. When toggled off, displays the following control:

- **Max records per flush**: Maximum number of records to send in a single request to the Amazon Kinesis Data Streams Service PutRecords API endpoint.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Record Formats in Detail

When sending multiple events within one record, the Record format will be as follows:

- A header line provides information about the payload (the one supported type is shown below).
- Each Kinesis record will contain multiple events serialized as Newline-Delimited JSON (NDJSON).
- Record payloads (including header and body) will be gzip-compressed if **Advanced Settings > Compression** is set to `Gzip`.

Sample Kinesis Record

```
{"format":"ndjson","count":8,"size":3960}
{"_raw":"07-03-2018 18:33:51.136 -0700 ERROR TcpOutputFd - Read error. Connection re
{"_raw":"07-03-2018 18:33:51.136 -0700 INFO  TcpOutputProc - Connection to 127.0.0.1
...
```

When sending one event per Record, the Record format will be as follows:

- No header will be included.
- Each Kinesis record will contain a single event serialized as JSON (**not** NDJSON).
- Record payloads will not be compressed.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.2.3. Amazon S3 Compatible Stores Destination

S3 is a non-streaming Destination type. Cribl Stream does **not** have to run on AWS in order to deliver data to S3.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

Stores that are S3-compatible will also work with this Destination type. For example, the S3 Destination can be adapted to send data to services like Databricks and Snowflake, for which Cribl Stream currently has no preconfigured Destination.

For guidance in configuring these adaptations, contact Cribl Support. For general guidance, see our Amazon S3 Better Practices guide. To replay data you've previously exported to S3-compatible stores, see our Using S3 Storage and Replay guide and our interactive Data Collection & Replay sandbox.

Configure Cribl Stream to Output to S3 Destinations

In Cribl Stream, configure Amazon S3:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this S3 definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **S3 bucket name**: Name of the destination S3 Bucket. This value can be a constant, or a JavaScript expression that will be evaluated only at init time. For example, referencing a Global Variable: `myBucket-${C.vars.myVar}`.

Event-level variables are not available for JavaScript expressions. This is because the bucket name is evaluated only at Destination initialization. If you want to use event-level variables in

file paths, Cribl recommends specifying them in the **Partitioning Expression** field (described below), because this is evaluated for each file.

- **Staging location**: Filesystem location in which to locally buffer files before compressing and moving to final destination. Cribl recommends that this location be stable and high-performance.

  The **Staging location** field is not displayed or available on Cribl.Cloud-managed Worker Nodes.

- **Key prefix**: Root directory to prepend to path before uploading. Enter either a constant, or a JS expression (enclosed in single quotes, double quotes, or backticks) that will be evaluated only at init time.
- **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (supported only on Linux, not Windows) exposes a Parquet Settings left tab, where you **must** configure certain options in order to export data in Parquet format.

3. Next, you can configure the following **Optional Settings**:
   - **Region**: Region where the S3 bucket is located.
   - **Partitioning expression**: JavaScript expression that defines how files are partitioned and organized. Default is date-based. If blank, Cribl Stream will fall back to the event's `__partition` field value (if present); or otherwise to the root directory of the **Output Location** and **Staging Location**.
   - **Compress**: Data compression format used before moving to final destination. Defaults to `gzip` (recommended). This setting is not available when **Data format** is set to `Parquet`.
   - **File name prefix expression**: The output filename prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
   - **File name suffix expression**: The output filename suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ' `` where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.

     To prevent files from being overwritten, Cribl appends a random sequence of 6 characters to the end of their names. This also applies to prefix and suffix expressions in file names.

     For example, if you set the **File name prefix expression** to `CriblExec` and set the **File name suffix expression** to `.csv`, the file name might display as `CriblExec-adPRWM.csv` with `adPRWM` appended.

   - **Backpressure behavior**: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.

- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Authentication, Assume Role, Processing, Parquet, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication method** drop-down to select one of these options:

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.

- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

The values for **Access key** and **Secret key** can be a constant or a JavaScript expression (such as `${C.env.MY_VAR}`).

Enclose values that contain special characters (like `/`) or environment variables in single quotes or backticks.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Stream's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for S3: Toggle to `Yes` to use Assume Role credentials to access S3.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID in order to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports `c*` wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Stream CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Working with Parquet for pointers on how to avoid problems such as data mismatches.
- In Cribl Edge 4.3 and later, the S3 Collector supports ingesting data in the Parquet format. Therefore, data that you export in Parquet format can be replayed via the Collector.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Stream writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported, and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: Set the target memory size for page segments. Generally, set lower values to improve reading speed, or set higher values to improve compression. Value must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle to `Yes` to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics – these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Advanced Settings

Max file size (MB): Maximum uncompressed output file size. Files of this size will be closed and moved to final output location. Defaults to `32`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Defaults to `30`.

Max open files: Maximum number of files to keep open concurrently. When this limit is exceeded, on any individual Worker Process, Cribl Stream will close the oldest open files, and move them to the final output location. Defaults to `100`.

Cribl Stream will close files when **any** of the four above conditions is met.

Staging file limit: Maximum number of files that the Destination will allow to wait for upload before it applies backpressure. Defaults to `100`; minimum is `10`; maximum is `4200`. For context, see Troubleshooting below.

Max concurrent file parts: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send the whole file at once. When set to `2` or above, IAM permissions must include those required for multipart uploads. Defaults to `4`; highest allowed value is `10`.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined **Min free disk space** amount.

Add Output ID: When set to `Yes` (the default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

For a Destination originally configured in a Cribl Stream version below 2.4.0, the **Add Output ID** behavior will be switched **off** on the backend, regardless of this toggle's state. This is to avoid losing any files pending in the original staging directory, upon Cribl Stream upgrade and restart. To enable this option for such Destinations, Cribl's recommended migration path is:

- Clone the Destination.
- Redirect the Routes referencing the original Destination to instead reference the new, cloned Destination.

This way, the original Destination will process pending files (after an idle timeout), and the new, cloned Destination will process newly arriving events with **Add output ID** enabled.

Remove empty staging dirs: Toggle this on to delete empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Endpoint: S3 service endpoint. If empty, Cribl Stream will automatically construct the endpoint from the AWS Region. To access the AWS S3 endpoints, use the path-style URL format. You don't need to specify the bucket name in the URL, because Cribl Stream will automatically add it to the URL path. For details, see AWS' Path-Style Requests topic.

Object ACL: Object ACL (Access Control List) to assign to uploaded objects.

Storage class: Select a storage class for uploaded objects. Defaults to `Standard`. The other options are: `Reduced Redundancy Storage`; `Standard, Infrequent Access`; `One Zone, Infrequent Access`; `Intelligent Tiering`; `Glacier Flexible Retrieval`; `Glacier Instant Retrieval`; or `Glacier Deep Archive`.

Server-side encryption: Encryption type for uploaded objects – used to enable encryption on data at rest. Defaults to no encryption; the other options are `Amazon S3 Managed Key` or `AWS KMS Managed Key`.

AWS S3 always encrypts data in transit using HTTPS, with default one-way authentication from server to clients. With other S3-compatible stores (such as our native MinIO Destination), use an `https://` URL to invoke in-transit encryption. Two-way authentication is not required to get encryption, and requires clients to possess a certificate.

Signature version: Signature version to use for signing S3 requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Verify if bucket exists: Toggle this to `No` if you can access files within the bucket, but not the bucket itself. This resolves errors of the form: `error initializing...Bucket does not exist`. For context, see Troubleshooting below.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

IAM Permissions

The following permissions are always needed to write to an Amazon S3 bucket:

- `s3:ListBucket`
- `s3:GetBucketLocation`
- `s3:PutObject`

If your Destination needs to do multipart uploads to S3, two more permissions are needed:

- `kms:GenerateDataKey`
- `kms:Decrypt`

See the AWS documentation.

Temporary Access via SSO Provider

You can use Okta or SAML to provide access to S3 buckets using temporary security credentials.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Destination Integrations: S3 short course. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

Common Issues

"Bucket does not exist - self signed certificate"

Example Error Text:

```
message: Bucket does not exist - self signed certificate
stack: Error: self signed certificate
    at TLSSocket.onConnectSecure (node:_tls_wrap_1535:34)
    at TLSSocket.emit (node:events:513:28)
    at TLSSocket.emit (node:events:489:12)
    at TLSSocket._fini... Show more
tmpPath: /opt/cribl/s3_bucket/cribl/2023/03/28/CriblOut-XTNGh5.0.json.tmp
```

Can occur when:

- the Destination uses a self-signed cert that has not yet been trusted by Cribl Stream.
- the user does not have appropriate permissions to view the bucket.
- the authentication token generated by your computer has a timestamp that is out of sync with the server's time, resulting in an authentication failure.

Recommendation

Disable **Advanced Settings** > **Reject unauthorized certificates** or; get the sender's cert and add it to the `NODE_EXTRA_CA_CERTS` path for validation; or verify that the user has appropriate permissions.

Misconfigured or Nonexistent Buckets

If the S3 bucket that the Destination is trying to send files to does not exist or is misconfigured, the Destination logs will reflect the following pattern:

1. Upon initialization, the Destination will log an error that says the bucket cannot be found. This error will not be logged if **Advanced Settings** > **Verify if bucket exists** is turned off.
2. Every time the Destination "rolls" a new file out of staging to try to upload it to S3, the Destination will log an error, until the number of files rolled exceeds the value of **Advanced Settings** > **Max files to stage**.

Once the Destination has begun to apply backpressure:

- The Destination will log a backpressure warning.
- Events will stop flowing through the Destination.
- The Destination will stop creating staging files.
- Although the Destination will periodically attempt to upload the staged files, it will not log any additional failures.

15.2.2.4. Amazon SQS Destination

Cribl Stream supports sending events to Amazon Simple Queuing Service.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Send Data to Amazon SQS

In Cribl Stream, configure Amazon SQS:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this SQS Destination.
    - **Description**: Optionally, enter a description.
    - **Queue name**: The name, URL, or ARN of the SQS queue to send events to. This value must be a JavaScript expression (which can evaluate to a constant), enclosed in single quotes, double quotes, or backticks. To specify a non-AWS URL, use the format: `'{url}/<queueName>'`. (For example, `':port/<myQueueName>'`.)
    - **Queue type**: The queue type used (or created). Defaults to `Standard`. `FIFO` (First In, First Out) is the other option.
3. Next, you can configure the following **Optional Settings**:
    - **Message group ID**: This parameter applies only to queues of type FIFO. Enter the tag that specifies that a message belongs to a specific message group. (Messages belonging to the same message group are processed in FIFO order.) Defaults to `cribl`. Use event field `__messageGroupId` to override this value.
    - **Create queue**: Specifies whether to create the queue if it does not exist. Defaults to `Yes`.
    - **Region**: Region where SQS queue is located.
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.)

Defaults to `Block`. When this field is set to `queue`, see Persistent Queue Settings for details.

- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Authentication, Assume Role, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Stream's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for SQS: Toggle to `Yes` to use Assume Role credentials to access SQS.

AWS account ID: Enter the SQS queue owner's AWS account ID. Leave empty if the SQS queue is in the same AWS account where this Cribl Stream instance is located.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Endpoint: SQS service endpoint. If empty, the endpoint will be automatically constructed from the region.

Signature version: Signature version to use for signing SQS requests. Defaults to `v4`.

Max queue size: Maximum number of queued batches before blocking. Defaults to `100`.

Max record size (KB): Maximum size of each individual record. Per the SQS spec, the maximum allowed value is 256 KB. (the default).

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Max concurrent requests: The maximum number of in-progress API requests before backpressure is applied. Defaults to `10`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

SQS Permissions

The following permissions are needed to write to an SQS queue:

- `sqs:ListQueues`
- `sqs:SendMessage`
- `sqs:SendMessageBatch`
- `sqs:CreateQueue`
- `sqs:GetQueueAttributes`
- `sqs:SetQueueAttributes`
- `sqs:GetQueueUrl`

Internal Fields

Cribl Stream uses a set of internal fields to assist in handling of data. These "meta" fields are **not** part of an event, but they are accessible, and functions can use them to make processing decisions.

Fields for this Destination:

- `__messageGroupId`
- `__sqsMsgAttrs`
- `__sqsSysAttrs`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.3. Azure

15.2.3.1. Azure Blob Storage Destination

Cribl Stream supports sending data to (and replaying specific events from) both Azure Blob Storage, and Azure Data Lake Storage Gen2, which implements a hierarchical namespace over blob data. This Destination can deliver data to Azure whether Cribl Stream is running on Azure, another cloud platform, or on-prem.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

For configuration examples, see Resources below.

Configure Cribl Stream to Output to Azure Blob Storage

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition.
    - **Description**: Optionally, enter a description.
    - **Container name**: Enter the container name. (A container organizes a set of blobs, similar to a directory in a file system.)

      Container names can include only lowercase letters, numbers, and/or hyphens (-). This restriction is imposed by Azure.
    - **Blob prefix**: Root directory to prepend to path before uploading.
    - **Staging location**: Local filesystem location in which to buffer files before compressing and moving them to the final destination. Cribl recommends that this location be stable and high-performance.

      In Cribl Stream, the **Staging location** field is not displayed or available on Cribl.Cloud-managed Worker Groups.

- **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (supported only on Linux, not Windows) exposes a **Parquet Settings** left tab, where you **must** configure certain options in order to export data in Parquet format.

3. Under **Authentication**, select an **Authentication method** from the dropdown:
   - **Manual**: Use this default option to enter your Azure Storage connection string directly. Exposes a **Connection string** field for this purpose. (If left blank, Cribl Stream will fall back to `env.AZURE_STORAGE_CONNECTION_STRING`.)
   - **Secret**: This option exposes a **Connection string (text secret)** drop-down, in which you can select a stored secret that references an Azure Storage connection string. A **Create** link is available to store a new, reusable secret. For details, see Connection String Format.
   - **Client secret**: This option allows you to use the Azure service principal's client secret to authenticate, and exposes Azure service principal settings.
   - **Certificate**: This option allows you to use a certificate registered with the Azure service principal to authenticate, and exposes Azure service principal settings.
4. Next, you can configure the following **Optional Settings**:
   - **Create container**: Toggle to `Yes` to create the configured container in Azure Blob Storage if one does not already exist.
   - **Partitioning expression**: JavaScript expression that defines how files are partitioned and organized. Default is date-based. If blank, Cribl Stream will fall back to the event's `__partition` field value (if present); or otherwise to the root directory of the **Output Location** and **Staging Location**.
   - **Compress**: Data compression format used before moving to final destination. Defaults to `gzip` (recommended). This setting is not available when **Data format** is set to `Parquet`.
   - **File name prefix expression**: The output filename prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
   - **File name suffix expression**: The output filename suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ' ``
     where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.

     To prevent files from being overwritten, Cribl appends a random sequence of 6 characters to the end of their names. This also applies to prefix and suffix expressions in file names.

     For example, if you set the **File name prefix expression** to `CriblExec` and set the **File name suffix expression** to `.csv`, the file name might display as `CriblExec-adPRWM.csv` with `adPRWM` appended.
   - **Backpressure behavior**: Whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.)

Defaults to `Block`.

- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the Processing, Parquet Settings, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Connection String Format

Manual and **Secret** authentication methods use an Azure Storage connection string in this format:

```
DefaultEndpointsProtocol=[http|https];AccountName=<your-account-name>;AccountKey=<you
```

A fictitious example, using Microsoft's recommended HTTPS option, is:

```
DefaultEndpointsProtocol=https;AccountName=storagesample;AccountKey=12345678...32;End
```

Service Principal Settings

Client secret and **Certificate** authentication methods expose the following additional settings:

- **Storage account name**: Enter the name of your Azure Storage Account.
- **Tenant ID**: Enter the service principal's tenant ID.
- **Client ID**: Enter the service principal's client ID.
- **Client secret (text secret)** (with **Client secret** method selected): Select a text secret containing the client secret, or create a new one.
- **Certificate** (with **Certificate** method selected): Select the certificate you registered as credentials for your app in the Azure portal, or create a new one.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Stream CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Working with Parquet for pointers on how to avoid problems such as data mismatches.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Stream writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported, and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: Set the target memory size for page segments. Generally, set lower values to improve reading speed, or set higher values to improve compression. Value must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle to `Yes` to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics – these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Advanced Settings

Max file size (MB): Maximum uncompressed output file size. Files reaching this size will be closed and moved to the final output location. Defaults to `32`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Default: `30`.

Max open files: Maximum number of files to keep open concurrently. When exceeded, the oldest open files will be closed and moved to final output location. Default: `100`.

Cribl Stream will close files when **either** of the `Max file size (MB)` or the `Max file open time (sec)` conditions are met.

Max concurrent file parts: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send one part at a time – that is, to upload the file's contents sequentially. Defaults to `1`; highest allowed value is `10`.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined Min free disk space amount.

Add Output ID: When set to `Yes` (the default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

For a Destination originally configured in a Cribl Stream version below 2.4.0, the **Add Output ID** behavior will be switched **off** on the backend, regardless of this toggle's state. This is to avoid losing any files pending in the original staging directory, upon Cribl Stream upgrade and restart. To enable this option for such Destinations, Cribl's recommended migration path is:

- Clone the Destination.
- Redirect the Routes referencing the original Destination to instead reference the new, cloned Destination.

This way, the original Destination will process pending files (after an idle timeout), and the new, cloned Destination will process newly arriving events with **Add output ID** enabled.

Remove staging dirs: When toggled on (the default), Cribl Stream deletes empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Resources

For examples of configuring Cribl Stream to interoperate with Azure services, see these guides:

- Preparing the Azure Workspace.
- SSO with Microsoft Entra ID and OIDC (On-Prem).
- SSO with Microsoft Entra ID and SAML (Cribl.Cloud).
- SSO with Microsoft Entra ID and SAML (On-Prem).

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.3.2. Azure Data Explorer Destination

Cribl Stream supports sending data to the Azure Data Explorer (ADX) managed data analytics service; you can then run Kusto queries against the data. This Destination can deliver data to Azure whether Cribl Stream is running on Azure, another cloud platform, or on-prem.

ADX stores log data in databases, which in turn contain one or more of the tables defined in the Azure namespace. You must create a separate Cribl Stream ADX Destination for each table that will store your data.

> Type: Non-Streaming **or** Streaming (configurable) | TLS Support: Yes | PQ Support: No
>
> For configuration examples, see Resources below.

Prerequisites

Before you configure the Destination, you need to collect some information from your Azure deployment. Start from **Home** (`portal.azure.com`), then navigate to the locations described below and collect the items specified.

Information About Your ADX Cluster

From **Home**, navigate to:

Azure Data Explorer Clusters > `your_Azure_cluster_name` > **Overview** > **Essentials**

- Copy the **URI**. In Cribl Stream, this will be the value for **General Settings** > **Cluster base URI**. Make a copy of the URI with `/.default` appended – this will be the value of **Authentication Settings** > **Scope**.
- Copy the **Data Ingestion URI**. In Cribl Stream, this will be the value for **General Settings** > **Ingestion service URI**.

Information About Your Azure Database

From **Home**, navigate to:

Azure Data Explorer Clusters > `your_Azure_cluster_name` | **Databases** > `database_name` | **Query**

- Note the name of your desired target table – this table name will be the value of **General Settings** > **Table name**.

Information About Your Azure App

First, from **Home**, navigate to:

App registrations > `your_Azure_app_name` | **Overview** | **Essentials**

- Copy the **Application (client) ID** – this will be the value of **Authentication Settings** > **Client ID**.
- Copy the **Directory (tenant) ID** – this will be the value of **Authentication Settings** > **Tenant ID**.

Nex, from **Home**, navigate to:

App registrations > `your_Azure_app_name` | **Certificates & secrets**

Now what you do depends on which method for **Authentication** you plan to use in Cribl Stream.

To use the Client secret method

- In the **Client secrets** tab, click **New client secret** and copy the **Value** of the new secret. In Cribl Stream, this will be the value of **Client secret**.

To use the Client secret (text secret) method

- In the **Client secrets** tab, click **New client secret** and copy the **Value** of the new secret. In Cribl Stream, this will be the value of **Create new secret** > **Value**.

To use the Certificate method

After you have generated a certificate and keys (if you do this later on in the configuration process, return to this section then):

- In the **Certificates** tab, click **Upload Certificate**. In the resulting drawer, follow the prompts to upload your certificate, and click **Add** to close the drawer.

The chosen certificate will then appear in the **Certificates** tab's list.

Data Mapping Prerequisites

Finally, you might need to note or copy data mapping information to obtain values for some of the **General Settings**.

ADX uses a data mapping to map fields from incoming data to fields in the target table. To see the data mapping, you'll run a Kusto query against your target table.

Here's the query syntax:

```
.show table EntityName ingestion MappingKind mapping MappingName
```

Here's an example query:

```
.show table SyslogTable ingestion json mapping "SyslogMapping"
```

The Kusto query that originally created this mapping would look like this:

```
.create table SyslogTable ingestion json mapping "SyslogMapping"
```

In Cribl Stream, you can use the names of mappings like the above example in the **General Settings** > **Data mapping** field. Alternatively, you can create a mapping without naming it, then copy and paste it (as a JSON object) into the Cribl Stream UI. To do this, toggle **General Settings** > **Mapping object** on. This hides the default **Data mapping** text field and opens a text window that expects JSON.

Configure Cribl Stream to Output to Azure Data Explorer

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition.
    - **Description**: Optionally, enter a description.
    - **Ingestion mode**: Use the buttons to select **Batching** mode (the default) or **Streaming** mode. For details, see Ingestion Mode.
    - **Cluster base URI**: Enter the base URI for your ADX cluster.
    - **Ingestion service URI**: Displayed only in **Batching** mode. Enter the Ingestion Service URI for your ADX cluster.
    - **Database name**: Enter the name of the ADX database where the target table resides.
    - **Table name**: Enter the name of the target table.
    - **Validate database settings**: When you save or start the Destination, validates the database name and credentials that you have entered in these settings. Also validates the table name, except

when **Add mapping object** (below) is on. Defaults to `Yes`. Disable if your Azure app does not have **both** the **Database Viewer** and the **Table Viewer** role.

- **Add mapping object**: Displayed only in **Batching** mode, this control is toggled off by default. Toggle on when you want to paste in a data mapping as a JSON object, instead of using a named data mapping. See Data Mapping Prerequisites above.
- **Data mapping**: If **Add mapping object** is off, enter the name of the desired data mapping. If **Add mapping object** is on, enter the desired data mapping as a JSON object.
- **Compress**: By default, this Destination compresses data using `gzip`; otherwise it sends the data uncompressed. This setting is not available when **Data format** is set to `Parquet`.
- **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (available only in **Batching** mode, and supported only on Linux, not Windows) exposes a **Parquet Settings** tab, where you select the Parquet schema.
- **Backpressure behavior**: Whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`. When **Ingestion mode** is set to **Streaming** mode, the **Persistent Queue** option becomes available. See **Persistent Queue Settings** below.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

3. Optionally, you can adjust the Authentication, Persistent Queue , Processing, Parquet, and Advanced settings outlined in the sections below.
4. Select **Save**, then **Commit & Deploy**.

Ingestion Mode

This Destination supports two ingestion modes:

- **Batching** (the default) stages data in a storage container from which ADX pulls batches of data, then writes them to the target ADX table. Batching works well when the Destination needs to ingest large amounts of data in short periods of time.
- **Streaming** sends data as HTTP request payloads, directly to the target ADX table, without staging them in a container first. Streaming can achieve lower latency than batching, as long as the data that the Destination ingests arrives in relatively small amounts. When in this mode, the Retries section (left tab) becomes available.

Authentication Settings

Microsoft Entra ID authentication endpoint: From the drop-down, select the Microsoft Entra ID endpoint that provides authentication tokens. To understand the available choices, see the Microsoft Entra documentation.

Tenant ID: Directory ID (tenant identifier) in Microsoft Entra ID.

Client ID: `client_id` to pass in the OAuth request parameter.

Scope: Scope to pass in the OAuth request parameter.

Use the **Authentication method** buttons to select one of these options:

- **Client secret**: Use this default option to enter the client secret that you generated for your app in the Azure portal.
- **Client secret (text secret)**: Use this option to select or create a stored text secret.
- **Certificate**: Use this option to select the certificate whose public key you register (or will register) for your app in the Azure portal. Or, create a new one.

Persistent Queue Settings

This tab is displayed when **General Settings** > **Ingestion mode** is set to **Streaming** mode and **Backpressure behavior** is set to **Persistent Queue**.

> On Cribl-managed Cloud Worker Nodes (with certain plan/license tiers), this tab should expose only the destructive **Clear Persistent Queue** button (described below in this section).
>
> Due to Known Issue CRIBL-21335, the on-prem Persistent Queue settings are still displayed in Cribl.Cloud – but you should ignore all controls other than the **Clear Persistent Queue** button.
>
> The other controls are not needed because Cribl.Cloud automatically allocates a maximum queue size of 1 GB disk space per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Destination will stop queueing data and apply the **Queue-full** behavior. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Stream will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue is exerting backpressure (because disk is low or at full capacity). **Block** is the same behavior as non-PQ blocking, corresponding to the `Block` option on the **Backpressure behavior** drop-down. **Drop new data** throws away incoming data, while leaving the contents of the PQ unchanged.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, toggle this off. Doing so will expose this additional control:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue's drain rate can boost the throughput of new/active connections, by reserving more resources for them. You can further optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Clear Persistent Queue: Click this "panic" button if you want to delete the files that are currently queued for delivery to this Destination. A confirmation modal will appear - because this will free up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (Appears only after **Output ID** has been defined.)

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Stream CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Working with Parquet for pointers on how to avoid problems such as data mismatches.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Stream writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: The target memory size for page segments. Generally, lower values improve reading speed, while higher values improve compression. Must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle to `Yes` to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics – these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Retries

This tab is displayed when **General Settings** > **Ingestion mode** is set to **Streaming** mode.

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
`408, 429, 503, 504, 520.`	Retry the request.
Any other status code.	Drop the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, `429 (Too Many Requests)` is the only response code configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

The controls on this tab vary depending on the **Ingestion mode** selected on the **General Settings** tab. Below you'll find one dedicated section for the Batching, and another for the Streaming controls.

Only the **Environment** control, at the bottom of the tab, is common to both:

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Advanced Settings for Batching Mode

Flush immediately: Toggle on to bypass the data management service's aggregation mechanism. See the ADX documentation.

Retain blob on success: By default, Cribl Stream deletes each data blob once ingestion is complete. Toggle this on if you prefer to retain blobs instead.

Extent tags: Optionally, add strings or tags to partitions of the target table – Azure calls these extents or data shards.

Enforce uniqueness via tag values: Use the **Add value** button to specify a list of `ingest-by` values. Cribl Stream will then check the `ingest-by` tags of incoming extents and discard those whose values match a listed value. This mechanism for avoiding ingesting duplicate extents uses the `ingestIfNotExists` property, as described in the ADX documentation.

Report level: Level for ingestion status reporting. Options are `DoNotReport`, `FailuresOnly` (the default), and `FailuresAndSuccesses`.

Report method: Target for ingestion status reporting. Options are `Queue` (the default), `Table`, and `QueueAndTable`.

Additional fields: Optionally, enter additional configuration properties to send to the ingestion service.

Staging location: Local filesystem location in which to buffer files before compressing and moving them to the final destination. Cribl recommends that this location be stable and high-performance. Defaults to `/tmp`.

File name suffix expression: The output filename suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks.

Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ""}` ``, where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.

To prevent files from being overwritten, Cribl appends a random sequence of 6 characters to the end of their names. This also applies to prefix and suffix expressions in file names.

For example, if you set the **File name prefix expression** to `CriblExec` and set the **File name suffix expression** to `.csv`, the file name might display as `CriblExec-adPRWM.csv` with `adPRWM` appended.

Max file size (MB): Maximum uncompressed output file size. Files reaching this size will be closed and moved to the storage container. Defaults to `32`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to the storage container. Defaults to `300` seconds (5 minutes).

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to the storage container. Default: `30`.

Max open files: Maximum number of files to keep open concurrently. When exceeded, the oldest open files will be closed and moved to the storage container. Default: `100`.

Max concurrent file parts: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send one part at a time – that is, to upload the file's contents sequentially. Defaults to `1`; highest allowed value is `10`.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined Min free disk space amount.

Add output ID: Toggle on if you want Cribl Stream to append the Destination name to staging directory pathnames. This can make it easier to organize and troubleshoot when you have multiple Destinations populating staging directories.

Remove empty staging dirs: When toggled on (the default), Cribl Stream deletes empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this

additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Advanced Settings for Streaming Mode

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Validate server certs: When toggled on (the default) Cribl Stream will reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (such as the system's CA, for example).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Keep alive: By default, Cribl Stream sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Stream to

close the connection immediately after sending a request.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Resources

For examples of configuring Cribl Stream to interoperate with Azure services, see these guides:

- Preparing the Azure Workspace.
- SSO with Microsoft Entra ID and OIDC (On-Prem).
- SSO with Microsoft Entra ID and SAML (Cribl.Cloud).
- SSO with Microsoft Entra ID and SAML (On-Prem).

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.3.3. Azure Event Hubs Destination

Cribl Stream supports sending data to Azure Event Hubs.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Azure Event Hubs uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Stream must send events directly to receivers. You might need to adjust your firewall rules to allow this traffic.

For configuration examples, see Resources below.

See Microsoft's Compare Azure Event Hubs Tiers topic to configure tiers whose features and quotas match your desired data volume and throughput.

Configuring Cribl Stream to Output to Azure Event Hubs

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Azure Event Hubs definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Brokers**: List of Event Hub Kafka brokers to connect to. (For example, `yourdomain.servicebus.windows.net:9093`.) Find the hostname in Shared Access Policies, in the host portion of the primary or secondary connection string. If omitted, the port will default to `9093`.
    - **Event Hub name**: The name of the Event Hub (a.k.a., Kafka Topic) on which to publish events. Can be overwritten using the `__topicOut` field.
3. Next, you can configure the following **Optional Settings**:
    - **Acknowledgments**: Control the number of required acknowledgments. Defaults to `Leader`. Setting this control to `Leader` or `All` may significantly slow throughput. If the impact is too great

for your use case, set this control to `None`.

- **Record data format**: Format to use to serialize events before writing to the Event Hub Kafka brokers. Defaults to `JSON`.
- **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the TLS, Authentication, Persistent Queue, Processing, Parquet, Retries and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

TLS Settings (Client Side)

Enabled Defaults to `Yes`.

Validate server certs: Defaults to `Yes`.

Authentication

Authentication parameters to use when connecting to brokers. Using TLS is highly recommended.

Enabled: With the default `Yes` setting, this section's remaining settings are displayed, and all are required settings.

SASL mechanism: SASL (Simple Authentication and Security Layer) authentication mechanism to use with Kafka brokers. Defaults to `PLAIN`, which exposes Basic Authentication options that rely on Azure Event Hubs connection strings. Select `OAUTHBEARER` to enable OAuth Authentication via a different set of options.

Basic Authentication

Selecting the `PLAIN` SASL mechanism provides the options listed in this section.

Username: The username for authentication. For Event Hubs, this should always be `$ConnectionString`.

Authentication method: Use the buttons to select one of these options:

- **Manual**: Use this default option to enter your Event Hubs connection string's primary or secondary key from the Event Hubs workspace. Exposes a **Password** field for this purpose.

- **Secret**: This option exposes a **Password (text secret)** drop-down, in which you can select a stored secret that references an Event Hubs connection string. The secret can reside in Cribl Stream's internal secrets manager or (if enabled) in an external KMS. A **Create** link is available if you need a new secret.

Connection String Format

Either authentication method above uses an Azure Event Hubs connection string in this format:

```
Endpoint=sb://<FQDN>/;SharedAccessKeyName=<your-shared-access-key-name>;SharedAccessKey=<your-shared-access-key-value>
```

A fictitious example is:

```
Endpoint=sb://dummynamespace.servicebus.windows.net/;SharedAccessKeyName=DummyAccessKeyN
```

OAuth Authentication

Selecting the `OAUTHBEARER` SASL mechanism provides the options listed in this section.

Microsoft Entra ID authentication endpoint: Specifies the Microsoft Entra ID endpoint from which to acquire authentication tokens. Defaults to `https://login.microsoftonline.com`. You can instead select `https://login.microsoftonline.us` or `https://login.partner.microsoftonline.cn`.

Client ID: Enter the `client_id` to pass in the OAuth request parameter.

Tenant identifier: Enter your Microsoft Entra ID subscription's directory ID (tenant ID).

Scope: Enter the scope to pass in the OAuth request parameter. This will be of the form: `https://<Event-Hubs-Namespace-Host-name>/.default`. (For example, for an Event Hubs Namespace > Host name: `goatyoga.servicebus.windows.net`, **Scope**: `https://goatyoga.servicebus.windows.net/.default`.)

Authentication method: Use the buttons to select one of these options:

- **Manual**: This default option exposes a **Client secret** field, in which to directly enter the `client_secret` to pass in the OAuth request parameter.
- **Secret**: Exposes a **Client secret (text secret)** drop-down, in which you can select a stored secret that references the `client_secret`. A **Create** link is available to define a new secret.
- **Certificate**: Exposes a **Certificate name** drop-down, in which you can select a stored certificate. A **Create** link is available to define a new cert.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.

- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Max retries: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2`–`20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Max record size (KB, uncompressed): Maximum size (KB) of each record batch before compression. Setting should be < `message.max.bytes` settings in Kafka brokers. Defaults to `768`.

Max events per batch: Maximum number of events in a batch before forcing a flush. Defaults to `1000`.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Connection timeout (ms): Maximum time to wait for a successful connection. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour).

Request timeout (ms): Maximum time to wait for a successful request. Defaults to `60000` ms (1 minute).

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Stream initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Destination from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Destination to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Working with Event Timestamps

By default, when an incoming event reaches this Destination, the underlying Kafka JS library adds a `timestamp` field set to the current time at that moment. The library gets the current time from the `Date.now()` JavaScript method. Events that this Destination sends to downstream Kafka receivers include this `timestamp` field.

Some production situations require the `timestamp` value to be the time an incoming event was originally created by an upstream sender, not the current time of its arrival at this Destination. For example, suppose the events were originally created over a wide time range, and arrive at the Destination hours or days later. In this case, the original creation time might be important to retain in events Cribl Stream sends to downstream Kafka receivers.

Here is how to satisfy such a requirement:

1. In a Pipeline that routes events to this Destination, use an Eval Function to add a field named `__kafkaTime` and write the incoming event's original creation time into that field. The value of `__kafkaTime` **must** be in UNIX epoch time (either seconds or milliseconds since the UNIX epoch – both will work). For context, see this explanation of the related fields `_time` and `__origTime`.

2. This Destination will recognize the `__kafkaTime` field and write its value into the `timestamp` field. (This is similar to the way you can use the `__topicOut` field to overwrite a topic setting, as described above.)

If the `__kafkaTime` field is **not** present, the Destination will apply the default behavior (using `Date.now()`) described previously.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__topicOut`
- `__key`
- `__headers`
- `__keySchemaIdOut`
- `__valueSchemaIdOut`

Resources

For examples of configuring Cribl Stream to interoperate with Azure services, see these guides:

- Preparing the Azure Workspace.
- SSO with Microsoft Entra ID and OIDC (On-Prem).
- SSO with Microsoft Entra ID and SAML (Cribl.Cloud).
- SSO with Microsoft Entra ID and SAML (On-Prem).

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Destination Integrations: Azure Event Hubs short course. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

15.2.3.4. Azure Monitor Logs Destination

Cribl Stream supports sending data to Azure Monitor Logs.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

For configuration examples, see Resources below.

Configure Cribl Stream to Output to Azure Monitor Logs

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Azure Monitor Logs definition.
    - **Description**: Optionally, enter a description.
    - **Log type**: The Record Type of events sent to this LogAnalytics workspace. Defaults to `Cribl`. Use only letters, numbers, and `_` characters. (See Microsoft's Azure Monitor documentation.) Can be overwritten by an event's `__logType` field.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Displays fields in which to enter your Azure Log Analytics **Workspace ID** and your Primary or Secondary Shared **Workspace key**. See the Azure Monitor documentation.
    - **Secret**: This option exposes a **Secret key pair** drop-down, in which you can select a stored secret that references the credentials described above. A **Create** link is available to store a new, reusable secret.
4. Next, you can configure the following **Optional Settings**:
    - **DNS name of API endpoint**: Enter the DNS name of the Log API endpoint that sends log data to a Log Analytics workspace in Azure Monitor. Defaults to: `.ods.opinsights.azure.com.`
      Cribl Stream will add a prefix and suffix around this DNS name, to construct a URI in this format: `https://<Workspace_ID><your_DNS_name>/api/logs?api-version=<API version>.`

- **Resource ID**: Resource ID of the Azure resource to associate the data with. This populates the `_ResourceId` property, and allows the data to be included in resource-centric queries. (Optional, but if this field is not specified, the data will not be included in resource-centric queries.)
- **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `1024` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the

downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low settings could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Azure Monitor Limitations

The Azure Monitor Logs architecture limits the number of columns per table, characters per column name, and other parameters. For details, see Microsoft's Azure Monitor Service Limits topic.

Azure will drop logs if your data exceeds these limits. To diagnose this, you can search in the Azure Data Explorer console with a query like this:

```
Operation | summarize count() by Detail
```

...for error messages of this form:

```
Data of type <type> was dropped: The number of custom fields <number> is above the limit of 500 fields per data type.
```

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is

to prevent sticking to a particular Destination when there is a constant flow of events.

- If keepalives are not supported by the server (or if the server closes a pooled connection while idle), a new connection will be established for the next request.
- When resolving the Destination's hostname, Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between destination cluster nodes.

Resources

For examples of configuring Cribl Stream to interoperate with Azure services, see these guides:

- Preparing the Azure Workspace.
- SSO with Microsoft Entra ID and OIDC (On-Prem).
- SSO with Microsoft Entra ID and SAML (Cribl.Cloud).
- SSO with Microsoft Entra ID and SAML (On-Prem).

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.3.5. Microsoft Sentinel Destination

Cribl Stream can send log and metric events to the Microsoft Sentinel SIEM. This Destination encrypts and sends events via the HTTPS protocol. The supported environments include:

- Azure Public Cloud
- Azure US Government Cloud
- Microsoft Azure operated by 21Vianet

Type: Streaming | TLS Support: No | PQ Support: Yes

For a walk-through of configuring this Destination with Microsoft Sentinel, see our Microsoft Sentinel SIEM Integration guide. Also see these Packs on the Cribl Packs Dispensary, which provide processing Pipelines that you can import and adapt to your needs:

- Microsoft Sentinel Pack.
- Microsoft Sentinel Syslog Pack
- Microsoft Sentinel Common Security Log Pack.

Prerequisites

Before configuring your Microsoft Sentinel Destination(s), you have to prepare the Azure workspace, create data collection rules (DCRs), and obtain the ingestion URL that will receive the data from your Destination(s).

Complete these preparatory steps, which are described in Microsoft Sentinel Integration, before configuring the Microsoft Sentinel Destination. That topic explains the overall Sentinel/Cribl workflow, provides necessary context, and shows you how to obtain the values you'll need to configure the Destination.

If you intend to send multiple event types, or tables, to Sentinel, you'll need a separate Destination for each event type. In this case, Cribl recommends you use a single URL to ingest all the data, with an Output Router to route each event type to the correct Microsoft Sentinel Destination.

Behind the scenes, this Destination uses the Azure Monitor Logs Ingestion API.

Configure Cribl Stream to Output to Microsoft Sentinel

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this HTTP output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Endpoint configuration**: Use the buttons to select **URL** or **ID**. This specifies the method for configuring the endpoint. For details, see Endpoint Configuration Options
3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication Settings, Processing, Retries and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Endpoint Configuration Options

The **Endpoint configuration** setting offers the following options:

- **URL** – lets you directly enter the data collection endpoint. This method is the simplest way of configuring the endpoint. See Obtaining a URL for more information.
- **ID** – lets you enter individual IDs that Cribl Stream uses to create the URL used as the data collection endpoint.

Selecting `URL` exposes the following field.

URL: Endpoint URL to send events to. The internal field `__url`, where present in events, will override the `URL` and `ID` values. See Internal Fields below.

Selecting `ID` exposes the following fields.

Data collection endpoint: Data collection endpoint (DCE) in the format `https://<endpoint-name>.<identifier>.<region>.ingest.monitor.azure.com`.

Data collection rule ID: Immutable ID for the data collection rule (DCR).

Stream name: Name of the Sentinel table in which to store events.

Optional Settings

Authentication Settings

Login URL: Endpoint for the OAuth API call. This URL varies depending on your Azure environment:

- Azure Public Cloud: `https://login.microsoftonline.com/<tenant-id>/oauth2/v2.0/token`
- Azure US Government Cloud: `https://login.microsoftonline.us/<tenant-id>/oauth2/v2.0/token`
- Microsoft Azure operated by 21Vianet: `https://login.chinacloudapi.cn/<tenant-id>/oauth2/v2.0/token`

OAuth secret: Secret parameter value to pass in the API call's request body.

Client ID: JavaScript expression used to compute the application (client) ID for the Azure application. Can be a constant.

Scope: The OAuth scope to the appropriate endpoint URL for your Azure environment. This ensures that your OAuth tokens are valid and that your data is correctly ingested into Microsoft Sentinel. This setting should match the specific endpoint for your Azure environment:

- Azure Public Cloud (default): `https://monitor.azure.com/.default`
- Azure US Government Cloud: `https://monitor.azure.us/.default`
- Microsoft Azure operated by 21Vianet: `https://monitor.azure.cn/.default`

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Toggle this to `No` if you want Cribl Stream to accept such certificates. Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: By default, Cribl Stream enables gzip-compress to compress the payload body before sending. Toggle this off if you want Cribl Stream not to gzip-compress the payload body.

Keep alive: By default, Cribl Stream sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Stream to close the connection immediately after sending a request.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `1000` KB, the maximum allowed size of API call. Be aware that high values can cause high memory usage per Worker Node, especially if a dynamically constructed URL (see Internal Fields) causes this Destination to send events to more than one URL. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass to all events as additional HTTP headers. Values will be sent encrypted. You can also add headers dynamically on a per-event basis in the `__headers` field. See Internal Fields below.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__criblMetrics`
- `__url`
- `__headers`

If an event contains the internal field `__criblMetrics`, Cribl Stream will send it to the HTTP endpoint as a metric event. Otherwise, Cribl Stream will send it as a log event.

If an event contains the internal field `__url`, that field's value will override the **General Settings** > **URL** value. This way, you can determine the endpoint URL dynamically.

For example, you could create a Pipeline containing an Eval Function that adds the `__url` field, and connect that Pipeline to your Microsoft Sentinel Destination. Configure the Eval Function to set `__url`'s value to a URL that varies depending on a global variable, or on some property of the event, or on some other dynamically-generated value that meets your needs.

If an event contains the internal field `__headers`, that field's value will be a JSON object containing Name-value pairs, each of which defines a header. By creating Pipelines that set the value of `__headers` according to conditions that you specify, you can add headers dynamically.

For example, you could create a Pipeline containing Eval Functions that add the `__headers` field, and connect that Pipeline to your Microsoft Sentinel Destination. Configure the Eval Functions to set `__headers` values to

Name-value pairs that vary depending on some properties of the event, or on dynamically-generated values that meet your needs.

Here's an overview of how to add headers:

- To add "dynamic" (a.k.a. "custom") headers to some events but not others, use the `__headers` field.
- To define headers to add to **all** events, use **Advanced Settings** > **Extra HTTP Headers**.
- An event can include headers added by both methods. So if you use `__headers` to add `{ "api-key": "foo" }` and **Extra HTTP Headers** to add `{ "goat": "Kid A" }`, you'll get both headers.
- Headers added via the `__headers` field take precedence. So if you use `__headers` to add `{ "api-key": "foo" }` and **Extra HTTP Headers** to add `{ "api-key": "bar" }`, you'll get only one header, and that will be `{ "api-key": "foo" }`.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, it will throw away the connection and attempt a new one. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), Cribl Stream will establish a new connection for the next request.
- When resolving the Destination's hostname, Cribl Stream will pick the first IP in the list for use in the next connection. Enable **Round-robin DNS** to better balance distribution of events among destination cluster nodes.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.4. Data Lakes

15.2.4.1. Cribl Lake Destination

The **Cribl Lake** Destination sends data to Cribl Lake and automatically selects a partitioning scheme that works well with Cribl Search.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

Requirements

Cribl Lake Destination is available only in Cribl.Cloud.

Cribl Lake Destination can send data to both Cribl-managed Cloud and customer-managed hybrid Stream Worker Groups. Hybrid Worker Groups must be running version 4.8 or higher.

Configure a Cribl Lake Destination

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect**. Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations**. Select the Destination you want. Next, select **Add Destination**.
2. In the Destination modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Cribl Lake Destination.
    - **Lake dataset**: Select Cribl Lake Dataset to send data to.

      You can't target the built-in `cribl_logs` and `cribl_metrics` Datasets with this Destination.
3. Next, you can configure the following **Optional Settings** that you'll find across many Cribl Destinations:
    - **Backpressure behavior**: Whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary)

tag names.

4. Optionally, configure any Post-Processing settings outlined in the below sections.
5. Click **Save**, then **Commit & Deploy**.
6. Verify that data is searchable in Cribl Lake.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports `c*` wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

15.2.4.2. Amazon S3 Destination

The **Data Lake Amazon S3 Destination** sends data to Amazon Simple Storage Service (**Amazon S3**) and uses a partitioning scheme that is designed to work with Cribl Search. You can organize your bucket structure by event fields for referencing in Cribl Search. See the Cribl Search setup for Data Lake Amazon S3 for details.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

Configuring Cribl Stream to Output to S3 Destinations

From the top nav, click **Manage**, then select a **Worker Group** to configure. Next, you have two options:

To configure via the graphical QuickConnect UI. Next, click **Add Destination** at right. From the resulting drawer's tiles, select **Data Lakes** > **Amazon S3**. Next, click either **Add Destination** or (if displayed) **Select Existing**. The resulting drawer will provide the options below.

Or, to configure via the Routing UI, click **Data** > **Destinations**. From the resulting page's tiles or the **Destinations** left nav, select **Data Lakes** > **Amazon S3**. Next, click **Add Destination** to open a **New Destination** modal that provides the options below.

General Settings

Output ID: Enter a unique name to identify this S3 definition.

S3 bucket name: Name of the destination S3 Bucket. This value can be a constant, or a JavaScript expression that will be evaluated only at init time. For example, referencing a Global Variable: `myBucket-${C.vars.myVar}`.

Optional Settings

Partition by fields: List of fields to partition the path by, in addition to time, which is included automatically.

The partitioning scheme is designed to work with Cribl Search. This scheme optimizes how objects are searched relative to the search's time range.

In AWS S3, bucket content is returned in ascending alphanumeric order, by default, they are sorted "oldest-first". This Destination uses alpha characters to prefix objects, so ascending sort returns them in "newest-first" order, allowing Search to find files that will likely have the requested objects soonest.

The effective partition will be `<4-letters>-YYYY/<2-letters>-MM/<2-letters>-DD/<2-letters>-HH/<list/of/fields>`. For example, `hjhh-2023/ag-07/ai-25/aj-14/<field>/`.

Backpressure behavior: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.

Tags: Optionally, add tags that you can use to filter and group Destinations in Cribl Stream's **Manage Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

Authentication

Use the **Authentication method** drop-downs to select one of these options:

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

The values for **Access key** and **Secret key** can be a constant, or a JavaScript expression (such as `${C.env.MY_VAR}`) enclosed in quotes or backticks, which allows configuration with environment variables.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Stream's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for S3: Toggle to `Yes` to use Assume Role credentials to access S3.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID in order to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports `c*` wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.

- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Max file size (MB): Maximum uncompressed output file size. Files of this size will be closed and moved to final output location. Defaults to `32`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Defaults to `30`.

Max open files: Maximum number of files to keep open concurrently. When this limit is exceeded, on any individual Worker Process, Cribl Stream will close the oldest open files, and move them to the final output location. Defaults to `100`.

Cribl Stream will close files when **any** of the four above conditions is met.

Max concurrent file parts: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send the whole file at once. When set to `2` or above, IAM permissions must include those required for multipart uploads. Defaults to `4`; highest allowed value is `10`.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined Min free disk space amount.

Add Output ID: When set to `Yes` (the default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

For a Destination originally configured in a Cribl Stream version below 2.4.0, the **Add Output ID** behavior will be switched **off** on the backend, regardless of this toggle's state. This is to avoid losing any files pending in the original staging directory, upon Cribl Stream upgrade and restart. To enable this option for such Destinations, Cribl's recommended migration path is:

- Clone the Destination.
- Redirect the Routes referencing the original Destination to instead reference the new, cloned Destination.

This way, the original Destination will process pending files (after an idle timeout), and the new, cloned Destination will process newly arriving events with **Add output ID** enabled.

Remove staging dirs: Toggle this on to delete empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Endpoint: S3 service endpoint. If empty, Cribl Stream will automatically construct the endpoint from the AWS Region. To access the AWS S3 endpoints, use the path-style URL format. You don't need to specify the bucket name in the URL, because Cribl Stream will automatically add it to the URL path. For details, see AWS' Path-Style Requests topic.

Object ACL: Object ACL (Access Control List) to assign to uploaded objects.

Storage class: Select a storage class for uploaded objects. Defaults to `Standard`. The other options are: `Reduced Redundancy Storage`; `Standard, Infrequent Access`; `One Zone, Infrequent Access`; `Intelligent Tiering`; `Glacier`; or `Deep Archive`.

Server-side encryption: Encryption type for uploaded objects – used to enable encryption on data at rest. Defaults to no encryption; the other options are `Amazon S3 Managed Key` or `AWS KMS Managed Key`.

AWS S3 always encrypts data in transit using HTTPS, with default one-way authentication from server to clients. With other S3-compatible stores (such as our native MinIO Destination), use an `https://` URL to invoke in-transit encryption. Two-way authentication is not required to get encryption, and requires clients to possess a certificate.

Signature version: Signature version to use for signing S3 requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

IAM Permissions

The following permissions are always needed to write to an Amazon S3 bucket:

- `s3:ListBucket`
- `s3:GetBucketLocation`
- `s3:PutObject`

If your Destination needs to do multipart uploads to S3, two more permissions are needed:

- `kms:GenerateDataKey`
- `kms:Decrypt`

See the AWS documentation.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

15.2.4.3. Amazon Security Lake Destination

This Destination delivers data to Amazon Security Lake, a fully-managed security data lake service backed by Amazon S3 buckets.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

Security Lake ingests events described by the Open Cybersecurity Schema Framework (OCSF) and conveyed as Parquet files. This Destination sends the Parquet files in batches. Cribl Stream does not read or replay the data sent to Security Lake.

A Complete Setup Scenario

Cribl recommends that you start with the Amazon Security Lake Integration topic, which will guide you through the following steps in the correct order:

1. Set up Amazon Security Lake.
2. Set up Cribl Stream.
3. Create an Amazon Security Lake custom source, This is an S3 bucket dedicated to a single OCSF event class.
4. Create a Cribl Amazon Security Lake Destination.
5. Connect a Cribl Source to the Amazon Security Lake Destination.
6. Send data to Amazon Security Lake.

As outlined above, you'll create and configure this Destination as the fourth of the six overall steps. The Integration topic covers the key points about configuring this Destination. Refer back to this reference topic, as needed, for details about any given setting. Some of the instructions below assume that you have recorded IDs, values, etc., from procedures you've already completed according to the Integration topic.

Although Cribl Stream does **not** need to be deployed in Cribl.Cloud in order to deliver data to Amazon Security Lake, setup procedures on Cribl>Cloud will differ from those documented here. To learn more, please contact Cribl via the `#packs` channel of Cribl Community Slack.

Configure Cribl Stream to Output to Amazon Security Lake

In Cribl Stream, configure Amazon Security Lake:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**: -**Output ID**: Enter a unique name to identify this Amazon Security Lake Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **S3 bucket name**: Name of the destination S3 Bucket you created when setting up Amazon Security Lake. This value can be a constant, or a JavaScript expression that will be evaluated only at init time. For example, referencing a Global Variable: `myBucket-${C.vars.myVar}`.

      Event-level variables are not available for JavaScript expressions. This is because the bucket name is evaluated only at Destination initialization.
    - **Region**: Region where the Amazon Security Lake is located.
    - **Account ID**: The ID of the AWS Account whose admin enabled Amazon Security Lake.
    - **Custom source name**: The name of the custom source you created in Amazon Security Lake to receive data from this Destination.
    - **Staging location**: Filesystem location in which to locally buffer files before compressing and moving to final destination. Cribl recommends that this location be stable and high-performance.

      The **Staging location** field is not displayed or available on Cribl.Cloud-managed Worker Nodes.
3. Next, you can configure the following **Optional Settings**:
    - **File name prefix expression**: The output filename prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
    - **Backpressure behavior**: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`. When this field is set to `queue`, see Persistent Queue Settings for details.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Authentication, Assume Role, Processing, Parquet, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

For the **Authentication Method**, you **must** leave the default **Auto** method selected.

This method uses the AWS instance's metadata service to automatically obtain short-lived credentials from the IAM role attached to an EC2 instance. The attached IAM role grants Cribl Stream Worker Nodes access to authorized AWS resources. Can also use the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. Works only when running on AWS.

Assume Role

For these settings, you'll enter values that you noted when creating the custom source in Security Lake.

AssumeRole ARN: The custom source's **Provider role ARN**.

External ID: In the custom source, this is the value of the `ExternalId` element of the trust relationship JSON object.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output. Use the drop-down to select the Pack you installed when setting up Cribl Stream.

System fields: Remove any fields specified here.

Parquet Settings

Row group size: Ideal memory size for row group segments. For example, 128 MB or 1 GB. Affects memory use when writing. Imposes a target, not a strict limit; the final size of a row group may be larger or smaller. Defaults to 16 MB.

Page size: Ideal memory size for page segments. For example, 1 MB or 128 MB. Generally, lower values improve reading speed, while higher values improve compression. Imposes a target, not a strict limit; the final

size of a row group may be larger or smaller. Defaults to 1 MB.

Parquet version: Which version of Parquet your schemas are in determines which data types are supported and how they are represented. Defaults to version 2.6.

Data page version: Serialization format of data pages. Note that not all reader implementations support Data page V2.

Cribl Edge Workers support Parquet only when running on Linux, not on Windows.

Advanced Settings

Max file size (MB): Maximum uncompressed output file size. Files of this size will be closed and moved to final output location. Defaults to `32`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Defaults to `30`.

Max open files: Maximum number of files to keep open concurrently. When this limit is exceeded, on any individual Worker Node Process, Cribl Stream will close the oldest open files, and move them to the final output location. Defaults to `100`.

Cribl Stream will close files when **any** of the four above conditions is met.

Max concurrent file parts: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send the whole file at once. When set to `2` or above, IAM permissions must include those required for multipart uploads. Defaults to `4`; highest allowed value is `10`.

Add Output ID: When set to `Yes` (the default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

Remove staging dirs: Toggle this on to delete empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Endpoint: Security Lake service endpoint. If empty, defaults to AWS' Region-specific endpoint. Otherwise, it must point to Security Lake-compatible endpoint.

Object ACL: Object ACL (Access Control List) to assign to uploaded objects.

Storage class: Select a storage class for uploaded objects. Defaults to `Standard`. The other options are: `Reduced Redundancy Storage`; `Standard, Infrequent Access`; `One Zone, Infrequent Access`; `Intelligent Tiering`; `Glacier`; or `Deep Archive`.

Server-side encryption: Encryption type for uploaded objects – used to enable encryption on data at rest. Defaults to no encryption; the other options are `Amazon S3 Managed Key` or `AWS KMS Managed Key`.

Amazon S3 always encrypts data in transit using HTTPS, with default one-way authentication from server to clients. Two-way authentication is not required to get encryption, and requires clients to possess a certificate.

Signature version: Signature version to use for signing Security Lake requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

IAM Permissions

The following permissions are always needed to write to an Amazon S3 bucket:

- `s3:ListBucket`

- `s3:GetBucketLocation`
- `s3:PutObject`

If your Destination needs to do multipart uploads to S3, two more permissions are needed:

- `kms:GenerateDataKey`
- `kms:Decrypt`

See the AWS documentation.

Creating and Modifying Parquet Schemas

When you need to add a new Parquet schema or modify an existing one:

1. Navigate to the Parquet Schema Library, located at **Processing** > **Knowledge** > **Parquet Schemas**.
2. Create or modify the schema, as described here.

Cribl strongly recommends that to modify an existing schema, you first clone it and give the clone its own distinct name.

3. Return to this Destination, and select the new or modified schema in the **Parquet schema** drop-down.
4. Click **Save**.

Cloning First is Safer Than Just Modifying

Modifying an existing schema in the Schema Library does **not** propagate your modifications to the Destination's copy of the schema.

- Cloning and renaming schemas is the safest approach, because in Step 3 above, it removes any doubt that your Destination will now use the newly-modified version of your schema.
- If you do **not** clone and rename the schema (i.e., you leave the schema name unchanged), you still must re-select the schema in the Destination's **Parquet schema** drop-down, and click **Save**, to bring the modified version into the Destination.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Troubleshooting Resources

Cribl University offers an Advanced Troubleshooting > Destination Integrations: S3 short course. Since Amazon Security Lake relies on S3 buckets, what you learn from the course can augment your Security Lake skills.

To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to click through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

15.2.5. Elastic

15.2.5.1. Elasticsearch Destination

Cribl Stream can send events to an Elasticsearch cluster using the Bulk API. As of v.3.3, Cribl Stream supports Elastic data streams.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

For an example of using Cribl Stream to parse and enrich inbound events for Elasticsearch, see our Splunk to Elasticsearch topic.

Configure Cribl Stream to Output to Elasticsearch

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Elasticsearch Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: When enabled (default), lets you specify multiple bulk API URLs and load weights. With the `No` setting, if you notice that Cribl Stream is not sending data to all possible IP addresses, enable **Advanced Settings** > **Round-robin DNS**.
    - **Bulk API URL or Cloud ID**: Specify either an Elasticsearch cluster or Elastic Cloud deployment to send events to. For an Elasticsearch cluster, enter a URL (for example, `http://<myElasticCluster>:9200/_bulk`). For an Elastic Cloud deployment, enter its Cloud ID. This setting is not available when **Load balancing** is enabled.
    - **Index or data stream**: Enter a JavaScript expression that evaluates to the name of the Elastic data stream or Elastic index where you want events to go. The expression is evaluated for each event, can evaluate to a constant value, and must be enclosed in quotes or backticks. An event's `__index` field can overwrite the index or data stream name.

3. Under **Authentication**, toggle **Authentication enabled** to `Yes` to display **Authentication method** dropdown. Select one of these options:
    - **Manual**: Enter your credentials directly in the resulting **Username** and **Password** fields.
    - **Secret**: Exposes a **Credentials secret** drop-down, in which you can select a stored secret that references the credentials described above. A **Create** link is available to store a new, reusable secret.
    - **Manual API Key**: Exposes an **API key** field to directly enter your Elasticsearch API key.
    - **Secret API Key**: Exposes an **API key (text secret)** drop-down, in which you can select a stored text secret that references your Elasticsearch API key. A **Create** link is available to store a new, reusable secret.
4. Next, you can configure the following **Optional Settings**:
    - **Exclude current host IPs**: This toggle appears when **Load balancing** is set to `Yes`. It determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Defaults to `No`, which keeps the current host available for load balancing.
    - **Type**: Specify document type to use for events. An event's `__type` field can overwrite this value.
    - **Backpressure behavior**: Specify whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Bulk API URLs

Use the **Bulk API URLs** table to specify a known set of receivers on which to load-balance data. To specify more receivers on new rows, click **Add URL**. Each row provides the following fields:

URL: Specify the URL to an Elastic node to send events to – for example, `http://elastic:9200/_bulk`

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (> `0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Stream will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

When you first enable load balancing, or if you edit the load weight once your data is load–balanced, give the logic time to settle. The changes might take a few seconds to register.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.

- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned. (This option is visible only when the **General Settings** > **Load balancing** option is set to `No`.)

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (s): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Extra parameters: Name-value pairs to pass as additional parameters. If you are using Elastic ingest pipelines, specify an extra parameter whose name is `pipeline` and whose value is the name of your pipeline, similar to these examples.

Elastic version: Determines how to format events. For Elastic Cloud, you must explicitly set version `7.x`. For other Elasticsearch clusters, the `Auto` default will discover the downstream Elasticsearch version automatically, but you have the option to explicitly set version `6.x` or `7.x`.

Elastic pipeline: To send data to an Elastic Ingest pipeline, optionally enter that pipeline's name as a constant. Or, enter a JavaScript expression that evaluates outgoing events and sends matching events to the desired Elastic Ingest pipeline(s). Cribl Stream will first interpret your entry as a constant and try to find a matching value in the event. If it finds no matching value, it will evaluate your **Elastic pipeline** entry as an expression.

For example, the expression `sourcetype=='access_common'?'cribl_pipeline':undefined` matches events whose `sourcetype` is `access_common`, and sends them to an Elastic Ingest pipeline named `cribl_pipeline`.

You can also specify the name of the pipeline in an event field. For example, `myPipelineField` would use the value from the event's `myPipelineField` property (if present) to identify the Elastic Ingest pipeline to process the event. Alternately, the expression `myPipelineField != null ? myPipelineField : undefined` would also identify this field. If the event does not contain such a field, `myPipelineField != null ? myPipelineField : 'theDefaultIndex'` will provide a default index. With this approach, you can override the Elastic Ingest pipeline at the event level.

See also the Elasticsearch Source documentation.

The next two fields appear only when the **General Settings** > **Load balancing** option is set to `Yes`.

DNS resolution period (seconds): Re-resolve any hostnames each time this interval recurs, and pick up destinations from the A records. Defaults to `600` seconds.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds.

Include document_id: Toggle this setting to `No` to omit the `document_id` field when sending events to an Elastic TSDS (time series data stream).

Write action: Action to use when writing events. Set this option to `Create` (default) when writing to a data stream, which is append-only. Set this option to `Index` only when you write directly to an index and need to update existing records. `Index` will fail if you use it to write to a data stream.

Failed request logging mode: Determines which data is logged when a request fails. Use the drop-down to select one of these options:

- `None` (default).
- `Payload`.
- `Payload + Headers`. Use the **Safe Headers** field below to specify the headers to log. If you leave that field empty, all headers are redacted, even with this setting.

Safe headers: List the headers you want to log, in plain text.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Field Normalization

This Destination normalizes the following fields:

- `_time` becomes `@timestamp` at millisecond resolultion.
- `host.name` is set to `host`.

See also our Elasticsearch Source documentation's **Field Normalization** section.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__id`
- `__type`
- `__index`
- `__host`

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular destination when there is a constant flow of events.

- If the server does not support keepalives (or if the server closes a pooled connection while idle), a new connection will be established for the next request.
- When resolving the Destination's hostname with load balancing disabled, Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between Elasticsearch cluster nodes.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.5.2. Elastic Cloud Destination

Cribl Stream can send events to Elastic Cloud.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

For an example of using Cribl Stream to parse and enrich inbound events for Elasticsearch, see our Splunk to Elasticsearch topic.

Configure Cribl Stream to Output to Elastic Cloud

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Elastic Cloud Destination definition.
    - **Description**: Optionally, enter a description.
    - **Cloud ID**: Enter the Cloud ID of the Elastic Cloud environment where you want to send events. You'll find it on the Deployments overview page of your Elastic Cloud environment.
    - **Data stream or index**: Enter a JavaScript expression that evaluates to the name of the Elastic data stream or Elastic index where you want events to go. The expression is evaluated for each event, can evaluate to a constant value, and must be enclosed in quotes or backticks. An event's `__index` field can overwrite the index or data stream name.
    - **Elastic pipeline**: Enter the name of the Elastic ingest pipeline (optional). You can use an expression to override the pipeline attribute received from the Elasticsearch Source.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Enter your credentials directly in the resulting **Username** and **Password** fields.
    - **Secret**: Exposes a **Credentials secret** drop-down, in which you can select a stored secret that references the credentials described above. A **Create** link is available to store a new, reusable secret.
    - **Manual API Key**: Exposes an **API key** field to directly enter your Elasticsearch API key.

- **Secret API Key**: Exposes an **API key (text secret)** drop-down, in which you can select a stored text secret that references your Elasticsearch API key. A **Create** link is available to store a new, reusable secret.

4. Next, you can configure the following **Optional Settings**:
   - **Backpressure behavior**: Specify whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (s): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Extra parameters: Name-value pairs to pass as additional parameters. If you are using Elastic ingest pipelines, specify an extra parameter whose name is `pipeline` and whose value is the name of your pipeline, similar to these examples.

Include document_id: Toggle this setting to `No` to omit the `document_id` field when sending events to an Elastic TSDS (time series data stream).

Failed request logging mode: Determines which data is logged when a request fails. Use the drop-down to select one of these options:

- `None` (default).
- `Payload`.
- `Payload + Headers`. Use the **Safe Headers** field below to specify the headers to log. If you leave that field empty, all headers are redacted, even with this setting.

Safe headers: List the headers you want to log, in plain text.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Field Normalization

This Destination normalizes the following fields:

- `_time` becomes `@timestamp` at millisecond resolultion.
- `host.name` is set to `host`.

See also our Elasticsearch Source documentation's **Field Normalization** section.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__id`

- `__type`
- `__index`
- `__host`

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), a new connection will be established for the next request.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.6. Google Cloud

15.2.6.1. Google Security Operations (SecOps) Destination

Cribl Stream supports sending data to Security Operations (SecOps), a cloud service for retaining, analyzing, and searching enterprise security and network telemetry data. This service was formerly known as Google Chronicle.

if you plan to use **V2** of the Google Security Operations API, you need your Google service account credentials to define a Google SecOps Destination.

If you plan to use **V1** of the Google Security Operations API, Cribl recommends using Google service account credentials for authentication, but alternatively, you can opt to use an API key from Google.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Output to SecOps

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this SecOps output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Send events as**: From the drop-down, choose how you want the Destination to send data to SecOps. The options are: **Unstructured** and **UDM**. See Options for Sending Data to SecOps below to learn about the differences between working with `Unstructured` and already-structured `UDM` data.
    - **API version**: The version of the Google Security Operations Ingestion API you want the Destination to use when communicating with SecOps. Defaults to `V2`.

- **Default log type**: This setting is available only when **Send events as** is set to `Unstructured` (the default). From the drop-down, select a log type to assign to events that lack a `__logType` field. For any events that **do** have a `__logType` field, Cribl Stream uses the value in that field, not the default log type. See Working with Log Types below to learn how Cribl Stream populates the drop-down and how to add log types missing from it.
  When **API version** is set to `V2` (the default), one or both of the following additional controls appear in **General Settings**:
- **Namespace**: This setting is available only when **Send events as** is set to `Unstructured` (the default). Optionally, configure an environment namespace to identify logs' originating data domain. You can use this as a tag when indexing and/or enriching data. The `__namespace` event field, if present, will overwrite this.
- **Customer ID**: A unique identifier (UUID) corresponding to a particular SecOps instance. To use this optional field, request the ID from your SecOps representative.
  When **API version** is set to `V1` and **Send events as** is set to `Unstructured`, both **Namespace** and **Customer ID** appear under **Optional Settings**.

3. Next, you can configure the following **Optional Settings**: When **General Settings** > **Send events as** is set to `Unstructured` (the default), the UI displays some or all of these settings, depending on how **API version** is set.
   - **Custom log types**: For each log type you want to define, click **Add type** and enter values for **Log type** and **Description** in the resulting table row. See Working with Log Types above for more details.
   - **Namespace**: Appears here when **API version** is set to `V1`. Described in **General Settings** above.
   - **Customer ID**: Appears here when **API version** is set to `V1`. Described in **General Settings** above.
   - **Custom labels**: You can (optionally) define labels for the Destination to add to events. These "custom labels" are a Google SecOps feature used for data role-based access control (data RBAC) and other purposes. See the Google SecOps documentation. Click **Add label** to create a new label and specify it as a key-value pair.
   - **Log text field**: Specify the event field that contains the log text to send. If you do not specify a log text field, Cribl Stream sends a JSON representation of the whole event.

     (The following settings are available regardless of how **General Settings** > **Send events as** is set.)

   - **Region**: The Google SecOps regional endpoint to send events to.
   - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Working with Log Types

Google SecOps supports a dynamic list of log types that evolves over time. Cribl Stream periodically updates the **Default log type** drop-down with the latest list from Google. However, if you need to use a log type that is not yet included in the drop-down or an older log type that has been removed, you can define and manage these log types using the **Custom log types** table under **Optional Settings**.

How Log Types are Assigned

- Event-specific: When processing an event, Cribl Stream first checks if the event has a `__logType` field. If this field is present, its value determines the log type for that event.
- Default: If the event lacks a `__logType` field, Cribl Stream assigns the log type specified in the **Default log type** drop-down.
- Custom: If the **Default log type** is set to `Custom`, Cribl Stream will use the first custom log type listed in the **Custom log types** table. Reorder the custom log types in the table using the grab handles to prioritize which custom log type should be used as the default. If the **Default log type** is set to a specific log type (not `Custom`), the custom log types defined in the **Custom log types** table will not be used as defaults. However, you can still use these custom log types by explicitly setting the `__logType` field in your events to one of the custom log types.

For Google's latest list of supported log types, see the API documentation or send a `GET` request to https://malachiteingestion-pa.googleapis.com/v1/logtypes.

Authentication

To complete this part of the Destination definition, you will need either a Google Security Operations API key or your Google SecOps service account credentials. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.

Use the **Authentication method** drop-down to select an option. Whether you have set **General Settings** > **API version** to `V2` or `V1` determines what options are displayed.

For API version `V2`, the options are:

- **Service Account Credentials**: This option exposes a field where you can enter your Google SecOps service account directly.
- **Service Account Credentials Secret**: This option exposes a drop-down, in which you can select a stored secret that references your Google SecOps service account. A **Create** link is available to store a new,

reusable secret.

For API version `V1`, the options include the two listed above plus two more:

- **API key**: This option exposes a field where you can enter your Google Security Operations API key.
- **API Key Secret**: This option exposes a drop-down, in which you can select a stored secret that references your Google Security Operations API key. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Options for Sending Data to SecOps

The options for Sending Data to SecOps are:

- Sending `Unstructured` data that SecOps then parses into UDM (Unified Data Model).
- Sending data **already structured** as `UDM`, bypassing the SecOps parsers.

Sending unstructured data to SecOps is best for writing **well-known data types** to SecOps. SecOps runs the unstructured data through a series of parsers that transform it to satisfy the required UDM schema. Where this can break down is when you need to write less-usual data types, which can stump SecOps's parsers, leading to parsing errors and additional time spent troubleshooting.

Sending data already structured as UDM into SecOps bypasses the parsing gauntlet. When the customer is working with **less-usual or unique, proprietary data types** that could confound the parsers, this can be essential.

Overall, support for sending data already structured as UDM provides more control and flexibility to land more data in SecOps. To gain that flexibility, you must be prepared to "own" the data transformation into UDM before sending it to SecOps – this method "gives you the keys." You will need to use Pipelines and Functions to transform your initially unstructured data to UDM before routing it to this Destination.

Processing Settings

Post-Processing

Pipeline: In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data from this input before the data is sent through the Routes.

System fields: Specify any fields you want Cribl Stream to automatically add to events using this output. Wildcards are supported. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, `429 (Too Many Requests)` and `503 (Service Unavailable)` are the only response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `30000` (30 seconds).
- **Backoff multiplier**: The base for the exponential backoff algorithm; defaults to `1`. A value of `2` means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Defaults to `30000` (30 seconds); minimum is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `Yes`.

Round-robin DNS: Enable to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Enter an amount of time, in seconds, to wait for a request to complete before aborting it. Defaults to `90`.

Request concurrency: Enter the maximum number of ongoing requests to allow before blocking.

Max body size (KB): Maximum size of the request body before compression. Defaults to `1024` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to five times the max body size (if set). If `0`, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Enter the maximum number of events to include in the request body. Defaults to `0` (unlimited).

Flush period (sec): Enter the maximum time to allow between requests. Be aware that small values could cause the payload size to be smaller than the configured **Max body size**.

Extra HTTP Headers: Click **Add Header** to insert extra headers as **Name/Value** pairs. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.6.2. Google Cloud Logging Destination

Cribl Stream supports sending log data to Google Cloud Logging, a real-time log storage and management service with search, analysis and alerting.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Output to Google Cloud Logging

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Google Cloud Logging definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Log location type**: Select an option from the dropdown to determine where your log entries are categorized. Choose **Project**, **organization**, **Billing Account**, or **Folder**. For details, see Log Location Types.
    - **Log name expression**: Enter a JavaScript expression to compute the log name's value.
3. Under **Field Mappings**, configure the following:
    - **Payload format**: Select an option from the dropdown specify how data is structured within a log entry. Choose `Text` or `JSON`. For details, see Field Mappings

      This Destination compresses all payloads, using gzip.
    - **Log labels**: Click **Add label** to apply one or more labels to log entries. On each row of the resulting table, define each label with:
    - **Label**: Arbitrary name for the label.
    - **Value**: JavaScript expression to compute the label's value.

- **Resource type expression**: JavaScript expression to compute the field value for the managed resource type. Must evaluate to one of the monitored resource types listed here. If not specified, falls back to `global`.
- **Resource labels**: Click **Add label** to apply one or more labels to the managed resource. For details, see Resource Labels.
- **Severity expression**: JavaScript expression to compute the severity field's value. Must evaluate to one of the `LogSeverity` values listed here. Case-insensitive. If not specified, falls back to `DEFAULT`.
- **Insert ID expression**: JavaScript expression to compute the insert ID field's value.

4. Next, you can configure the following **Optional Settings**:
   - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Authentication, Processing, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Log Location Types

Log Location Types allow you to categorize your log entries based on organizational structures. Choose one of the following options to associate log entries with a specific project, organization, billing account, or folder:

- `Project`: Displays a **Project ID expression** field. Here, enter a JavaScript expression to compute the value of the project ID to associate log entries with.
- `Organization`: Displays a **Organization ID expression** field. Enter a JS expression to compute the value of the organization ID to associate log entries with.
- `Billing Account`: Displays a **Billing account ID expression** field. Enter a JS expression to compute the value of the billing account ID to associate log entries with.
- `Folder`: Displays a **Folder expression** field. Enter a JS expression to compute the value of the folder ID to associate log entries with.

Field Mappings

Field Mappings specify how log entries should be structured. Choose one of the following options:

- `Text`: This default option displays a **Payload text expression** field. Here, enter JavaScript expression to compute the payload's value. Must evaluate to a JavaScript string value; if validation fails, this will default

to a JSON string representation of the event.

- `JSON`: Displays a **Payload object expression** field. Enter a JS expression to compute the payload's value. Must evaluate to a JavaScript object value; if validation fails, this will default to the entire event.

Resource Labels

Each **Resource label** must correspond to a valid label for the resource type you've specified in the **Resource type expression**, or else Google Cloud Logging will drop it. On each row of the resulting table, define each label with:

- **Label**: Arbitrary name for the label.
- **Value**: JavaScript expression to compute the label's value.

Authentication

Use the **Authentication method** drop-down to select one of these options:

- **Auto**: This option uses the `GOOGLE_APPLICATION_CREDENTIALS` environment variable, and requires no configuration here.
- **Manual**: This default option displays a **Service account credentials** field for you to enter the contents of your service account credentials file (a set of JSON keys), as downloaded from Google Cloud. To insert the file itself, click the upload button at this field's upper right. As an alternative, you can use environment variables, as outlined here.
- **Secret**: This option exposes a drop-down in which you can select a stored secret that references the service account credentials described above. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish before retrying. Defaults to `10000` (10 sec.).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30` sec.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. Defaults to `0` (unlimited).

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` sec.

Throttle request rate: Enter a maximum number of requests to send per second, as necessary to comply with Google Cloud's API limits. This field defaults to empty (no throttling), and accepts throttling rates as high as `2000` requests per second.

Environment: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

Google Cloud Roles and Permissions

Your Google Cloud service account must have at least the following role:

- `Logs Writer`

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.6.3. Google Cloud Pub/Sub Destination

Cribl Stream supports sending data to Google Cloud Pub/Sub, a managed real-time messaging service for sending and receiving messages between applications.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Prerequisites

When working with Google Cloud Pub/Sub, you need to know:

- The project where your credentials originated.
- The project that contains any topic you want to work with.

If the desired topic resides in the same project where your credentials originated, describe it using either its short name **or** its fully-qualified name.

If the desired topic resides in a different project than the one where your credentials originated, you **must** describe it using its fully-qualified name.

Here's an example of a fully-qualified topic name: `projects/my-project-id/topics/my-topic-id`.

The short name for the same topic would be: `my-topic-id`.

Configure Cribl Stream to Output to Pub/Sub

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Pub/Sub output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.

    - **Topic ID**: ID of the Pub/Sub topic to send events to. This static initial configuration of the topic is required; but you can optionally also override it dynamically on a per-event basis.

3. Next, you can configure the following **Optional Settings**:

- **Create topic**: Toggle to `Yes` if you want Cribl Stream to create the topic on Pub/Sub if it does not exist.
- **Ordered delivery**: Toggle to `Yes` if you want Cribl Stream to send events in the order that they arrived in the queue. For ordered delivery to work correctly, ensure that both the process receiving events and the subscription from which messages are read have ordered delivery enabled.
- **Region**: Region to publish messages to. Select `default` to allow Google to auto-select the nearest region. (If you've enabled **Ordered delivery**, the selected region must be allowed by message storage policy.)
- **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Persistent Queue, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication method** drop-down to select one of these options:

- **Auto**: This option uses the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to provide the location of a credential JSON file. The environment variable can also be set directly in JSON format. When this option is set, Cribl Stream will first check whether the `GOOGLE_APPLICATION_CREDENTIALS` environment variable exists and properly set with valid credentials. If this environmental variable is missing or incorrect, Cribl Stream checks for credentials in two additional fallback locations, as described in the official Google Cloud documentation: How Application Default Credentials works. In addition to using the `GOOGLE_APPLICATION_CREDENTIALS` environment variable, you can use credentials attached to your Google Cloud instance.
- **Manual**: This default option displays a **Service account credentials** field for you to enter the contents of your service account credentials file (a set of JSON keys), as downloaded from Google Cloud.
  To insert the file itself, select the upload button at this field's upper right. As an alternative, you can use environment variables, as outlined here.
- **Secret**: This option exposes a drop-down in which you can select a stored secret that references the service account credentials described above. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.

- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Batch size: The maximum number of items the Google API should batch before it sends them to the topic. Defaults to `10` items.

Batch timeout (ms): The maximum interval (in milliseconds) that the Google API should wait to send a batch (if the configured **Batch size** limit has not been reached).. Defaults to `100` ms.

Max queue size: Maximum number of queued batches before blocking. Defaults to `100`.

Max batch size (KB): Maximum size for each sent batch. Defaults to `256` KB.

Max concurrent requests: The maximum number of in-progress API requests before Cribl Stream applies backpressure. Defaults to `10`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Google Cloud Roles and Permissions

Your Google Cloud service account should have at least the following roles on topics:

- `roles/pubsub.publisher`
- `roles/pubsub.viewer` or `roles/viewer`

To enable Cribl Stream's **Create topic** option, your service account should have one of the following (or higher) roles:

- `roles/pubsub.editor`
- `roles/editor`

Either `editor` role confers multiple permissions, including those from the lower `viewer`, `subscriber`, and `publisher` roles. For additional details, see the Google Cloud Access Control topic.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Let's Change the Topic

The Pub/Sub Destination supports alternate topics specified at the event level in the `__topicOut` field. So (for example) if a Pub/Sub Destination is configured to send to main topic `topic1`, and Cribl Stream receives an event with `__topicOut: topic2`, then Cribl Stream will override the main topic and send this event to `topic2`.

However, a topic specified in the event's `__topicOut` field must already exist on Pub/Sub. If it does not, Cribl Stream cannot dynamically create the topic, and will drop the event. On the Destination's **Status** tab, the **Dropped** metric tracks the number of events dropped because a specified alternate topic did not exist.

(This example uses the short topic name, and that works as long as the topic resides in the project where your GCP credentials originated. If the topic resides in a different project, you must use the fully-qualified topic name, for example `__topicOut: projects/<my-project-id>/topics/topic2`.)

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.6.4. Google Cloud Storage Destination

Google Cloud Storage is a non-streaming Destination type.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

Configure Cloud Storage Permissions

Configure access permissions on the Cloud Storage side based on the authentication method you'll use on this Destination:

- **Auto authentication**: Supports both uniform and fine-grained access control.
- **Manual authentication**: Requires fine-grained access control on the buckets because it relies on ACLs to access resources.

The Google service account or user can have the Storage Admin or Owner role. For narrower access, the Google account should have the following access to buckets:

- `roles/storage.objectCreator` role.
- `roles/storage.objectViewer` role.
- If the `Verify if bucket exists` advanced option is enabled, one bucket-level `storage.buckets.list` permission.

For details, see the Cloud Storage Overview of Access Control and Understanding Roles documentation.

Configure Cribl Stream to Output to Cloud Storage Destinations

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:

- **Output ID**: Enter a unique name to identify this Cloud Storage definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
- **Description**: Optionally, enter a description.
- **Bucket name**: Name of the destination bucket. This value can be a constant, or a JavaScript expression that can be evaluated only at init time. For example, referencing a Global Variable: `myBucket-${C.vars.myVar}`.
- **Region**: Region where the bucket is located.
- **Staging location**: Filesystem location in which to locally buffer files before compressing and moving to final destination. Cribl recommends that this location be stable and high-performance.

  In Cribl Stream, the **Staging location** field is not displayed or available on Cribl.Cloud-managed Worker Groups.

- **Key prefix**: Root directory to prepend to path before uploading. Enter a constant, or a JS expression enclosed in single quotes, double quotes, or backticks.
- **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (supported only on Linux, not Windows) exposes a Parquet Settings left tab, where you **must** configure certain options in order to export data in Parquet format.

3. Next, you can configure the following **Optional Settings**:
   - **Partitioning expression**: JavaScript expression that defines how files are partitioned and organized. Default is date-based. If blank, Cribl Stream will fall back to the event's `__partition` field value (if present); or otherwise to the root directory of the **Output Location** and **Staging Location**.
   - **Compress**: Data compression format used before moving to final destination. Defaults to `gzip` (recommended). This setting is not available when **Data format** is set to `Parquet`.
   - **File name prefix expression**: The output filename prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
   - **File name suffix expression**: The output filename suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ' ``
     where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.

     To prevent files from being overwritten, Cribl appends a random sequence of 6 characters to the end of their names. This also applies to prefix and suffix expressions in file names.

     For example, if you set the **File name prefix expression** to `CriblExec` and set the **File name suffix expression** to `.csv`, the file name might display as `CriblExec-adPRWM.csv` with `adPRWM` appended.

- **Backpressure behavior**: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Parquet, Processing, Retries and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication method** drop-down to select one of these options:

- **Auto**: This option authenticates with the attached Google Cloud Platform (GCP) Service Account, relying on GCP IAM roles to access the appropriate GCP resources. This option is available only when Cribl Stream is on-prem, and the Worker Nodes are running in Google Compute Engine VMs on GCP. Supports both uniform and fine-grained access control.
- **Manual**: With this default option, authentication is via HMAC (Hash-based Message Authentication Code). To create a key and secret, see Google Cloud's Managing HMAC Keys for Service Accounts documentation. This option requires fine-grained access control on the GCS bucket because it relies on ACLs to access resources. Uniform access control is not supported with this method. This option exposes these two fields:
  - **Access key**: Enter the HMAC access key.
  - **Secret key**: Enter the HMAC secret.

The values for **Access key** and **Secret key** can be a constant, or a JavaScript expression (such as `${C.env.MY_VAR}`) enclosed in quotes or backticks, which allows configuration with environment variables.

- **Secret**: This option exposes a **Secret key pair** drop-down, in which you can select a stored secret that references the secret key pair described above. A **Create** link is available to store a new, reusable secret.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports `c*` wildcards. Other

options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Stream CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Working with Parquet for pointers on how to avoid problems such as data mismatches.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Stream writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported, and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: Set the target memory size for page segments. Generally, set lower values to improve reading speed, or set higher values to improve compression. Value must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle to `Yes` to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics – these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Advanced Settings

Max file size (MB): Maximum uncompressed output file size. Files of this size will be closed and moved to final output location. Defaults to `32`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Defaults to `30`.

Max open files: Maximum number of files to keep open concurrently. When exceeded, the oldest open files will be closed and moved to final output location. Defaults to `100`.

Cribl Stream will close files when **either** of the `Max file size (MB)` or the `Max file open time (sec)` conditions are met.

Add Output ID: Whether to append output's ID to staging location. Defaults to `Yes`.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined Min free disk space amount.

Remove staging dirs: Toggle this on to delete empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Endpoint: The Google Cloud Storage service endpoint. Typically, there is no reason to change the default https://storage.googleapis.com endpoint.

Object ACL: Select an Access Control List to assign to uploaded objects. Defaults to `private`.

Storage class: Select a storage class for uploaded objects.

Signature version: Signature version to use for signing requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Common Issue

Nonspecific messages from Google Cloud of the form `Error: failed to close file` can indicate problems with the permissions listed above.

15.2.7. Kafka

15.2.7.1. Kafka Destination

Cribl Stream supports sending data to a Kafka topic.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Kafka uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Stream must send events directly to receivers. You might need to adjust your firewall rules to allow this traffic.

Configure Cribl Stream to Output to Kafka

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Kafka definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Brokers**: List of Kafka brokers to connect to (for example, `localhost:9092`).
    - **Topic**: The topic on which to publish events. Can be overwritten using event's `__topicOut` field.
3. Next, you can configure the following **Optional Settings**:
    - **Acknowledgments**: Select the number of required acknowledgments. Defaults to `Leader`.
    - **Record data format**: Format to use to serialize events before writing to Kafka. Defaults to `JSON`. When set to `Protobuf`, the **Protobuf Format Settings** section (left tab) becomes available.
    - **Compression**: Codec to compress the data before sending to Kafka. Select `None`, `Gzip` `Snappy`, or `LZ4`.

      Cribl strongly recommends enabling compression. Doing so improves Cribl Stream's performance, enabling faster data transfer using less bandwidth.

- **Backpressure behavior**: Select whether to block, drop, or queue incoming events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Persistent Queue, TLS, Authentication, Processing, Retries, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high

as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Calculating the Time PQ Will Take to Engage

PQ will not engage until Cribl Stream has exhausted all attempts to send events to the Kafka receiver. This can take several minutes if requests continue to fail or time out.

To calculate the longest possible time this can take, multiply the values of **Request timeout** and **Max retries**. For the default values (`60` seconds and `5`, respectively), this would be `60` seconds times `5` retries = 300 seconds, or 5 minutes.

TLS Settings (Client Side)

Enabled Defaults to `No`. When toggled to `Yes`:

- **Validate server certs**: Require client to reject any connection that is not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `No`.

Server name (SNI): Leave this field blank. See Connecting to Kafka below.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Authentication

This section documents the SASL (Simple Authentication and Security Layer) authentication settings to use when connecting to brokers. Using TLS is highly recommended.

Enabled: Defaults to `No`. When toggled to `Yes`:

SASL mechanism: Use this drop-down to select the SASL authentication mechanism to use. The mechanism you select determines the controls displayed below.

PLAIN, SCRAM-256, or SCRAM-512

With any of these SASL mechanisms, select one of the following buttons:

Manual: Displays **Username** and **Password** fields to enter your Kafka credentials directly.

Secret: This option exposes a **Credentials secret** drop-down in which you can select a stored text secret that references your Kafka credentials. A **Create** link is available to store a new, reusable secret.

GSSAPI/Kerberos

Kerberos authentication is not supported for Cribl-managed Workers in Cribl.Cloud, but it is enabled for customer-managed (hybrid or on-prem) Worker Groups, whether the Leader is based in Cribl.Cloud or on-prem.

Selecting Kerberos as the authentication mechanism displays the following options:

Keytab location: Enter the location of the keytab file for the authentication principal.

Principal: Enter the authentication principal, for example: `kafka_user@example.com`.

Broker service class: Enter the Kerberos service class for Kafka brokers, for example: `kafka`.

You will also need to set up your environment and configure the Cribl Stream host for use with Kerberos. For details, see Kafka Authentication with Kerberos.

Schema Registry

This section governs Kafka Schema Registry Authentication for Avro-encoded data with a schema stored in the Confluent Schema Registry.

Enabled: defaults to `No`. When toggled to `Yes`, displays the following controls:

Schema registry URL: URL for access to the Confluent Schema Registry. (For example, `http://localhost:8081`.)

Default key schema ID: Used when `__keySchemaIdOut` is not present to transform key values. Leave blank if key transformation is not required by default.

Default value schema ID: Used when `__valueSchemaIdOut` not present to transform `_raw`. Leave blank if value transformation is not required by default.

Connection timeout (ms): Specifies the maximum time allowed for establishing a successful connection to the schema registry. Defaults to 30000 ms (30 seconds). Valid range is 1000 ms - 60000 ms (or 1 sec to 60 sec).

Request timeout (ms): Maximum time to wait for a successful request from the schema registry. Defaults to 60000 ms (or 1 minute).

Retry Limit: Max number of times to retry requests to the schema registry before dropping the outgoing message. Defaults to 1; enter 0 to not retry at all.

Authentication enabled: Toggle to `Yes` if your schema registry requires authentication.

- **Credentials secret**: Select or **Create** a stored text secret containing the username and password provided by your schema registry administrator.

TLS enabled: defaults to `No`. When toggled to `Yes`, displays the following TLS settings for the Schema Registry (in the same format as the TLS Settings (Client Side) above):

- **Validate server certs**: Require client to reject any connection that is not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `No`.
- **Server name (SNI)**: Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.
- **Minimum TLS version**: Optionally, select the minimum TLS version to use when connecting.
- **Maximum TLS version**: Optionally, select the maximum TLS version to use when connecting.
- **Certificate name**: The name of the predefined certificate.
- **CA certificate path**: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.
- **Private key path (mutual auth)**: Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.
- **Certificate path (mutual auth)**: Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.
- **Passphrase**: Passphrase to use to decrypt private key.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Max retries: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2`-`20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Max record size (KB, uncompressed): Maximum size (KB) of each record batch before compression. Setting should be < `message.max.bytes settings` in Kafka brokers. Defaults to `768`.

Max events per batch: Maximum number of events in a batch before forcing a flush. Defaults to `1000`.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Connection timeout (ms): Maximum time to wait for a successful connection. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour).

Request timeout (ms): Maximum time to wait for a successful request. Defaults to `60000` ms (1 minute).

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Stream initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Destination from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Destination to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Protobuf Format Settings

Definition set: From the drop-down, select `OpenTelemetry`. This makes the **Object type** setting available.

Object type: From the drop-down, select `Logs`, `Metrics`, or `Traces`.

Working with Protobufs

This Destination supports supports Binary Protobuf payload encoding. The Protobufs it sends can encode traces, metrics, or logs, the three types of telemetry data defined in the OpenTelemetry Project's Data Sources documentation:

- A **trace** tracks the progression of a single request.

    - Each trace is a tree of **spans**.
    - A span object represents the work being done by the individual services, or components, involved in a request as that request flows through a system.
- A **metric** provides aggreggated statistical information.
    - A metric contains individual measurements called **data points**.
- A **log**, in OpenTelemetry terms, is "any data that is not part of a distributed trace or a metric".

When configuring Pipelines (including pre-processing and post-processing Pipelines), you need to ensure that events sent to this Destination conform to the relevant Protobuf specification:

- For traces, opentelemetry/proto/trace/v1/trace.proto.
- For metrics, opentelemetry/proto/metrics/v1/metrics.proto.
- For logs, opentelemetry/proto/logs/v1/logs.proto.

This Destination will drop non-conforming events. If the Destination encounters a parsing error when trying to convert an event to OTLP, it discards the event and Cribl Stream logs the error.

Connecting to Kafka

Leave the TLS Settings > Server name (SNI) field blank

In Cribl Stream's Kafka-based Sources and Destinations (including this one), the Kafka library that Cribl Stream uses manages SNI (Server Name Indication) without any input from Cribl Stream. Therefore, you should leave the **TLS Settings** > **Server name (SNI)** field blank.

Setting this field in the Cribl Stream UI can cause traffic to be routed to the wrong brokers, because it interferes with the Kafka library's operation.

Connecting to a Kafka cluster entails working with hostnames for **brokers** and **bootstrap servers**.

Brokers are servers that comprise the storage layer in a Kafka cluster. Bootstrap servers handle the initial connection to the Kafka cluster, and then return the list of brokers. A broker list can run into the hundreds. Every Kafka cluster has a `bootstrap.servers` property, defined as either a single `hostname:port` K-V pair, or a list of them. If Cribl Stream tries to connect via one bootstrap server and that fails, Cribl Stream then tries another one on the list.

In the **General Settings** > **Brokers** list, you can enter either the hostnames of brokers that your Kafka server has been configured to use, or, the hostnames of one or more bootstrap servers. If Kafka returns a list of brokers that's longer than the list you entered, Cribl Stream keeps the full list internally. Cribl Stream neither saves the list nor makes it available in the UI. The connection process simply starts at the beginning whenever the Source or Destination is started.

Here's an overview of the connection process:

1. From the **General Settings** > **Brokers** list – where each broker is listed as a hostname and port – Cribl Stream takes a hostname and resolves it to an IP address.
2. Cribl Stream makes a connection to that IP address. Notwithstanding the fact that Cribl Stream resolved **one** particular hostname to that IP address, there may be **many** services running at that IP address – each with its own distinct hostname.
3. Cribl Stream establishes TLS security for the connection.

Although SNI is managed by the Kafka library rather than in the Cribl Stream UI, you might want to know how it fits into the connection process. The purpose of the SNI is to specify one hostname – that is, service – among many that might be running on a given IP address within a Kafka cluster. Excluding the other services is one way that TLS makes the connection more secure.

Working with Event Timestamps

By default, when an incoming event reaches this Destination, the underlying Kafka JS library adds a `timestamp` field set to the current time at that moment. The library gets the current time from the `Date.now()` JavaScript method. Events that this Destination sends to downstream Kafka receivers include this `timestamp` field.

Some production situations require the `timestamp` value to be the time an incoming event was originally created by an upstream sender, not the current time of its arrival at this Destination. For example, suppose the events were originally created over a wide time range, and arrive at the Destination hours or days later. In this case, the original creation time might be important to retain in events Cribl Stream sends to downstream Kafka receivers.

Here is how to satisfy such a requirement:

1. In a Pipeline that routes events to this Destination, use an Eval Function to add a field named `__kafkaTime` and write the incoming event's original creation time into that field. The value of `__kafkaTime` **must** be in UNIX epoch time (either seconds or milliseconds since the UNIX epoch – both will work). For context, see this explanation of the related fields `_time` and `__origTime`.
2. This Destination will recognize the `__kafkaTime` field and write its value into the `timestamp` field. (This is similar to the way you can use the `__topicOut` field to overwrite a topic setting, as described above.)

If the `__kafkaTime` field is **not** present, the Destination will apply the default behavior (using `Date.now()`) described previously.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__topicOut`
- `__key`
- `__headers`
- `__keySchemaIdOut`
- `__valueSchemaIdOut`

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.7.2. Confluent Cloud Destination

Cribl Stream supports sending data to Kafka topics on the Confluent Cloud managed Kafka platform.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Confluent Cloud uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Stream must send events directly to receivers. You might need to adjust your firewall rules to allow this traffic.

Send Kafka Topic Data to Confluent Cloud

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition.
    - **Description**: Optionally, enter a description.
    - **Bootstrap servers**: List of Confluent Cloud bootstrap servers to connect to (for example, `myAccount.confluent.cloud:9092`).
    - **Topic**: The topic on which to publish events. Can be overwritten using event's `__topicOut` field.
3. Next, you can configure the following **Optional Settings**:
    - **Acknowledgments**: Select the number of required acknowledgments. Defaults to `Leader`.
    - **Record data format**: Format to use to serialize events before writing to Kafka. Defaults to `JSON`. When set to `Protobuf`, the **Protobuf Format Settings** section (left tab) becomes available.
    - **Compression**: Codec to use to compress the data before sending to Kafka. Select `None`, `Gzip`, `Snappy`, or `LZ4`. Defaults to `Gzip`.
    - **Backpressure behavior**: Select whether to block, drop, or queue incoming events when all receivers are exerting backpressure. Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any Persistent Queue, Authentication, TLS, Schema Registry, Processing, Retries, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Calculating the Time PQ Will Take to Engage

PQ will not engage until Cribl Stream has exhausted all attempts to send events to the Kafka receiver. This can take several minutes if requests continue to fail or time out.

To calculate the longest possible time this can take, multiply the values of **Request timeout** and **Max retries**. For the default values (`60` seconds and `5`, respectively), this would be `60` seconds times `5` retries = 300 seconds, or 5 minutes.

TLS Settings (Client Side)

Enabled When toggled to `Yes` (the default):

Autofill?: This setting is experimental.

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (such as the system's CA).

Server name (SNI): Leave this field blank. See Connecting to Kafka below.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Authentication

This section documents the SASL (Simple Authentication and Security Layer) authentication settings to use when connecting to bootstrap servers. Using TLS is highly recommended.

Enabled: Defaults to `No`. When toggled to `Yes`:

- **SASL mechanism**: Select the SASL (Simple Authentication and Security Layer) authentication mechanism to use. Defaults to `PLAIN`. `SCRAM-SHA-256`, `SCRAM-SHA-512`, and `GSSAPI/Kerberos` are also available. The mechanism you select determines the controls displayed below.

PLAIN, SCRAM-256, or SCRAM-512

With any of these SASL mechanisms, select one of the following buttons:

Manual: Displays **API key** and **Secret** fields to enter your Kafka credentials directly.

Secret: This option exposes a **Credentials secret** drop-down in which you can select a stored text secret that references your Kafka credentials. A **Create** link is available to store a new, reusable secret.

GSSAPI/Kerberos

Kerberos authentication is not supported for Cribl-managed Workers in Cribl.Cloud, but it is enabled for on-prem Worker Groups, whether the Leader is based in Cribl.Cloud or on-prem.

Selecting Kerberos as the authentication mechanism displays the following options:

Keytab location: Enter the location of the keytab file for the authentication principal.

Principal: Enter the authentication principal, for example: `kafka_user@example.com`.

Broker service class: Enter the Kerberos service class for Kafka brokers, for example: `kafka`.

You will also need to set up your environment and configure the Cribl Stream host for use with Kerberos. See Kafka Authentication with Kerberos for further detail.

Schema Registry

This section governs Kafka Schema Registry Authentication for Avro-encoded data with a schema stored in the Confluent Schema Registry.

Enabled: Defaults to `No`. When toggled to `Yes`, displays the following controls:

Schema registry URL: URL for access to the Confluent Schema Registry. (For example, `http://localhost:8081`.)

Default key schema ID: Used when `__keySchemaIdOut` is not present to transform key values. Leave blank if key transformation is not required by default.

Default value schema ID: Used when `__valueSchemaIdOut` not present to transform `_raw`. Leave blank if value transformation is not required by default.

Connection timeout (ms): Specifies the maximum time allowed for establishing a successful connection to the schema registry. Defaults to 30000 ms (30 seconds). Valid range is 1000 ms to 60000 ms (or 1 sec to 60 sec).

Request timeout (ms): Maximum time to wait for a successful request from the schema registry. Defaults to 60000 ms (or 1 minute).

Retry Limit: Max number of times to retry requests to the schema registry before dropping the outgoing message. Defaults to 1; enter 0 to not retry at all.

Authentication enabled: Toggle to `Yes` if your schema registry requires authentication.

- **Credentials secret**: Select or **Create** a stored text secret containing the username and password provided by your schema registry administrator.

TLS enabled: defaults to `No`. When toggled to `Yes`, displays the following TLS settings for the Schema Registry (in the same format as the TLS Settings (Client Side) above):

- **Validate server certs**: Require client to reject any connection that is not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `No`.
- **Server name (SNI)**: Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

With a dedicated Confluent Cloud cluster hosted in Microsoft Azure, be sure to specify the **Server name (SNI)**. If this is omitted, Confluent Cloud might reset the connection to Cribl Stream.

- **Minimum TLS version**: Optionally, select the minimum TLS version to use when connecting.
- **Maximum TLS version**: Optionally, select the maximum TLS version to use when connecting.
- **Certificate name**: The name of the predefined certificate.
- **CA certificate path**: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.
- **Private key path (mutual auth)**: Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.
- **Certificate path (mutual auth)**: Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.
- **Passphrase**: Passphrase to use to decrypt private key.

Processing Settings

Post-Processing

In this section's **Pipeline** drop-down list, you can select a single existing Pipeline to process data before it is sent through this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Max retries: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2`-`20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Max record size (KB, uncompressed): Maximum size (KB) of each record batch before compression. Setting should be < `message.max.bytes settings` in Kafka brokers. Defaults to `768`.

Max events per batch: Maximum number of events in a batch before forcing a flush. Defaults to `1000`.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Connection timeout (ms): Maximum time to wait for a successful connection. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour).

Request timeout (ms): Maximum time to wait for a successful request. Defaults to `60000` ms (1 minute).

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Stream initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Destination from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Destination to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Protobuf Format Settings

Definition set: From the drop-down, select `OpenTelemetry`. This makes the **Object type** setting available.

Object type: From the drop-down, select `Logs`, `Metrics`, or `Traces`.

Working with Protobufs

This Destination supports supports Binary Protobuf payload encoding. The Protobufs it sends can encode traces, metrics, or logs, the three types of telemetry data defined in the OpenTelemetry Project's Data Sources documentation:

- A **trace** tracks the progression of a single request.

    - Each trace is a tree of **spans**.
    - A span object represents the work being done by the individual services, or components, involved in a request as that request flows through a system.
- A **metric** provides aggreggated statistical information.
    - A metric contains individual measurements called **data points**.
- A **log**, in OpenTelemetry terms, is "any data that is not part of a distributed trace or a metric".

When configuring Pipelines (including pre-processing and post-processing Pipelines), you need to ensure that events sent to this Destination conform to the relevant Protobuf specification:

- For traces, opentelemetry/proto/trace/v1/trace.proto.
- For metrics, opentelemetry/proto/metrics/v1/metrics.proto.
- For logs, opentelemetry/proto/logs/v1/logs.proto.

This Destination will drop non-conforming events. If the Destination encounters a parsing error when trying to convert an event to OTLP, it discards the event and Cribl Stream logs the error.

Connecting to Kafka

Leave the TLS Settings > Server name (SNI) field blank

In Cribl Stream's Kafka-based Sources and Destinations (including this one), the Kafka library that Cribl Stream uses manages SNI (Server Name Indication) without any input from Cribl Stream. Therefore, you should leave the **TLS Settings** > **Server name (SNI)** field blank.

Setting this field in the Cribl Stream UI can cause traffic to be routed to the wrong brokers, because it interferes with the Kafka library's operation. This is especially important for Confluent Cloud Dedicated clusters, which rely on SNI – as managed by the Kafka library – for routing.

Connecting to a Kafka cluster involves using hostnames for two key components: bootstrap servers and brokers.

Brokers are servers that comprise the storage layer in a Kafka cluster. Bootstrap servers handle the initial connection to the Kafka cluster, and then return the list of brokers. A broker list can run into the hundreds. Every Kafka cluster has a `bootstrap.servers` property, defined as either a single `hostname:port` K-V pair, or a list of them. If Cribl Stream tries to connect via one bootstrap server and that fails, Cribl Stream then tries another one on the list.

In the **General Settings** > **Bootstrap servers** list, you can enter either the hostnames of brokers that your Kafka server has been configured to use, or, the hostnames of one or more bootstrap servers. If Kafka returns a list of brokers that's longer than the list you entered, Cribl Stream keeps the full list internally. Cribl Stream

neither saves the list nor makes it available in the UI. The connection process simply starts at the beginning whenever the Source or Destination is started.

Here's an overview of the connection process:

1. From the **General Settings** > **Bootstrap servers** list – where each broker is listed as a hostname and port – Cribl Stream takes a hostname and resolves it to an IP address.
2. Cribl Stream makes a connection to that IP address. Notwithstanding the fact that Cribl Stream resolved **one** particular hostname to that IP address, there may be **many** services running at that IP address – each with its own distinct hostname.
3. Cribl Stream establishes TLS security for the connection.

Although SNI is managed by the Kafka library rather than in the Cribl Stream UI, you might want to know how it fits into the connection process. The purpose of the SNI is to specify one hostname – that is, service – among many that might be running on a given IP address within a Kafka cluster. Excluding the other services is one way that TLS makes the connection more secure.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__topicOut`
- `__key`
- `__headers`
- `__keySchemaIdOut`
- `__valueSchemaIdOut`

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.7.3. Amazon MSK Destination

Cribl Stream supports sending data to an Amazon Managed Streaming for Apache Kafka (MSK) topic.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Kafka uses a binary protocol over TCP. It does not support HTTP proxies, so Cribl Stream must send events directly to receivers. You might need to adjust your firewall rules to allow this traffic.

Configuring Cribl Stream to Output to Amazon MSK

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Amazon MSK Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Brokers**: List of Kafka brokers to connect to (for example, `localhost:9092`).
    - **Topic**: The topic on which to publish events. Can be overwritten using the event's `__topicOut` field.
    - **Region**: From the drop-down, select the name of the AWS Region where your Amazon MSK cluster is located.
3. Next, you can configure the following **Optional Settings**:
    - **Acknowledgments**: Select the number of required acknowledgments. Defaults to `Leader`.
    - **Record data format**: Format to use to serialize events before writing to Kafka. Defaults to `JSON`. When set to `Protobuf`, the **Protobuf Format Settings** section (left tab) becomes available.
    - **Compression**: Codec to compress the data before sending to Kafka. Select `None`, `Gzip`, `Snappy`, or `LZ4`. Defaults to `Gzip`.

Cribl strongly recommends enabling compression. Doing so improves Cribl Stream's performance, enabling faster data transfer using less bandwidth.

- **Backpressure behavior**: Select whether to block, drop, or queue incoming events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Persistent Queue, TLS, Authentication, Processing, Retries, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Calculating the Time PQ Will Take to Engage

PQ will not engage until Cribl Stream has exhausted all attempts to send events to the Kafka receiver. This can take several minutes if requests continue to fail or time out.

To calculate the longest possible time this can take, multiply the values of **Request timeout** and **Max retries**. For the default values (`60` seconds and `5`, respectively), this would be `60` seconds times `5` retries = 300 seconds, or 5 minutes.

TLS Settings (Client Side)

For Amazon MSK Sources and Destinations:

- IAM is the only type of authentication that Cribl Stream supports.
- Because IAM auth requires TLS, TLS is automatically enabled.

- **Validate server certs**: Require client to reject any connection that is not authorized by a CA in the **CA certificate path**, or by another trusted CA (such as the system's CA). Defaults to `Yes`.

Server name (SNI): Leave this field blank. See Connecting to Kafka below.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Authentication

Use the **Authentication method** drop-down to select an AWS authentication method.

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS VPC, such as those running in a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. The **Secret** option exposes this additional field:

- **Secret key pair**: Use the drop-down to select an API key/secret key pair that you've configured in Cribl Stream's secrets manager. A **Create** link is available to store a new, reusable secret.

Assume Role

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

Enable for MSK: Toggle on to use Assume Role credentials to access MSK.

AssumeRole ARN: Enter the Amazon Resource Name (ARN) of the role to assume.

External ID: Enter the External ID to use when assuming role. This is required only when assuming a role that requires this ID in order to delegate third-party access. For details, see AWS' documentation.

Duration (seconds): Duration of the Assumed Role's session, in seconds. Minimum is 900 (15 minutes). Maximum is 43200 (12 hours). Defaults to 3600 (1 hour).

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

These settings provide flexibility in handling retries for failed messages, allowing you to balance between quick retries and avoiding excessive load on the system.

The default configuration starts with a 300 milliseconds retry interval, doubles the interval after each retry, and caps the maximum retry interval at 30 seconds. The system will attempt to retry the request up to five times before considering it a failure.

Max retries: Maximum number of times to retry a failed request before the message fails. Defaults to `5`. Enter `0` to not retry at all. For example, if set to `5`, the system will attempt to retry the request up to five times before considering it a failure.

Initial retry interval (ms): Initial value used to calculate the retry interval, in milliseconds. This value determines the starting point for the retry delay. The default (and minimum) is `300` ms (three seconds). The maximum allowed value is `600000` ms (10 minutes). For example, if set to `1000` ms, the first retry will occur after one second.

Backoff multiplier: Set the backoff multiplier (`2`–`20`) to control the retry frequency for failed messages. The multiplier is used in an exponential backoff formula to increase the delay between retries. For faster retries, use a lower multiplier. For slower retries with more delay between attempts, use a higher multiplier. For example, with an initial retry interval of `1000` ms and a multiplier of `2`, the retry intervals will be 1,000 ms, 2,000 ms, 4,000 ms, and so on. See the Kafka documentation for details.

Backoff limit (ms): The maximum wait time for a retry, in milliseconds. This setting caps the exponential backoff delay to prevent excessively long wait times. The default (and minimum) value is `30000` ms (30 seconds), and the maximum is `180000` ms (180 seconds). For example, if the calculated retry interval exceeds 180,000 ms, the retry will occur after 180,000 ms instead.

Advanced Settings

Max record size (KB, uncompressed): Maximum size (KB) of each record batch before compression. Setting should be < `message.max.bytes settings` in Kafka brokers. Defaults to `768`.

Max events per batch: Maximum number of events in a batch before forcing a flush. Defaults to `1000`.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Connection timeout (ms): Maximum time to wait for a connection to complete successfully. Defaults to `10000` ms (10 seconds). Valid range is `1000` to `3600000` ms (1 second to 1 hour).

Request timeout (ms): Maximum time to wait for Kafka to respond to a request. Defaults to `60000` ms (1 minute).

Authentication timeout (ms): Maximum time to wait for Kafka to respond to an authentication request. Defaults to `1000` (1 second).

Reauthentication threshold (ms): If the broker requires periodic reauthentication, this setting defines how long before the reauthentication timeout Cribl Stream initiates the reauthentication. Defaults to `10000` (10 seconds).

A small value for this setting, combined with high network latency, might prevent the Destination from reauthenticating before the Kafka broker closes the connection.

A large value might cause the Destination to send reauthentication messages too soon, wasting bandwidth.

The Kafka setting `connections.max.reauth.ms` controls the reuthentication threshold on the Kafka side.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Protobuf Format Settings

Definition set: From the drop-down, select `OpenTelemetry`. This makes the **Object type** setting available.

Object type: From the drop-down, select `Logs`, `Metrics`, or `Traces`.

Working with Protobufs

This Destination supports supports Binary Protobuf payload encoding. The Protobufs it sends can encode traces, metrics, or logs, the three types of telemetry data defined in the OpenTelemetry Project's Data Sources documentation:

- A **trace** tracks the progression of a single request.
  - Each trace is a tree of **spans**.
  - A span object represents the work being done by the individual services, or components, involved in a request as that request flows through a system.
- A **metric** provides aggreggated statistical information.
  - A metric contains individual measurements called **data points**.
- A **log**, in OpenTelemetry terms, is "any data that is not part of a distributed trace or a metric".

When configuring Pipelines (including pre-processing and post-processing Pipelines), you need to ensure that events sent to this Destination conform to the relevant Protobuf specification:

- For traces, opentelemetry/proto/trace/v1/trace.proto.
- For metrics, opentelemetry/proto/metrics/v1/metrics.proto.
- For logs, opentelemetry/proto/logs/v1/logs.proto.

This Destination will drop non-conforming events. If the Destination encounters a parsing error when trying to convert an event to OTLP, it discards the event and Cribl Stream logs the error.

Connecting to Kafka

Leave the TLS Settings > Server name (SNI) field blank

In Cribl Stream's Kafka-based Sources and Destinations (including this one), the Kafka library that Cribl Stream uses manages SNI (Server Name Indication) without any input from Cribl Stream. Therefore, you should leave the **TLS Settings** > **Server name (SNI)** field blank.

Setting this field in the Cribl Stream UI can cause traffic to be routed to the wrong brokers, because it interferes with the Kafka library's operation.

Connecting to a Kafka cluster entails working with hostnames for **brokers** and **bootstrap servers**.

Brokers are servers that comprise the storage layer in a Kafka cluster. Bootstrap servers handle the initial connection to the Kafka cluster, and then return the list of brokers. A broker list can run into the hundreds. Every Kafka cluster has a `bootstrap.servers` property, defined as either a single `hostname:port` K-V pair, or a list of them. If Cribl Stream tries to connect via one bootstrap server and that fails, Cribl Stream then tries another one on the list.

In the **General Settings** > **Brokers** list, you can enter either the hostnames of brokers that your Kafka server has been configured to use, or, the hostnames of one or more bootstrap servers. If Kafka returns a list of brokers that's longer than the list you entered, Cribl Stream keeps the full list internally. Cribl Stream neither saves the list nor makes it available in the UI. The connection process simply starts at the beginning whenever the Source or Destination is started.

Here's an overview of the connection process:

1. From the **General Settings** > **Brokers** list – where each broker is listed as a hostname and port – Cribl Stream takes a hostname and resolves it to an IP address.
2. Cribl Stream makes a connection to that IP address. Notwithstanding the fact that Cribl Stream resolved **one** particular hostname to that IP address, there may be **many** services running at that IP address – each with its own distinct hostname.
3. Cribl Stream establishes TLS security for the connection.

Although SNI is managed by the Kafka library rather than in the Cribl Stream UI, you might want to know how it fits into the connection process. The purpose of the SNI is to specify one hostname – that is, service – among many that might be running on a given IP address within a Kafka cluster. Excluding the other services is one way that TLS makes the connection more secure.

Working with Event Timestamps

By default, when an incoming event reaches this Destination, the underlying Kafka JS library adds a `timestamp` field set to the current time at that moment. The library gets the current time from the `Date.now()` JavaScript method. Events that this Destination sends to downstream Kafka receivers include this `timestamp` field.

Some production situations require the `timestamp` value to be the time an incoming event was originally created by an upstream sender, not the current time of its arrival at this Destination. For example, suppose the events were originally created over a wide time range, and arrive at the Destination hours or days later. In this case, the original creation time might be important to retain in events Cribl Stream sends to downstream Kafka receivers.

Here is how to satisfy such a requirement:

1. In a Pipeline that routes events to this Destination, use an Eval Function to add a field named `__kafkaTime` and write the incoming event's original creation time into that field. The value of `__kafkaTime` **must** be in UNIX epoch time (either seconds or milliseconds since the UNIX epoch – both will work). For context, see this explanation of the related fields `_time` and `__origTime`.
2. This Destination will recognize the `__kafkaTime` field and write its value into the `timestamp` field. (This is similar to the way you can use the `__topicOut` field to overwrite a topic setting, as described above.)

If the `__kafkaTime` field is **not** present, the Destination will apply the default behavior (using `Date.now()`) described previously.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__topicOut`
- `__key`
- `__headers`
- `__keySchemaIdOut`
- `__valueSchemaIdOut`

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.8. Metrics

15.2.8.1. Graphite Destination

Cribl Stream supports sending data to a Graphite backend Destination.

Type: Streaming | TLS Support: No | PQ Support: Yes

Configure Cribl Stream to Output to a Graphite Backend

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Graphite definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Destination protocol**: Protocol to use when communicating with the Destination. Defaults to `UDP`.
    - **Host**: The hostname of the Destination.
    - **Port**: Destination port. Defaults to `8125`.
3. Next, you can configure the following **Optional Settings**:
    - **Throttling**: Displayed only when **General Settings** > **Destination protocol** is set to `TCP`. Rate (in bytes per second) at which at which to throttle while writing to an output. Also takes numerical values in multiples of bytes (KB, MB, GB, etc.). Default value of `0` indicates no throttling.
    - **Backpressure behavior**: Displayed only when **General Settings** > **Destination protocol** is set to `TCP`. Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Persistent Queue, Timeout, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Timeout Settings

This section is displayed only when **General Settings** > **Destination protocol** is set to `TCP`.

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish, before retrying. Defaults to `10000`.

Write timeout: Amount of time (milliseconds) to wait for a write to complete, before assuming connection is dead. Defaults to `60000`.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced

Max record size (bytes): Used when Protocol is UDP. Specifies the maximum size of packets sent to the Destination. (Also known as the MTU – maximum transmission unit – for the network path to the destination system.) Defaults to `512`.

Flush period (sec): Used when Protocol is TCP. Specifies how often buffers should be flushed, sending records to the Destination. Defaults to `1`.

DNS resolution period (sec): Specify the interval (in seconds) to re-resolve hostnames. This reduces the frequency of DNS lookups, improving performance. Use this setting to balance the overhead of DNS lookup calls with the expected frequency of changes in the DNS records. Defaults to `0` seconds, meaning DNS lookups occur for every outgoing batch.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.8.2. StatsD Destination

Cribl Stream supports sending data to a StatsD Destination.

Type: Streaming | TLS Support: No | PQ Support: Yes

Configure Cribl Stream to Output via StatsD

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this StatsD definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Destination protocol**: Protocol to use when communicating with the Destination. Defaults to `UDP`.
    - **Host**: The hostname of the Destination.
    - **Port**: Destination port. Defaults to `8125`.
3. Next, you can configure the following **Optional Settings**:
    - **Throttling**: Displayed only when **General Settings** > **Destination protocol** is set to `TCP`. Rate (in bytes per second) at which at which to throttle while writing to an output. Also takes numerical values in multiples of bytes (KB, MB, GB, etc.). Default value of `0` indicates no throttling.
    - **Backpressure behavior**: Displayed only when **General Settings** > **Destination protocol** is set to `TCP`. Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Persistent Queue, Timeout, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Timeout Settings

This section is displayed only when **General Settings** > **Destination protocol** is set to `TCP`.

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish, before retrying. Defaults to `10000`.

Write timeout: Amount of time (milliseconds) to wait for a write to complete, before assuming connection is dead. Defaults to `60000`.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Max record size (bytes): Used when Protocol is UDP. Specifies the maximum size of packets sent to the Destination. (Also known as the MTU – maximum transmission unit – for the network path to the Destination system.) Defaults to `512`.

Flush period (sec): Used when Protocol is TCP. Specifies how often buffers should be flushed, sending records to the Destination. Defaults to `1`.

DNS resolution period (sec): Specify the interval (in seconds) to re-resolve hostnames. This reduces the frequency of DNS lookups, improving performance. Use this setting to balance the overhead of DNS lookup calls with the expected frequency of changes in the DNS records. Defaults to `0` seconds, meaning DNS lookups occur for every outgoing batch.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.8.3. StatsD Extended Destination

Cribl Stream's StatsD Extended Destination supports sending out data in expanded StatsD format.

The output is an expanded StatsD metric protocol that supports dimensions, along with a sample rate for counter metrics. As with StatsD, downstream components listen for application metrics over UDP or TCP, can aggregate and summarize those metrics, and can relay them to virtually any graphing or monitoring backend.

For details about the syntax expected by one common downstream service, see Splunk's Expanded StatsD Metric Protocol documentation.

Type: Streaming | TLS Support: No | PQ Support: Yes

Configure Cribl Stream to Output via StatsD Extended

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this StatsD Extended definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Destination protocol**: Protocol to use when communicating with the Destination. Defaults to `UDP`.
    - **Host**: The hostname of the Destination.
    - **Port**: Destination port. Defaults to `8125`.
3. Next, you can configure the following **Optional Settings**:
    - **Throttling**: Displayed only when **General Settings** > **Destination protocol** is set to `TCP`. Rate (in bytes per second) at which at which to throttle while writing to an output. Also takes numerical values in multiples of bytes (KB, MB, GB, etc.). Default value of `0` indicates no throttling.
    - **Backpressure behavior**: Displayed only when **General Settings** > **Destination protocol** is set to `TCP`. Select whether to block, drop, or queue events when all receivers are exerting backpressure.

(Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.

- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Persistent Queue, Timeout, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Max record size (bytes): Used when Protocol is UDP. Specifies the maximum size of packets sent to the Destination. (Also known as the MTU – maximum transmission unit – for the network path to the Destination system.) Defaults to `512`.

Flush period (sec): Used when Protocol is TCP. Specifies how often buffers should be flushed, sending records to the Destination. Defaults to `1`.

DNS resolution period (sec): Specify the interval (in seconds) to re-resolve hostnames. This reduces the frequency of DNS lookups, improving performance. Use this setting to balance the overhead of DNS lookup calls with the expected frequency of changes in the DNS records. Defaults to `0` seconds, meaning DNS lookups occur for every outgoing batch.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.9. New Relic Ingest

15.2.9.1. New Relic Events Destination

Cribl Stream supports sending events to New Relic via the New Relic Event API. Use this Destination to export ad hoc events that New Relic ingestion treats as custom events.

To export structured log and/or metric events, use Cribl Stream's New Relic Logs & Metrics Destination.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Output Events to New Relic

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination.
    - **Description**: Optionally, enter a description.
    - **Region**: Select which New Relic region endpoint to use. Select `Custom` to manually enter your New Relic region's URL if it's not listed.
    - **Account ID**: Enter your New Relic account ID. (You can access this ID from New Relic's **account** drop-down, by selecting **Manage your plan**.)
    - **Event type**: Default `eventType` to apply when not specified in an event. You can use arbitrary values, as long as they do not conflict with New Relic reserved words. (Where an `eventType` is specified in an event, it will override this value.)
3. Under **Authentication**, select an **Authentication method** from the dropdown:

If an incoming event contains an internal field named `__newRelic_apiKey`, the New Relic Events Destination will use that field's value as the API key when sending the event to New Relic.

> For events that do not contain a `__newRelic_apiKey` field, the Destination will use whatever API key you have configured in this section.

- **Manual**: This default option exposes an **API key** field. Directly enter your New Relic Ingest License API key, as you created or accessed it from New Relic's **account** drop-down. (For details, see the New Relic API Keys documentation.)
- **Secret**: This option exposes an **API key (text secret)** drop-down, in which you can select a stored secret that references a New Relic Ingest License API key. A **Create** link is available to store a new, reusable secret.

4. Next, you can configure the following **Optional Settings**:
   - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`. For the `Persistent Queue` option, see the section just below.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page.. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.

Mode	Description
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears.

Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out via this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Defaults to `Yes`, meaning compress the payload body before sending.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `1024` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. Defaults to `0`, allowing unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` second.

Extra HTTP headers: Click **Add Header** to insert extra headers as **Name/Value** pairs. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Verifying the New Relic Events Destination

Once you've configured event sources, create one or more Routes to send data to New Relic.

In New Relic, you can create visualizations incorporating the Cribl Stream-supplied data, then add them to new or existing dashboards as widgets.

Alternatively, in the New Relic backend, you can select **Query you data** (top nav) > **Events** (left tab), and then select the event type you exported from Cribl Stream.

To view more events, change the time frame at the upper right. To see raw events, click **Raw data** on the right.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.9.2. New Relic Logs & Metrics Destination

Cribl Stream supports sending events to the New Relic Log API and the New Relic Metric API.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

In Cribl Stream v.3.1.2 and later, this Destination now authenticates using New Relic's Ingest License API key. (New Relic will retire the Insights Insert API keys, which this Destination previously used for authentication.)

Also in v.3.1.2 and later, Cribl Stream provides a separate New Relic Events Destination that you can use to send ad hoc (loosely structured) events to New Relic via the New Relic Event API.

Within New Relic's platform, you can monitor Cribl Stream's performance and data flow by installing New Relic's Cribl dashboard.

Configure Cribl Stream to Output to New Relic

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**: **Output ID**: Enter a unique name to identify this New Relic definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Region**: Select which New Relic region endpoint to use. Select `Custom` to manually enter your New Relic region's URL if it's not listed.
3. Under **Authentication**, select an **Authentication method** from the dropdown:

If an incoming event contains an internal field named `__newRelic_apiKey`, the New Relic Logs & Metrics Destination uses that field's value as the API key when sending the event to New Relic.

For events that do not contain an `__newRelic_apiKey` field, the Destination uses whatever API key you have configured in the **Authentication method** settings.

- **Manual**: This default option exposes an **API key** field. Directly enter your New Relic Ingest License API key, as you created or accessed it from New Relic's **account** drop-down. (For details, see the New Relic API Keys documentation.)
- **Secret**: This option exposes an **API key (text secret)** drop-down, in which you can select a stored secret that references a New Relic Ingest License API key. A **Create** link is available to store a new, reusable secret.

4. Next, you can configure the following **Optional Settings**:
   - **Log type**: Name of the `logType` to send with events. For example, `observability` or `access_log`.

     This sets a default. Where a `sourcetype` is specified in an event, it will override this value.
   - **Log message field**: Name of the field to send as the log `message` value. If not specified, the event will be serialized and sent as JSON.
   - **Fields**: Additional fields to (optionally) add, as **Name-Value** pairs. Click **Add Field** to add more. For details, see [Fields]{#fields}
   - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`. For the `Persistent Queue` option, see the section just below.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Fields

These custom fields allow you to enrich your log data with specific details that are relevant to your use case. Click **Add Field** for more.

- **Name**: Enter the field name.
- **Value**:JavaScript expression to compute field's value, enclosed in single quotes, double quotes, or backticks. (Can evaluate to a constant.)

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.

- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `1024` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` second.

Extra HTTP headers: Click **Add Header** to insert extra headers as **Name/Value** pairs. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Verifying the New Relic Destination

Once you've configured log and/or metrics sources, create one or more Routes to send data to New Relic.

In New Relic, you can create visualizations incorporating the Cribl Stream-supplied data, then add them to new or existing dashboards as widgets.

Logs and metrics land in two different places in New Relic.

Log Queries

To access and query log data:

- Navigate to the New Relic home screen's **Logs** header option, and click the **(+)** button at right.
- Then to build your queries, use the **Find logs where** input field, and add desired columns to the table view below the graph,.

Metrics Queries

To access and query metrics data:

- From the New Relic home screen, *Click **Browse Data** > **Metrics** > **Can Search for metricNames**.
- Then, customize time range and dimensions to build the desired logic for your queries.
- Alternatively, you can use NRQL to build your own query searches.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.10. Prometheus

15.2.10.1. Prometheus Destination

Cribl Stream can send metric events to targets and third-party platforms that support Prometheus' remote write specification (overview here).

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

For an example of using this Destination to send host metrics to Grafana's Cribl Node Observability dashboard, see our System Metrics to Grafana topic.

Configure Cribl Stream to Output to Prometheus

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Prometheus output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Remote Write URL**: The endpoint to send events to, for example: `http://localhost:9200/write`
3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header.
- **Auth token (text secret)**: This option exposes a **Token (text secret)** drop-down, in which you can select a stored text secret that references the bearer token described above. A **Create** link is available to store a new, reusable secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: This option exposes a **Credentials secret** drop-down, in which you can select a stored text secret that references the Basic authentication credentials described above. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues

- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_host` (Cribl Stream Node that processed the event) and `cribl_wp` (Cribl Stream Worker Process that processed the event). Supports wildcards. Other options include:

- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_pipe` – Cribl Stream Pipeline that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit**

(ms). At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Metric renaming expression: A JavaScript expression that can be used to rename metrics.
The default expression – `name.replace(/\\./g, \'_\')` – replaces all `.` characters in a metric's name with the Prometheus-supported `_` character. Use the `name` global variable to access the metric's name. You can access event fields' values via `__e.<fieldName>`.

Send metadata: Whether to generate and send metrics' metadata (`type` and `metricFamilyName`) along with the metrics. The default `Yes` value displays this additional field:

- **Metadata flush period (sec)**: How frequently metrics metadata is sent out. Value must at least equal the base **Flush period (sec)**. (In other words, metadata cannot be flushed on a shorter interval.) Defaults to `60` seconds.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

If an event contains the internal field `__criblMetrics`, Cribl Stream will send it to the HTTP endpoint as a metric event. Otherwise, Cribl Stream will drop the event.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Unlike other HTTP-based Destinations, Prometheus does not display an **Advanced Settings > Compress** option. The Prometheus `remote_write` spec assumes that payloads are snappy-compressed by default.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), a new connection will be established for the next request.
- When resolving the Destination's hostname, Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between Prometheus cluster nodes.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.10.2. Grafana Cloud Destination

Cribl Stream can send data to two of the services available in Grafana Cloud: Loki for logs and Prometheus for metrics. The Grafana Cloud Destination shapes events appropriately for Loki and Prometheus, and routes events to the correct endpoint for each service.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

For an alternative scenario that relies on our Prometheus Destination to send host metrics to Grafana's Cribl Node Observability dashboard, see our System Metrics to Grafana topic.

Preparing Prometheus and Loki to Receive Data from Cribl Stream

To define a Grafana Cloud Destination, you need a Grafana Cloud account.

While logged in to your Grafana account, navigate to the Grafana Cloud Portal, which should be located at `https://grafana.com/orgs/<your-organization-name>`, and complete the following steps.

Obtain an API key, setting its Role to `MetricsPublisher`. If you want Cribl Stream or an external KMS to manage the API key, configure a key pair that references the API key.

In the Prometheus tile, select **Send Metrics** to open the Prometheus configuration page. Write down:

- Your **Remote Write Endpoint** URL, for example: `https://prometheus-blocks-prod-us-central1.grafana.net/api/prom/push`.
- Your Prometheus **Username**.

In the Loki tile, select **Send Logs** to open the Loki configuration page. Write down:

- Your **Grafana Data Source settings** URL, for example: `https://logs-prod-us-central1.grafana.net`.
- Your Loki **User** ID.

Decide what type of authentication to use and prepare accordingly:

- If you choose Basic authentication, the username (**Username** in Prometheus, **User** in Loki) and password (simply your Grafana API key) will remain separate.
- If you choose token-based authentication, construct your tokens by concatenating username, colon (`:`), and password, for example `12345:cOQvDj6sJGFS3Bk2MguBW==`. Because the Prometheus and Loki

usernames differ, you need to construct a separate token for each service.

Configure Cribl Stream to Output to Grafana Cloud

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Grafana Cloud output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Loki URL**: The endpoint to send log events to, for example: `https://logs-prod-us-central1.grafana.net`. This is the **Grafana Data Source settings** URL you wrote down earlier.
    - **Prometheus URL**: The endpoint to send metric events to, for example: `https://prometheus-blocks-prod-us-central1.grafana.net/api/prom/push`. This is the **Remote Write Endpoint** URL you wrote down earlier.
3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Persistent Queue, Authentication, Processing, Retries, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB

> disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Authentication

The **Authentication** tab provides separate **Loki** and **Prometheus** sections, enabling you to configure these inputs separately. The two sections provide identical options.

Select one of the following options for authentication:

- **Auth token**: Enter the bearer token that must be included in the authorization header. Use the token that you constructed earlier. In Grafana Cloud, the bearer token is generally built by concatenating the username and the API key, separated by a colon. For example: `<your-username>:<your-api-key>`.
- **Auth token (text secret)**: This option exposes a drop-down in which you can select a stored text secret that references the bearer token described above. A **Create** link is available to store a new, reusable secret.
- **Basic**: This default option displays fields for you to enter HTTP Basic authentication credentials. **Username** is the Loki **User** or Prometheus **Username** that you wrote down earlier. **Password** is your API key in the Grafana Cloud domain.
- **Basic (credentials secret)**: This option exposes a **Credentials secret** drop-down, in which you can select a stored text secret that references the Basic authentication credentials described above. A **Create** link is available to store a new, reusable secret.

Processing Settings

Metric events can have dimensions, and log events have labels. Dimensions, labels, and their values are determined by several different settings in Cribl Stream. This section explains how that works, along with other kinds of settings.

Loki uses labels to define separate streams of logging data. This is a key concept. Cribl recommends that you familiarize yourself with the information and documentation Grafana provides about labels in Loki.

One canonical example is processing logs from servers in three environments: production, staging, and testing. You could create a label named `env` whose possible values are `prod`, `staging`, and `test`.

One basic principle is that if you set too many labels, you can end up with too many streams.

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output—both metric events, as dimensions; and, log events, as labels. Supports wildcards.

By default, includes `cribl_host` (Cribl Stream Node that processed the event) and `cribl_wp` (Cribl Stream Worker Process that processed the event). On the Loki side, this creates different streams, which prevents Loki from rejecting some events as being out of order when different Nodes or Worker Processes are emitting at different rates.

Other options include:

- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_pipe` – Cribl Stream Pipeline that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Loki and Prometheus might complain about entries being delivered out of order when **Request concurrency** is set > `1` and any of **Flush period (sec)**, **Max body size (KB)**, or **Max events per request** are set to low values.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Metric renaming expression: A JavaScript expression that can be used to rename metrics. The default expression – `name.replace(/\\./g, \'_\')` – replaces all `.` characters in a metric's name with the Prometheus-supported `_` character. Use the `name` global variable to access the metric's name. You can access event fields' values via `__e.<fieldName>`.

Message format: Whether to send events as `Protobuf` (the default) or `JSON`.

Compress: When the **Message format** is `JSON`, this setting controls the data compression format used before sending the data to Grafana Cloud. Defaults to `Yes` for GZIP-compression. (Applies only to Loki's JSON

payloads. This toggle is hidden when the **Message format** is `Protobuf`, because both Prometheus' and Loki's Protobuf implementations are Snappy-compressed by default.)

Logs message field: The event field to send as log output, for example: `_raw`. All other event fields are discarded. If left blank, Cribl Stream sends a JSON representation of the whole event.

Logs labels: Name/value pairs where the value can be a static or dynamic expression that has access to all log event fields.

Failed request logging mode: Determines which data is logged when a request fails. Use the drop-down to select one of these options:

- `None` (default).
- `Payload`.
- `Payload + Headers`. Use the **Safe Headers** field below to specify the headers to log. If you leave that field empty, all headers are redacted, even with this setting.

Safe headers: List the headers you want to log, in plain text.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

If an event contains the internal field `__criblMetrics`, Cribl Stream will send it Prometheus as a metric event. If `__criblMetrics` is absent, Cribl Stream will treat the event as a log and send it to Loki.

The internal field `__labels` specifies labels to add to log events. If a label is set in both the `__labels` field and in **Logs labels** and/or **System fields**, Cribl Stream sends the value from `__labels` to Loki. Setting the `__labels` field in a Pipeline gives you a quick way to experiment with the logs being sent.

If there are no labels set (this would happen when **System fields**, **Logs labels**, and `__labels` are all empty), Cribl Stream adds a default `source` label, which prevents Loki from rejecting events. The `source` label the concatenation of `cribl`, underscore (`_`), source type, colon (`:`), source-name, where source name and type are values in the `__inputId` event field, for example: `cribl_metrics:in_prometheus_rw`. If `__inputId` is missing, `source` is set to `cribl`.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- The **Advanced Settings** > **Compress** toggle determines whether to compress the payload body before sending to Loki only. The toggle setting does not apply to Prometheus payloads, which are always compressed using Snappy.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), a new connection will be established for the next request.
- When resolving the Destination's hostname, Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between Grafana Cloud nodes.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.10.3. Loki Destination

Cribl Stream can send log events to Grafana's Loki log aggregation system.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configuring Cribl Stream to Output to Loki

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Loki output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Loki URL**: The endpoint to send events to, for example: `https://logs-prod-us-central1.grafana.net`.

      To proxy outbound HTTP/S requests, see System Proxy Configuration.
3. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Authentication, Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header.
- **Auth token (text secret)**: This option exposes a drop-down in which you can select a stored text secret that references the bearer token described above. A **Create** link is available to store a new, reusable secret.
- **Basic**: This default option displays fields for you to enter HTTP Basic authentication credentials. **Username** is the Loki **User**. **Password** is your API key in the Grafana Cloud domain.
- **Basic (credentials secret)**: This option exposes a **Credentials secret** drop-down, in which you can select a stored text secret that references the Basic authentication credentials described above. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Loki uses labels to define separate streams of logging data. This is a key concept. Cribl recommends that you familiarize yourself with the information and documentation Grafana provides about labels in Loki.

One canonical example is processing logs from servers in three environments: production, staging, and testing. You could create a label named `env` whose possible values are `prod`, `staging`, and `test`.

One basic principle is that if you set too many labels, you can end up with too many streams.

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to log events as labels. Supports wildcards.

By default, includes `cribl_host` (Cribl Stream Node that processed the event) and `cribl_wp` (Cribl Stream Worker Process that processed the event). On the Loki side, this creates different streams, which prevents Loki from rejecting some events as being out of order when different Nodes or Worker Processes are emitting at different rates.

Other options include:

- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_pipe` – Cribl Stream Pipeline that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Validate server certs: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Defaults to `Yes`.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `1`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `15`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Message format: Whether to send events as `Protobuf` (the default) or `JSON`.

Compress: When the **Message format** is `JSON`, this setting controls the data compression format used before sending the data to Loki. Defaults to `Yes` for GZIP-compression. (Applies only to Loki's JSON payloads. This toggle is hidden when the **Message format** is `Protobuf`, because both Prometheus' and Loki's Protobuf implementations are Snappy-compressed by default.)

Logs message field: The event field to send as log output, for example: `_raw`. All other event fields are discarded. If left blank, Cribl Stream sends a JSON or Protobuf representation of the whole event.

Logs labels: Name/value pairs where the value can be a static or dynamic expression that has access to all log event fields.

Failed request logging mode: Determines which data is logged when a request fails. Use the drop-down to select one of these options:

- `None` (default).
- `Payload`.
- `Payload + Headers`. Use the **Safe Headers** field below to specify the headers to log. If you leave that field empty, all headers are redacted, even with this setting.

Safe headers: List the headers you want to log, in plain text.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.11. Splunk

15.2.11.1. Splunk HEC Destination

The **Splunk HEC** Destination can stream data to a Splunk HEC (HTTP Event Collector) receiver through the event endpoint. The data arrives to Splunk cooked and parsed, so it enters at the Splunk data pipeline's indexing segment.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Looking for a quick way to switch all of your S2S Destinations to Splunk HEC Destinations? Follow our how-to guide: Switch Cribl Stream Destinations from S2S to Splunk HEC.

The Splunk HEC Destination is recommended for Splunk Cloud. For details, see Splunk Cloud Platform and BYOL Integrations.

Configure Cribl Stream to Output to Splunk HEC Destinations

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Splunk HEC definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: When enabled (default), lets you specify multiple Splunk HEC endpoints and load weights. With the default `No` setting, if you notice that Cribl Stream is not sending data to all possible IP addresses, enable **Advanced Settings** > **Round-robin DNS**.
    - **Splunk HEC endpoint(s)**: URLs of Splunk HEC endpoints to send events to.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Displays an **HEC Auth token** field for you to enter your Splunk HEC token.

- **Secret**: This option exposes an **HEC Auth token (text secret)** drop-down, in which you can select a stored secret that references the HEC token described above. A **Create** link is available to store a new, reusable secret.

This Destination does not support Mutual TLS (mTLS).

4. Next, you can configure the following **Optional Settings**:
   - **Exclude current host IPs**: This toggle appears when **Load balancing** is set to `Yes`. It determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Defaults to `No`, which keeps the current host available for load balancing.
   - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.

If you're sending data to Splunk Cloud, Cribl recommends a maximum value of `1 MB` for **Max body size (KB)** under Advanced settings. This upper limit is defined by the maximum content length for the default HTTP Event Collector (HEC) provided by Splunk Cloud.

6. Select **Save**, then **Commit & Deploy**.

Splunk HEC Endpoints

Use the **Splunk HEC Endpoints** table to specify a known set of receivers on which to load-balance data. The table appears only when **Load balancing** is toggled to `Yes`.

To specify more receivers on new rows, click **Add Endpoint**. Each row provides the following fields:

- **HEC Endpoint**: Specify the URL to a Splunk HEC endpoint to send events to. See the Splunk documentation for details on getting your URL. For Splunk Cloud endpoints, `https` protocol is recommended.
- **Load Weight**: Set the relative traffic-handling capability for each connection by assigning a weight (`> 0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Stream will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

When you first enable load balancing, or if you edit the load weight once your data is load-balanced, give the logic time to settle. The changes might take a few seconds to register.

For details on configuring all these options, see About Load Balancing.

Indexer Acknowledgement

Do not set **Enable Indexer Acknowledgement** on the Splunk token. With this setting enabled, Splunk receivers expect the Channel GUID to be passed in, and requests will fail with errors of this form:

```
channel: output:splunk_cloud_hec
cid: w2
level: error
message: Request failed
reason: Received status code=400, method=POST, url=https://http-inputs-bazookatron.s
response: {"text":"Data channel is missing","code":10}
time: 2023-02-14T15:26:03.413Z
```

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time,

Mode	Description
	Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.

Status Code	Action
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Output multi-metrics: Toggle to `Yes` to output multiple-measurement metric data points. (Supported in Splunk 8.0 and above, this format enables sending multiple metrics in a single event, improving the efficiency of your Splunk capacity.)

Validate server certs: Reject certificates that are not authorized by a trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned. (This setting is available only when **General Settings** > **Load balancing** is set to `No`.)

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`. Each request can potentially hit a different HEC receiver.

Max body size (KB): Maximum size, in KB, of the request body. Defaults to `4096`. Lowering the size can potentially result in more parallel requests and also cause outbound requests to be made sooner.

If you're sending data to Splunk Cloud, Cribl recommends a maximum value of `1 MB` for **Max body size (KB)**. This upper limit is defined by the maximum content length for the default HTTP Event Collector (HEC) provided by Splunk Cloud.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than the configured **Max body size**. Defaults to `1`.

- Retries happen on this flush interval.
- Any HTTP response code in the `2xx` range is considered success.
- Any response code in the `5xx` range is considered a retryable error, which will not trigger Persistent Queue (PQ) usage.
- Any other response code will trigger PQ (if PQ is configured as the Backpressure behavior).

Extra HTTP headers: Click **Add Header** to add **Name/Value** pairs to pass as additional HTTP headers. Values will be sent encrypted.

The next two fields appear only when the **General Settings** > **Load balancing** option is set to `Yes`.

DNS resolution period (seconds): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from A records. Defaults to `600` seconds.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds. (Note that if multiple receivers are behind a hostname – i.e., multiple A records – all resolved IPs will inherit the weight of the host, unless each IP is specified separately. In Cribl Stream load balancing, IP settings take priority over those from hostnames.)

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Splunk App Settings provides two fields that take effect only in the Cribl App for Splunk. (Cribl Stream ignores their values.)

- **Next processing queue**: Specify the next Splunk processing queue to send the events to, after HEC processing. Defaults to `indexQueue`.
- **Default _TCP_ROUTING**: Specify the value of the `_TCP_ROUTING` field for events that do not have `_ctrl._TCP_ROUTING` set. Defaults to `nowhere`. This is useful only when you expect the HEC receiver to route this data on to another destination.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new connection will be reattempted. This is to prevent sticking to a particular Destination when there is a constant flow of events.
- If the server does not support keepalives – or if the server closes a pooled connection while idle – a new connection will be established for the next request.
- When resolving the Destination's hostname with load balancing disabled, Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of

events between Splunk HEC servers.

- See Splunk's documentation on editing `fields.conf` to ensure the visibility of index-time fields sent to Splunk by Cribl Stream.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Destination Integrations: Splunk Cloud short course. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to select through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

15.2.11.2. Splunk Single Instance Destination

This Splunk Destination can stream data to a **free** Splunk Cloud instance. From the perspective of the receiving Splunk Cloud instance, the data arrives cooked and parsed.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Looking for a quick way to switch all of your S2S Destinations to Splunk HEC Destinations? Follow our how-to guide: Switch Cribl Stream Destinations from S2S to Splunk HEC.

Splunk Cloud Platform

To establish secure connections to Splunk Cloud, you'll need to configure SSL settings using the private and public keys from the Splunk Cloud Universal Forwarder credentials package.

For details on which Destination to use for Splunk Cloud, see Splunk Cloud Platform and BYOL Integrations. The Splunk HEC Destination is recommended for most use cases.

Configure Cribl Stream to Output to Splunk Destinations

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Splunk Single Instance definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Address**: Hostname of the Splunk receiver.
    - **Port**: The port number on the host.
3. Next, you can configure the following **Optional Settings**:

- **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Persistent Queue, TLS, Processing, Timeout, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high

as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

TLS Settings (Client Side)

Enabled defaults to `No`. When toggled to `Yes`:

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`. **Validate server certs**: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key. Often the value of the `sslPassword` or similar parameter in the `outputs.conf` or `server.conf` file.

Single .pem File

If you have a **single** .pem file containing `cacert`, `key`, and `cert` sections, enter it in all of these fields above: **CA certificate path**, **Private key path (mutual auth)**, and **Certificate path (mutual auth)**.

Timeout Settings

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish, before retrying. Defaults to `10000`.

Write timeout: Amount of time (in milliseconds) to wait for a write to complete, before assuming connection is dead. Defaults to `60000`.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Output multiple metrics: Toggle to `Yes` to output multiple-measurement metric data points. (Supported in Splunk 8.0 and above, this format enables sending multiple metrics in a single event, improving the efficiency of your Splunk capacity.)

Minimize in-flight data loss: If set to `Yes` (the default), Cribl Stream will check whether the indexer is shutting down, and if so, will stop sending data. This helps minimize data loss during shutdown. (Note that Splunk logs will indicate that the Cribl app has set `UseAck` to `true`, even though Cribl does not enable full `UseAck` behavior.) If toggled to `No`, exposes the following alternative option:

Max failed health checks: Displayed (and set to `1` by default) only if **Minimize in-flight data loss** is disabled. This option sends periodic requests to Splunk once per minute, to verify that the Splunk endpoint is still alive and can receive data. Its value governs how many failed requests Cribl Stream will allow before closing this connection.

A low threshold value improves connections' resilience, but by proliferating connections, this can complicate troubleshooting. Set to `0` to disable health checks entirely – here, if the connection to Splunk is forcibly closed, you risk some data loss.

Max S2S version: The highest version of the Splunk-to-Splunk protocol to expose during handshake. Defaults to `v4`; `v3` is also available.

Throttling: Throttle rate, in bytes per second. Defaults to `0`, meaning no throttling. Multiple-byte units such as KB, MB, GB, and so forth, are also allowed – for example, `42 MB`. When throttling is engaged, your

Backpressure behavior selection determines whether Cribl Stream will handle excess data by blocking it, dropping it, or queueing it to disk.

- When used in conjunction with **Max connections**, the throttling rate is applied per connection. For instance, if **Max connections** is set to `2` and throttling is set to `3 MB`, each of the two connections can send data at a rate of up to 3 MB per second, resulting in a total potential throughput of 6 MB per second across both connections.

Nested field serialization: Specifies how to serialize nested fields into index-time fields. Defaults to `None`.

Authentication method: Use the buttons to select one of these options:

- **Manual**: In the resulting **Auth token** field, enter the shared secret token to use when establishing a connection to a Splunk indexer.
- **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the auth token described above. A **Create** link is available to store a new, reusable secret.

Log failed requests to disk: Toggling to `Yes` makes the payloads of any (future) failed requests available for inspection. See Inspecting Payloads to Troubleshoot Closed Connections below.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Inspecting Payloads to Troubleshoot Closed Connections

When a downstream receiver closes connections from this Destination (or just stops responding), inspecting the payloads of the resulting failed requests can help you find the cause. For example:

- Suppose you send an event whose size is larger than the downstream receiver can handle.
- Suppose you send an event that has a `number` field, but the value exceeds the highest number that the downstream receiver can handle.

When **Log failed requests to disk** is enabled, you can inspect the payloads of failed requests. Here is how:

1. In the Destination UI, navigate to the **Logs** tab.
2. Find a log entry with a `connection error` message.
3. Expand the log entry.
4. If the message includes the phrase `See payload file for more info`, note the path in the `file` field on the next line.

Now you have the path to the directory where Cribl Stream is storing payloads from failed requests. At the command line, navigate to that directory and inspect any payloads that you think might be relevant.

Notes about Forwarding to Splunk

- Data sent to Splunk is not compressed.
- The only `ack` from indexers that Cribl Stream listens for and acts upon is the shutdown signal described in Minimize in-flight data loss above.
- If events have a Cribl Stream internal field called `__criblMetrics`, they'll be forwarded to Splunk as metric events.
- If events do **not** have a `_raw` field, they'll be serialized to JSON prior to sending to Splunk.
- See Splunk's documentation on editing `fields.conf` to ensure the visibility of index-time fields sent to Splunk by Cribl Stream.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University offers an Advanced Troubleshooting > Destination Integrations: Splunk Cloud short course. To follow the direct course link, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to select through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

15.2.11.3. Splunk Load Balanced Destination

The **Splunk Load Balanced** Destination can load-balance the data it streams to multiple Splunk receivers. Downstream Splunk instances receive the data cooked and parsed.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Looking for a quick way to switch all of your S2S Destinations to Splunk HEC Destinations? Follow our how-to guide: Switch Cribl Stream Destinations from S2S to Splunk HEC.

Splunk Cloud Platform

To establish secure connections to Splunk Cloud, you'll need to configure SSL settings using the private and public keys from the Splunk Cloud Universal Forwarder credentials package.

For details on which Destination to use for Splunk Cloud, see Splunk Cloud Platform and BYOL Integrations. The Splunk HEC Destination is recommended for most use cases.

Configure Cribl Stream to Load-Balance to Multiple Splunk Destinations

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Splunk LB Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Indexer discovery**: When enabled, Cribl Stream will automatically discover the indexers in an indexer clustering environment. </
      This hides both **Exclude current host IPs** and the **Destinations** section, and displays the following fields:

- **Site**: Clustering site whose indexers need to be discovered. In the case of a single site cluster, `default` is the default entry.
- **Cluster Manager URI**: Full URI of Splunk cluster manager, in the format: `scheme://host:port`. (Worker Nodes normally access the cluster manager on **port 8089** to get the list of currently online indexers.)
- **Refresh period**: Time interval (in seconds) between two consecutive fetches of the indexer list from the cluster manager. Defaults to `300` seconds (five minutes).
- **Validate cluster manager certificates**: By default, Cribl Stream is configured to reject any cluster manager certificate during indexer discovery that is not authorized by your system's Certificate Authority (CA). This behavior is controlled by a toggle set to `Yes` by default. Cribl strongly recommends keeping this setting enabled unless you must allow untrusted (for example, self-signed) certificates.

3. Under **Authentication tokens**, select one of the **Authentication method** options for authenticating to the cluster manager for indexer discovery:
   - **Manual**: In the resulting **Auth token** field, enter the required token.
   - **Secret**: This option exposes an **Auth token (text secret)** drop-down, from which you can select a stored secret that references the auth token. A **Create** link is available to store a new, reusable secret.

     If you use multiple cluster managers, you can add multiple tokens to cycle through them if a connection to the primary cluster manager fails. Select **Add token** to configure another authentication token.

     Each Worker Process performs its own indexer discovery according to the above settings.

4. The **Destinations** section appears only when **Indexer discovery** is set to its `No` default. Here, you specify a known set of Splunk receivers on which to load-balance data. Then you assign a weight to Cribl Stream's connection to each receiver. The higher the weight assigned to a given connection, the more traffic Cribl Stream will attempt to allocate to that connection. Click **Add Destination** to specify more receivers on new rows. Each row provides the following fields:
   - **Address**: Hostname or IP address of the receiver. If you enter a hostname, Cribl Stream tries to resolve it to its IP address or addresses. If a hostname has multiple A records – that is, if multiple receivers are behind it – Cribl Stream will assign the weight you assigned to the host to all of its IP addresses.
   - **Port**: Port number to send data to.
   - **TLS**: Whether to inherit TLS configs from group setting, or disable TLS. Defaults to `inherit`.

- **TLS servername**: Servername to use if establishing a TLS connection. If not specified, defaults to the connection host (if not an IP). Otherwise, uses the global TLS settings.
- **Load weight**: Set the relative traffic-handling capability for each connection by assigning a weight greater than `0`. For details, see [Destinations]{#destinations} below.

5. Next, you can configure the following **Optional Settings**:
   - **Exclude current host IPs**: Enable if you want to exclude all the current host's IP addresses from the list of resolved hostnames.
   - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers in this group are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`. When toggled to `Persistent Queue`, adds the Persistent Queue Settings section (left tab) to the modal.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
6. Optionally, you can adjust the Persistent Queue, TLS, Processing, Timeout, and Advanced settings outlined in the sections below.
7. Select **Save**, then **Commit & Deploy**.

Destinations

- For best results, the weights for all connections should have the same order of magnitude. For example, if you have three connections, weights of `10`, `50`, and `40` would work; so would weights of `1`, `5`, and `4` – but weights like `10`, `120`, and `9` mix different orders of magnitude and should be avoided.
- You can add connections and keep them unused except for special circumstances such as testing. Just assign these connections a weight of `0` and Cribl Stream will ignore them. When you want to use such a "parked" connection, assign it a weight greater than `0`.

The final column provides an `X` button to delete any row from the **Destinations** table.

For details on configuring all load balancing settings, see About Load Balancing.

Enabling Cluster Manager Authentication

To enable token authentication on the Splunk cluster manager, you can find complete instructions in Splunk's Enable or Disable Token Authentication documentation. This option requires Splunk 7.3.0 or higher, and requires the following capabilites: `list_indexer_cluster` and `list_indexerdiscovery`.

For details on creating the token, see Splunk's Create Authentication Tokens topic – especially its section on how to Configure Token Expiry and "Not Before" Settings.

Be sure to give the token an **Expiration** setting well in the future, whether you use **Relative Time** or **Absolute Time**. Otherwise, the token will inherit Splunk's default expiration time of `+30d` (30 days in the future), which will cause indexer discovery to fail.

If you have a failover site configured on Splunk's cluster manager, Cribl respects this configuration, and forwards the data to the failover site in case of site failure.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high

as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

TLS Settings (Client Side)

Enabled defaults to `No`. When toggled to `Yes`:

Validate server certs: Reject any server (indexer) certificate that is not authorized by a CA in the **CA certificate path** or by another trusted CA (such as the CA for your system). Defaults to `Yes`.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key. Often the value of the `sslPassword` or similar parameter in the `outputs.conf` or `server.conf` file.

Single PEM File

If you have a **single** `.pem` file containing `cacert`, `key`, and `cert` sections, enter this file's path in all of these fields above: **CA certificate path**, **Private key path (mutual auth)**, and **Certificate path (mutual auth)**.

Timeout Settings

- **Connection timeout**: Amount of time (in milliseconds) to wait for the connection to establish, before retrying. Defaults to `10000` ms.
- **Write timeout**: Amount of time (in milliseconds) to wait for a write to complete, before assuming connection is dead. Defaults to `60000` ms.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Output multiple metrics: Toggle to `Yes` to output multiple-measurement metric data points. (Supported in Splunk 8.0 and above, this format enables sending multiple metrics in a single event, improving the efficiency of your Splunk capacity.)

Minimize in-flight data loss: If set to `Yes` (the default), Cribl Stream will check whether the indexer is shutting down, and if so, will stop sending data. This helps minimize data loss during shutdown. (Note that Splunk logs will indicate that the Cribl app has set `UseAck` to `true`, even though Cribl does not enable full `UseAck` behavior.) If toggled to `No`, exposes the following alternative option:

Max failed health checks: Displayed (and set to `1` by default) only if **Minimize in-flight data loss** is disabled. This option sends periodic requests to Splunk once per minute, to verify that the Splunk endpoint is still alive and can receive data. Its value governs how many failed requests Cribl Stream will allow before closing this connection.

A low threshold value improves connections' resilience, but by proliferating connections, this can complicate troubleshooting. Set to `0` to disable health checks entirely – here, if the connection to Splunk is forcibly closed, you risk some data loss.

Max S2S version: The highest version of the Splunk-to-Splunk protocol to expose during handshake. Defaults to `v4`; `v3` is also available.

DNS resolution period (seconds): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from A records. Defaults to `600` seconds.

Load balance stats period (seconds): How far back in time to keep traffic stats for load balancing purposes. Defaults to `300` seconds (five minutes).

Max connections: Constrains the number of concurrent indexer connections, per Worker Process, to limit memory utilization. If set to a number > `0`, then on every DNS resolution period (or indexer discovery), Cribl Stream will randomly select this subset of discovered IPs to connect to. Cribl Stream will rotate IPs in future resolution periods – monitoring weight and historical data, to ensure fair load balancing of events among IPs.

Nested field serialization: Specifies whether and how to serialize nested fields into index-time fields. Select `None` (the default) or `JSON`.

Authentication method: Use the buttons to select one of these options:

- **Manual**: In the resulting **Auth token** field, enter the shared secret token to use when establishing a connection to a Splunk indexer.
- **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the auth token described above. A **Create** link is available to store a new, reusable secret.

Log failed requests to disk: Toggling to `Yes` makes the payloads of any (future) failed requests available for inspection. See Inspecting Payloads to Troubleshoot Closed Connections below.

Endpoint health fluctuation time allowance (ms): How long (in milliseconds) each receiver endpoint can report blocked, before this Destination as a whole reports unhealthy, blocking senders. (Grace period for transient fluctuations.) Use `0` to disable the allowance; default is `100` ms; maximum allowed value is `60000` ms (1 minute).

Throttling: Throttle rate, in bytes per second. Multiple byte units such as KB, MB, GB, and so forth, are also allowed – for example, `42 MB`. A value of `0` (the default) indicates no throttling. When throttling is engaged, excess data will be dropped only if **Backpressure behavior** is set to **Drop events**. (Data will be blocked for all other **Backpressure behavior** settings.)

- The throttling rate is applied per Worker Process, per configured endpoint. For example, if you have two Worker Processes, each with two endpoints, and you set the throttling rate to `3 MB`, the total potential throughput rate is 12 MB per second: up to 3 MB per second for each of the four endpoints. The **Max connections** setting is also applied per Worker Process. To continue the example, if you set **Max connections** to `1`, the total potential throughput is 6 MB per second, even though each Worker Process has two configured endpoints.
- The throttling rate is applied after compression.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Inspecting Payloads to Troubleshoot Closed Connections

When a downstream receiver closes connections from this Destination (or just stops responding), inspecting the payloads of the resulting failed requests can help you find the cause. For example:

- Suppose you send an event whose size is larger than the downstream receiver can handle.
- Suppose you send an event that has a `number` field, but the value exceeds the highest number that the downstream receiver can handle.

When **Log failed requests to disk** is enabled, you can inspect the payloads of failed requests. Here is how:

1. In the Destination UI, navigate to the **Logs** tab.
2. Find a log entry with a `connection error` message.
3. Expand the log entry.
4. If the message includes the phrase `See payload file for more info`, note the path in the `file` field on the next line.

Now you have the path to the directory where Cribl Stream is storing payloads from failed requests. At the command line, navigate to that directory and inspect any payloads that you think might be relevant.

SSL Configuration for Splunk Cloud

To connect to Splunk Cloud, you will need to extract the private and public keys from the Splunk-provided Splunk Cloud Universal Forwarder credentials package. You will also need to reference the CA Certificate located in the same package.

You can reuse many of the settings in this Splunk Cloud package to set up Splunk Cloud Destinations. Use the following steps:

Step 1. Extract the `splunkclouduf.spl` package on the Cribl Stream instance that you will be connecting to Splunk Cloud. You will have a folder that looks something like this:

```
100_my-splunk-cloud_splunkcloud
        /default/
                outputs.conf
                limits.conf
                your-splunk-cloud_server.pem
                your-splunk-cloud_cacert.pem
```

Step 2. (optional) Test connectivity to Splunk Cloud, using the Root CA certificate:

```
echo | openssl s_client -CAfile 100_<your-splunk-cloud>_splunkcloud/default/my-splunl
```

To test the connection, you can use any of the URLs listed in the `[tcpout:splunkcloud]` stanza's `outputs.conf` section.

You can simplify Steps 3 and 4 below by dragging and dropping (or uploading) the `.pem` files into Cribl Stream's **New Certificates** modal. See Configure TLS for API and UI Access.

Step 3. Extract the private key from the Splunk Cloud certificate. At the prompt, you will need the `sslPassword` value from the `outputs.conf`. Using Elliptic Curve keys:

```
openssl ec -in 100_<your-splunk-cloud>_splunkcloud/default/<your-splunk-cloud>_serve
```

If you are using RSA keys, instead use:

```
openssl rsa -in 100_<your-splunk-cloud>_splunkcloud/default/<your-splunk-cloud>_serv
```

Step 4. Extract the public key for the Server Certificate:

```
openssl x509 -in 100_<your-splunk-cloud>_splunkcloud/default/<your-splunk-cloud>_ser
```

Step 5. In the Splunk Load Balanced Destination's TLS Settings (Client Side) section, enter the following:

- CA Certificate Path: Path to `<your-splunk-cloud>_cacert.pem`.
- Private Key Path (mutual auth): Path to `private.pem` (Step 3 above).
- Certificate Path (mutual auth): Path to `server.pem` (Step 4 above).

In a distributed deployment, enter this Destination configuration on each Worker Group/Fleet that forwards to Splunk Cloud. Then commit and deploy your changes.

Step 6. In a distributed deployment, enable Worker UI access, and verify that the Certificate files have been distributed to individual workers. If they are not present, copy the Certificate files to the Workers, using exactly the same paths you used at the Group level.

Notes About Forwarding to Splunk

- Data sent to Splunk is **not** compressed.

- The only `ack` from indexers that Cribl Stream listens for and acts upon is the shutdown signal described in Minimize in-flight data loss above.
- If events have a Cribl Stream internal field called `__criblMetrics`, they'll be forwarded to Splunk as metric events.
- If events do not have a `_raw` field, they'll be serialized to JSON prior to sending to Splunk.
- You can copy and paste the Splunk Cloud servers from the `[tcpout:splunkcloud]` stanza into **General Settings** > **Destinations**. For example, from the example stanza below, you would copy only the bolded contents:

  ~~[tcpout:splunkcloud]~~
  ~~server =~~ **inputs1.your-splunk-cloud.splunkcloud.com:9997, inputs2.your-splunk-cloud.splunkcloud.com:9997, inputs3.your-splunk-cloud.splunkcloud.com:9997, inputs4.your-splunk-cloud.splunkcloud.com:9997, inputs5.your-splunk-cloud.splunkcloud.com:9997, inputs6.your-splunk-cloud.splunkcloud.com:9997, inputs7.your-splunk-cloud.splunkcloud.com:9997, inputs8.your-splunk-cloud.splunkcloud.com:9997, inputs9.your-splunk-cloud.splunkcloud.com:9997, inputs10.your-splunk-cloud.splunkcloud.com:9997, inputs11.your-splunk-cloud.splunkcloud.com:9997, inputs12.your-splunk-cloud.splunkcloud.com:9997, inputs13.your-splunk-cloud.splunkcloud.com:9997, inputs14.your-splunk-cloud.splunkcloud.com:9997, inputs15.your-splunk-cloud.splunkcloud.com:9997**
  ~~compressed = false~~
- From `limits.conf`, copy the `[thruput]` value, then paste it into **Advanced Settings** > **Throttling**.
- If you enable both (1) indexer discovery and (2) TLS with certificate validation, you see might errors. This happens because the IPs discovered (by default) for the indexers will not match the fully qualified domain names (FQDNs) referenced by the indexer certificates. This causes the TLS handshake to fail.
  - As a workaround, use `server.conf` on each indexer, setting `register_forwarder_address = <your.idx.fqdn>`. Cribl Stream will now get that value, and the certificates will match.
- See Splunk's documentation on editing `fields.conf` to ensure the visibility of index-time fields sent to Splunk by Cribl Stream.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Cribl University's Advanced Troubleshooting short courses include Destination Integrations: Splunk LB and Destination Integrations: Splunk Cloud. To follow these direct course links, first log into your Cribl University account. (To create an account, select the **Sign up** link. You'll need to select through a short **Terms & Conditions** presentation, with chill music, before proceeding to courses – but Cribl's training is always free of charge.) Once logged in, check out other useful Advanced Troubleshooting short courses and Troubleshooting Criblets.

15.2.12. Internal

15.2.12.1. Cribl HTTP Destination

The Cribl HTTP Destination sends data to a Cribl HTTP Source connected to the same Leader. Relaying data between a Cribl HTTP Destination and Cribl HTTP Source pair prevents double-billing: You'll be charged no additional charges or credits after initial ingest to the first Worker Group.

It's common to send data from Cribl Edge to a Cribl Stream Worker Group using this kind of pairing.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

For guidance on when to choose this Source versus the Cribl TCP Destination, see Interoperation Protocols.

Within Cribl Stream, the Cribl HTTP Destination is available only in Distributed deployments.
In single-instance mode, or for testing, you can use the Webhook Destination instead. However, this substitution will not facilitate sending all internal fields, as described below.

How It Works

You can use the Cribl HTTP Destination to transfer data between Worker Nodes and Workers. If the Cribl HTTP Destination sends data to its Cribl HTTP Source counterpart on another Worker, you're billed for ingress only once – when Cribl first receives the data. All data subsequently relayed to other Workers via a Cribl HTTP Destination/Source pair is not charged.

This use case is common in hybrid Cribl.Cloud deployments, where a customer-managed (hybrid) Worker Node sends data to a Worker in Cribl.Cloud for additional processing and routing to Destinations. However, the Cribl HTTP Destination/Source pair can similarly reduce your metered data ingress in other scenarios, such as on-prem Edge to on-prem Stream.

As one usage example, assume that you want to send data from one Node deployed on-prem, to another that is deployed in Cribl.Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl.Cloud.
- Create an on-prem Cribl HTTP Destination.
- Create a Cribl HTTP Source, on the target Stream Worker Group or Edge Fleet in Cribl.Cloud.
- For an on-prem Node configure a File System Collector to send data to the Cribl HTTP Destination, and from there to the Cribl HTTP Source in Cribl.Cloud.

- On Cribl-managed Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl HTTP Destination and the Cribl HTTP Source it's sending data to, or enabled on both. Otherwise, no data will flow. On Cribl.Cloud instances, the Cribl HTTP Source ships with TLS enabled by default.

Configuration Requirements

The key points about configuring this architecture are:

- The Cribl HTTP Destination must be on a Node that is connected to the same Leader as the Cribl HTTP Source(s).
- This Destination's **Cribl endpoint** field must point to the **Address** and **Port** you've configured on its peer Cribl HTTP Source(s).
- Cribl 3.5.4 was a breakpoint in Cribl HTTP Leader/Worker communications. Nodes running the Cribl HTTP Destination on Cribl 3.5.4 and later can receive data only from Nodes running v.3.5.4 and later. Nodes running the Cribl HTTP Destination on Cribl 3.5.3 and earlier can receive data only from Nodes running v.3.5.3 and earlier.

Configure a Cribl HTTP Destination

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: Set to `No` by default. When toggled to `Yes`, see Load Balancing Settings below. With the default `No` setting, if you notice that Cribl Stream is not sending data to all possible IP addresses, enable **Advanced Settings** > **Round-robin DNS**.
    - **Cribl endpoint**: URL of a Cribl Worker to send events to, for example, `http://localhost:10200`.

The **Cribl endpoint** field appears only when **Load balancing** is toggled to `Off`. Its value must point to the **Address** and **Port** you've configured on the peer Cribl HTTP Source to which

you're sending.

3. Next, you can configure the following **Optional Settings**:
   - **Compression**: Codec to use to compress the data before sending. Defaults to `Gzip`.
   - **Backpressure behavior**: Specifies whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`. See Persistent Queue Settings below.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any TLS settings, Persistent Queue, Retries, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Load Balancing Settings

Enabling the **Load balancing** toggle displays the following controls.

Exclude Current Host IPs: Displays under **Optional Setting** when **Load balancing** is toggled to `Yes`. This toggle determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Defaults to No, which keeps the current host available for load balancing.

Cribl Worker Endpoints: In this table, you specify a set of Cribl Workers on which to load-balance data. To specify more Workers on new rows, click **Add Endpoint**. Each row provides the following fields.

Cribl Endpoint: Enter the URL of a Worker to send events to.

Must point to the **Address** and **Port** configured on a peer Cribl HTTP Source to which you're sending.

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (> `0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Stream will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

TLS Settings (Client Side)

Use TLS defaults to `No`. When toggled to `Yes`:

Autofill?: This setting is experimental.

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`. Overrides the **Validate server certs** setting in **Advanced Settings**.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`. This setting is also configurable in **TLS Settings (Client Side)**. If you enable Client-Side TLS, the validation rules defined there will override this setting.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned. Only displayed when the General Settings tab's **Load balancing** option is disabled.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Exclude fields: Fields to exclude from the event. This Destination excludes `__kube_*`, `__metadata`, and `__winEvent` by default and forwards all other Internal Fields. For more information about `__winEvent`, see the Windows Event Logs Source topic.

If you are running Cribl Stream 4.0.x (or earlier) and are using the Kubernetes Metrics Source with this Destination, consider excluding the following fields to reduce event size:

```
!__inputId,!__outputId,!__criblMetrics,__* .
```

The contents of `__raw` are often redundant with the `_raw` field's contents. Where they are identical, consider excluding one of the two.

Auth Token TTL minutes: The number of minutes before the internally generated authentication token expires, valid values between 1 and 60.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

The following options are added if you enable the General Settings tab's **Load balancing** option:

DNS resolution period (seconds): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from A records. Defaults to `600` seconds.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds. (Note that If multiple receivers are behind a hostname – i.e., multiple A records – all resolved IPs will inherit the weight of the host, unless each IP is specified separately. In Cribl Stream load balancing, IP settings take priority over those from hostnames.)

Internal Fields Loopback to Sources

The Cribl HTTP and Cribl TCP Destinations differ from all other Destinations in the way they handle internal fields: They normally send data back to their respective Cribl Sources – where Cribl internal fields, metrics, and sender-generated fields can all be useful.

These Destinations forward all internal fields by default, except for any that you exclude in **Advanced Settings** > **Exclude fields**.

As examples, if the following fields are present on an event forwarded by a Cribl HTTP or Cribl TCP Destination, they'll be accessible in the ingesting Cribl HTTP/TCP Source: `__criblMetrics`, `__srcIpPort`, `__inputId`, and `__outputId`.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

15.2.12.2. Cribl TCP Destination

The Cribl TCP Destination sends data to a Cribl TCP Source connected to the same Leader. Relaying data between a Cribl TCP Destination and Cribl TCP Source pair prevents double-billing: You'll be charged no additional charges or credits after initial ingest to the first Worker Group.

It's common to send data from Cribl Edge to a Cribl Stream Worker Group using this kind of pairing.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

For guidance on when to choose this Source versus the Cribl HTTP Destination, see Interoperation Protocols.

Within Cribl Stream, the Cribl TCP Destination is available only in Distributed deployments. In single-instance mode, or for testing, you can use the TCP JSON Destination instead. However, this substitution will not facilitate sending all internal fields, as described below.

How It Works

You can use the Cribl TCP Destination to transfer data between Worker Nodes and Workers. If the Cribl TCP Destination sends data to its Cribl TCP Source counterpart on another Worker, you're billed for ingress only once – when Cribl first receives the data. All data subsequently relayed to other Workers via a Cribl TCP Destination/Source pair is not charged.

This use case is common in hybrid Cribl.Cloud deployments, where a customer-managed (hybrid) Worker Node sends data to a Worker in Cribl.Cloud for additional processing and routing to Destinations. However, the Cribl TCP Destination/Source pair can similarly reduce your metered data ingress in other scenarios, such as on-prem Cribl Edge to on-prem Cribl Stream.

As one usage example, assume that you want to send data from one Node deployed on-prem, to another that is deployed in Cribl.Cloud. You could do the following:

- Create an on-prem File System Collector (or whatever Collector or Source is suitable) for the data you want to send to Cribl.Cloud.
- Create an on-prem Cribl TCP Destination.
- Create a Cribl TCP Source, on the target Cribl Stream Worker Group or Cribl Edge Fleet in Cribl.Cloud.
- For an on-prem Node configure a File System Collector to send data to the Cribl TCP Destination, and from there to the Cribl TCP Source in Cribl.Cloud.
- On Cribl-managed Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl TCP Destination and the Cribl TCP Source it's sending data to, or enabled on both. Otherwise, no data will

flow. On Cribl.Cloud instances, the Cribl TCP Source ships with TLS enabled by default.

Configuration Requirements

The key points about configuring this architecture are:

- The Cribl TCP Destination must be on a Node that is connected to the same Leader as the Cribl TCP Source.
- When you configure the Cribl TCP Destination, its **Address** and **Port** values must point to the **Address** and **Port** you've configured on the Cribl TCP Source.
- Cribl 3.5.4 was a breakpoint in Cribl TCP Leader/Worker communications. Nodes running the Cribl TCP Source on Cribl 3.5.4 and later can send data only to Nodes running v.3.5.4 and later. Nodes running the Cribl TCP Source on Cribl 3.5.3 and earlier can send data only to Nodes running v.3.5.3 and earlier.

Configure a Cribl TCP Destination

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: When toggled to `Yes`, see Load Balancing Settings below.

      The following two fields appear **only** with **Load balancing**'s default `No` setting, and must match the **Address** and **Port** you've configured on the peer Cribl TCP Source to which you're sending.

    - **Address**: Hostname of the receiver.
    - **Port**: Port number to connect to on the host, for example, `10300`.
3. Next, you can configure the following **Optional Settings**:
    - **Compression**: Codec to use to compress the data before sending. Defaults to `Gzip`.

- **Throttling**: Throttle rate, in bytes per second. Defaults to `0`, meaning no throttling. Multiple-byte units such as KB, MB, and so forth, are also allowed – for example, `42 MB`. When throttling is engaged, your **Backpressure behavior** selection determines whether Cribl Stream will handle excess data by blocking it, dropping it, or queueing it to disk. When used in conjunction with **Max connections**, the throttling rate is applied per connection. For instance, if **Max connections** is set to `2` and throttling is set to `3 MB`, each of the two connections can send data at a rate of up to 3 MB per second, resulting in a total potential throughput of 6 MB per second across both connections.
- **Backpressure behavior**: Specifies whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`. See Persistent Queue Settings below.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, configure any TLS settings, Persistent Queue, Timeout, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Load Balancing Settings

Enabling the **Load balancing** toggle displays the following controls:

Exclude Current Host IPs

Displays under **Optional Setting** when **Load balancing** is toggled to `Yes`. This toggle determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Defaults to `No`, which keeps the current host available for load balancing.

Destinations

The **Destinations** table is where you specify a set of receivers on which to load-balance data.
Click **Add Destination** to specify more receivers on new rows. Each row provides the following fields:

Address: Hostname of a receiver. Optionally, you can paste in a comma-separated list, in `<host>:<port>` format.

Port: Port number to send data to on the host.

Each **Address**/**Port** combination must match the **Address** and **Port** configured on a peer TCP Source to which you're sending.

TLS: Whether to inherit TLS configs from group setting, or disable TLS. Defaults to `inherit`.

TLS servername: Servername to use if establishing a TLS connection. If not specified, defaults to connection host (if not an IP); otherwise, uses the global TLS settings.

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (> `0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Stream will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior.

Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

TLS Settings (Client Side)

Use TLS defaults to `No`. When toggled to `Yes`:

Autofill?: This setting is experimental.

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `No`.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Timeout Settings

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish before retrying. Defaults to `10000`.

Write timeout: Amount of time (in milliseconds) to wait for a write to complete before assuming connection is dead. Defaults to `60000`.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Auth Token TTL minutes: The number of minutes before the internally generated authentication token expires, valid values between 1 and 60.

Exclude fields: Fields to exclude from the event. This Destination excludes `__kube_*`, `__metadata`, and `__winEvent` by default and forwards all other Internal Fields. For more information about `__winEvent`, see the Windows Event Logs Source topic.

If you are running Cribl Stream 4.0.x (or earlier) and are using the Kubernetes Metrics Source with this Destination, consider excluding the following fields to reduce event size:

`!__inputId,!__outputId,!__criblMetrics,__* .`

The contents of `__raw` are often redundant with the `_raw` field's contents. Where they are identical, consider excluding one of the two.

Log failed requests to disk: Toggling to `Yes` makes the payloads of any (future) failed requests available for inspection. See Inspecting Payloads to Troubleshoot Closed Connections below.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

The following options are added if you enable the General Settings tab's **Load balancing** option:

DNS resolution period (seconds): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from A records. Defaults to `600` seconds.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds. (Note that If multiple receivers are behind a hostname – i.e., multiple A records – all resolved IPs will inherit the weight of the host, unless each IP is specified separately. In Cribl Stream load balancing, IP settings take priority over those from hostnames.)

Max connections: Constrains the number of concurrent receiver connections, per Worker Process, to limit memory utilization. If set to a number > `0`, then on every DNS resolution period, Cribl Stream will randomly

select this subset of discovered IPs to connect to. Cribl Stream will rotate IPs in future resolution periods – monitoring weight and historical data, to ensure fair load balancing of events among IPs.

Inspecting Payloads to Troubleshoot Closed Connections

When a downstream receiver closes connections from this Destination (or just stops responding), inspecting the payloads of the resulting failed requests can help you find the cause. For example:

- Suppose you send an event whose size is larger than the downstream receiver can handle.
- Suppose you send an event that has a `number` field, but the value exceeds the highest number that the downstream receiver can handle.

When **Log failed requests to disk** is enabled, you can inspect the payloads of failed requests. Here is how:

1. In the Destination UI, navigate to the **Logs** tab.
2. Find a log entry with a `connection error` message.
3. Expand the log entry.
4. If the message includes the phrase `See payload file for more info`, note the path in the `file` field on the next line.

Now you have the path to the directory where Cribl Stream is storing payloads from failed requests. At the command line, navigate to that directory and inspect any payloads that you think might be relevant.

Internal Fields Loopback to Sources

The Cribl TCP and Cribl HTTP Destinations differ from all other Destinations in the way they handle internal fields: They normally send data back to their respective Cribl Sources – where Cribl internal fields, metrics, and sender-generated fields can all be useful.

These Destinations forward all internal fields by default, except for any that you exclude in **Advanced Settings** > **Exclude fields**.

As examples, if the following fields are present on an event forwarded by a Cribl HTTP or Cribl TCP Destination, they'll be accessible in the ingesting Cribl HTTP/TCP Source: `__criblMetrics`, `__srcIpPort`, `__inputId`, and `__outputId`.

15.2.12.3. Cribl Stream Destination (Deprecated)

This Destination was deprecated as of Cribl Stream 3.5, and has been removed as of v.4.0. Please instead use the Cribl TCP or the Cribl HTTP Destination to enable Worker Nodes to send data to peer Nodes.

The Cribl Stream Destination enables Edge Nodes, and/or Cribl Stream instances, to send data to one or multiple Cribl Stream instances.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Use New Destinations Instead

The replacement Destinations, Cribl TCP and Cribl HTTP, don't rely on IP filtering, for the following reasons:

- Load balancers and/or proxies between the Cribl Destination and Cribl Source can change the IP address, resulting in a bad match and rejected ingest.
- A Lookup table of all IP addresses needed to be sent to each Worker Node/Edge Node from the Leader, which is not scalable.
- The Lookup table of IP addresses required constant communication between the Worker Node/Edge Nodes and the Leader, making this fragile and placing an arbitrary reliance on the Leader that shouldn't be there.

Configuring a Cribl Stream Destination

In the **QuickConnect** UI: Click **Add Destination** beside **Destinations**. From the resulting drawer's tiles, select **Cribl Stream**. Next, click **Add Destination** to open a **New Cribl Stream** drawer.

Or, in the **Data Routes** UI: From the top nav of a Cribl Stream instance or Group, select **Data** > **Destinations**. From the top nav of a Cribl Edge instance or Fleet, select **More** > **Destinations**.

From the resulting page's tiles or the **Destinations** left nav, select **Cribl Stream**. Next, click **New Destination** to open a **Cribl Stream** > **New Destination** modal that provides the following options and fields.

General Settings

Output ID: Enter a unique name to identify this Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.

Address: Hostname of the receiver.

Port: Port number to connect to on the host.

Authentication Settings

Use the **Authentication method** buttons to select one of these options:

- **Manual**: In the resulting **Auth token** field, you can optionally enter an auth token to use in the connection header.
- **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the `authToken` header field value described above. A **Create** link is available to store a new, reusable secret.

Optional Settings

Compression: Codec to use to compress the data before sending. Defaults to `None`.

Throttling: Throttle rate, in bytes per second. Defaults to `0`, meaning no throttling. Multiple-byte units such as KB, MB, GB etc. are also allowed, for example, `42 MB`. When throttling is engaged, your **Backpressure behavior** selection determines whether Cribl Stream will handle excess data by blocking it, dropping it, or queueing it to disk.

Backpressure behavior: Specifies whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`. See Persistent Queue Settings below.

Tags: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

Persistent Queue Settings

This tab is displayed when the **Backpressure behavior** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described below in this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Destination will stop queueing data and apply the **Queue-full** behavior. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Stream will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue is exerting backpressure (because disk is low or at full capacity). **Block** is the same behavior as non-PQ blocking, corresponding to the **Block** option on the **Backpressure behavior** drop-down. **Drop new data** throws away incoming data, while leaving the contents of the PQ unchanged.

Clear Persistent Queue: Click this "panic" button if you want to delete the files that are currently queued for delivery to this Destination. A confirmation modal will appear - because this will free up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (Appears only after **Output ID** has been defined.)

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, toggle this off. Doing so will expose this additional control:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue's drain rate can boost the throughput of new/active connections, by reserving more resources for them. You can further optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

TLS Settings (Client Side)

Enabled defaults to `No`. When toggled to `Yes`:

Autofill?: This setting is experimental.

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `No`.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Timeout Settings

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish before retrying. Defaults to `10000`.

Write timeout: Amount of time (in milliseconds) to wait for a write to complete before assuming connection is dead. Defaults to `60000`.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.

- `cribl_output` – Cribl Stream Destination that processed the event.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.12.4. Default Destination

The **Default** Destination simply enables you to specify a default output from among your already-configured Destinations.

Type: Internal | TLS Support: N/A | PQ Support: N/A

Configure Cribl Stream's Default Destination

In Cribl Stream configure Default.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). A **Default** Destination is preconfigured and ready to use in the right **Destinations** column. Hover over the tile and click its **Configure** button to proceed.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. From the resulting **Destinations** page, click anywhere on the `default` row to proceed.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: This is prefilled with the default value `default`, which cannot be changed via the UI.
    - **Default Output ID** drop-down to select one of your configured Destinations.
3. Select **Save**, then **Commit & Deploy**.

Preventing Circular References

If you've configured an Output Router Destination with a branch that points to this Default Destination (`default:default`), you cannot select that Output Router here. This restriction prevents a circular dependency.

15.2.12.5. DevNull Destination

The DevNull Destination simply drops events. Cribl provides this as a basic output to test Pipelines and Routes.

Type: Internal | TLS Support: N/A | PQ Support: N/A

Configure Cribl Stream to Forward to DevNull

DevNull requires no configuration: A DevNull Destination is preconfigured and active as soon as you install Cribl Stream. To verify this, follow the direction below.

On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:

- To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). A **DevNull** Destination is preconfigured and ready to use in the right **Destinations** column.
- To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. From the resulting **Destinations** page, click anywhere on the `devnull` row to proceed.

15.2.12.6. Output Router Destination

Output Routers are meta-destinations that allow for output selection based on rules. Rules are evaluated in order, top-down, with the first match being the winner.

Type: Internal | TLS Support: N/A | PQ Support: N/A

Configure Cribl Stream to Send to an Output Router

In Cribl Stream, configure Output Router:

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Router name**: Enter a unique name to identify this Router definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Rules**: A list of event routing rules. For details, see Rules below.
3. Next, you can configure the following **Optional Settings**:
    - **System fields**: A list of fields to automatically add to events that use this output. For details, see System Fields below.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Rules

Configure the following event routing rules settings.

- **Filter expression**: JavaScript expression to select events to send to output.
- **Output**: Output to send matching events to.
- **Description**: Optionally, enter a description of this rule's purpose.
- **Final**: Toggle to `No` if you want the event to be checked against other rules lower in the stack.

System Fields

By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Limitations/Options

- An Output Router cannot reference another. This is by design, to avoid circular references.
- Also to avoid circular references, an Output Router cannot reference a Default Destination that points back to Output Router.
- **Events that do not match any of the rules are dropped**. Use a catch-all rule to change this behavior.
- No post-processing (conditioning) can be attached to the Output Router Destination itself. But you are free to use pre-processing Pipelines on the Source tier, and post-processing Pipelines on any or all Destinations that the Output Router references.
- Data can be cloned by toggling the `Final` flag to `No`. (The default is `Yes`, i.e., no cloning.)

Example

Scenario:

- Send all events where `host` starts with `66` to Destination `San Francisco`.

- From the rest of the events: Send all events with `method` field `POST` or `GET` to both `Seattle` and `Los Angeles` (i.e., clone them).
- Send the remaining events to `New York City`.

Router Name: **router66**

Filter Expression	Output	Final
`host.startsWith('66')`	**San Francisco**	Yes
`method=='POST' || method=='GET`	**Seattle**	No
`method=='POST' || method=='GET'`	**Los Angeles**	Yes
`true`	**New York**	Yes

15.2.13. CrowdStrike Falcon LogScale Destination

The **CrowdStrike Falcon LogScale** Destination can stream data to a LogScale HEC (HTTP Event Collector) in JSON or Raw format.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

(In Cribl Stream 3.5.x, this Destination was labeled **Humio HEC**. Some links from this page might still lead to "Humio"-branded resources that CrowdStrike has not renamed.)

Recommendations

To load-balance to customer-managed LogScale receivers, Cribl recommends placing a load balancer in front of cluster nodes, following LogScale Manual Cluster Deployment recommendations. If you are using LogScale Cloud, it provides its own load balancing.

We recommend sending events with the `sourceType` field set to a LogScale parser. This tells LogScale which parser to use to extract fields (for example, `"sourceType":"json"`).

If LogScale cannot match the `sourceType` value to a parser, it will use the `kv` parser, and you will get an error that LogScale could not resolve the specified parser. Alternatively, you can assign a parser to the ingest token that you use to authenticate this Destination.

The `fields` element does not support Nested JSON. Any nested elements will be dropped.

Configure Cribl Stream to Output to CrowdStrike Falcon LogScale Destinations

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:

- **Output ID**: Enter a unique name to identify this CrowdStrike Falcon LogScale definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
- **Description**: Optionally, enter a description.
- **LogScale endpoint**: URL of a CrowdStrike Falcon LogScale endpoint to send events to (for example, `https://cloud.us.humio.com:443/api/v1/ingest/hec`).

  JSON-formatted events normally go to `/api/v1/ingest/hec` or `/services/collector`.

  Raw (simple line-delimited) events normally go to `/api/v1/ingest/hec/raw` or `/services/collector/raw`.

- **Request format**: Select how you want events formatted, either `JSON` or `Raw`. Make sure your selection here matches the **LogScale endpoint** you specify above.

3. Under **Authentication**, select an **Authentication method** from the dropdown:
   - **Manual**: Displays a **LogScale Auth token** field for you to enter your CrowdStrike Falcon LogScale HEC API token.
   - **Secret**: Displays a **LogScale token (text secret)** drop-down, in which you can select a stored secret that references the API token described above. A **Create** link is available to store a new, reusable secret.
4. Next, you can configure the following **Optional Settings**:
   - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Defaults to `Yes` to reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA).

Round-robin DNS: Defaults to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Defaults to `Yes` to compress the payload body before sending.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`. Each request can potentially hit a different HEC receiver.

Max body size (KB): Maximum size, in KB, of the request body. Defaults to `4096`. Lowering the size can potentially result in more parallel requests and also cause outbound requests to be made sooner.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than the configured **Max body size**. Defaults to `1`.

- Retries happen on this flush interval.
- Any HTTP response code in the `2xx` range is considered success.
- Any response code in the `5xx` range is considered a retryable error, which will not trigger Persistent Queue (PQ) usage.
- Any other response code will trigger PQ (if PQ is configured as the Backpressure behavior).

Extra HTTP headers: Click **Add Header** to add **Name**/**Value** pairs to pass as additional HTTP headers. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers that you want to declare as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new connection will be reattempted. This is to prevent sticking to a particular Destination when there is a constant flow of events.
- If the server does not support keepalives – or if the server closes a pooled connection while idle – a new connection will be established for the next request.
- Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between CrowdStrike Falcon LogScale servers.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.14. ClickHouse Destination

The ClickHouse Destination enables seamless integration with ClickHouse. This Destination routes observability data, including logs, metrics, and traces, to ClickHouse for enhanced monitoring and analysis.

Data is formatted and transmitted via HTTP requests, offering both synchronous and asynchronous insert options for flexibility. Authentication is secured with Basic or SSL User Certificate methods, while robust retry settings ensure reliable data delivery. Flexible data mapping, including automatic and manual field-to-column mapping, guarantees structured ingestion. To optimize performance, the integration supports batching and asynchronous inserts, leveraging ClickHouse's capabilities for efficient data delivery.

To get started, connecting to ClickHouse is simple. Grab your ClickHouse instance's HTTP interface URL, database name, and table name, then add these details to your Destination settings. Need more detailed instructions or configuration options? See below!

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Configure a ClickHouse Destination

In Cribl Stream, set up a ClickHouse Destination.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing**.
    - To configure via the Routes, select **Data** > **Destinations** (Stream) or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the Destination modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**. A **Description** is optional.
    - **URL**: The URL of your ClickHouse instance's HTTP interface. This should include the protocol (http or https) and the port number if it's not the default. Example: `http://localhost:8123`.
    - **ClickHouse database**: Enter the name of the ClickHouse database where the target table resides. Ensure that the database exists and the authenticated user has the necessary permissions to write to it.
    - **ClickHouse table**: Enter the name of the target table. The name can contain letters (`A-Z`, `a-z`), numbers (`0-9`), and underscores `_`, and must start with either a letter or underscore. The table

must exist and have a schema compatible with the data being sent.

- **Format**: Choose the format for events sent to ClickHouse. Choose between:
  - **JSONCompactEachRowWithNames** (default): Optimized for efficiency by minimizing data size, making it ideal for transmitting data to ClickHouse over networks where bandwidth is a concern.
  - **JSONEachRow**: Standard JSON format with extra spacing, useful for debugging or human inspection. If the time spent reformatting data into the compact format exceeds the cost of transmitting more data, `JSONEachRow` may be preferable. For example, in scenarios where the ClickHouse instance runs on the same machine as Cribl, the network cost is negligible, and the time spent reformatting doesn't provide significant benefits.
- **Authentication type**: ClickHouse supports several authentication methods for its HTTP interface.
  - **None**: Don't use authentication.
  - **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
  - **Basic (credentials secret)**: This option exposes a **Credentials secret** drop-down to select a stored text secret that contains your username and password credentials referenced by a secret. A **Create** link is available to store a new, reusable secret.
  - **SSL User Certificate**: Use to securely connect to ClickHouse. Provide the username for certificate authentication. This method ensures a higher level of security by using SSL certificates to verify the identity of the client.
- **Mapping**: Determines how fields from Cribl events are mapped to ClickHouse columns. Options include `Automatic` and `Custom`.
  - **Automatic**: Uses default mappings.
    - **Exclude fields**: A list of fields to exclude from the data sent to ClickHouse. This can help reduce the size of the data and avoid sending unnecessary information.
  - **Custom**: Manually specify column mappings. Select **Retrieve table columns** to connect to a publicly accessible ClickHouse instance, authenticate using the provided credentials, and fetch the table schema. The retrieved column names and types will be automatically populated in the **Column Mapping** table, allowing you to focus on mapping the appropriate data values.
    - The **Column Mapping** table allows you to define how event data fields are mapped to ClickHouse table columns. This is essential for ensuring that data is correctly ingested into ClickHouse with the appropriate structure and types. See Data Types in ClickHouse for details.
      - **Column name**: The name of the column in the ClickHouse table. This should match the column name defined in the ClickHouse schema.
      - **Column type**: The data type of the column in the ClickHouse table (such as, `String`, `Int32`, `DateTime`). This ensures that the data is stored in the correct

format.

- **Column value**: A JavaScript expression that defines how to extract or transform the event data to fit into the specified column. This allows for flexible data manipulation and transformation before ingestion.

- **Async**: The **Async inserts** toggle enables asynchronous inserts, allowing ClickHouse to buffer data in memory before writing it to disk. This can improve performance but may risk data loss if the server crashes before the data is written.
  - **Wait for async inserts** waits for the ClickHouse server to confirm that the data has been fully written to disk before proceeding. This ensures a higher level of data integrity by reducing the risk of data loss if the server encounters an issue before full insertion. This setting balances throughput and data assurance, making it suitable for high-volume logging where occasional data loss is acceptable.
- **Optional Settings**:
  - **Backpressure behavior**: Whether to `Block`, `Drop`, or `Persistent Queue` events when all receivers are exerting backpressure.
  - **Tags**: Optionally, add tags that you can use to filter and group Destinations in Cribl Stream's **Manage Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

3. If you're using TLS, select **TLS Settings (Client Side)** on the left tabs and toggle **Use TLS** to `Yes`. See the TLS Settings section for details. Defaults to `No`.
4. The **Processing Settings**, **Retries**, and **Advanced Settings** provide granular control over how data is handled and transmitted.
   - Processing Settings allow you to define pre-processing and post-processing Pipelines, ensuring that events conform to the relevant Protobuf specifications for traces, metrics, and logs. This includes adding metadata, applying transformations, and conditioning the data before it is sent to the destination.
   - Retries allow you to specify how the system should handle different HTTP response status codes and timeouts, ensuring reliable data delivery.
   - Advanced Settings offer additional configuration options that enhance the flexibility and performance of data transmission.
5. Select **Save**, then **Commit & Deploy**.
6. Use the **Test** tab in the Destination's configuration modal to validate the configuration and connectivity of your Destination.

TLS Settings (Client Side)

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Persistent Queue Settings

This tab is displayed when the **Backpressure behavior** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described below in this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Choose the condition for engaging persistent queues. Options include `Smart` and `Always On`.

- **Smart**: Engages persistent queues only when the Destination detects backpressure. This mode helps optimize performance by using disk storage only when necessary.
- **Always On**: Always write events into the persistent queue before forwarding them. This mode ensures maximum data durability but may require more disk space.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space the queue is allowed to consume. Once this limit is reached, queueing is stopped and data blocking is applied. Enter a numeral with units of KB, MB, and so on.

Queue file path: The location for the persistent queue files. This will be of the form: `your/path/here/<worker-id>/<output-id>`. Defaults to: `$CRIBL_HOME/state/queues`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue is exerting backpressure (because disk is low or at full capacity). **Block** is the same behavior as non-PQ blocking, corresponding to the **Block** option on the **Backpressure behavior** drop-down. **Drop new data** throws away incoming data, while leaving the contents of the PQ unchanged.

Clear Persistent Queue: Select this "panic" button if you want to delete the files that are currently queued for delivery to this Destination. A confirmation modal will appear - because this will free up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (Appears only after **Output ID** has been defined.)

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, toggle this off. Doing so will expose this additional control:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue's drain rate can boost the throughput of new/active connections, by reserving more resources for them. You can further optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output – both metric events, as dimensions; and log events, as labels. Supports wildcards.

By default, includes `cribl_pipe` (Cribl Stream Pipeline that processed the event).

Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.

- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this to `Yes` to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. You can set this limit to as high as 500 MB (`512000` KB). Be aware that high values can cause high memory usage per Worker Node, especially if a dynamically constructed URL (see Internal Fields) causes this Destination to send events to more than one URL. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass to all events as additional HTTP headers. Values will be sent encrypted. You can also add headers dynamically on a per-event basis in the `__headers` field. See Internal

Fields below.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Troubleshoot

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.15. CrowdStrike Falcon Next-Gen SIEM Destination

The **CrowdStrike Falcon Next-Gen SIEM** Destination sends data to CrowdStrike Falcon Next-Gen SIEM.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Configuring a CrowdStrike Falcon Next-Gen SIEM Destination

1. From the top nav, click **Manage**, then select a **Worker Group** to configure. Next, you have two options:
    - To configure via QuickConnect, click **Routing** then **QuickConnect** (Cribl Stream) or **Collect** (Cribl Edge). Next, click **Add Destination** and from the resulting drawer's tiles, select **CrowdStrike Falcon Next-Gen SIEM**. Next, click either **Add Destination** or (if displayed) **Select Existing**.
    - To configure via the Routes, click **Data** then **Destinations** (Cribl Stream) or **More** then **Destinations** (Cribl Edge). Select **CrowdStrike Falcon Next-Gen SIEM** from the list of tiles or the **Destinations** list. Next, click **Add Destination** to open a **New Destination** modal.
2. In the Destination modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Next-Gen SIEM endpoint**: The URL for sending data to CrowdStrike's Falcon Next-Gen SIEM. This URL is generated within the CrowdStrike platform and directs your data to the appropriate SIEM instance for processing.
    - **Request format**: Select how you want events formatted, either `JSON` or `Raw`.
        - `JSON` automatically structures the data in a standard JSON format.
        - `Raw` (the default) sends only the event's `_raw` value.
3. Under **Authentication** select an **Authentication method** from the drop-down:
    - **Manual**: Displays a **Next-Gen SIEM auth token** field for you to enter your authentication token.
    - **Secret**: Displays a **Next-Gen SIEM auth token (text secret)** drop-down, in which you can select a stored secret that references the API token described above. A **Create** link is available to store a new, reusable secret.
4. Next, you can configure the following **Optional Settings** that you'll find across many Cribl Destinations:
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.

- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, configure any Persistent Queue, Processing, Retries, and Advanced settings outlined in the below sections.
6. Click **Save**, then **Commit & Deploy**.
7. Use the **Test** tab in the Destination's configuration modal to validate the configuration and connectivity of your Destination.

Persistent Queue Settings

This tab is displayed when the **Backpressure behavior** is set to **Persistent Queue**.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Destination will stop queueing data and apply the **Queue-full** behavior. Required, and defaults to `5` GB. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Stream will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue is exerting backpressure (because disk is low or at full capacity). **Block** is the same behavior as non-PQ blocking, corresponding to the **Block** option on the **Backpressure behavior** drop-down. **Drop new data** throws away incoming data, while leaving the contents of the PQ unchanged.

Clear Persistent Queue: Click this "panic" button if you want to delete the files that are currently queued for delivery to this Destination. A confirmation modal will appear - because this will free up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (Appears only after **Output ID** has been defined.)

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, toggle this off. Doing so will expose this additional control:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue's drain rate can boost the throughput of new/active connections, by reserving more resources for them. You can further optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Defaults to `Yes` to reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA).

Round–robin DNS: Defaults to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Defaults to `Yes` to compress the payload body before sending.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`. Each request can potentially hit a different HEC receiver.

Max body size (KB): Maximum size, in KB, of the request body. Defaults to `4096`. Lowering the size can potentially result in more parallel requests and also cause outbound requests to be made sooner.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than the configured **Max body size**. Defaults to `1`.

- Retries happen on this flush interval.
- Any HTTP response code in the `2xx` range is considered success.
- Any response code in the `5xx` range is considered a retryable error, which will not trigger Persistent Queue (PQ) usage.
- Any other response code will trigger PQ (if PQ is configured as the Backpressure behavior).

Extra HTTP headers: Click **Add Header** to add **Name/Value** pairs to pass as additional HTTP headers. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers that you want to declare as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.

- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new connection will be reattempted. This is to prevent sticking to a particular Destination when there is a constant flow of events.
- If the server does not support keepalives – or if the server closes a pooled connection while idle – a new connection will be established for the next request.
- Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between CrowdStrike Falcon LogScale servers.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.16. Datadog Destination

Cribl Stream can send log and metric events to Datadog. Datadog supports metrics of type `gauge`, `counter`, `rate`, and `distribution` via its REST API.

Cribl Stream sends data via two primary Datadog endpoints, which must be accessible from your Cribl environment:

- Logs: Data is routed through `http-intake.logs.{domain}`
- Metrics: Data is sent via `api.{domain}`

The `{domain}` placeholder in the endpoints represents the specific Datadog region you're using. By default, this is set to `datadoghq.com` for the US region. You can configure an alternative region with the **Datadog site** under **Optional Settings** below.

Supported Domains:

- US: `datadoghq.com` (default)
- US3: `us3.datadoghq.com`
- US5: `us5.datadoghq.com`
- Europe: `datadoghq.eu`
- US1-FED: `ddog-gov.com`
- AP1: `ap1.datadoghq.com`
- Custom: `custom.datadoghq.com`

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Output to Datadog

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:

- **Output ID**: Enter a unique name to identify this Destination definition.
- **Description**: Optionally, enter a description.

3. Under **Authentication**, select an **Authentication method** from the dropdown:
   - **Manual**: Displays a field for you to enter an **API key** that is available in your Datadog profile.
   - **Secret**: This option exposes an **API key (text secret)** drop-down, in which you can select a stored secret that references the API access token described above. A **Create** link is available to store a new, reusable secret.
   - **API key**: Enter your Datadog organization's API key.
4. Next, you can configure the following **Optional Settings**:
   - **Datadog site**: Select the Datadog region you are sending to. Defaults to `US`; the other options are `US3`, `US5`, `Europe`, `US1-FED`, `AP1`, and `Custom`. Select `Custom` to manually enter your Datadog region's URL if it's not listed.
   - **Send logs as**: Specify the content type to use when sending logs. Defaults to `application/json`, where each log message is represented by a JSON object. The alternative `text/plain` option sends one message per line, with newline `\n` delimiters.
   - **Message field**: Name of the event field that contains the message to send. If not specified, Cribl Stream sends a JSON representation of the whole event (regardless of whether **Send logs as** is set to JSON or plain text).
   - **Source**: Name of the source to send with logs. If you're sending logs as JSON objects (that is, you've selected **Send logs as**: `application/json`), the event's `source` field (if set) will override this value.
   - **Host**: Name of the host to send with logs. If you're sending logs as JSON objects, the event's `host` field (if set) will override this value.
   - **Service**: Name of the service to send with logs. If you're sending logs as JSON objects, the event's `__service` field (if set) will override this value.
   - **Datadog tags**: List of tags to send with logs (for example, `env:prod`, `env_staging:east`).
   - **Severity**: Default value for message severity. If you're sending logs as JSON objects, the event's `__severity` field (if set) will override this value. Defaults to `info`; the drop-down offers many other severity options.

Datadog uses the above five fields (`source`, `host`, `__service`, `tags`, and `__severity`) to enhance searches.

   - **Allow API key from events**: If toggled to `Yes`, any API key in the `__agent_api_key` internal field will override the **API key** field's value. This option is useful if events originate from multiple Datadog Agent Sources, each configured with a different API key. (For further details, see Managing API Keys.)

- **Backpressure behavior**: Specify whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high

as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (s): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

If an event contains the internal field `__criblMetrics`, Cribl Stream will send it to Datadog as a metric event. Otherwise, Cribl Stream will send it as a log event.

You can use these fields to override outbound event values for log events:

- `__service`
- `__severity`

No internal fields are supported for metric events.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

- Metrics Types

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.17. Dynatrace HTTP Destination

The Dynatrace HTTP Destination sends logs to Dynatrace's SaaS or ActiveGate endpoints.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Configure a Dynatrace HTTP Destination

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing**.
    - To configure via the Routes, select **Data** > **Destinations** (Stream) or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the Destination modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**. A **Description** is optional.
    - **Endpoint**: Select the type of Dynatrace endpoint where you want to send your data.
        - **Cloud**: Sends data to Dynatrace's SaaS endpoint. Provide your Dynatrace **Environment ID**. This ID uniquely identifies your Dynatrace environment and is required for routing data correctly. You can find your environment ID in your Dynatrace account settings.
        - **ActiveGate**: Choose this option if you are routing data through an ActiveGate. Provide your Dynatrace **Environment ID** and **ActiveGate domain** in the additional fields that appear. Your ActiveGate domain is displayed in your Dynatrace settings in the **Details** section of an ActiveGate under the **Hostname** field. The format should be a fully qualified domain name (FQDN) or IP address. For example, `https://{activeGate-domain}:9999/e/{environment-id}/api/v2/logs/ingest`.
        - **Manual**: Select this option if you want to manually specify the endpoint URL. This is useful for custom setups or non-standard configurations. You will need to enter the full **URL** in the field that appears. Can be overwritten by an event's `__url` field.
3. Next, you can configure the following **Optional Settings**:
    - **Dynatrace processing type**: Choose the processing type for your data in Dynatrace. This setting determines how Dynatrace will handle and analyze the incoming data.
        - `Grail with OpenPipeline`: Logs are processed using Dynatrace's Grail with OpenPipeline. This allows for advanced log processing and analysis capabilities.

        - `Grail without OpenPipeline`: Logs are stored and analyzed in Grail without the additional processing provided by OpenPipeline.
        - `Log Classic`: Uses Dynatrace's classic log monitoring capabilities without the advanced features of Grail.
        - `Other / Unknown`: This option provides flexibility for custom or non-standard processing setups in Dynatrace.
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations in Cribl Stream's **Manage Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Select **Authentication** from the sidebar and select an **Authentication type**.
    - `Auth token`: Provide a Dynatrace API access token to authenticate in the **Token** field. This is the most common method for securing data transmission to Dynatrace. You can generate this token in your Dynatrace account settings under the API tokens section. Ensure that the token has the necessary permissions for the data you are sending.
    - `Token (text secret)`: Create or select a Cribl stored text secret that contains your Dynatrace API access token.
5. Optionally, configure any Persistent Queue, Processing, Retries, and Advanced settings outlined in the below sections.
    - **Persistent Queue** ensures data durability and reliability by buffering and preserving incoming events when the receiver is down or exhibiting backpressure.
    - **Processing Settings** allow you to define pre-processing and post-processing Pipelines. This includes adding metadata, applying transformations, and conditioning the data before it's sent.
    - **Retries** allow you to specify how the system should handle different HTTP response status codes and timeouts, ensuring reliable data delivery.
    - **Advanced Settings** offer additional configuration options that enhance the flexibility and performance of data transmission.

To track data sent via Cribl, you can add a custom attribute in the **Extra HTTP headers** section under Advanced Settings. For example, select `Add Header` and enter `cribl` as the name and `yes` as the value.

6. Select **Save**, then **Commit & Deploy**.
7. Use the **Test** tab in the Destination's configuration modal to validate the configuration and connectivity of your Destination.

Persistent Queue Settings

This tab is displayed when the **Backpressure behavior** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described below in this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue is allowed to consume on each Worker Process. Once this limit is reached, this Destination will stop queueing data and apply the **Queue-full** behavior. Required, and defaults to `5 GB`. Accepts positive numbers with units of `KB`, `MB`, `GB`, etc. Can be set as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** in Group Settings.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Stream will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`; `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue is exerting backpressure (because disk is low or at full capacity). **Block** is the same behavior as non-PQ blocking, corresponding to the **Block** option on the **Backpressure behavior** drop-down. **Drop new data** throws away incoming data, while leaving the contents of the PQ unchanged.

Clear Persistent Queue: Select this "panic" button if you want to delete the files that are currently queued for delivery to this Destination. A confirmation modal will appear - because this will free up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (Appears only after **Output ID** has been defined.)

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, toggle this off. Doing so will expose this additional control:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue's drain rate can boost the throughput of new/active connections, by reserving more resources for them. You can further optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Keep alive: By default, Cribl Stream sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Stream to

close the connection immediately after sending a request.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. You can set this limit to as high as 500 MB (`512000` KB). Be aware that high values can cause high memory usage per Worker Node, especially if a dynamically constructed URL (see Internal Fields) causes this Destination to send events to more than one URL. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass to all events as additional HTTP headers. Values will be sent encrypted. You can also add headers dynamically on a per-event basis in the `__headers` field. See Internal Fields below.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__criblMetrics`
- `__url`
- `__headers`

If an event contains the internal field `__url`, that field's value will override the **General Settings** > **Endpoint** value. This way, you can determine the endpoint URL dynamically.

For example, you could create a Pipeline containing an Eval Function that adds the `__url` field, and connect that Pipeline to your Dynatrace HTTP Destination. Configure the Eval Function to set `__url`'s value to a URL that varies depending on a global variable, or on some property of the event, or on some other dynamically-generated value that meets your needs.

If an event contains the internal field `__headers`, that field's value will be a JSON object containing Name-value pairs, each of which defines a header. By creating Pipelines that set the value of `__headers` according to conditions that you specify, you can add headers dynamically.

For example, you could create a Pipeline containing Eval Functions that add the `__headers` field, and connect that Pipeline to your Dynatrace HTTP Destination. Configure the Eval Functions to set `__headers` values to Name-value pairs that vary depending on some properties of the event, or on dynamically-generated values that meet your needs.

Here's an overview of how to add headers:

- To add "dynamic" (a.k.a. "custom") headers to some events but not others, use the `__headers` field.
- To define headers to add to **all** events, use **Advanced Settings** > **Extra HTTP Headers**.
- An event can include headers added by both methods. So if you use `__headers` to add `{ "api-key": "foo" }` and **Extra HTTP Headers** to add `{ "goat": "Kid A" }`, you'll get both headers.
- Headers added via the `__headers` field take precedence. So if you use `__headers` to add `{ "api-key": "foo" }` and **Extra HTTP Headers** to add `{ "api-key": "bar" }`, you'll get only one header, and that will be `{ "api-key": "foo" }`.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, it will throw away the connection and attempt a new one. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), Cribl Stream will establish a new connection for the next request.
- When resolving the Destination's hostname, Cribl Stream will pick the first IP in the list for use in the next connection. Enable **Round-robin DNS** to better balance the distribution of events among destination cluster nodes.

Troubleshoot

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.18. Dynatrace OTLP Destination

The Dynatrace OTLP Destination sends telemetry data, including traces, logs, and metrics, to Dynatrace using the OpenTelemetry Protocol (OTLP). It can send data to various Dynatrace endpoints, including SaaS, Environment ActiveGate, and Containerized Environment ActiveGate.

To get started, connecting to Dynatrace is simple. Select your endpoint and provide your access token. Need more detailed instructions or configuration options? See below!

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Configure a Dynatrace OTLP Destination

In Cribl Stream, set up a Dynatrace OTLP Destination.

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing**.
    - To configure via the Routes, select **Data** > **Destinations** (Stream) or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the Destination modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**. A **Description** is optional.
    - **OTLP version**: Already set to `1.3.1` and cannot be changed.
    - **Protocol**: Already set to `HTTP` and cannot be changed. Uses Binary Protobuf encoding (does not support JSON Protobuf).
    - **Endpoint type**: Select the type of Dynatrace endpoint where you want to send your data.
        - **SaaS**: Sends data to Dynatrace's SaaS endpoint.
        - **ActiveGate**: Choose this option if you are routing data through an ActiveGate.
    - **Endpoint**: The endpoint URL for the Dynatrace environment. You'll need to provide your Dynatrace environment ID. This ID uniquely identifies your Dynatrace environment and is required for routing data correctly. You can find your environment ID in your Dynatrace account settings.
        - **SaaS** defaults to `https://{your-environment-id}.live.dynatrace.com/api/v2/otlp`. Replace the `{your-environment-id}` placeholder with your environment ID.

        - **ActiveGate** defaults to `https://{your-activegate-domain}:9999/e/{your-environment-id}/api/v2/otlp`. Replace the `{your-activegate-domain}` placeholder with your ActiveGate domain, and `{your-environment-id}` with your environment ID. Your ActiveGate domain is displayed in your Dynatrace settings in the **Details** section of an ActiveGate under the **Hostname** field. The format should be a fully qualified domain name (FQDN) or IP address.
        - You can specify a custom endpoint using either a valid URL or an IP address (IPv4 or IPv6). Enclose IPv6 addresses in square brackets (for example, `[2001:db8:85a3:0000:0000:8a2e:0370:7334]`).
        - To proxy outbound HTTP/S requests, see System Proxy Configuration.
    - **Auth token (text secret)**: Create or select a Cribl stored text secret that contains your Dynatrace API access token, ensuring secure authentication for data transmission. You can generate this token in your Dynatrace account settings under the API tokens section. Ensure that the token has the necessary permissions for the data you are sending.
    - **Optional Settings**:
        - You can customize the path instead of using the default cloud endpoints. This is useful when integrating with a hosted Lightstep satellite.
        - **Backpressure behavior**: Whether to `Block`, `Drop`, or `Persistent Queue` events when all receivers are exerting backpressure.
        - **Tags**: Optionally, add tags that you can use to filter and group Destinations in Cribl Stream's **Manage Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
3. The **Processing Settings**, **Retries**, and **Advanced Settings** provide granular control over how data is handled and transmitted.
    - Processing Settings allow you to define pre-processing and post-processing Pipelines, ensuring that events conform to the relevant Protobuf specifications for traces, metrics, and logs. This includes adding metadata, applying transformations, and conditioning the data.
    - Retries allow you to specify how the system should handle different HTTP response status codes and timeouts, ensuring reliable data delivery.
    - Advanced Settings offer additional configuration options that enhance the flexibility and performance of data transmission.
4. Select **Save**, then **Commit & Deploy**.
5. Use the **Test** tab in the Destination's configuration modal to validate the configuration and connectivity of your Destination.

Custom HTTP Path

To send data to a custom location, override the default endpoint paths. When the **Protocol** is set to `HTTP`, this Destination sends data to the following endpoints by default:

- Traces: `<endpoint>/v1/traces`
- Metrics: `<endpoint>/v1/metrics`
- Logs: `<endpoint>/v1/logs`

`<endpoint>` refers to the base URL you specified in the **Endpoint** setting above.

To override a default path, provide only the desired path in the corresponding field: **Traces endpoint override**, **Metrics endpoint override**, or **Logs endpoint override**.

Persistent Queue Settings

This tab is displayed when the **Backpressure behavior** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan/license tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described below in this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, and so on. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space the queue is allowed to consume. Once this limit is reached, queueing is stopped and data blocking is applied. Enter a numeral with units of KB, MB, and so on.

Queue file path: The location for the persistent queue files. This will be of the form: `your/path/here/<worker-id>/<output-id>`. Defaults to: `$CRIBL_HOME/state/queues`.

Compression: Codec to use to compress the persisted data, once a file is closed. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue is exerting backpressure (because disk is low or at full capacity). **Block** is the same behavior as non-PQ blocking, corresponding to the **Block** option on the **Backpressure behavior** drop-down. **Drop new data** throws away incoming data, while leaving the contents of the PQ unchanged.

Clear Persistent Queue: Select this "panic" button if you want to delete the files that are currently queued for delivery to this Destination. A confirmation modal will appear - because this will free up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (Appears only after **Output ID** has been defined.)

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, toggle this off. Doing so will expose this additional control:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue's drain rate can boost the throughput of new/active connections, by reserving more resources for them. You can further optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output – both metric events, as dimensions; and log events, as labels. Supports wildcards.

By default, includes `cribl_pipe` (Cribl Stream Pipeline that processed the event).

Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this to `Yes` to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (e.g., the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Keep alive: By default, Cribl Stream sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Stream to close the connection immediately after sending a request.

Compression: Compression type to apply to messages sent to the OpenTelemetry endpoint. `Gzip` (the default) and `None` are available for both protocols.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30` sec.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `2048` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events. See Dynatrace's best practices.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` sec.

Extra HTTP headers: Select **Add Header** to define additional HTTP headers to pass to all events. Each row is a **Name-Value** pair. Values will be sent encrypted. You can also add headers dynamicall,y on a per-event basis, in the `__headers` field.

Safe headers: Add headers here to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

Protocol and Transport Support

This Destination leverages the OpenTelemetry Protocol (OTLP) v1.3.1 to send observability data to ServiceNow. OTLP defines Protocol buffer (Protobuf) schemas for its payloads (requests and responses). With the HTTP transport, this Destination supports Binary Protobuf payload encoding, but currently does not support JSON Protobuf.

When configuring Pipelines (including pre-processing and post-processing Pipelines), you need to ensure that events sent to this Destination conform to the relevant Protobuf specification.

- For traces, opentelemetry/proto/trace/v1/trace.proto
- For metrics, opentelemetry/proto/metrics/v1/metrics.proto
- For logs, opentelemetry/proto/logs/v1/logs.proto

This Destination will drop non-conforming events. If the Destination encounters a parsing error when trying to convert an event to OTLP, it discards the event and Cribl Stream logs the error.

Troubleshoot

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.19. Exabeam Security Operations Platform Destination

Cribl Stream supports sending data to the Exabeam security operations platform or (as some people think of it) SIEM.

The Exabeam Destination supersedes and improves upon the "old way" to get data from Cribl Stream to Exabeam using the Cribl Webhook Destination.

Type: Non-Streaming | TLS Support: Yes | PQ Support: No

For examples of using Cribl Stream to optimize inbound events for Exabeam, see:

- Splunk to Exabeam, which demonstrates combining several Cribl Functions to transform events before forwarding to Exabeam.
- Several Exabeam Packs on the Cribl Packs Dispensary, which provide processing Pipelines that you can import and adapt to your needs.

Understand How Exabeam and Cribl Stream Work Together

Exabeam parsers expect to receive events in original, unmodified form. To make sure this happens, you'll sometimes need to use a combination of Event Breakers and Pipelines. In general, knowing this can help you avoid problems or troubleshoot any that do crop up.

When you send data to Exabeam, Cribl Packs are your friends, because Cribl and Exabeam have partnered to create a set of Exabeam-specific Packs, each of which ensures that events from one common data source arrives at Exabeam in precisely the expected form. Cribl Packs also give you the option of dropping events on a per-data-source basis, so that Cribl Stream never sends irrelevant events to Exabeam. To view the Exabeam-specific Cribl Packs, navigate to **Processing** > **Packs**. Then select **Add Pack** > **Add from Dispensary**, and enter `Exabeam` in the search field.

Cribl strongly recommends that you use **only** the Exabeam-specific, Cribl-authored Packs with this Destination. Other Packs can perform transformations – especially reduction – that prevent the Exabeam parsers from triggering.

When the original data source is Microsoft Active Directory (AD) or LDAP, you'll need to set up an Exabeam Site Collector to perform the initial data capture.

Because Exabeam runs in the Google Cloud Storage (GCS) platform, some setting names include references to GCS.

Finally, Cribl recommends placing Cribl Stream Worker Nodes as close as possible to the sources of the events you want to send to Exabeam. This reduces the length of the path that data must traverse before Cribl Stream optimizes it with compression, reduction, dropping events, and/or redacting sensitive information.

Configure Cloud Storage Permissions

For Cribl Stream to send data to Exabeam buckets, the following access permissions must be set on the Cloud Storage side:

- Fine-grained access control must be enabled on the buckets.
- The Google service account or user must have the Storage Admin or Owner role.

For details, see the Cloud Storage Overview of Access Control and Understanding Roles documentation.

Create the Cribl Cloud Collector in Exabeam

Log in to the Exabeam Security Operations Platform, and on the **Home** page, select **Cloud Collectors**. In the resulting page, select the **Cribl** tile to see a list of Cribl Collectors (the first time you do this, the list will be empty).

Select **New Collector**, and in the resulting **Collector for Cribl** drawer:

1. Enter a name for your new Cribl Cloud Collector.
2. Optionally, in **Advanced Settings**, configure the **Metadata** value **TIMEZONE**
3. If your desired site already exists, select it from the **SITE** drop-down.
    - If your desired site does not exist yet, skip the drop-down and select the **manage your sites** link underneath. This will take you to a separate UI where you will enter a value for the **Metadata** value **SITENAME**, and Exabeam will generate the associated metadata value **SITE ID**. When you have done this, Exabeam will take you back to the previous UI, and you must then select your newly-created site from the **SITE** drop-down.
4. Select **Install**.

A `Hooray!` confirmation modal will now replace the **Collector for Cribl** drawer. In this modal:

1. Select the copy icon to the right of the encoded **Connection String**. Save this string in a secure and handy location – it is required when configuring the Cribl Stream Exabeam Destination.
2. Select **Go to Overview** to exit the modal.

Although optional, configuring metadata is useful because it allows a single instance of the Exabeam SIEM to differentiate between data from multiple sources. This is relevant for large enterprises whose IT infrastructure comprises many sources whose IP addresses overlap.

Configure Cribl Stream to Output to Cloud Storage Destinations

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Exabeam Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - Select **Autofill with Exabeam Connection String** to automatically enter the values for the following **Exabeam Settings**. Or enter them directly.
    - **Google Cloud Storage bucket**: Name of the destination bucket – in Exabeam's Cribl Cloud Collector this is called **GCS Bucket Name**. This value can be a constant, or a JavaScript expression that can be evaluated only at init time. For example, you can reference a Global Variable like this: `myBucket-${C.vars.myVar}`.
    - **Google Cloud Storage bucket region**: In Exabeam's Cribl Cloud Collector this is called **GCS Bucket Region**. It is the GCS region where the bucket is located.
    - **Collector instance ID**: In Exabeam's Cribl Cloud Collector this is called **Instance ID**.
    - **Access key**: In Exabeam's Cribl Cloud Collector this is called **Access Key**.
    - **Secret**: In Exabeam's Cribl Cloud Collector this is called **Secret Key**.
    - **Site name**: In Exabeam's Cribl Cloud Collector this is called **SITENAME**. This determines where your data is categorized. Set a static site name or dynamically assign it using a JavaScript expression. For example, to dynamically set the site name based on the `cribl_pipeline` field you'd use the expression `${C.vars.cribl_pipeline}`. This assigns the site name based on the Pipeline value.
    - **Site ID**: In Exabeam's Cribl Cloud Collector this is called **SITE ID**.
    - **Timezone offset**: In Exabeam's Cribl Cloud Collector this is called **TIMEZONE**.

3. Optionally, you can adjust the Processing and Advanced settings outlined in the sections below.
4. Select **Save**, then **Commit & Deploy**.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports `c*` wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Backpressure behavior: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300` seconds (5 minutes).

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Defaults to `30`.

Max open files: Maximum number of files to keep open concurrently. When exceeded, the oldest open files will be closed and moved to final output location. Defaults to `100`.

Cribl Stream will also close any files larger than 10 MB.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined Min free disk space amount.

Remove empty staging dirs: When toggled on (the default), deletes empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove empty staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates (such as self-signed certificates, for example) that cannot be verified against a valid Certificate Authority. Defaults to `Yes`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Tags: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Troubleshooting

Verify that you are sending the original, unmodified events. Study the applicable Exabeam parsers to make sure you understand exactly what they're doing. If you need to modify events, make sure that when you do, the

relevant parsers still trigger.

Nonspecific messages from Google Cloud of the form `Error: failed to close file` can indicate problems with the permissions listed above.

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.20. Filesystem/NFS Destination

Filesystem is a non-streaming Destination type that Cribl Stream can use to output files to a local file system or a network-attached file system (NFS).

Type: Non-Streaming | TLS Support: N/A | PQ Support: N/A

In Cribl.Cloud, the Filesystem Destination is only available on customer-managed hybrid Worker Nodes.

Configure Cribl Stream to Output to Filesystem Destinations

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Filesystem definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Output location**: Final destination for the output files.
    - **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (supported only on Linux, not Windows) exposes a **Parquet Settings** left tab, where you **must** configure certain options in order to export data in Parquet format.
3. Next, you can configure the following **Optional Settings**:
    - **Staging location**: Local filesystem location in which to buffer files before compressing and moving them to the final destination. Cribl recommends that this location be stable and high-performance.

      The **Staging location** field is not displayed or available on Cribl.Cloud-managed Worker Nodes.

- **Partitioning expression**: JavaScript expression that defines how files are partitioned and organized. Default is date-based. If blank, Cribl Stream will fall back to the event's `__partition` field value (if present); or otherwise to the root directory of the **Output Location** and **Staging Location**.
- **Compress**: Data compression format used before moving to final destination. Defaults to `gzip` (recommended). This setting is not available when **Data format** is set to `Parquet`.
- **File name prefix expression**: The output filename prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
- **File name suffix expression**: The output filename suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ' `` where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.

  > To prevent files from being overwritten, Cribl appends a random sequence of 6 characters to the end of their names. This also applies to prefix and suffix expressions in file names.
  >
  > For example, if you set the **File name prefix expression** to `CriblExec` and set the **File name suffix expression** to `.csv`, the file name might display as `CriblExec-adPRWM.csv` with `adPRWM` appended.

- **Backpressure Behavior**: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Processing, Parquet, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.

- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Stream CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Working with Parquet for pointers on how to avoid problems such as data mismatches.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Stream writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported, and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: Set the target memory size for page segments. Generally, set lower values to improve reading speed, or set higher values to improve compression. Value must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle to `Yes` to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics – these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Advanced Settings

Max file size (MB): Maximum uncompressed output file size. Files of this size will be closed and moved to final output location. Defaults to `32`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this will be closed and moved to final output location. Defaults to `300`.

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this will be closed and moved to final output location. Defaults to `30`.

Max open files: Maximum number of files to keep open concurrently. When exceeded, the oldest open files will be closed and moved to final output location. Defaults to `100`.

Cribl Stream will close files when **either** of the `Max file size (MB)` or the `Max file open time (sec)` conditions are met.

Compression level: Specifies the level of compression to apply before moving files to the final destination. Higher compression levels reduce file size but increase CPU usage. Choose from `Best Speed`, `Normal`, or `Best Compression`. The default level, `Best Speed` will prioritize faster compression over smaller file sizes.

Writing high watermark (KB): Sets the high watermark for writing files, in kilobytes. This determines the buffer size for file writes, impacting performance and memory usage. Enter a numeric value representing the buffer size in kilobytes. The default size, `64` will use a 64 KB buffer for file writes.

Header line: If set, this line will be written to the beginning of each output file, followed by a newline character. This can be useful for adding a header row to CSV files.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined Min free disk space amount.

Add Output ID: When set to `Yes` (the default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

> For a Destination originally configured in a Cribl Stream version below 2.4.0, the **Add Output ID** behavior will be switched **off** on the backend, regardless of this toggle's state. This is so that upon Cribl Stream upgrade and restart, any files pending in the original staging directory will not be lost. To enable this option for such Destinations, Cribl's recommended migration path is:
>
> - Clone the Destination.
> - Where Routes reference the original Destination, redirect them to instead reference the new, cloned Destination.
>
> This way, the original Destination will process pending files (after an idle timeout), and the new, cloned Destination will process newly arriving events with **Add output ID** enabled.

Remove staging dirs: Toggle this on to delete empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

To export events from an intermediate stage **within a Pipeline** to a file, see the Tee Function.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.21. Honeycomb Destination

Cribl Stream supports sending events to a Honeycomb dataset.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Output to Honeycomb

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Honeycomb definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Dataset name**: Name of the dataset to send events to. (For example, `iLoveObservabilityDataset`.)
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Displays a field for you to enter the **API key** for the team to which the dataset belongs.
    - **Secret**: This option exposes an **API key (text secret)** drop-down, in which you can select a stored secret that references the API key described above. A **Create** link is available to store a new, reusable secret.
    - **API key**: Enter your Honeycomb organization's API key.
4. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.

- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular Destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), a new connection will be established for the next request.
- When resolving the Destination's hostname, Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between destination cluster nodes.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.22. InfluxDB Destination

Cribl Stream supports sending data to InfluxDB (versions 1.x and 2.0.x) and InfluxDB Cloud.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Configure Cribl Stream to Output to InfluxDB

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this InfluxDB definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Write API URL**: The URL of an InfluxDB cluster to send events to. (For example, `http://localhost:8086/write`.)
    - **Use v2 API**: You can enable the InfluxDB v2 API with InfluxDB version 1.8 or later. This toggle defaults to `No` – which falls back to the v1 API, and displays a **Database** field.

    If you toggle **Use v2 API** to `Yes`, Cribl Stream communicates using InfluxDB's v2 API, and instead displays these two fields:
    - **Bucket**: Enter the bucket to write to. (Required.)
    - **Organization**: The Organization ID corresponding to the specified **Bucket**. (Required in this configuration, although InfluxDB v.1.8 will ignore it.)
    - **Database**: Name of the database on which to write data points. (Required.)
3. Next, you can configure the following **Optional Settings**:
    - **Timestamp precision**: Sets the precision for the supplied UNIX time values. Defaults to `Milliseconds`.
    - **Dynamic value fields**: When enabled, Cribl Stream will pull the value field from the metric name. (For example, `db.query.user` will use `db.query` as the measurement and `user` as the value field). Defaults to `Yes`.

- **Value field name**: Name of the field in which to store the metric when sending to InfluxDB. This will be used as a fallback if dynamic name generation is enabled but fails. Defaults to `value`.
- **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Authentication

Use the **Authentication type** drop-down to select one of these options:

None: This default setting does not use authentication.

Auth token: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header.

Auth token (text secret): This option exposes a **Token (text secret)** drop-down, in which you can select a stored text secret that references the bearer token described above. A **Create** link is available to store a new, reusable secret.

Basic: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.

Basic (credentials secret): This option exposes a **Credentials secret** drop-down, in which you can select a stored text secret that references the Basic authentication credentials described above. A **Create** link is available to store a new, reusable secret.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.23. MinIO Destination

MinIO is a non-streaming Destination type, to which Cribl Stream can output objects.

Type: Non-Streaming | TLS Support: Configurable | PQ Support: No

Configure Cribl Stream to Output to MinIO Destinations

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this MinIO definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **MinIO endpoint**: MinIO service URL (for example, http://minioHost:9000).
    - **MinIO bucket name**:Name of the destination MinIO bucket. This value can be a constant, or a JavaScript expression that will be evaluated only at init time. For example, referencing a Global Variable: `myBucket-${C.vars.myVar}`. Ensure that the bucket already exists, otherwise MinIO will generate "bucket does not exist" errors.

      Event-level variables are not available for JavaScript expressions. This is because the bucket name is evaluated only at Destination initialization. If you want to use event-level variables in file paths, Cribl recommends specifying them in the **Partitioning Expression** field (described below), because this is evaluated for each file.

    - **Staging location**: Filesystem location in which to locally buffer files before compressing and moving to final destination. Cribl recommends that this location be stable and high-performance.

      The **Staging location** field is not displayed or available on Cribl.Cloud-managed Worker Nodes.

- **Data format**: The output data format defaults to `JSON`. `Raw` and `Parquet` are also available. Selecting `Parquet` (supported only on Linux, not Windows) exposes a **Parquet Settings** left tab, where you **must** configure certain options in order to export data in Parquet format.

3. Next, you can configure the following **Optional Settings**:
   - **Key prefix**: Root directory to prepend to path before uploading. Enter a constant, or a JS expression enclosed in single quotes, double quotes, or backticks. Prefix to apply to files/objects before uploading to the specified bucket. MinIO will display key prefixes as folders.
   - **Partitioning expression**: JavaScript expression that defines how files are partitioned and organized. Default is date-based. If blank, Cribl Stream will fall back to the event's `__partition` field value (if present); or otherwise to the root directory of the **Output Location** and **Staging Location**.

     Cribl Stream's internal `__partition` field can be populated in multiple ways. The precedence order is: explicit **Partitioning expression** value -> `${host}/${sourcetype}` (default) **Partitioning expression** value -> user-defined `event.__partition`, set with an Eval Function (takes effect only where this **Partitioning expression** field is blank).

   - **Compress**: Data compression format used before moving to final destination. Defaults to `gzip` (recommended). This setting is not available when **Data format** is set to `Parquet`.
   - **File name prefix expression**: The output filename prefix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `CriblOut`.
   - **File name suffix expression**: The output filename suffix. Must be a JavaScript expression (which can evaluate to a constant), enclosed in quotes or backticks. Defaults to `` `.${C.env["CRIBL_WORKER_ID"]}.${__format}${__compression === "gzip" ? ".gz" : ' `` where `__format` can be `json` or `raw`, and `__compression` can be `none` or `gzip`.
   - **Backpressure behavior**: Select whether to block or drop events when all receivers are exerting backpressure. (Causes might include an accumulation of too many files needing to be closed.) Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

4. Optionally, you can adjust the Authentication, Processing, Parquet, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

How MinIO Composes File Names

The full path to a file consists of:

`<bucket_name>/<keyprefix><partition_expression | __partition><file_name_prefix><filename>.<extension>`

As an example, assume that the **MinIO bucket name** is `bucket1`, the **Key prefix** is `aws`, the **Partitioning expression** is `` `${host}/${sourcetype}` ``, the source is undefined, the **File name prefix** is the default `CriblOut`, and the **Data format** is `json`. Here, the full path as displayed in MinIO would have this form: `/bucket1/aws/192.168.1.241/undefined/CriblOut-<randomstring>0.json`

Although MinIO will display the **Key prefix** and **Partitioning expression** values as folders, both are actually just part of the overall key name, along with the file name.

Authentication

Use the **Authentication Method** drop-down to select one of these options:

Auto: This default option uses the AWS SDK for JavaScript to automatically obtain credentials in the following order of attempts:

1. **IAM Roles for Amazon EC2**: Loaded from AWS Identity and Access Management (IAM) roles attached to an EC2 instance.
2. **Shared Credentials File**: Loaded from the shared credentials file (`~/.aws/credentials`).
3. **Environment Variables**: Loaded from environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`.
4. **JSON File on Disk**: Loaded from a JSON file on disk.
5. **Other Credential-Provider Classes**: Other credential-provider classes provided by the AWS SDK for JavaScript.

The `Auto` method works both when running on AWS and in other environments where the necessary credentials are available through one of the above methods.

SSO Providers

When using the auto authentication method, you can leverage SSO providers like SAML and Okta to issue temporary credentials. These credentials should be set in the environment variables `AWS_ACCESS_KEY_ID` and `AWS_SECRET_ACCESS_KEY`. The AWS SDK will then use these environment variables to authenticate.

Manual: If not running on AWS, you can select this option to enter a static set of user-associated IAM credentials (your access key and secret key) directly or by reference. This is useful for Workers not in an AWS

VPC, for example, those running a private cloud. The **Manual** option exposes these corresponding additional fields:

- **Access key**: Enter your AWS access key. If not present, will fall back to the `env.AWS_ACCESS_KEY_ID` environment variable, or to the metadata endpoint for IAM role credentials.
- **Secret key**: Enter your AWS secret key. If not present, will fall back to the `env.AWS_SECRET_ACCESS_KEY` environment variable, or to the metadata endpoint for IAM credentials.

The values for **Access key** and **Secret key** can be a constant, or a JavaScript expression (such as `${C.env.MY_VAR}`) enclosed in quotes or backticks, which allows configuration with environment variables.

Secret: If not running on AWS, you can select this option to supply a stored secret that references an AWS access key and secret key. This option exposes a **Secret key pair** drop-down, in which you can select a stored secret that references the set of user-associated IAM credentials described above. A **Create** link is available to store a new, reusable secret.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Parquet Settings

To write out Parquet files, note that:

- On Linux, you can use the Cribl Stream CLI's `parquet` command to view a Parquet file, its metadata, or its schema.
- Cribl Edge Workers support Parquet only when running on Linux, not on Windows.
- See Working with Parquet for pointers on how to avoid problems such as data mismatches.

Automatic schema: Toggle on to automatically generate a Parquet schema based on the events of each Parquet file that Cribl Stream writes. When toggled off (the default), exposes the following additional field:

- **Parquet schema**: Select a schema from the drop-down.

If you need to modify a schema or add a new one, follow the instructions in our Parquet Schemas topic. These steps will propagate the freshest schema back to this drop-down.

Parquet version: Determines which data types are supported, and how they are represented. Defaults to `2.6`; `2.4` and `1.0` are also available.

Data page version: Serialization format for data pages. Defaults to `V2`. If your toolchain includes a Parquet reader that does not support `V2`, use `V1`.

Group row limit: The number of rows that every group will contain. The final group can contain a smaller number of rows. Defaults to `10000`.

Page size: Set the target memory size for page segments. Generally, set lower values to improve reading speed, or set higher values to improve compression. Value must be a positive integer smaller than the **Row group size** value, with appropriate units. Defaults to `1 MB`.

Log invalid rows: Toggle to `Yes` to output up to 20 unique rows that were skipped due to data format mismatch. Log level must be set to `debug` for output to be visible.

Write statistics: Leave toggled on (the default) if you have Parquet tools configured to view statistics – these profile an entire file in terms of minimum/maximum values within data, numbers of nulls, etc.

Write page indexes: Leave toggled on (the default) if your Parquet reader uses statistics from Page Indexes to enable page skipping. One Page Index contains statistics for one data page.

Write page checksum: Toggle on if you have configured Parquet tools to verify data integrity using the checksums of Parquet pages.

Metadata (optional): The metadata of files the Destination writes will include the properties you add here as key-value pairs. For example, one way to tag events as belonging to the OCSF category for security findings would be to set **Key** to `OCSF Event Class` and **Value** to `2001`.

Advanced Settings

Max file size (MB): Maximum uncompressed output file size. Files of this size will be closed and moved to final output location. Defaults to `32`.

Max file open time (sec): Maximum amount of time to write to a file. Files open for longer than this limit will be closed and moved to final output location. Defaults to `300`.

Max file idle time (sec): Maximum amount of time to keep inactive files open. Files open for longer than this limit will be closed and moved to final output location. Defaults to `30`.

Max open files: Maximum number of files to keep open concurrently. When exceeded, the oldest open files will be closed and moved to final output location. Defaults to `100`.

Cribl Stream will close files when **either** of the `Max file size (MB)` or the `Max file open time (sec)` conditions is met.

Max concurrent file parts: Maximum number of parts to upload in parallel per file. A value of `1` tells the Destination to send the whole file at once. When set to `2` or above, IAM permissions must include those required for multipart uploads. Defaults to `4`; highest allowed value is `10`.

Disk space protection: Specifies whether to `Block` (default) or `Drop` incoming events when the disk space falls below the globally defined **Min free disk space** amount.

Add Output ID: When set to `Yes` (the default), adds the **Output ID** field's value to the staging location's file path. This ensures that each Destination's logs will write to its own bucket.

For a Destination originally configured in a Cribl Stream version below 2.4.0, the **Add Output ID** behavior will be switched **off** on the backend, regardless of this toggle's state. This is to avoid losing any files pending in the original staging directory, upon Cribl Stream upgrade and restart. To enable this option for such Destinations, Cribl's recommended migration path is:

- Clone the Destination.
- Redirect the Routes referencing the original Destination to instead reference the new, cloned Destination.

This way, the original Destination will process pending files (after an idle timeout), and the new, cloned Destination will process newly arriving events with **Add output ID** enabled.

Remove staging dirs: Toggle this on to delete empty staging directories after moving files. This prevents the proliferation of orphaned empty directories. When enabled, exposes this additional option:

- **Staging cleanup period**: How often (in seconds) to delete empty directories when **Remove staging dirs** is enabled. Defaults to `300` seconds (every 5 minutes). Minimum configurable interval is `10` seconds; maximum is `86400` seconds (every 24 hours).

Enable dead-lettering: Toggle this on to set a maximum number of retries, and to move files to a designated directory when write failures exceed that limit. This prevents data flow blockage and excessive error logging due to undeliverable files. When enabled, exposes two additional fields:

- **Dead-letter location**: Specify the storage location for undeliverable files. Defaults to `$CRIBL_HOME/state/outputs/dead-letter`.
- **Maximum retry limit**: Configure the retry limit for failed file deliveries. This setting defines how many times the system will attempt to move a file to its intended location before it is deemed undeliverable and placed in the dead-letter directory. Defaults to `20`.

Region: Region where the MinIO service/cluster is located. Leave blank when using a containerized MinIO.

Object ACL: ACL (Access Control List) to assign to uploaded objects. Defaults to `Private`.

Storage class: Select a storage class for uploaded objects. Defaults to `Standard`.

Server-side encryption: Server side encryption type for uploaded objects. Defaults to `none`.

Signature version: Signature version to use for signing MinIO requests. Defaults to `v4`.

Reuse connections: Whether to reuse connections between requests. The default setting (`Yes`) can improve performance.

Reject unauthorized certificates: Whether to accept certificates that cannot be verified against a valid Certificate Authority (for example, self-signed certificates). Defaults to `Yes`.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

IAM Permissions

The following permissions are always needed to write to an Amazon S3-compatible object store:

- `s3:ListBucket`
- `s3:GetBucketLocation`
- `s3:PutObject`

If your Destination needs to do multipart uploads to S3, two more permissions are needed:

- `kms:GenerateDataKey`
- `kms:Decrypt`

See the AWS documentation.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__partition`

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Common Issues

"Parse Error: Expected HTTP/"

The Worker is trying to use HTTP, but the server is expecting HTTPS.

Parse Error: Expected HTTP

“Bucket does not exist - self signed certificate”

Example Error Text:

```
message: Bucket does not exist - self signed certificate
stack: Error: self signed certificate
    at TLSSocket.onConnectSecure (node:_tls_wrap_1535:34)
    at TLSSocket.emit (node:events:513:28)
    at TLSSocket.emit (node:events:489:12)
    at TLSSocket._fini... Show more
tmpPath: /opt/cribl/s3_bucket/cribl/2023/03/28/CriblOut-XTNGh5.0.json.tmp
```

Can occur when:

- the Destination uses a self-signed cert that has not yet been trusted by Cribl Stream.
- the user does not have appropriate permissions to view the bucket.
- the authentication token generated by your computer has a timestamp that is out of sync with the server’s time, resulting in an authentication failure.

Recommendation

Disable **Advanced Settings** > **Reject unauthorized certificates** or; get the sender’s cert and add it to the `NODE_EXTRA_CA_CERTS` path for validation; or verify that the user has appropriate permissions.

15.2.24. NetFlow Destination

Cribl Stream supports passing through NetFlow v5 and v9 UDP traffic to NetFlow Collectors.

Type: Non-Streaming | TLS Support: No | PQ Support: Yes

Configurie Cribl Stream to Output to NetFlow

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this NetFlow definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **NetFlow Destinations**: Add the downstream NetFlow Collectors to which Cribl Stream should send data.
    - **Address:** Hostname or IP address of the Collector.
    - **Port:** Port number to connect to on the Collector. Defaults to `2055`, which is the standard port for NetFlow traffic.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Processing and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

Advanced Settings

DNS resolution period (sec): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from records. Defaults to `0` seconds. A value of `0` means every datagram sent will incur a DNS lookup. A non-zero value improves performance but can reduce the overall reliability if the DNS records for the downstream Collectors change frequently.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Field for this Destination:

- `__netflowRaw` : Directly routes the raw NetFlow packet data to a downstream NetFlow Collector.

Considerations for Working with NetFlow Data FlowSets

For both NetFlow v5 and v9, Cribl Stream:

- Can forwards NetFlow packets to other NetFlow Collectors. However, it cannot modify the the contents of the incoming packet. In other words, Cribl Stream forwards the packets verbatim as they came in.
- Only routes NetFlow packets from upstream Exporters and cannot generate its own NetFlow packets.
- Cannot send non-NetFlow input data to NetFlow Collectors.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.25. OpenTelemetry (OTel) Destination

Cribl Stream supports sending events to OpenTelemetry Protocol (OTLP)-compliant targets. (Cribl Stream can receive OTel events through the OTel Source.) Besides native OTel Trace, Metric, and Log events, you can send Cribl Stream's Gauge metric events through this OTel Destination.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Protocol and Transport Support

In Cribl Stream 4.1 and later, this Destination supports either of the transports that OTLP specifies: gRPC or HTTP. OTLP defines Protocol buffer (Protobuf) schemas for its payloads (requests and responses). With the HTTP transport, this Destination supports Binary Protobuf payload encoding, but currently does not support JSON Protobuf.

When configuring Pipelines (including pre-processing and post-processing Pipelines), you need to ensure that events sent to this Destination conform to the relevant Protobuf specification. Links below are for OTLP 1.3.1:

- For traces, opentelemetry/proto/trace/v1/trace.proto
- For metrics, opentelemetry/proto/metrics/v1/metrics.proto
- For logs, opentelemetry/proto/logs/v1/logs.proto

The OTel Destination will drop non-conforming events. If the Destination encounters a parsing error when trying to convert an event to OTLP, it discards the event and Cribl Stream logs the error.

If sending data to a downstream receiver that accepts OTLP 1.3.1 log events, you must select **Advanced Settings** > **OTLP version** > `1.3.1`. Otherwise, the Destination will send log events formatted for OTLP `0.10.0`. For context, see Breaking Changes Between OTLP 0.19.0 and 1.3.1.

Configure Cribl Stream to Output to OTel

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.

- To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.

2. In the **New Destination** modal, configure the following under **General Settings**:
   - **Output ID**: Enter a unique name to identify this OTel output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
   - **Description**: Optionally, enter a description.
   - **OTLP version**: The drop-down offers `0.10.0` (default) and `1.3.1`.
   - **Protocol**: Use the drop-down to choose the protocol to use when sending data: `gRPC` (the default), or `HTTP`. Additional settings display in the Advanced for both gRPC and HTTP.

     When set to `HTTP`, the UI adds the Retries section (left tab) and displays three additional settings below:
   - **Traces endpoint override**: By default, the Destination will send traces to `<endpoint>/v1/traces`, where `<endpoint>` is what you specified for the **Endpoint** setting above. To send traces to a different endpoint, enter that endpoint here.
   - **Metrics endpoint override**: By default, the Destination will send metrics to `<endpoint>/v1/metrics`, where `<endpoint>` is what you specified for the **Endpoint** setting above. To send metrics to a different endpoint, enter that endpoint here.
   - **Logs endpoint override**: By default, the Destination will send logs to `<endpoint>/v1/logs`, where `<endpoint>` is what you specified for the **Endpoint** setting above. To send logs to a different endpoint, enter that endpoint here.
   - **Endpoint**: Where to send events, in any of a variety of formats (FQDN, PQDN, IP address and port, etc). Supports both IPv4 and IPv6 – IPv6 addresses must be enclosed in square brackets. The same endpoint is used for both Traces and Metrics. If no port is specified, we normally default to the standard port for OTel Collectors, 4137 – however, if TLS is enabled or the endpoint is an HTTPS-based URL, we default instead to port 443.

     To proxy outbound HTTP/S requests, see System Proxy Configuration.
   - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
3. Optionally, you can adjust the Authentication, TLS, Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.
4. Select **Save**, then **Commit & Deploy**.

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Enter the bearer token that must be included in the authorization header. Since OpenTelemetry runs over gRPC, authorization headers are sent as Metadata entries which are essentially key-value pairs. For example: `Bearer <your-configured-token>`.
- **Auth token (text secret)**: This option exposes a drop-down in which you can select a stored text secret that references the bearer token described above. A **Create** link is available to store a new, reusable secret.
- **Basic**: This default option displays fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: This option exposes a **Credentials secret** drop-down, in which you can select a stored text secret that references the Basic authentication credentials described above. A **Create** link is available to store a new, reusable secret.

TLS Settings (Client Side)

TLS is available only when **General Settings** > **Protocol** is set to `gRPC`.

Enabled Defaults to `No`. When toggled to `Yes`:

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output – both metric events, as dimensions; and log events, as labels. Supports wildcards.

By default, includes `cribl_pipe` (Cribl Stream Pipeline that processed the event).

Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

This tab is displayed when **General Settings** > **Optional Settings** > **Protocol** is set to `HTTP`.

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).

- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

This tab's options depend on whether **General Settings** > **Protocol** is set to the `gRPC` or `HTTP` transport. The common settings directly are displayed for both transports.

Compression: Compression type to apply to messages sent to the OpenTelemetry endpoint. `Gzip` (the default) and `None` are available for both protocols; `Deflate` is available for gRPC only.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30` sec.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` sec.

Environment: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

Additional Settings for gRPC

When **General Settings** > **Protocol** is set to `gRPC`, the **Advanced Settings** tab adds the following options.

Connection timeout: Amount of time (milliseconds) to wait for the connection to establish before retrying. Defaults to `10000` (10 sec.).

Keep alive time (seconds): How often the sender should ping the peer to keep the connection alive. Defaults to `30`.

Metadata: Extra information to send with each gRPC request. Click **Add Metadata** to add each item as a **Key**-**Value** pair. The **Key** field is arbitrary. The **Value** field is a JavaScript expression that is evaluated just once, when this Destination is initialized. If you pass credentials as metadata, Cribl recommends using C.Secret().

Additional Settings for HTTP

When **General Settings** > **Protocol** is set to `HTTP`, the **Advanced Settings** tab adds the following options.

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Keep alive: By default, Cribl Stream sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Stream to close the connection immediately after sending a request.

Extra HTTP headers: Click **Add Header** to define additional HTTP headers to pass to all events. Each row is a **Name**-**Value** pair. Values will be sent encrypted. You can also add headers dynamicall,y on a per-event basis, in the `__headers` field.

Safe headers: Add headers here to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.26. SentinelOne DataSet Destination

Cribl Stream can send log events to the SentinelOne/Scalyr DataSet platform via the DataSet API. This Destination sends batches of events, as JSON, to that API's addEvents endpoint.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Output to DataSet

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this output definition.
    - **Description**: Optionally, enter a description.
3. Under **Authentication**, select an **Authentication method** from the dropdown:
    - **Manual**: Displays a field for you to enter an **API key** that is available in your DataSet profile.
    - **Secret**: This option exposes an **API key (text secret)** drop-down to select a stored secret that references an API key. A **Create** link is available to store a new, reusable secret.
    - **API key**: Enter your DataSet API key that has `Log Write Access`.
4. Next, you can configure the following **Optional Settings**:
    - **DataSet site**: Select the `US` (default), `Europe`, or `Custom` region. If you select `Custom`, enter your custom endpoint URL.
    - **Message field**: Name of the event field that contains the message to send. If not specified, Cribl Stream sends all non-internal fields of events passing through the Destination. For details, see Message Field.
    - **Exclude fields**: Fields to exclude from the event if the **Message field** either is unspecified or refers to an object. Ignored if the **Message field** is a string, number, or boolean. If empty, Cribl Stream sends all non-internal fields. Default exclude fields are `sev`, `_time`, `ts`, and `thread`. We automatically send these fields as metadata of the event, in DataSet's required format. This is to avoid charges for field bytes – metadata bytes do not count toward ingestion.

- **Server/host field**: Name of the event field that contains the server or host that generated the event. Cribl Stream groups events by the value of this field, and gives them a unique session token to conform to the DataSet API. Each group is sent out as a separate batch; therefore, Cribl recommends specifying a field with a low cardinality, to avoid queuing up many different batches at the Destination. If not specified, or not a string, the implicit default value is `cribl_<outputId>`. For more details, see Rate Limiting and Session Management.
- **Timestamp field**: Name of the event field that contains the event timestamp. Cribl Stream sends this value as part of each event's metadata, not as an attribute field on the event.

  Timestamps are automatically converted to a nanosecond-precision string. If an event does not contain the field specified **Timestamp field**, or if the value cannot be converted into a nanosecond-precision string, Cribl Stream assigns a timestamp using the first valid output returned from `ts`, `_time`, or `Date.now()`, in that order.

- **Severity**: Use the drop-down to assign a default value to the `severity` field (which is sent as event metadata, not as an attribute field). Cribl Stream falls back to this value when an event contains no valid `sev` or `__severity` field. For details, see Severity.
- **Backpressure behavior**: Specify whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Message Field

If **Message field** is specified, we follow this logic:

- If an event does not contain the specified field, send the whole event (except internal fields).
- If an event has the specified field, and the field's value is a non-object, send the event in the format: `{ message: <value from event> }`.
- If an event has the specified field, and the field's value is an object, send the event in the format: `{ <all fields from the object> }`.

Severity

DataSet's severity model ranges from `0` least-severe (finest) to `6` most-severe (fatal).

- Where an event's `sev` field contains an integer in this range, Cribl Stream passes it through as the severity.
- Where the `sev` field contains a string matching DataSet's enum (`finest`, `finer`, `fine`, `info`, `warning`, `error`, `fatal`), Cribl Stream converts it to the corresponding integer.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5` GB. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, `429 (Too Many Requests)` is the only response code configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.

- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Defaults to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Click **Add header** to define **Name**/**Value** pairs to pass as additional HTTP headers.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers here to declare them as safe to log in plaintext. (Sensitive headers like `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Rate Limiting and Session Management

DataSet rate limits incoming data per session, not based on API key or IP address. The rate limit is 10 MB/sec per session, but the recommended limit is 2.5 MB/sec. To exceed this limit, split events into multiple sessions.

In Cribl Stream, the session contains:

- A unique session ID
- An optional `serverHost` describing the data source, defaulting to `cribl_${this.outId}`
- Optional properties like `logfile` and `parser` (not currently configurable)

Events are grouped into batches based on `serverHost`, with each batch having its own session ID and rate limit.

Configuration Tips

- **Default Configuration**: If **Server/host field** is left empty, all events will have `serverHost: cribl_${this.outId}`, sharing the same session ID and rate limit.
- **Increasing Sessions**: Set **Server/host field** to an event field with higher cardinality to create multiple sessions and increase the combined rate limit.
- **Practical Solutions**:

- **Original Source Server/Host**: Set **Server/host field** to a field describing the original source server/host name.
- **Worker Process ID**: In a Pipeline, set a field like `worker_id` to `C.env.CRIBL_WORKER_LABEL` and configure **Server/host field** to `worker_id`.
- **Random Distribution**: Use an **Eval** function to set a field to `Math.floor(Math.random() * 8)` and configure **Server/host field** to this field to divide events into multiple sessions.

Internal Fields

The `__severity` field is included in the severity assignment order, after the `sev` field. The order is `sev`, `__severity`, then the configured default **Severity**.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.27. ServiceNow Cloud Observability

The ServiceNow Cloud Observability Destination enables seamless integration with ServiceNow's Cloud Observability platform. This Destination routes observability data, including logs, metrics, and traces, to ServiceNow for enhanced monitoring and analysis. To ensure your data conforms to the expected format, refer to the Protocol section below.

To get started, connecting to ServiceNow Cloud Observability is simple. Grab your ServiceNow Cloud Observability access token, pick your preferred protocol and endpoint, then add the token to your Destination settings. Need more detailed instructions or configuration options? See below!

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Configuring a ServiceNow Cloud Observability Destination

In Cribl Stream, set up a ServiceNow Cloud Observability Destination.

1. From the top nav, click **Manage**, then select a **Worker Group** to configure. Next, you have two options:
    - To configure via QuickConnect, click **Routing** then **QuickConnect** (Cribl Stream) or **Collect** (Cribl Edge). Next, click **Add Destination** and from the resulting drawer's tiles, select **ServiceNow Cloud Observability**. Next, click either **Add Destination** or (if displayed) **Select Existing**.
    - To configure via the Routes, click **Data** then **Destinations** (Cribl Stream) or **More** then **Destinations** (Cribl Edge). Select **ServiceNow Cloud Observability** from the list of tiles or the **Destinations** list. Next, click **Add Destination** to open a **New Destination** modal.
2. In the Destination modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **OTLP version**: Already set to `1.3.1` and cannot be changed.
    - **Protocol**: Use the drop-down to choose the protocol to use when sending data:
        - gRPC (default): Uses Protocol Buffers (Protobuf) for serialization.
        - HTTP: Uses Binary Protobuf encoding (does not support JSON Protobuf).
    - **Endpoint**: The endpoint to send data to ServiceNow. Default options are `ingest.lightstep.com:443` (United States) and `ingest.eu.lightstep.com:443` (Europe).
        - You can specify a custom endpoint using either a valid URL or an IP address (IPv4 or IPv6). Enclose IPv6 addresses in square brackets (for example,

`[2001:db8:85a3:0000:0000:8a2e:0370:7334]`).

- To proxy outbound HTTP/S requests, see System Proxy Configuration.

- **Auth token (text secret)**: Create or select a Cribl stored text secret that contains your ServiceNow Cloud Observability access token, ensuring secure authentication for data transmission.
- **Optional Settings**:
  - When using `HTTP`, you can customize the path instead of using the default cloud endpoints. This is useful when integrating with a hosted Lightstep satellite.
  - **Backpressure behavior**: Whether to `Block`, `Drop`, or `Persistent Queue` events when all receivers are exerting backpressure.
  - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

3. Depending on the protocol you've selected, you have the following options:
   - **gRPC** provides TLS settings.
   - **HTTP** provides retry options, in addition to custom paths.
4. The **Processing Settings** and **Advanced Settings** provide granular control over how data is handled and transmitted.
   - Processing Settings allow you to define pre-processing and post-processing Pipelines, ensuring that events conform to the relevant Protobuf specifications for traces, metrics, and logs. This includes adding metadata, applying transformations, and conditioning the data.
   - Advanced Settings offer additional configuration options that enhance the flexibility and performance of data transmission.
     - For `gRPC`, this includes connection timeout, keep-alive time, and metadata headers.
     - For `HTTP`, this includes options like custom path overrides for traces, metrics, and logs, as well as settings for validating server certificates and using round-robin DNS. HTTP is simpler to set up and more widely compatible with existing tools and platforms.
5. Click **Save**, then **Commit & Deploy**.
6. Use the **Test** tab in the Destination's configuration modal to validate the configuration and connectivity of your Destination.

Custom HTTP Path

To send data to a custom location, override the default endpoint paths. When the **Protocol** is set to `HTTP`, this Destination sends data to the following endpoints by default:

- Traces: `<endpoint>/traces/otlp/v0.9`
- Metrics: `<endpoint>/metrics/otlp/v0.9`

- Logs: `<endpoint>/v1/logs`

`<endpoint>` refers to the base URL you specified in the **Endpoint** setting above.

To override a default path, provide only the desired path in the corresponding field: **Traces endpoint override**, **Metrics endpoint override**, or **Logs endpoint override**.

TLS Settings (Client Side)

TLS is available only when **General Settings** > **Protocol** is set to `gRPC`.

Use TLS Defaults to `No`. When toggled to `Yes`:

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output – both metric events, as dimensions; and log events, as labels. Supports wildcards.

By default, includes `cribl_pipe` (Cribl Stream Pipeline that processed the event).

Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

This tab is displayed when **General Settings** > **Protocol** is set to `HTTP`.

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, click **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this to `Yes` to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

This tab's options depend on whether **General Settings** > **Protocol** is set to the `gRPC` or `HTTP` transport.

Compression: Compression type to apply to messages sent to the OpenTelemetry endpoint. `Gzip` (the default) and `None` are available for both protocols; `Deflate` is available for gRPC only.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30` sec.

Request concurrency: Maximum number of concurrent requests before blocking. This is set per Worker Process. Defaults to `5`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `2048` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` sec.

Auth token name: Name of the header or metadata key that will carry your ServiceNow Cloud Observability access token during data transmission. The default is `lightstep-access-token` and is customizable to match your specific requirements.

Environment: Optionally, specify a single Git branch on which to enable this configuration. If this field is empty, the config will be enabled everywhere.

Additional Settings for gRPC

When **General Settings** > **Protocol** is set to `gRPC`, the **Advanced Settings** tab adds the following options.

Connection timeout: Amount of time (milliseconds) to wait for the connection to establish before retrying. Defaults to `10000` (10 sec.).

Keep alive time (seconds): How often the sender should ping the peer to keep the connection alive. Defaults to `30`.

Metadata: Extra information to send with each gRPC request. Click **Add Metadata** to add each item as a **Key-Value** pair. The **Key** field is arbitrary. The **Value** field is a JavaScript expression that is evaluated just once, when this Destination is initialized. If you pass credentials as metadata, Cribl recommends using C.Secret().

Additional Settings for HTTP

When **General Settings** > **Protocol** is set to `HTTP`, the **Advanced Settings** tab adds the following options.

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (e.g., the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Keep alive: By default, Cribl Stream sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Stream to close the connection immediately after sending a request.

Extra HTTP headers: Click **Add Header** to define additional HTTP headers to pass to all events. Each row is a **Name-Value** pair. Values will be sent encrypted. You can also add headers dynamicall,y on a per-event basis, in the `__headers` field.

Safe headers: Add headers here to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Protocol and Transport Support

This Destination leverages the OpenTelemetry Protocol (OTLP) v1.3.1 to send observability data to ServiceNow. It supports both gRPC and HTTP protocols, ensuring flexibility in data transmission. OTLP defines Protocol buffer (Protobuf) schemas for its payloads (requests and responses). With the HTTP transport, this Destination supports Binary Protobuf payload encoding, but currently does not support JSON Protobuf.

When configuring Pipelines (including pre-processing and post-processing Pipelines), you need to ensure that events sent to this Destination conform to the relevant Protobuf specification.

- For traces, opentelemetry/proto/trace/v1/trace.proto
- For metrics, opentelemetry/proto/metrics/v1/metrics.proto
- For logs, opentelemetry/proto/logs/v1/logs.proto

This Destination will drop non-conforming events. If the Destination encounters a parsing error when trying to convert an event to OTLP, it discards the event and Cribl Stream logs the error.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.28. SignalFx Destination

Cribl Stream supports sending events to SignalFx, now rebranded as Splunk Observability Cloud.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Output to SignalFx

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this SignalFX definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Realm**: Observability Cloud realm name (for example, `us0`). Required.
3. In the **Authentication** settings, select one of the following options from the menu:
    - **Manual**: Displays an **Auth token** field for you to enter your Observability Cloud API access token. See the Authentication tokens topic in the API Reference.
    - **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the API access token described above. A **Create** link is available to store a new, reusable secret.
4. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, you can adjust the Persistent Queue, Processing, Retries and Advanced settings outlined in the sections below.

6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.

- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA – for example, the system's CA.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` second.

Extra HTTP headers: Click **Add Header** to insert extra headers as **Name/Value** pairs. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream

will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Notes About SignalFx

SignalFx has been rebranded as Splunk Observability Cloud, but the API endpoints still have URLs at `signalfx.com`.

For details on integrating with SignalFx, see the Developer Guide. Especially relevant is the Send Traces, Metrics and Events section of the Observability Cloud API Reference.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.29. SNMP Trap Destination

Cribl Stream supports forwarding of SNMP Traps out.

Type: Streaming | TLS Support: No | PQ Support: No

If you've modified SNMP trap events within the Pipeline, use the SNMP Trap Serialize Function to serialize compliant events into SNMP traps before sending them to an SNMP Trap Destination.

Configure Cribl Stream to Forward to SNMP Traps

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this SNMP Trap definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **SNMP trap destinations**: For each destination configured, enter the destination host **Address** and destination **Port**. **Port** defaults to `162`. To specify additional SNMP trap destinations to forward traps to on new rows, select **Add Destination**.
3. Next, you can configure the following **Optional Settings**:
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Processing and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

Advanced Settings

DNS resolution period (sec): Specify the interval (in seconds) to re-resolve hostnames. This reduces the frequency of DNS lookups, improving performance. Use this setting to balance the overhead of DNS lookup calls with the expected frequency of changes in the DNS records. Defaults to `0` seconds, meaning DNS lookups occur for every outgoing trap.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Considerations for Working with SNMP Traps Data

- It's possible to work with SNMP metadata (i.e., we'll decode the packet). Options include dropping, routing, etc. However, packets **cannot** be modified and sent to another SNMP Destination.
- SNMP packets can be forwarded to non-SNMP Destinations (for example, Splunk, Syslog, S3, etc.).
- SNMP packets can be forwarded to other SNMP Destinations. However, the contents of the incoming packet cannot be modified – i.e., we'll forward the packets verbatim as they came in.
- Non-SNMP input data **cannot** be sent to SNMP Destinations.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.30. Sumo Logic Destination

Cribl Stream can send logs and metrics to Sumo Logic over HTTP. Sumo Logic offers a Hosted Collector that supports HTTP Sources to receive data over an HTTP POST request.

To send traces to Sumo Logic you can use Cribl's OpenTelemetry Destination pointing to Sumo Logic's OTLP/HTTP Source.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

How Sumo Logic Handles Data

- When an event contains the internal field `__criblMetrics`, it's sent to Sumo Logic as a metric event. Otherwise, it's sent as a log event.
- Data sent to Sumo Logic needs to be UTF-8 encoded and they recommend a data payload have a size, before compression, of 100 KB to 1 MB.
- Sumo Logic may impose throttling and caps on your log ingestion to prevent your account from using On-Demand Capacity, see Sumo Logic's manage ingestion documentation for details.

Prerequisites

In Sumo Logic, create or retrieve an HTTP Logs and Metrics Source's unique endpoint URL. See Sumo Logic's HTTP Logs and Metrics Source documentation for details. You will need the `Manage Collectors` role capability in Sumo Logic.

After creating the Source in Sumo Logic, the URL associated with the Source is displayed. Copy the endpoint URL so you can enter it when you configure the Cribl Stream Sumo Logic Destination.

Configure a Sumo Logic Destination

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.

2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Sumo Logic Destination definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **API URL**: Enter the endpoint URL of the Sumo Logic HTTP Source. This is provided by Sumo Logic after creating the Source, see prerequisites for details. For example, `https://endpoint6.collection.us2.sumologic.com/receiver/v1/http/<long-hash>`.
3. Next, you can configure the following **Optional Settings**:
    - **Custom source name** and **Custom source category** are unique settings to Sumo Logic. These allow you to override the Sumo Logic HTTP Source's **Source Name** and **Source Category** values with HTTP headers. Alternatively, you can define the `__sourceName` and `__sourceCategory` fields on events to assign a custom value at the event level.

    The remaining configurations are Cribl settings that you'll find across many Cribl Destinations.

    - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure.
    - **Data Format**: This drop-down defaults to `JSON`. Change this to `Raw` if you prefer to preserve outbound events' raw format instead of JSONifying them.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, configure any Persistent Queue, Processing, Retries, and Advanced settings outlined in the below sections.

> Requests to Sumo Logic are created in separate batches for each unique combination of **Source Name** and **Source Category** within the event payload. If you have a large number of unique pairs, this could lead to many individual batches being held in memory at any given time. You can increase the **Buffer memory limit** to give more memory allowance for buffering outgoing requests, allowing batches to grow larger before being flushed. The default flushing mechanism would discard smaller batches before they reach an expected size due to reaching the **Buffer memory limit**.

5. Click **Save**, then **Commit & Deploy**.
6. Verify that data is searchable in Sumo Logic. See the Verify Data Flow section below.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.

This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.

- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `1024` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass as additional HTTP headers. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

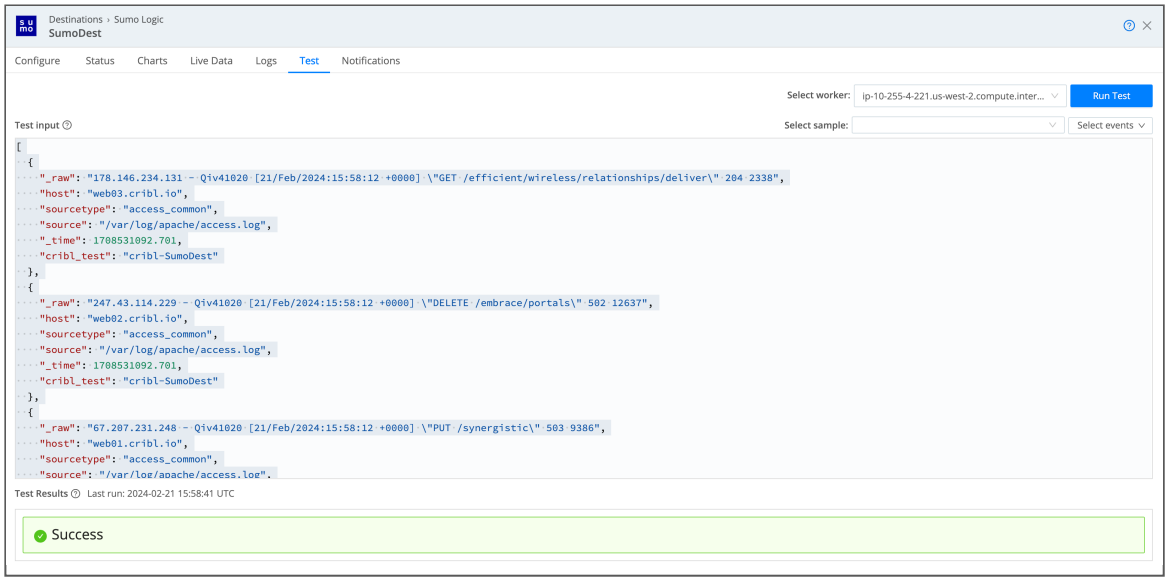
Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Verify Data Flow

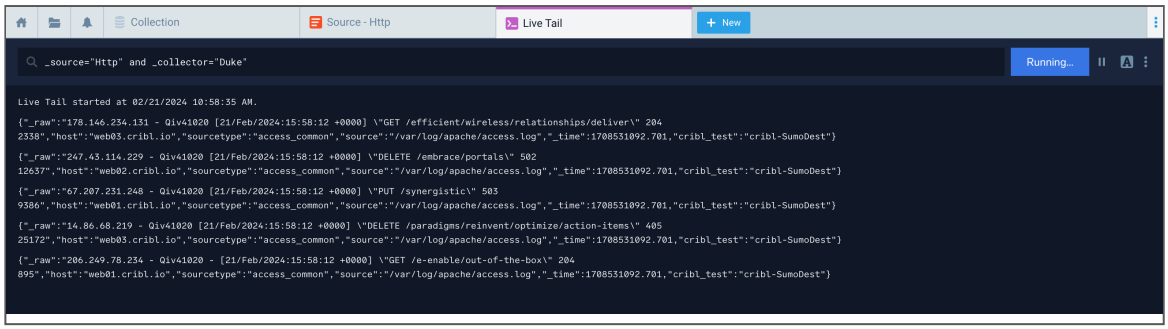
To verify data flow, we'll use the Destination's **Test** feature while running a **Live Tail** session in Sumo Logic.

1. In Sumo Logic, run a new Live Tail session against the name of the HTTP Logs and Metrics Source or the **Custom source name** you defined when you configured the Sumo Logic Destination. You'll need to use the `_source` metadata field. For example, if the name of the Source is `HTTP` your search would be `_source="HTTP"`. Ensure you've clicked the **Run** button to start the Live Tail session.
2. In Cribl Stream, open the Destination configuration modal and select the **Test** tab. You can leave the default data or select from the available samples. Click **Run Test**.



Example Destination Test

3. Look back to your Sumo Logic Live Tail session and you should see the sample data from the Cribl test displayed in your Live Tail results.



Example Live Tail Results

Troubleshooting

If you receive an error when verifying data flow, take note of the response code and reference Sumo Logic's documentation for common issues to investigate.

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, the connection will be thrown away, and a new one will be reattempted. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), a new connection will be established for the next request.
- When resolving the Destination's hostname, Cribl Stream will pick the first IP in the list for use in the next connection. Enable Round-robin DNS to better balance distribution of events between destination cluster nodes.

15.2.31. Syslog Destination

Cribl Stream supports sending out data over syslog via TCP or UDP.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

This Syslog Destination supports RFC 3164 and RFC 5424. **Before** you configure this Destination, review Syslog Format Options and Structure Syslog Output below. This will help you ensure that your configuration will structure RFC-compliant outbound events that downstream services can read.

Configure Cribl Stream to Output Data in Syslog Format

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Syslog definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Protocol**: The network protocol to use for sending out syslog messages. Defaults to `TCP`; `UDP` is also available.
    - **Load balancing**: Cribl Stream displays this option only when the **Protocol** is set to `TCP`. When enabled (default), lets you specify multiple destinations. See Load Balancing Settings below.

    Turning **Load balancing** off displays the following two additional fields:

    - **Address**: Address/hostname of the receiver.
    - **Port**: Port number to connect to on the host.

    If **Load balancing** is disabled and you notice that Cribl Stream is not sending data to all possible IP addresses, enable **Advanced Settings > Round-robin DNS**.

- **Record size limit**: Displayed when **Protocol** is set to `UDP`. Sets the maximum size of syslog messages. Defaults to `1500`, and must be ≤ `2048`. To avoid packet fragmentation, keep this value less than or equal to the MTU (maximum transmission unit) for the network path to the downstream receiver. When the message length exceeds the size limit, it is truncated and followed with an ellipsis ("…").

3. Next, you can configure the following **Optional Settings**:
   - **Facility**: Default value for message facility. If set, will be overwritten by the value of `__facility`. Defaults to `user`.
   - **Severity**: Default value for message severity. If set, will be overwritten by the value of `__severity`. Defaults to `notice`.
   - **App name**: Default value for application name. If set, will be overwritten by the value of `__appname`. Defaults to `Cribl`.
   - **Message format**: The syslog message format supported by the receiver. Defaults to `RFC3164`.
   - **Timestamp format**: The timestamp format to use when serializing an event's time field. Options include `Syslog` (default) and `ISO8601`. For details, see Timestamp format below.
   - **Throttling**: Throttle rate, in bytes per second. Defaults to `0`, meaning no throttling. Multiple-byte units such as KB, MB, or GB are also allowed – for example, `42 MB`. When throttling is engaged, your **Backpressure behavior** selection determines whether Cribl Stream will handle excess data by blocking it, dropping it, or queueing it to disk. For details, see Throttling below.
   - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
   - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
4. Optionally, you can adjust the Persistent Queue, TLS, Processing, Timeout, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Load Balancing Settings

Load balancing is available only when the **Protocol** is set to `TCP`.

Enabling the **Load balancing** toggle replaces the static **General Settings** > **Address** and **Port** fields with the following controls:

Exclude current host IPs: This toggle appears when **Load balancing** is set to `Yes`. It determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Defaults to `No`, which keeps the current host available for load balancing.

Destinations

Use the **Destinations** table to specify a known set of receivers on which to load-balance data. To specify more receivers on new rows, click **Add Destination**. Each row provides the following fields:

Address: Hostname of the receiver. Optionally, you can paste in a comma-separated list, in `<host>:<port>` format.

Port: Port number to send data to on this host.

TLS: Whether to inherit TLS configs from group setting, or disable TLS. Defaults to `inherit`.

TLS servername: Servername to use if establishing a TLS connection. If not specified, defaults to connection host (if not an IP). Otherwise, uses the global TLS settings.

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (> `0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Stream will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

Timestamp Format

For `Syslog`, the timestamp format is `Mmm dd hh:mm:ss`, using the timezone of the syslog device. For example: `Jan 18 16:56:36`.

For `ISO8601`, the basic timestamp format is `YYYY-MM-DD`. For example: `2023-01-18`. For extended formats, add hours, minutes, seconds, decimal fractions (optional), and timezone. For example: `2023-01-18T16:56:36.996-08:00`.

Throttling

When **Throttling** is used in conjunction with **Max connections**, the throttling rate is applied per connection. For instance, if **Max connections** is set to `2` and throttling is set to `3 MB`, each of the two connections can send

data at a rate of up to 3 MB per second, resulting in a total potential throughput of 6 MB per second across both connections.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

TLS Settings (Client Side)

Enabled defaults to `No`. When toggled to `Yes`:

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA – for example, the system's CA. Defaults to `Yes`.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Timeout Settings

These timeout settings apply only to the TCP protocol.

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish, before retrying. Defaults to `10000`.

Write timeout: Amount of time (milliseconds) to wait for a write to complete, before assuming connection is dead. Defaults to `60000`.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

The first three options are always displayed:

Octet count framing: When enabled, Cribl Stream prefixes messages with their byte count, regardless of whether the messages are constructed from `message` or `__syslogout`. When disabled, Cribl Stream omits prefixes, and instead appends a `\n` to messages. RFCs 5425 and 6587 describe how octet counting works in syslog.

Log failed requests to disk: Toggling to `Yes` makes the payloads of any (future) failed requests available for inspection. See Inspect Payloads to Troubleshoot Closed Connections below.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

The following options are added if you enable the General Settings tab's **Load balancing** option:

DNS resolution period (seconds): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from A records.

- For TCP: This helps maintain up-to-date IP addresses for your TCP connections. Defaults to `600` seconds.
- For UDP: This reduces the frequency of DNS lookups for UDP destinations, improving performance. Defaults to `0` seconds, meaning DNS lookups occur for every outgoing message.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds. If multiple receivers – that is, multiple A records – are behind a hostname, all resolved IPs will inherit the weight of the host unless each IP is specified separately. In Cribl Stream load balancing, IP settings take priority over those from hostnames.

Max connections: Constrains the number of concurrent receiver connections per Worker Process, to limit memory utilization. If you set this to a number greater than `0`, Cribl Stream will randomly select that many discovered IPs to connect to on every DNS resolution period. Cribl Stream will rotate IPs in future resolution periods – monitoring weight and historical data, to ensure fair load balancing of events among IPs.

Inspect Payloads to Troubleshoot Closed Connections

When a downstream receiver closes connections from this Destination (or just stops responding), inspecting the payloads of the resulting failed requests can help you find the cause. For example:

- Suppose you send an event whose size is larger than the downstream receiver can handle.

- Suppose you send an event that has a `number` field, but the value exceeds the highest number that the downstream receiver can handle.

When **Log failed requests to disk** is enabled, you can inspect the payloads of failed requests. Here is how:

1. In the Destination UI, navigate to the **Logs** tab.
2. Find a log entry with a `connection error` message.
3. Expand the log entry.
4. If the message includes the phrase `See payload file for more info`, note the path in the `file` field on the next line.

Now you have the path to the directory where Cribl Stream is storing payloads from failed requests. At the command line, navigate to that directory and inspect any payloads that you think might be relevant.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to downstream services. Fields for this Destination:

- `__priority`
- `__facility`
- `__severity`
- `__procid`
- `__appname`
- `__msgid`
- `__syslogout`

Syslog Format Options

Unlike other Cribl Stream Destinations, the Syslog Destination applies an additional post-processing step after the Pipeline(s) transform events. This additional step structures the data for compliance with the syslog transport protocol (RFC 3164 and/or RFC 5424) before it is transmitted to downstream services.

- With RFC 3164-compliant messages, you'll get `priority`, `timestamp`, `host`, and `message`, such that `message` includes `appname` and `procid`. You will not get `msgid` or `STRUCTURED-DATA`.
- With RFC 5424-compliant messages – that is, structured data – Cribl Stream will send the contents of `event.structuredData`, whether or not that content is valid according to the RFC. Cribl Stream will make no attempt to frame, enclose, or validate the data. If present, structured data **should** be in the

form `[ SD-ID *PARAM-NAME=PARAM-VALUE]` but Cribl Stream will not enforce this. Cribl Stream will send whatever is in that field, or, if the field is missing, send a dash (`-`).

In General Settings, you can format the timestamps, format the message delivering the event, and set defaults for **Facility**, **Severity**, and **App name** (in RFC 5424, these are Facility, Severity, and APP-NAME, respectively).

Here is an example of an RFC 3164-compliant syslog event:

- `<13>Jul 11 10:34:35 testbox testing[42]`

Here is an example of an RFC 5424-compliant syslog event:

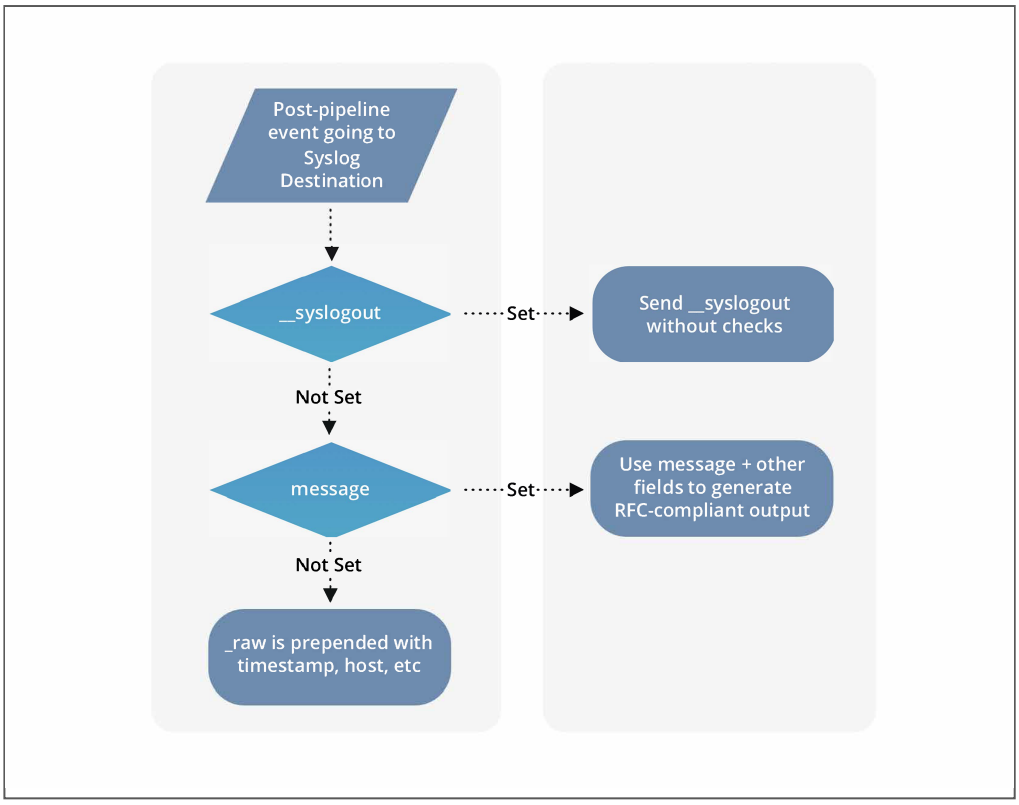
- `<214>1 2022-07-11T18:58:45.000Z testbox testapp 42 - [exampleSDID@32473 iut="3" foo="bar" this="that"] Here is a message`

Structure Syslog Output

Two approaches are available for specifying how the Syslog Destination will structure its output. One relies on the `message` field, and the other relies on the `__syslogout` field. The Syslog Destination determines what to do based on whether or not those fields are set, as the flowchart below makes clear.

- Use `message` (Simplest Approach): Cribl recommends using this option, which requires you to configure `message` and to leave `__syslogout` unset. When `message` is defined, Cribl Stream discards `_raw` and composes a new payload using the other syslog-related fields. Cribl Stream automatically processes the values of the `message`, `_time`, `host`, and other fields, and creates an ISO-compliant timestamp and a properly formatted event. In the flowchart, the rounded rectangle that reads "Use message + other fields ..." represents this approach.
- Export `__syslogout` (Alternative Approach): When you define `__syslogout`, Cribl Stream sends this field and its value as the entire syslog message, discards `_raw`, and ignores all the other fields. In the flowchart, the rounded rectangle that reads "Send __syslogout ..." represents this approach.

As the flowchart shows, if **neither** `message` nor `__syslogout` are set, Cribl Stream uses the existing `_raw` field as the `message` field (with or without a header), and prepends all the other syslog-related fields to the event. While this could be considered a third approach, Cribl does not recommend it, and we will not describe it further in this topic.



Syslog output flow

Before you configure this Destination, review the subsection below that explains the approach that you prefer.

Use `message` (Simplest Approach)

Cribl recommends this approach for environments where events enter Cribl Stream from the Syslog Source, because that Source supplies all required fields.

This approach is the simplest and least error-prone because Cribl Stream creates the payload for you. The following fields are required:

- `facility`
- `severity`
- `_time`
- `host`
- `message`

Cribl Stream will create a new syslog-adherent payload using these required fields. See Field Logic and Behavior below. To specify which RFC your events should adhere to, use **General Settings** > **Optional Settings** > **Message format**.

If these optional fields are included in the event, Cribl Stream will use them appropriately when constructing the payload:

- `appname`
- `host`
- `procid`
- `msgid` (RFC 5424 only)
- `structuredData` (RFC 5424 only)

Field Logic and Behavior

Let's examine the fields in a syslog-formatted event. Keep in mind that if Severity, Facility, or APP-NAME are not set on the event, Cribl Stream defaults to the corresponding value(s) configured in the Syslog Destination (**Severity**, **Facility**, and **App name**, respectively).

- `__priority`: If this field is present Cribl Stream will use it and ignore `facility` and `severity`.
- The version (used for RFC 5424 only, and not a field that you can set) follows priority (with no spaces in between).
- `__facility` or `facility`: Cribl Stream uses this field to calculate priority. The RFCs define Facility codes.
- `__severity` or `severity`: Cribl Stream also uses this field to calculate priority. The RFCs define Severity levels.

Use either (a) `__facility` and `__severity` or (b) `facility` and `severity`. For these fields, avoid mixing double-underscore naming with no-underscore naming, because if you mix them, Cribl Stream will ignore one of them and you will get unintended results.

If `__priority` is not set, Cribl Stream calculates the Priority from the values of Severity and Facility. Cribl Stream uses the formula: Priority = ((8 * Facility) + Severity).

- For example, if the `facility` is `13` (Security) and the `severity` is `2` (Critical), the `priority` will be `(13 * 8) + 2 = 106`.

Now let's look at the rest of the fields. The list below shows field names in priority order: if both `__appname` and `appname` are present, Cribl Stream uses `__appname`.

- `_time`: The value of `_time` in Cribl events is in epoch format, but the syslog RFCs dictate that each event's timestamp must be in human-readable format (see TIMESTAMP in RFC 3164 or RFC 5424). When defining a Syslog Destination, you configure this with **General Settings** > **Timestamp format**. The

`ISO8601` option (ISO 8601 format) defines the method for specifying time zone and year, while the older `Syslog` format lacks this information. For this reason, Cribl recommends `ISO8601`.

- `host`: the value for the required host field in a syslog event (see HOSTNAME in RFC 3164 or RFC 5424), following the timestamp.
- `__appname` or `appname`: The required application name (APP-NAME in RFC 5424). This is typically the name of the daemon or process that is logging any given event.
- `__procid` or `procid`: This optional field (PROCID in RFC 5424) is the Process ID. Use a numeric value, optionally surrounded with brackets – for example, `[4321]`. Cribl Stream will automatically adjust the spaces and syntax to ensure RFC-compliant formatting.
- `__msgid` or `msgid`: This optional field (MSGID in RFC 5424 only) is the Message ID.
- `structuredData`: This optional field (STRUCTURED-DATA in RFC 5424 only) contains a namespace and zero or more key-value pairs. Cribl Stream does not validate whether it adheres to the RFC.

Export `__syslogout` (Alternative Approach)

The most common use of this approach is to send to a non-syslog downstream receiver such as a raw TCP listener. While there is no native "raw TCP" Destination in Cribl Stream, this approach – where you configure a Syslog Destination with the TCP protocol and `__syslogout` – can be an effective method for delivering raw data over TCP to a downstream receiver that does not enforce syslog RFCs.

When you set `__syslogout`, that field becomes the entire syslog message sent. Neither `_raw` nor any other metadata are sent downstream.

If you enable **Octet count framing**, Cribl Stream will prepend the number of bytes of the constructed `__syslogout` field to the message before sending it.

Cribl Stream does not check whether the value of `__syslogout` is RFC-compliant. This means that to send proper, RFC-compliant syslog messages, you must manually construct the `__syslogout` payload, starting with `_time`, for all the fields that Cribl Stream would automatically handle with the first approach above.

If the value of `__syslogout` fails to adhere to the syslog RFCs, a downstream syslog server may misinterpret the event; drop non-compliant events entirely; or, try to "fix" the format by supplying missing fields.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.32. TCP JSON Destination

Cribl Stream supports sending data over TCP in JSON format.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Configure Cribl Stream to Output Data in TCP JSON Format

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this TCP JSON definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: When enabled (default), lets you specify multiple destinations. For details, see Load Balancing Settings below.
      The following two fields appear **only** with the `No` setting.
    - **Address**: Hostname of the receiver.
    - **Port**: Port number to connect to on the host.
3. In the **Authentication** settings, select one of the following options from the menu:
    - **Manual**: In the resulting **Auth token** field, you can optionally enter an auth token to use in the connection header.
    - **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the `authToken` header field value described above. A **Create** link is available to store a new, reusable secret.
4. Next, you can configure the following **Optional Settings**:
    - **Exclude current host IPs**: This toggle appears when **Load balancing** is set to `Yes`. It determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Defaults to `No`, which keeps the current host available for load balancing.

- **Compression**: Codec to use to compress the data before sending. Defaults to `Gzip`.
- **Throttling**: Throttle rate, in bytes per second. Defaults to `0`, meaning no throttling. Multiple-byte units such as KB, MB, GB, and so forth, are also allowed – for example, `42 MB`. When throttling is engaged, your **Backpressure behavior** selection determines whether Cribl Stream will handle excess data by blocking it, dropping it, or queueing it to disk. For details, see Throttling below.
- **Backpressure behavior**: Specifies whether to block, drop, or queue events when all receivers are exerting backpressure. Defaults to `Block`. For details, see Persistent Queue Settings below.
- **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.

5. Optionally, you can adjust the Persistent Queue, TLS, Processing, and Advanced settings outlined in the sections below.
6. Select **Save**, then **Commit & Deploy**.

Load Balancing Settings

Enabling the **Load balancing** toggle replaces the static **General Settings** > **Address** and **Port** fields with the following controls:

Destinations

Use the **Destinations** table to specify a known set of receivers on which to load-balance data. To specify more receivers on new rows, click **Add Destination**. Each row provides the following fields:

Address: Hostname of the receiver. Optionally, you can paste in a comma-separated list, in `<host>:<port>` format.

Port: Port number to send data to on this host.

TLS: Whether to inherit TLS configs from group setting, or disable TLS. Defaults to `inherit`.

TLS servername: Servername to use if establishing a TLS connection. If not specified, defaults to connection host (if not an IP). Otherwise, uses the global TLS settings.

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (> `0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Stream will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

Throttling

When used **Throttling** is used in conjunction with **Max connections**, the throttling rate is applied per connection. For instance, if **Max connections** is set to `2` and throttling is set to `3 MB`, each of the two connections can send data at a rate of up to 3 MB per second, resulting in a total potential throughput of 6 MB per second across both connections.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

TLS Settings (Client Side)

Use TLS defaults to `No`. When toggled to `Yes`:

Autofill?: This setting is experimental.

Validate server certs: Reject certificates that are not authorized by a CA in the **CA certificate path**, or by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Timeout Settings

Connection timeout: Amount of time (in milliseconds) to wait for the connection to establish before retrying. Defaults to `10000`.

Write timeout: Amount of time (in milliseconds) to wait for a write to complete before assuming connection is dead. Defaults to `60000`.

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.

- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Advanced Settings

Log failed requests to disk: Toggling to `Yes` makes the payloads of any (future) failed requests available for inspection. See Inspecting Payloads to Troubleshoot Closed Connections below.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Setting General Settings > **Load balancing** to `Yes` adds the following settings:

DNS resolution period (seconds): Re-resolve any hostnames after each interval of this many seconds, and pick up destinations from A records. Defaults to `600` seconds.

Load balance stats period (seconds): Lookback traffic history period. Defaults to `300` seconds. (Note that If multiple receivers are behind a hostname – i.e., multiple A records – all resolved IPs will inherit the weight of the host, unless each IP is specified separately. In Cribl Stream load balancing, IP settings take priority over those from hostnames.)

Max connections: Constrains the number of concurrent receiver connections, per Worker Process, to limit memory utilization. If set to a number > `0`, then on every DNS resolution period, Cribl Stream will randomly select this subset of discovered IPs to connect to. Cribl Stream will rotate IPs in future resolution periods – monitoring weight and historical data, to ensure fair load balancing of events among IPs.

Inspecting Payloads to Troubleshoot Closed Connections

When a downstream receiver closes connections from this Destination (or just stops responding), inspecting the payloads of the resulting failed requests can help you find the cause. For example:

- Suppose you send an event whose size is larger than the downstream receiver can handle.
- Suppose you send an event that has a `number` field, but the value exceeds the highest number that the downstream receiver can handle.

When **Log failed requests to disk** is enabled, you can inspect the payloads of failed requests. Here is how:

1. In the Destination UI, navigate to the **Logs** tab.
2. Find a log entry with a `connection error` message.

3. Expand the log entry.
4. If the message includes the phrase `See payload file for more info`, note the path in the `file` field on the next line.

Now you have the path to the directory where Cribl Stream is storing payloads from failed requests. At the command line, navigate to that directory and inspect any payloads that you think might be relevant.

Format

TCP JSON events are sent in newline-delimited JSON format, consisting of:

1. A header line. Can be empty, for example: `{}`. If **Auth Token** is enabled, the token will be included here as a field called `authToken`. In addition, if events contain common fields, they will be included here under `fields`.
2. A JSON event/record per line.

See an example in our TCP JSON Source topic.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.33. Wavefront Destination

Cribl Stream supports sending events to Wavefront analytics.

Type: Streaming | TLS Support: Yes | PQ Support: Yes

Configure Cribl Stream to Output to Wavefront

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this Wavefront definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Domain name**: WaveFront domain name, for example, `longboard`. Required.
3. In the **Authentication** settings, select one of the following options from the menu:
    - **Manual**: Displays an **API key** field for you to enter your Wavefront API auth token. See Wavefront's Generating an API Token topic.
    - **Secret**: This option exposes an **Auth token (text secret)** drop-down, in which you can select a stored secret that references the API auth token described above. A **Create** link is available to store a new, reusable secret.
4. Next, you can configure the following **Optional Settings**:
    - **Backpressure behavior**: Select whether to block, drop, or queue events when all receivers are exerting backpressure. (Causes might include a broken or denied connection, or a rate limiter.) Defaults to `Block`.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary) tag names.
5. Optionally, configure any Persistent Queue, Processing, Retries, and Advanced settings outlined in the sections below.

6. Select **Save**, then **Commit & Deploy**.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.

- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Toggle to `Yes` to reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA).

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Flush period (sec): Maximum time between requests. Low values can cause the payload size to be smaller than the configured **Max body size**. Defaults to `1` second.

Extra HTTP headers: Click **Add Header** to insert extra headers as **Name/Value** pairs. Values will be sent encrypted.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Proxying Requests

If you need to proxy HTTP/S requests, see System Proxy Configuration.

Notes About Wavefront

For details on integrating with Wavefront, see these Wavefront resources:

- Direct Data Ingestion, and adjacent topics on Wavefront Proxies.
- Wavefront Data Format.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.2.34. Webhook Destination

Cribl Stream can send log and metric events to webhooks and other generic HTTP endpoints.

Type: Streaming | TLS Support: Configurable | PQ Support: Yes

Configure Cribl Stream to Output via HTTP

1. On the top bar, select **Products**, and then select **Cribl Stream**. Under **Worker Groups**, select a Worker Group. Next, you have two options:
    - To configure via QuickConnect, navigate to **Routing** > **QuickConnect** (Stream) or **Collect** (Edge). Select **Add Destination** and select the Destination you want from the list, choosing either **Select Existing** or **Add New**.
    - To configure via the Routes, select **Data** > **Destinations** or **More** > **Destinations** (Edge). Select the Destination you want. Next, select **Add Destination**.
2. In the **New Destination** modal, configure the following under **General Settings**:
    - **Output ID**: Enter a unique name to identify this HTTP output definition. If you clone this Destination, Cribl Stream will add `-CLONE` to the original **Output ID**.
    - **Description**: Optionally, enter a description.
    - **Load balancing**: When enabled (default), lets you specify multiple Webhook URLs and load weights. With the default `No` setting, if you notice that Cribl Stream is not sending data to all possible IP addresses, enable **Advanced Settings** > **Round-robin DNS**.
    - **Webhook URL**: Endpoint URL to send events to. For details, see Webhook URLs below.
3. Next, you can configure the following **Optional Settings**:
    - **Exclude current host IPs**: This toggle appears when **Load balancing** is set to `Yes`. It determines whether to exclude all IPs of the current host from the list of any resolved hostnames. Defaults to `No`, which keeps the current host available for load balancing.
    - **Method**: The HTTP verb to use when sending events. Defaults to `POST`. Change this to `PUT` or `PATCH` where required by the endpoint.
    - **Format**: The format in which to send out events. The choices are: `NDJSON`, `JSON Array`, `Custom`, and `Advanced`. For details, see Format below.
    - **Backpressure behavior**: Whether to block, drop, or queue events when all receivers are exerting backpressure.
    - **Tags**: Optionally, add tags that you can use to filter and group Destinations on the **Destinations** page. These tags aren't added to processed events. Use a tab or hard return between (arbitrary)

tag names.

4. Optionally, you can adjust the TLS, Authentication, Persistent Queue Settings, Processing, and Advanced settings outlined in the sections below.
5. Select **Save**, then **Commit & Deploy**.

Webhook URLs

Use the **Webhook URLs** table to specify a known set of receivers on which to load-balance data. To specify more receivers on new rows, click **Add URL**. Each row provides the following fields:

Webhook LB URL: Specify the Webhook URL to send events to – for example, `http://webhook:8000/`

Load weight: Set the relative traffic-handling capability for each connection by assigning a weight (`> 0`). This column accepts arbitrary values, but for best results, assign weights in the same order of magnitude to all connections. Cribl Stream will attempt to distribute traffic to the connections according to their relative weights.

The final column provides an `X` button to delete any row from the table.

For details on configuring all these options, see About Load Balancing.

When you first enable load balancing, or if you edit the load weight once your data is load–balanced, give the logic time to settle. The changes might take a few seconds to register.

Format

When sending events to a Webhook Destination, you can choose the format in which they are delivered.

- `NDJSON`: Newline-delimited JSON (the default).
- `JSON Array`: Arrays in JSON-parseable format.
- `Custom`: Events and event batches (payloads) whose format you define using JavaScript **expressions**. See Custom Format below.
- `Advanced`: Events and event batches (payloads) whose format you define using JavaScript **code**. Enables the Webhook Destination to integrate with APIs not otherwise supported in Cribl Stream. See Advanced Format below.

TLS Settings (Client Side)

Enabled Defaults to `No`. When toggled to `Yes`:

Server name (SNI): Server name for the SNI (Server Name Indication) TLS extension. This must be a host name, not an IP address.

Minimum TLS version: Optionally, select the minimum TLS version to use when connecting.

Maximum TLS version: Optionally, select the maximum TLS version to use when connecting.

Certificate name: The name of the predefined certificate.

CA certificate path: Path on client containing CA certificates (in PEM format) to use to verify the server's cert. Path can reference `$ENV_VARS`.

Private key path (mutual auth): Path on client containing the private key (in PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Certificate path (mutual auth): Path on client containing certificates in (PEM format) to use. Path can reference `$ENV_VARS`. **Use only if mutual auth is required**.

Passphrase: Passphrase to use to decrypt private key.

Authentication

Select one of the following options for authentication:

- **None**: Don't use authentication.
- **Auth token**: Use HTTP token authentication. In the resulting **Token** field, enter the bearer token that must be included in the HTTP authorization header.
- **Auth token (text secret)**: This option exposes a **Token (text secret)** drop-down, in which you can select a stored text secret that references the bearer token described above. A **Create** link is available to store a new, reusable secret.
- **Basic**: Displays **Username** and **Password** fields for you to enter HTTP Basic authentication credentials.
- **Basic (credentials secret)**: This option exposes a **Credentials secret** drop-down, in which you can select a stored text secret that references the Basic authentication credentials described above. A **Create** link is available to store a new, reusable secret.
- **OAuth**: Configure authentication via the OAuth protocol. Exposes multiple extra options – see OAuth Authentication below.

OAuth Authentication

Selecting **OAuth** exposes the following additional fields:

- **Login URL**: Endpoint for the OAuth API call, which is expected to be a POST call.

- **OAuth secret**: Secret parameter value to pass in the API call's request body.
- **OAuth secret parameter name**: Secret parameter name to pass in API call's request body.
- **Token attribute name**: Name of the auth token attribute in the OAuth response. Can be top-level (for example, `token`); or nested, using a period (for example, `data.token`).
- **Authorize expression**: JavaScript expression used to compute the Authorization header to pass in requests. Uses `${token}` to reference the token obtained from the login POST request, for example: `` `Bearer ${token}` ``.
- **Refresh interval (secs.)**: How often to refresh the OAuth token. Default `3600` seconds (1 hour); minimum `1` second; maximum `300000` seconds (about 83 hours).
- **OAuth parameters**: Optionally, select **Add parameter** for each additional parameter you want to send in the OAuth login request. Cribl Stream will combine the secret with these parameters, and will send the URL-encoded result in a POST request to the endpoint specified in the **Login URL**. We'll automatically add the `Content-Type` header `application/x-www-form-urlencoded` when sending this request.
  In each row of the resulting table, enter the parameter's **Name**. The corresponding **Value** is a JavaScript expression to compute the parameter's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `id` instead of `` `${id}` `` – will be evaluated as strings.
- **Authentication headers**: Optionally, select **Add Header** for each custom auth header you want to define and send in the OAuth login request. Stream will automatically add the `Content-Type` header `application/x-www-form-urlencoded` when sending this request.
  In each row of the resulting table, enter the custom OAuth header's **Name**. The corresponding **Value** is a JavaScript expression to compute the header's value. This can also evaluate to a constant. Values not formatted as expressions – for example, `id` instead of `` `${id}` `` – will be evaluated as strings.

Persistent Queue Settings

This tab displays when the **Backpressure behavior** option in **General settings** is set to **Persistent Queue**.

> On Cribl-managed Cloud Workers (with certain plan tiers), this tab exposes only the destructive **Clear Persistent Queue** button (described at the end of this section). A maximum queue size of 1 GB disk space is automatically allocated per PQ-enabled Destination, per Worker Process. The 1 GB limit is on outbound uncompressed data, and no compression is applied to the queue.
>
> This limit is not configurable. If the queue fills up, Cribl Stream/Edge will block outbound data. To configure the queue size, compression, queue-full fallback behavior, and other options below, use a hybrid Group.

Mode: Use this menu to select when Cribl Stream/Edge engages the persistent queue in response to backpressure events from this Destination. The options are:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream/Edge queues and stores data to a disk until the backpressure event resolves.
Always on	Cribl Stream/Edge immediately queues and stores all data on a disk for all events, even when there is no backpressure.

Max file size: The maximum data volume to store in each queue file before closing it. Enter a numeral with units of KB, MB, etc. Defaults to `1 MB`.

Max queue size: The maximum amount of disk space that the queue can consume on each Worker Process. When the queue reaches this limit, the Destination stops queueing data and applies the **Queue-full** behavior. Defaults to `5 GB`. This field accepts positive numbers with units of `KB`, `MB`, `GB`, and so on. You can set it as high as `1 TB`, unless you've configured a different **Max PQ size per Worker Process** on the Group Settings/Fleet Settings page.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. Cribl Stream/Edge will append `/<worker-id>/<output-id>` to this value.

Compression: Set the codec to use when compressing the persisted data after closing a file. Defaults to `None`. `Gzip` is also available.

Queue-full behavior: Whether to block or drop events when the queue begins to exert backpressure. A queue begins to exert backpressure when the disk is low or at full capacity. This setting has two options:

- **Block**: The output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender.
- **Drop new data**: Discard all new events until the backpressure event has resolved and the receiver is ready.

Strict ordering: The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream/Edge will send earlier queued events before forwarding newly arrived events. To instead prioritize new events before draining the queue, switch this to `No`. When `No` is enabled, this option appears:

- **Drain rate limit (EPS)**: Optionally, set a throttling rate (in events per second) on writing from the queue to receivers. (The default `0` value disables throttling.) Throttling the queue drain rate can boost the throughput of new and active connections by reserving more resources for them. You can further optimize Worker startup connections and CPU load in the **Group Settings/Fleet Settings** > Worker Processes settings.

Clear Persistent Queue: For Cloud Enterprise only, click this button if you want to delete the files that are currently queued for delivery to this Destination. If you click this button, a confirmation modal appears. Clearing the queue frees up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (This button only appears after **Output ID** has been defined.)

To learn more about persistent queue behavior and how to use it with your system, see:

- Persistent Queues
- Planning for Persistent Queues
- Configuring Persistent Queues

Processing Settings

Post-Processing

Pipeline: Pipeline to process data before sending the data out using this output.

System fields: A list of fields to automatically add to events that use this output. By default, includes `cribl_pipe` (identifying the Cribl Stream Pipeline that processed the event). Supports wildcards. Other options include:

- `cribl_host` – Cribl Stream Node that processed the event.
- `cribl_input` – Cribl Stream Source that processed the event.
- `cribl_output` – Cribl Stream Destination that processed the event.
- `cribl_route` – Cribl Stream Route (or QuickConnect) that processed the event.
- `cribl_wp` – Cribl Stream Worker Process that processed the event.

Retries

Honor Retry-After header: Whether to honor a `Retry-After` header, provided that the header specifies a delay no longer than 180 seconds. Cribl Stream limits the delay to 180 seconds even if the `Retry-After` header specifies a longer delay. When enabled, any `Retry-After` header received takes precedence over all other options configured in the **Retries** section. When disabled, all `Retry-After` headers are ignored.

Settings for failed HTTP requests: When you want to automatically retry requests that receive particular HTTP response status codes, use these settings to list those response codes.

For any HTTP response status codes that are not explicitly configured for retries, Cribl Stream applies the following rules:

Status Code	Action
Greater than or equal to `400` and less than or equal to `500`.	Drop the request.
Greater than `500`.	Retry the request.

Upon receiving a response code that's on the list, Cribl Stream first waits for a set time interval called the **Pre-backoff interval** and then begins retrying the request. Time between retries increases based on an exponential backoff algorithm whose base is the **Backoff multiplier**, until the backoff multiplier reaches the **Backoff limit (ms)**. At that point, Cribl Stream continues retrying the request without increasing the time between retries any further.

By default, this Destination has no response codes configured for automatic retries. For each response code you want to add to the list, select **Add Setting** and configure the following settings:

- **HTTP status code**: A response code that indicates a failed request, for example `429 (Too Many Requests)` or `503 (Service Unavailable)`.
- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Retry timed-out HTTP requests: When you want to automatically retry requests that have timed out, toggle this control on to display the following settings for configuring retry behavior:

- **Pre-backoff interval (ms)**: The amount of time to wait before beginning retries, in milliseconds. Defaults to `1000` (one second).
- **Backoff multiplier**: The base for the exponential backoff algorithm. A value of `2` (the default) means that Cribl Stream will retry after 2 seconds, then 4 seconds, then 8 seconds, and so on.
- **Backoff limit (ms)**: The maximum backoff interval Cribl Stream should apply for its final retry, in milliseconds. Default (and minimum) is `10,000` (10 seconds); maximum is `180,000` (180 seconds, or 3 minutes).

Advanced Settings

Validate server certs: Reject certificates that are **not** authorized by a CA in the **CA certificate path**, nor by another trusted CA (for example, the system's CA). Defaults to `Yes`.

Round-robin DNS: Toggle to `Yes` to use round-robin DNS lookup across multiple IPv6 addresses. When a DNS server returns multiple addresses, this will cause Cribl Stream to cycle through them in the order returned.

Compress: Compresses the payload body before sending. Defaults to `Yes` (recommended).

Keep alive: By default, Cribl Stream sends `Keep-Alive` headers to the remote server and preserves the connection from the client side up to a maximum of 120 seconds. Toggle this off if you want Cribl Stream to close the connection immediately after sending a request.

Request timeout: Amount of time (in seconds) to wait for a request to complete before aborting it. Defaults to `30`.

Request concurrency: Maximum number of concurrent requests per Worker Process. When Cribl Stream hits this limit, it begins throttling traffic to the downstream service. Defaults to `5`. Minimum: `1`. Maximum: `32`.

Max body size (KB): Maximum size of the request body before compression. Defaults to `4096` KB. You can set this limit to as high as 500 MB (`512000` KB). Be aware that high values can cause high memory usage per Worker Node, especially if a dynamically constructed URL (see Internal Fields) causes this Destination to send events to more than one URL. The actual request body size might exceed the specified value because the Destination adds bytes when it writes to the downstream receiver. Cribl recommends that you experiment with the **Max body size** value until downstream receivers reliably accept all events.

Buffer memory limit (KB): Total amount of memory used to buffer outgoing requests waiting to be sent. If left blank, defaults to 5 times the max body size (if set). If 0, no limit is enforced. This provides granular control over the memory allocated for buffering outgoing batched requests. Increasing the limit allows batches to grow larger before being flushed, improving efficiency for data with high cardinality (a large number of unique batches). Finding the optimal balance between efficient data transfer and memory usage involves adjusting both the **Buffer memory limit** and **Max Body Size** settings.

Max events per request: Maximum number of events to include in the request body. The `0` default allows unlimited events.

Flush period (sec): Maximum time between requests. Low values could cause the payload size to be smaller than its configured maximum. Defaults to `1`.

Extra HTTP headers: Name-value pairs to pass to all events as additional HTTP headers. Values will be sent encrypted. You can also add headers dynamically on a per-event basis in the `__headers` field. See Internal Fields below.

Failed request logging mode: Use this drop-down to determine which data should be logged when a request fails. Select among `None` (the default), `Payload`, or `Payload + Headers`. With this last option, Cribl Stream will redact all headers, except non-sensitive headers that you declare below in **Safe headers**.

Safe headers: Add headers to declare them as safe to log in plaintext. (Sensitive headers such as `authorization` will always be redacted, even if listed here.) Use a tab or hard return to separate header names.

Environment: If you're using GitOps, optionally use this field to specify a single Git branch on which to enable this configuration. If empty, the config will be enabled everywhere.

Custom Format

Choosing `Custom` from the **General Settings** > **Format** drop-down exposes the additional fields described in this section. **Source expression** and most of the rest of the controls define the format of individual events – that is, what data you want to make available from the event. **Batch expression** defines the wrapper object for batched events – that is, how to package events within the request payload. Both expressions **must** be enclosed in backticks.

- **Source expression**: JavaScript expression to evaluate on every event; Cribl Stream will send the result of that evaluation instead of the original event. Sample expression: `` `${fieldA}, ${fieldB}` `` (with literal backticks). Defaults to `__httpOut` – that is, the value of the `__httpOut` field. Use the button at right to open a validation modal.
- **Drop when null**: If toggled to `Yes`, Cribl Stream will drop events when the **Source expression** evaluates to `null`.
- **Event delimiter**: Delimiter string to insert between events. Defaults to the newline character (`\n`). Cannot be a space (this will be converted to `\n`).
- **Content type**: Content type to use for requests. Defaults to `application/x-ndjson`. Any content types set in **Advanced Settings > Extra HTTP headers** will override this entry.
- **Batch expression**: Expression specifying how to format the payload for each batch. Defines a wrapper object in which to include the formatted events, such as a JSON document. This enables requests to APIs that require such objects. To reference the events to send, use the `${events}` variable. An example expression to send the batch inside a JSON object would be: `{"items" : [${events}] }`.

Custom Format Example

Suppose that the API you're sending events to requires request payloads in the following form:

```
{
   "Events":[
      {
         "one":"1",
         "two":"2"
      },
      {
         "one":"1.1",
         "two":"2.2"
      }
   ]
}
```

And here's how the events coming into your Webhook Destination look – note that the field names need to change, and `field3` and `field4` need to be dropped:

```
{ "field1": 1, "field2": 2, "field3": 3, "field4": 4 }
{ "field1": 1.1, "field2": 2.2, "field3": 3.3, "field4": 4.4 }
```

To send these events in the required form, you'd do the following:

- Set the **Source expression** to `` `{ "one": "${field1}", "two": "${field2}" }` `` – note that this renames and sends only the desired fields (`one` and `two`).
- Enter the comma (`,`) as your **Event delimiter**.
- Set the **Batch expression** to `` `{ "Events": [${events}] }` ``.

Advanced Format

Choosing `Advanced` from the **General Settings** > **Format** drop-down exposes the JavaScript code blocks described in this section. You can define a format using either one of the code blocks, or both.

- **Format inbound event**: JavaScript code block that receives incoming events (as JavaScript objects) and converts them into strings. Multiple strings are concatenated to form a batch, the batches constituting the payloads of the HTTP requests that the Destination sends to the downstream API.
- **Format outbound payload**: JavaScript code block that receives batches before they are sent out as HTTP request payloads. This gives you the opportunity to modify the payload format from the way it arrives – as a string of concatenated events – to whatever format the downstream API requires.

Code Block Restrictions

Generally speaking, anything forbidden in JavaScript strict mode is forbidden in the code blocks. Specifically, the following are **not allowed**:

- `console`, `eval`, `uneval`, `Function (constructor)`, `Promises`, `setTimeout`, `setInterval`, `global`, `globalThis`, `window`, and `set`.

Code blocks **can** include `for` loops, `while` loops, and JavaScript methods such as `map`, `reduce`, `forEach`, `some`, and `every`. For further details, see Supported JavaScript Options.

Only skilled JavaScript developers should use the Advanced format. This is to avoid unintended results – such as creating infinite loops, or otherwise failing to return – that could needlessly add to your throughput burden.

Advanced Format Syntax

Here are the syntax conventions for manipulating events and payloads within the code blocks.

Format inbound event Syntax

- `__e`: References the event object.
- `__e['fieldName']`: References an individual field in the event object.
- `__e.asJSON(): string`: Method to safely convert the object to JSON by removing internal content that is not relevant for a downstream system. **Always** use this method instead of directly converting the object to JSON string using `JSON.stringify(__e)`. This avoids circular references that can cause `JSON.stringify(__e)` to fail.

Format outbound event Syntax

In addition to the syntax conventions defined above, the **Format outbound event** code block has its own special conventions:

- `__e['__payload']`: Accesses the `payload` attribute of the JavaScript object that the code block receives. The `__payload` attribute contains the actual batch (payload) to be formatted.
- `__e['__payloadOut']`: After you modify the batch (payload) as desired, assign it to this variable. If the `__payloadOut` attribute is not present, the code block sends the payload as-is. See the JSON Array Example below.

Advanced Format Examples

The **Format inbound event** and **Format outbound payload** code blocks are populated by placeholder JavaScript code. This code expresses the basic flow you must understand to define an Advanced format. Let's examine the code – then you'll be able to see how defining any given Advanced format is just a matter of manipulating events and payloads within the basic flow.

The Format inbound event Code Block

The event to format appears in the first line, referenced as `__e: CriblEvent`. First, you serialize the event as a string; the simplest way to do that is with the method `e.asJSON()`. Then, you assign it back to the object in a variable named `__eventOut`.

```
formatEvent (__e : CriblEvent) {
  // TODO: Serialize the event to a string here.
  let formattedEvent = __e.asJSON();

  // Assign formatted event to __eventOut.
  __e['__eventOut'] = formattedEvent;
}
```

At this point, the `formatEvent()` function ensures that each incoming event will be serialized as a string. (In the more elaborate examples below, the format of that string will be manipulated.) Each new event, in string form, is appended to the last, building a longer string that will become a **batch**. How many events can be in a batch is governed by **Advanced Settings** > **Max events per request**.

Once a batch is complete, the next code block can operate on it.

The Format outbound payload Code Block

Now the `formatPayload ()` function receives an event whose `payload` attribute is the batch produced by the previous code block. You assign that attribute to the `formattedPayload` variable. If you want to manipulate the batch, do that here. Once you have transformed the batch, you assign it to the `__payloadOut` variable, and the Webhook Destination sends the batch out as the payload of an HTTP request.

Transforming batches is not required. To send batches out exactly how they leave the **Format inbound event** code block, just leave the **Format outbound payload** code block blank.

```
formatPayload: (__e : CriblEvent) {
  // Access payload to format here
  let formattedPayload = __e['payload']

  // TODO: Format payload here

  // Assign formatted payload to payloadOut
  __e['payloadOut'] = formattedPayload
}
```

JSON Array Example

Suppose you want to communicate with an API that accepts data in JSON array format.

Use the **Format inbound event** code block to format the events:

```
__e['__eventOut'] = `${__e.asJSON()},` // Serialize to JSON and add trailing comma
```

Use the **Format outbound event** code block to format the payload:

```
// Remove trailing comma and wrap payload in array
__e['__payloadOut'] = `[${payload.substring(0,payload.length-1)}]`
```

Elasticsearch Bulk API Example

The Elasticsearch Bulk API requires each event to be formatted with two lines of output. While this cannot be done with the Webhook Destination's other format options, it is doable with Advanced Format. (The Elasticsearch API Source, Elasticsearch Destination and Elastic Cloud Destination **do** work with the Elasticsearch Bulk API.)

Here's how Bulk API events must be formatted, structurally:

```
{ <action>:  { <metadata> } }
{ <serializedEvent> }
```

Here's an example of an event formatted for Bulk API:

```
{ "index" : { "_index" : "test", "_id" : "1" } }
{ "field1" : "value1", "field2" "value2", "field3" : "value3" }
```

Use the **Format inbound event** code block to format the events:

```
let time=__e['_time'] || Date.now();
__e['_time'] = undefined;
__e['@timestamp'] = C.Time.strftime(time, '%Y-%m-%dT%H:%M:%S.%LZ');
if(typeof __e['host'] === 'string') {
  const host = __e['__host'] || {};
  host.name = __e['host'];
  __e['host'] = host;
}
__e['__eventOut'] = `{"create":{"_index":"${__e['_index'] || 'cribl'}", "pipeline":"
```

Leave the **Format outbound event** code block blank.

Splunk HEC Example

Use the **Format inbound event** code block to format the events:

```
    const eventIn = __e;
    const time = eventIn._time;
    const event = eventIn._raw;
    const {host, source, sourcetype, index} = eventIn;
    eventIn._time = undefined;
    eventIn._raw = undefined;
    eventIn.host = undefined;
    eventIn.source = undefined;
    eventIn.sourcetype = undefined;
    eventIn.index = undefined;
    const fields = {};
    const obj2send = {time, index, host, source, sourcetype, event, fields};
    for (const key of ['index', 'host', 'source', 'sourcetype']) {
      // only convert if the key/val is present and is not a string
      const oldValue = obj2send[key];
      if (oldValue != null && typeof oldValue !== 'string') {
        obj2send[key] = JSON.stringify(oldValue);
      }
    }
    for (let key of Object.keys(eventIn)) {
      if(key.startsWith('__'))
        continue;
      let val = eventIn[key];
      if(val === undefined)
        continue;
      if(typeof val === 'object')
        val = JSON.stringify(val);
      obj2send.fields[key] = val;
    }
  __e['__eventOut'] = `${JSON.stringify(obj2send)}\n`;
```

Leave the **Format outbound event** code block blank.

Internal Fields

Cribl Stream uses a set of internal fields to assist in forwarding data to a Destination.

Fields for this Destination:

- `__criblMetrics`

- `__url`
- `__headers`

If an event contains the internal field `__criblMetrics`, Cribl Stream will send it to the HTTP endpoint as a metric event. Otherwise, Cribl Stream will send it as a log event.

When **Load balancing** is disabled, if an event that contains the internal field `__url`, that field's value will override the **General Settings** > **Webhook URL** value. This way, you can determine the endpoint URL dynamically.

For example, you could create a Pipeline containing an Eval Function that adds the `__url` field, and connect that Pipeline to your Webhook Destination. Configure the Eval Function to set `__url`'s value to a URL that varies depending on a global variable, or on some property of the event, or on some other dynamically-generated value that meets your needs.

If an event contains the internal field `__headers`, that field's value will be a JSON object containing Name-value pairs, each of which defines a header. By creating Pipelines that set the value of `__headers` according to conditions that you specify, you can add headers dynamically.

For example, you could create a Pipeline containing Eval Functions that add the `__headers` field, and connect that Pipeline to your Webhook Destination. Configure the Eval Functions to set `__headers` values to Name-value pairs that vary depending on some properties of the event, or on dynamically-generated values that meet your needs.

Here's an overview of how to add headers:

- To add "dynamic" (a.k.a. "custom") headers to some events but not others, use the `__headers` field.
- To define headers to add to **all** events, use **Advanced Settings** > **Extra HTTP Headers**.
- An event can include headers added by both methods. So if you use `__headers` to add `{ "api-key": "foo" }` and **Extra HTTP Headers** to add `{ "goat": "Kid A" }`, you'll get both headers.
- Headers added via the `__headers` field take precedence. So if you use `__headers` to add `{ "api-key": "foo" }` and **Extra HTTP Headers** to add `{ "api-key": "bar" }`, you'll get only one header, and that will be `{ "api-key": "foo" }`.

Use Cases

See these examples of configuring a Webhook Destination to integrate with specific services:

- Azure Analytics/Sentinel Integration
- Webhook/BigPanda Integration

- Webhook/Slack Integration

Notes on HTTP-Based Outputs

- To proxy outbound HTTP/S requests, see System Proxy Configuration.
- Cribl Stream will attempt to use keepalives to reuse a connection for multiple requests. After two minutes of the first use, it will throw away the connection and attempt a new one. This is to prevent sticking to a particular destination when there is a constant flow of events.
- If the server does not support keepalives (or if the server closes a pooled connection while idle), Cribl Stream will establish a new connection for the next request.
- When resolving the Destination's hostname, Cribl Stream will pick the first IP in the list for use in the next connection. Enable **Round-robin DNS** to better balance distribution of events among destination cluster nodes.

Troubleshooting

The Destination's configuration modal has helpful tabs for troubleshooting:

Live Data: Try capturing live data to see real-time events as they flow through the Destination. On the **Live Data** tab, click **Start Capture** to begin viewing real-time data.

Logs: Review and search the logs that provide detailed information about the delivery process, including any errors or warnings that may have occurred.

Test: Ensures that the Destination is correctly set up and reachable. Verify that sample events are sent correctly by clicking **Run Test**.

You can also view the Monitoring page that provides a comprehensive overview of data volume and rate, helping you identify delivery issues. Analyze the graphs showing events and bytes in/out over time.

15.3. Destination Backpressure Triggers

This topic describes the conditions that can trigger backpressure in Cribl Stream Destinations. Backpressure exists when a destination receives more data than it can currently send. It typically results from network connectivity problems or when a Destination is receiving data faster than it can forward that data to the downstream service.

When a Destination signals backpressure, it does so to notify the Sources generating data that its buffers are full and that the incoming data flow should be paused until there is room for more data.

You can configure your desired behavior through a Destination's **Backpressure Behavior** drop-down. Where other options are not displayed, Cribl Stream's default behavior is **Block**. For details about all the above behaviors and options, see Persistent Queues.

HTTP-Based Destinations

HTTP-based Destinations trigger backpressure when they encounter errors while connecting or when they receive certain HTTP response codes. If the HTTP call returns a `500` series (`500`–`599`) HTTP code, the Destination adds the events in the buffer back to its internal buffer and tries to send them again. The retry attempt can also trigger backpressure, depending on the frequency at which this happens.

If the Destinaton receives a `400` series response code, it will drop (not retry) the events, because these response codes indicate an error in payload or formatting (for example). See this Mozilla page on the `400 Bad Request code` for more information.

Finally, HTTP-based Destinations trigger backpressure when their processing loads exceed the specified limit. HTTP-based Destinations handle requests by creating a connection, sending the request payload, and receiving and parsing a response. Because this process can take time, HTTP Destinations allow more than one request to be in progress at a time. When the number of requests in flight exceeds the value set in **Advanced Settings** > **Request concurrency**, the Destination will trigger backpressure.

The following conditions will trigger backpressure:

- Connection failure.
- Connection or request timeouts.
- Data overload – i.e., the Source sends more data than the Destination will accept.
- Reaching the limit on concurrent (in-flight) requests.
- HTTP `500` series responses.

You can set the number of in-flight or concurrent requests in **Advanced Settings** > **Request concurrency**.

HTTP-based Destinations include:

- Splunk HEC
- Elasticsearch
- Wavefront
- SignalFx
- Sumo Logic
- Honeycomb
- Datadog
- NewRelic Ingest Logs & Metrics
- NewRelic Ingest Events
- Microsoft Sentinel
- CloudWatch Logs
- Webhook
- Grafana Cloud
- Prometheus
- Loki
- Cribl HTTP
- InfluxDB
- Google Cloud Chronicle
- Google Cloud Logging

Filesystem-Based Destinations

Filesystem-based Destinations that send data to cloud-based services trigger backpressure when Cribl Stream can't move a file or upload it to the cloud.

Filesystem-based Destinations queue events in files on disk in a staging directory. When a batch of events is ready for transmission, Cribl Stream closes the file, optionally compresses it, and transmits the file to the downstream service.

For the Filesystem Destination, the batch simply moves from the staging directory to the output directory.

For other filesystem-based Destinations, Cribl Stream uploads the file to a cloud service, such as AWS S3, Azure Blob Storage, or other. For these Destinations, a failure to upload the file will trigger backpressure.

These scenarios include:

- Permissions problem writing to the staging directory – i.e., the user running the Cribl Stream process does not have permission to write to the staging directory.
- The filesystem for the staging or output directory is full (impacts Filesystem Destination only).
- The credentials provided for the cloud service are invalid.
- The Destination doesn't have the permissions required to upload to the cloud service.
- Cloud service permissions issue – i.e., upload fails because the cloud user (identified in credentials) does not have write permissions.
- Network connectivity – The Destination can't communicate with the cloud service due to network connectivity issues.

Filesystem-based Destinations include:

- Filesystem
- Azure Blob Storage
- Google Cloud Storage
- Amazon S3
- MinIO
- CrowdStrike Falcon LogScale
- Amazon Security Lake
- Amazon Data Lakes S3

TCP-Based Destinations

TCP Sources establish a persistent connection with a Destination and send data. These Sources maintain connection to the Destination and will re-establish that connection if they detect a close or write timeout.

If the connection fails, Cribl Stream uses a backoff algorithm to avoid spiking the CPU. This backoff logic makes the first retry at 2 seconds, then gradually increases the time between retries up to a maximum of 60 seconds.

The following conditions can trigger backpressure from a TCP-based Destination:

- Connection failure.
- Authentication failure.
- Write timeout, where a Source sends data but doesn't receive an `ack` at the TCP layer. In this case, Cribl Stream closes the connection to the Destination and tries to re-establish it.
- The Destination receives data from the Source faster than it can send data over the network to the downstream service, causing internal buffers to fill up. This condition can occur due to a slow network

connection or slow processing on the downstream service. When space in the internal buffers becomes available, backpressure is relieved, allowing the Source to send more data.

The following Destinations are TCP-based and adhere to the rules described above. Some Destinations use either TCP or UDP to send messages, but they trigger backpressure and use the backoff algorithm described above only when used with the TCP protocol:

- Splunk Single Instance
- Splunk Load-Balanced
- TCP JSON
- Cribl TCP
- Syslog (TCP or UDP)
- StatsD (TCP or UDP)
- StatsD Extended (TCP or UCP)
- Graphite (TCP or UCP)

Kafka

Kafka is a binary protocol that runs over TCP. The protocol defines three roles – producers, consumers, and brokers.

Producers send data to a Kafka topic (think of it as a message queue). Kafka consumers read data from Kafka topics. Brokers receive data from topic producers and send data to topic consumers – i.e., serve as go-betweens for producers and consumers.

Cribl Stream's Kafka-based Destinations are producers. They send data to Kafka brokers. Since the protocol is TCP-based, the conditions that trigger backpressure are similar to those of Cribl Stream's TCP Destinations.

The specifics for connection and request retries are defined by the Kafka JS library in conjunction with the configuration parameters defined for each Destination. In all cases, the Destinations have internal buffers that are sent to the Broker when they're considered full (on a size and time basis).

The following conditions can trigger backpressure for Kafka-based Sources:

- Failure to connect to the broker, lack of network connectivity, or the broker is down.
- Invalid credentials – Destination connects successfully, but the connection is rejected due to a failure to authenticate.
- Invalid permissions – The credentials assigned do not have proper permissions to send events to the topic.

- The Destination is attempting to send data faster than the broker can receive it. Backpressure will be relieved when internal buffers have room for more events.

Cribl Stream supports the following Kafka-based Destinations:

- Kafka
- Azure Event Hubs
- Confluent Cloud
- MSK

Kafka Retries and PQ

In some situations, Kafka Destinations may take a long time to engage the PQ (1 to 6 minutes by default).

This delay can result from the default settings used with the Kafka Destination. The relevant settings are all in the **Advanced Settings** UI:

- **Connection timeout (ms)**: Defaults to `10000`,
- **Request timeout (ms)**: Defaults to `60000`.
- **Max retries**: Defaults to `5`.

These default settings mean that Cribl Stream will retry five times after a failed connection, with a 10-second timeout between each attempt. It will also retry five files after a failed request, with a timeout of 60 seconds between each attempt.

For faster PQ engagement, update these values. You can use smaller values for **Connection timeout** and **Request timeout** to decrease the interval between retries. You can also use smaller values for **Max retries** or even set it to `0` to eliminate retries altogether.

UDP

UDP is a connectionless protocol, so there is no concept of backpressure at the network layer. As a result, UDP Destinations will never trigger backpressure.

The following Destinations support UDP. Except for SNMP Trap, these Destinations also support TCP, but the UDP versions do not trigger backpressure.

- SNMP Trap
- Syslog
- StatsD
- StatsD Extended

- Graphite

SQS

The SQS (Simple Queue Service) Destination uses the AWS SQS library to send events to the Destination's configured queue. Like Kafka, this Destination acts as a producer that publishes messages to the provisioned SQS queue.

This Destination has five buffers with 10 events per buffer for a total of 50 events that can be queued before backpressure is enabled. The reason that backpressure might be generated for this Destination include:

- Invalid credentials.
- Invalid permissions.
- Queue does not exist and **Create Queue** is disabled.
- Lack of network connectivity.

Amazon Kinesis

Kinesis runs over HTTPS and behaves like Pub/Sub Destinations.

This Destination serializes and publishes events in a newline-delimited JSON format. In the context of the Kinesis Destination, it behaves as a producer where a Kinesis source is considered a consumer. Since the protocol is HTTP-based, the conditions that trigger backpressure are similar to those of other Cribl Stream HTTP Destinations.

The Kinesis library defines the specifics for connection and request retries in conjunction with the configuration parameters defined for each Destination. In all cases, the Destinations have internal buffers that are sent to the Broker when they're considered full (on a size and time basis).

The following conditions can trigger backpressure for Kinesis-based Destinations:

- Failure to connect to the Kinesis service, network connectivity, or the service is down.
- Invalid credentials – Connects successfully but connection is rejected due to a failure to authenticate.
- Invalid permissions – The credentials assigned do not have proper permissions to send events to the Kinesis stream.
- The Destination is attempting to send data faster than the service can receive it. Backpressure will be relieved when internal buffers have room for more events.

Google Cloud Pub/Sub

Google Cloud Pub/Sub is similar to Kafka and Kinesis in that there are producers that send data and consumers that receive data. The Cribl Stream Google Cloud Pub/Sub Destination is a producer that sends data to the Google Cloud Pub/Sub service. Google Cloud Pub/Sub leverages gRCP, however, which uses protocol buffers as both its interface definition language (IDL) and as its underlying message interchange format.

The conditions that trigger backpressure for a Google Cloud Pub/Sub Destination are:

- Failure to connect to the Google Pub/Sub service, network connectivity, or the service is down.
- Invalid credentials – Connects successfully but connection is rejected due to a failure to authenticate.
- Invalid permissions – The credentials assigned do not have proper permissions to send events to the topic.
- The Destination is attempting to send data faster than the service can receive it. Backpressure will be relieved when internal buffers have room for more events.

OpenTelemetry

OpenTelemetry supports gRPC or HTTP to send messages. For the gRPC protocol, the same rules described for other TCP Destinations generally apply to OpenTelemetry. The key difference is that this Destination uses the OpenTelemetry library, which handles write timeouts and reconnection logic.

For the HTTP protocol, the same rules apply to our HTTP Destinations for retries based on connectivity or `500` series response codes.

Load-Balanced Destinations

HTTP-Based Load-Balanced Destinations

Some HTTP-based Destinations support two modes – single host and multiple load-balanced hosts.

With a load-balanced version of an HTTP Destination, Cribl Stream spreads events across all configured Destinations, using a weighted algorithm. Under normal circumstances, this algorithm spreads the load across the configured Destinations according to the weight assigned to the Destination.

When one of the load-balanced Destinations is out of service (due to a write timeout or `500` series response code - buffers full), Cribl Stream removes that Destination from the list of hosts and moves any in-flight buffers to the next available host. Cribl Stream will try to resend events to the downed host in the background, and it will resume sending data to that host once the connection is restored.

HTTP Destinations that support load balancing include:

- Splunk HEC
- Elasticsearch
- Cribl HTTP

TCP Load-Balanced Destinations

Some TCP-based Destinations support two modes – single host and multiple load-balanced hosts.

With a load-balanced TCP Destination, Cribl Stream spreads events across all configured Destinations using a weighted algorithm. Under normal circumstances, this algorithm spreads the load across the configured Destinations according to the weight assigned to each Destination.

When one of the load-balanced Destinations is out of service (due to a write timeout or connection failure), Cribl Stream removes that Destination from the list of hosts and moves any in-flight buffers to the next available host. Cribl Stream will try to reconnect to the downed host and will resume sending data to that host once the connection is restored.

TCP load-balanced Destinations can be configured with one or multiple receivers. If one or more receivers go down, Cribl Stream will continue sending data to any healthy receivers.

TCP load-balanced Destinations include:

- Splunk Load-Balanced
- TCP JSON
- Cribl TCP
- Syslog (TCP version only)

Output Router

The Output Router is a wrapper destination that groups together 1..*N* Destinations. It's used in conjunction with event filters to route data to a selected Destination. The Output Router Destination emits backpressure only when one of its downstream Destinations is blocking.

15.4. Persistent Queues

Cribl Stream's persistent queues (PQ) supplement in-memory queues to prevent data loss during a backpressure event. When a backpressure event occurs, Cribl Stream can engage a backpressure queue and write data to disk for the duration of the outage. When the outage resolves, Cribl Stream then forwards data from the queue.

Cribl Stream's persistent queue (PQ) feature helps minimize data loss if:

- A downstream Destination receiver is unreachable.
- A downstream Destination receiver is slow to respond.
- During backpressure from Cribl Stream internal processing on configured Sources.

Persistent queues are best in environments that need more durability and reliability, such as systems where:

- Outages last longer than memory queues can sustain.
- Upstream senders do not support backpressure, such as ephemeral or network senders.

Persistent queues can be enabled:

- On Push Sources.
- On Streaming Destinations.

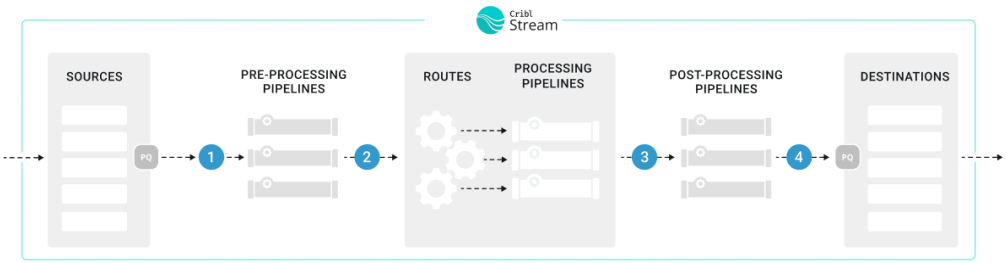
Sources can also take advantage of a Destination's queue to keep data flowing. See Supported Sources and Supported Destinations for more information.

The Persistent queue feature is only available for certain Cribl licenses. See the Pricing page for details.

How Persistent Queues Work

Backpressure events occur when there is a temporary imbalance between the rates of inbound and outbound data that is either coming in or going out of Cribl Stream. Different events trigger persistent queues on Sources and Destinations.

When persistent queue engages, it writes and stores data on a local file system in your environment until the backpressure event resolves.



You can enable persistent queues at both ends of the data flow

How Destinations Handle Backpressure

Destinations handle data rates using the following order of operations:

1. Under normal conditions, Destinations store data on in-memory buffers before sending the data to a receiver. These in-memory buffers on Destinations help absorb temporary imbalances between inbound and outbound data rates.
2. If there is an inbound burst of data, a Worker Process stores events in Destination buffers. It then attempts to output events at a more appropriate rate for the downstream receiver.

   The threshold for triggering a backpressure event varies by Destination type. See Destination Backpressure Triggers for more information.
3. If the Destination buffer becomes too full, the Destination triggers a backpressure event.
4. During a backpressure event, Cribl Stream will respond in one of the following ways, based on the Destination **Backpressure behavior** settings:

Setting	Description
Block	All data is blocked until the backpressure event has resolved. If set to Block, the output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender. If the sender also supports backpressure events, the sender may stop sending data. Consult the documentation for the sender to ensure you know how that specific sender handles a backpressure signal. In general, TCP-based senders support backpressure and stop sending data once Cribl Stream stops sending TCP acknowledgments back to it.
Drop Events	The Destination will discard all new events until the backpressure event has resolved and the receiver is ready.
Persistent Queue	If the Destination supports it, the Destination will engage the persistent queue behavior.

5. If the persistent queue behavior engages, Cribl Stream will respond in one of the following ways, based on its configured backpressure mode:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream queues and stores data to a disk until the backpressure event resolves.
Always On	Cribl Stream immediately queues and stores all data on a disk for all events, even when there is no backpressure.

You can configure additional settings to determine the amount of data stored in memory and what happens to data when the queue reaches its capacity limit.

6. By default, after data flow is re-established, a Destination will forward events in first in, first out (FIFO) order. It will send out earlier queued events before newly arriving events. However, in Cribl Stream 4.1 and later, you can instead prioritize new events by disabling Strict ordering on a Destination.

How Sources Handle Backpressure

Sources that have persistent queue support have the option to supplement in-memory buffering with persistent queue. When you enable persistent queue, you can choose between two trigger conditions:

Condition	Description
Always On	Uses persistent queue as a disk buffer for all events.
Smart	Only engages persistent queue upon backpressure from downstream receivers or Cribl internal processes.

Once enabled on a specific Source, in `Smart` mode, PQ will engage when any of the following occur:

- A connected Destination is fully down, and Destination-side PQ is not enabled.
- A connected Destination is slow, or blocking.
- A downstream Cribl Pipeline/Route is slow.

These triggers are not relevant if you've enabled Source PQ in `Always On` mode. In that case, it's always on.

When PQ engages on a Source:

- Events queue *before* any pre-processing Pipeline takes effect.
- Metrics (data in) will show `0` bytes/events while events are buffered to the disk queue.

- Cribl Stream Pipelines/Routes will process the data with a delay, when PQ later drains.

Because PQ always carries some latency penalty, it is redundant to enable PQ on a Source whose upstream sender is configured to safeguard events in its own disk buffer.

If you turn off Source PQ (or the whole Source) before its queues drain, any events still queued on disk will be orphaned.

Persistent Queue Details and Constraints

Persistent queues:

- Are implemented at the Worker Process level, with independent sizing configuration and dynamic engagement per Worker Process.
- Are not infinite in size. If data cannot be delivered out, your system might run out of disk space.
- Cannot fully protect data in cases of application failure. For example, if a crash occurs, in-memory data might get lost.
- Cannot fully protect data in cases of hardware failure, such as disk failure, corruption, or machine/host loss.
- TLS-encrypted only for data in flight, and only on Destinations where TLS is supported and enabled. In an on-prem deployment, to encrypt data at rest, including disk writes/reads, you must configure encryption on the underlying storage volume(s). In Cribl.Cloud, persistent queue storage keeps the data encrypted on disk.

Cribl Stream begins to drain persistent queues when at least one receiver can accept data.

Beyond these failure scenarios, if you turn off PQ on a Source or Destination (or shut down the whole Source/Destination) before the disk queue has drained, the queued events will be orphaned on disk.

The following constraints apply to certain Destinations:

- With load-balanced Destinations, persistent queue engages only when *all of the Destination's receivers* are blocking data flow. A single live receiver will prevent persistent queue from engaging on the corresponding Destination. PQ will not engage if at least one outbound TCP socket connection is active, even if the receiver is sending a backpressure signal.
- For Kafka-based Destinations (such as Kafka, Confluent Cloud, Amazon MSK, and Azure Event Hubs), PQs engage when the brokers can't be reached.
- On HTTP/S-based Destinations, controlled to prevent retries of failed events when the buffer drains. (Some events in transit to the Destination might still emerge as duplicates.)

Supported Sources

Cribl Stream supports persistent queue for Push Sources. These sources ingest streaming data, which makes it possible to enable persistent queue.

Persistent queue is not available for Pull and Collector Sources, which ingest data intermittently and/or from static files.

To determine whether Cribl Stream supports persistent queue for a specific Source, consult the documentation for that Source.

Supported Destinations

Cribl Stream supports persistent queue for:

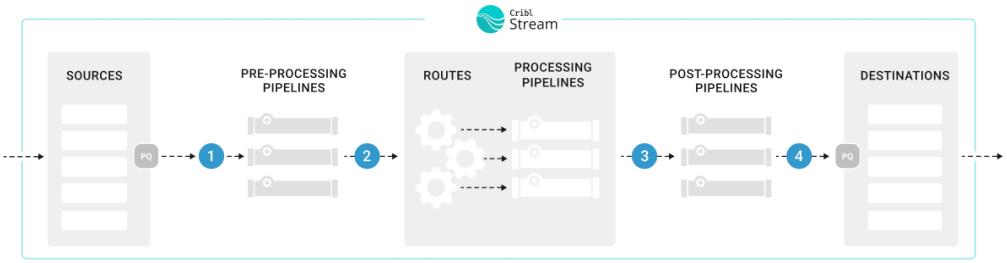
- HTTP-based Destinations
- TCP Load-Balanced Destinations
- Destinations that write to a single receiver (without load balancing enabled)

To determine whether Cribl Stream supports persistent queue for a specific Destination, consult the documentation for that Destination.

15.4.1. Planning For Persistent Queues

Use this page to guide your decision making as you decide how to handle data backpressure in your system and whether implementing persistent queue is the right strategy. This page explains:

- Use cases for implementing persistent queues (PQ).
- Details about persistent queue behavior on Sources and Destinations, with various configuration and tuning options.
- Choices you should make before enabling persistent queue.
- The implications of those choices for your system's requirements and performance.



You can enable persistent queues at both ends of the data flow

Better Practices When Implementing Persistent Queues

In general, these factors should guide your decisions about persistent queues in on-prem environments:

- The likelihood of backpressure events that could result in data loss.
- Your business requirements and your organization's level of tolerance for data loss.
- The cost of maintaining the resources and infrastructure necessary to engage persistent queues to prevent data loss. Persistent queues incur costs related to processing, computing, and storage because you have to write the data to disk and devote Worker processes to the persistent queue. Depending on your settings, persistent queues can be resource intensive.

When planning and tuning the performance of your persistent queues setting, start by monitoring your system performance and throughput and Worker processes capacity. Pay attention to metrics such CPU utilization. If needed, you can teleport into a single Worker and view all the processes and their individual CPU utilization.

After you implement a change in your system, continue to monitor the impacts of that change. Tune it as needed using the considerations discussed in the rest of this guide.

Source-Side Persistent Queue

Source-Side persistent queue can serve as a stopgap for upstream senders that don't provide their own buffering, or whose small buffers cannot queue for very long. This applies to several syslog senders and HTTP-based Sources.

Persistent queue prevents data loss when the Source is unable to handle backpressure for an extended period. Backpressure might be triggered by error conditions, or by degraded performance (slowdowns or short backups), in downstream Cribl resources or outside receivers.

Always On Versus Smart Mode

You should consider enabling the persistent queue for Push Sources in situations where:

- Senders do not provide their own buffering.
- Destination-Side PQ is not enabled.

In this situation use either `Smart` or `Always On` mode:

- `Always On` mode is a good match for highly valuable data (such as security data), and for data ingested via UDP. (Relevant UDP Sources are Raw UDP, SNMP Trap, Metrics, and Syslog with UDP enabled.)
- `Smart` mode might be sufficient for lower-grade data, such as events that are overwhelmingly `debug`-level.

Always On Requirements

`Always On` mode provides the most reliable data delivery, but you should plan for its impacts on throughput, memory, and hosts' disk resources.

Throughput

Each Source configured in `Always On` mode imposes a significant performance penalty on Workers' data ingestion rate, as compared to Sources without PQ enabled. This primarily involves the overhead to write to the filesystem. As a starting point, assume that each event will incur approximately 1 second of added latency.

Memory

`Always On` mode can also increase memory demands, as compared to Sources without PQ enabled. If memory is a constraint, you can experiment with tuning the **Max buffer size** in each Source's UI, or the

`maxBufferSize` configuration key. However, smaller buffers will reduce the efficiency of disk writes, adding more latency.

Disk

`Always On` also imposes more disk requirements than `Smart` mode. Cribl generally recommends that you allocate each Worker Node enough disk space for at least 1 day's worth of queued throughput. For example: If one Source is sending 1 TB/day to two Worker Processes (evenly weighted), you should provision at least 500 GB queue storage for each Worker Process. Expand this basic calculation for additional Sources. From there, expand or contract it based on the typical length of outages you experience.

Cribl also recommends that you deploy the highest-performance storage available. This prevents IOPS (input/output operations per second) and throughput bottlenecks for both read and write operations.

Compression

Enabling the PQ compression option conserves disk space, with a compression ratio of about 8:1. But you get these savings at the cost of worsening the performance impact to throughput. Navigate this trade-off based on which factor is most valuable in your deployment.

Smart Mode Details

`Smart` mode engages only when a Source receives an unhealthy signal from a downstream process, such as when a Pipeline or Destination is down or blocked. When engaged, `Smart` mode's latency penalty is about the same as with `Always On` mode. But this latency is highly variable, because `Smart` mode engages intermittently. So expect less latency overall, with less predictability with some spikes and valleys.

`Smart` mode's CPU performance penalty is about twice that of `Always On`, because of the overhead to switch queueing on and off. But again, this is highly variable, because performance will degrade only when PQ engages/disengages. As with `Always On`, if memory is a constraint, you can experiment with reducing **Max buffer size** (UI) or `maxBufferSize` (config-file) values. Compression is supported in `Smart` mode, as in `Always On` modes.

Smart Mode Interaction with Multiple Destinations

If you enable `Smart` mode on a Source that's routed to multiple Destinations, you should plan around the unintended interaction that PQ can cause among these Destinations:

If at least one connected Destination sends an unhealthy signal, this Source will queue new events to disk even if some peer Destinations remain up. This will delay data delivery to the peer healthy Destinations. The same

interaction can occur between Destinations grouped in a connected Output Router.

To prevent this unintended behavior, you can either:

- Disable PQ on the Source, and instead configure PQ on individual Destinations.

Or

- Configure separate Worker Groups to connect this Source to separate Destinations.

Destination-Side Persistent Queue

Destination-side persistent queue can engage when the Destination is either slow or completely unavailable.

Consider enabling persistent queue on supported Destinations when:

- You need to safeguard against data loss during extended errors.
- You need to smooth out CPU load spikes when a Destination recovers from a transient outage.
- You send data to receivers that have intermittent outages, such as Splunk or Chronicle.

Backpressure Modes

When persistent queue is enabled, Destinations have three available modes for responding to slow or unavailable Destinations:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream queues and stores data to a disk until the backpressure event resolves.
Always On	Cribl Stream immediately queues and stores all data on a disk for all events, even when there is no backpressure.

You can configure additional settings to determine the amount of data stored in memory and what happens to data when the queue reaches its capacity limit.

Consider using `Always On` if you need to prevent data loss and ensure that you retain all data. This mode will queue and store data for all events. However, be aware that choosing `Always On` could impact your system performance because writing and reading data to disk is resource-intensive. You might experience slower system throughput or notice that your Worker Nodes are over-utilized or regularly run at full capacity.

Always size your disk capacity according to your risk tolerance. Cribl's initial recommendation is to size for at least 1 day's worth of storage on each Worker Node.

Fallback (Queue-Full) Behavior

Unlike Source PQ, on Destinations where you've enabled PQ, you also select a fallback **Queue-full behavior**.

With the default `Block` option, if a Destination's persistent queue fills up, the Destination will block back to the corresponding Source. (Remember that a Destination can be fed by multiple Sources.) If the Source has its own PQ option enabled, it will begin queueing data. If not, the block signal will go all the way back to connected senders.

If you instead set the **Queue-full behavior** to `Drop new data`, Cribl Stream will simply discard data intended for the unavailable Destination, but will still allow the data to proceed to parallel Destinations.

Good use cases for `Block`: A simple Cribl Stream Route relaying Universal Forwarder data to a Splunk receiver; or, any Destination where you absolutely **must not** lose data.

Destination PQ Better Practices

- Cribl generally recommends enabling the PQ **Compression** option on Destinations. (Disable compression if you find that it adds excessive latency.)
- When draining large volumes after recovery from an outage, you might find that PQ is crushing its Destination. In this case, disable **Strict ordering**, and tune the **Drain rate limit (EPS)** to maintain reasonable throughput for new data.

Better Practices for Source and/or Destination PQ

If your Source(s) and Destination(s) both support PQ, which side should you enable?

Enabling Source-side PQ (in `Always On` mode) is the most versatile and reliable choice. Source PQ is further upstream than Destination PQ, and can safeguard data bound for multiple Destinations.

However, you might opt for Destination-side PQ if your senders provide their own buffering, or if you don't want to add the system resources that Source Always On mode requires.

Enabling **both** Source- and Destination-side PQ on a Route is likely overkill. It can also complicate diagnosing issues.

Warning for Auto-Scaling Environments

With **persistent** storage, events on disk survive a Cribl Stream/Edge or OS restart. But you cannot count on this with ephemeral/auto-scaling environments. Stream Workers must **not** be destroyed while data has not drained from a PQ.

PQ Status Notifications and Monitoring

Depending on your Cribl license, you may be able to configure Notifications that will be sent when PQ files exceed a configurable percentage of allocated storage, or when a Destination reaches the queue-full state described above.

These notifications always appear in Cribl Stream's UI and internal logs. You can also send them to external systems. For setup details, see Destination-State Notifications.

Destination PQ Notifications

With Destination PQ enabled, you can configure Notifications around two trigger conditions. Cribl recommends that you create both:

- Destination Backpressure Activated. This will send Notifications whenever backpressure engages, causing blocked or dropped events. It will also send Notifications when a queue fills up, falling back to blocked or dropped events.
- Persistent Queue Usage (saturation). Note that you can set these Notifications for **multiple** saturation levels.

Source PQ Alerting

Currently, Cribl Stream does not support Notifications around Source PQ states. However, if you've enabled `Always On` mode, alerts that PQ has engaged would be pointless – because all of the Source's incoming data is automatically written to the disk queue.

Also, if desired: On Fleets or customer-managed (hybrid or on-prem) Worker Groups, you can enable the internal CriblLogs Source, create a Route to forward Cribl's internal logs to a downstream service of your choice, and configure alerts from there.

Monitoring PQ

Cribl Stream's native Monitoring dashboards interact with PQ in particular ways. When PQ engages, assume that your sole sources of truth about Sources' or Destinations' throughput are the dashboards at:

- **Monitoring** > **System** > **Queues (Sources),** and
- **Monitoring** > **System** > **Queues (Destinations)**.

Other Monitoring resources become unreliable during queueing. These include the top-level **Monitoring** dashboard, and:

- **Monitoring** > **Data** > **Sources,** or
- **Monitoring** > **Data** > **Destinations**.

These will not accurately represent queued data because, once PQ engages, data will be queued to disk, rather than arriving into Pipelines and downstream resources (with Source PQ) or into the affected Destinations (with Destination PQ). While the data is queueing, the two above dashboards for:

- Affected Sources will show no events per second (EPS) or bytes ingested while their data is queueing.
- Affected Destinations will show EPS and bytes sent while their data is queueing, but these metrics can be misleading. Here, they measure data going into the queue, but not proceeding to downstream receivers.

Some other Monitoring quirks to keep in mind:

- Activity in the **Monitoring** > **System** > **Queues (Sources)** and **Monitoring** > **System** > **Queues (Destinations)** dashboards sometimes shows up only when queues drain.
- Cribl Stream currently does not provide a Monitoring dashboard for disk queues' own volumes.

These gaps provide another reason to enable PQ Notifications where available.

Remember that with **or** without PQ enabled, Monitoring dashboards do not show usage of integrations' in-memory buffers.

After the unhealthy condition resolves, and disk queues start to drain, dashboards will resume accurately representing delivery rates and volumes.

Metrics and Capture Limitations

Finally, while PQ provides many benefits, also note the following limitations:

- While events go to a Source-side queue, Cribl Stream does not record metrics about that Source's inbound data (events/second or bytes).
- While events go to a Destination-side queue, metrics reflect events/second and bytes going into that Destination's queue, not proceeding beyond Cribl Stream.
- Data captures might not work while a Destination is blocked.

15.4.2. Configuring Persistent Queues

The following sections outline configuring PQ for Cribl.Cloud Workers managed by Cribl, and then for on-prem and hybrid Cribl.Cloud Workers.

Configuring PQ for Cribl-Managed Workers in Cribl.Cloud

Cribl may support persistent queuing Cribl-managed Workers in Cribl.Cloud deployments, depending on your Cribl license. Configuration is considerably simpler with Cribl-managed Workers in Cribl.Cloud than with customer-managed (hybrid or on-prem) Workers (both covered below). You configure PQ individually on each Source and Destination that supports it.

Sources

1. Select a Source to open its configuration modal.
2. Select the **Persistent Queue Settings** tab.
3. Toggle **Enable Persistent Queue** to on.

On Cribl-managed Workers in Cribl.Cloud, this tab exposes only the **Enable Persistent Queue** toggle. When enabled, PQ is automatically configured in `Always On` mode, with a maximum queue size of 1 GB of data per PQ-enabled Source, per Worker Process. The 1 GB limit is on uncompressed inbound data, and there is no compression applied to the queue.

These options are not configurable. If you want to finely configure the maximum queue size, compression, PQ mode, and other options, use a hybrid Group.

Destinations

1. Select a Destination to open its configuration modal.
2. Set **Backpressure behavior** to `Persistent Queueing`.

On Cribl-managed Workers in Cribl.Cloud, the resulting **Persistent Queue Settings** tab exposes only a **Clear Persistent Queue** button. Once enabled, PQ is automatically configured with a maximum queue size of 1 GB of uncompressed data per PQ-enabled Destination, per Worker Process. The 1 GB limit is on uncompressed outbound data, and no compression is applied to the queue. If the queue fills up, Cribl Stream will block data flow.

These options are not configurable. If you want to finely configure the maximum queue size, compression, queue-full fallback behavior, and other options, use a hybrid Group.

If you want to disable persistent queuing:

1. Wait for the queue to fully drain. (The **Clear Persistent Queue** button is available as a destructive fallback. This will free up disk space, but will do so by deleting the queued data **without** sending it on to receivers.)
2. In the config modal's **General Settings**, select a different **Backpressure behavior**.
3. Re-save the config.

Logs

Cribl internal logs for Cribl-managed Workers in Cribl.Cloud might include entries labeled `Revived PQ Worker Process`. These indicate where a Cloud Worker was newly assigned to drain a persistent queue left over from a shut-down Worker Node. You can use these log events to troubleshoot Cloud PQ issues.

Configuring PQ for On-Prem and Hybrid Workers

Cribl may support persistent queuing may for Workers in on-prem deployments and for hybrid Cribl.Cloud Workers, depending on your Cribl license. (Cribl-managed Workers in Cribl.Cloud have a simpler configuration.) You configure persistent queueing individually for each Source and Destination that supports it.

On Sources:

1. Select a Source to open its configuration modal.
2. Select **Persistent Queue Settings**.
3. Toggle **Enable Persistent Queue** to on.

On Destinations:

1. Select a Destination to open its configuration modal.
2. Set **Backpressure behavior** to `Persistent Queueing`.

These selections expose the additional controls outlined below.

For an example of optimizing several PQ throttling options listed below, see our How Does Persistent Queuing Work Inside Cribl Stream? blog post.

Source-Side PQ Only

Mode: Select a condition for engaging persistent queues.

- `Always On`: This default option will always write events to the persistent queue, before forwarding them to Cribl Stream's data processing engine.
- `Smart`: This option will engage PQ only when the Source detects backpressure from Cribl Stream's data processing engine.

Max buffer size: The maximum number of events to hold in memory before reporting backpressure to the sender and writing the queue to disk. Defaults to `1000`. (This buffer is per connection, not just per Worker Process – and this can dramatically expand memory usage.)

Commit frequency: The number of events to send downstream before committing that Stream has read them. Defaults to `42`.

Always On versus Smart Mode

In Cribl Stream 4.1 and later, Source-side PQ defaults to `Always On` mode when you configure a new Source. `Always On` offers the highest data durability, by minimizing backpressure and potential data loss on senders. However, this mode can slightly slow down data throughput, and can require you to provision more machines and/or faster disks.

If you are upgrading from a pre-4.1 version where `Smart` mode was the default, this change does not affect your existing Sources' configurations. However:

- If you create new Stream Sources programmatically, and you want to enforce the previous `Smart` mode, you'll need to update your existing code.
- You can optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Consider switching to `Always On` mode if you find `Smart` mode causing Source-side PQ to frequently engage, and you've configured PQ with a large **Max file size** (e.g., 1 GB). However, a second option here is to retain `Smart` mode, but reduce the **Max file size** to a value no higher than the default `1 MB`.

(Source-side PQ excessively triggers backpressure only when it reaches the last queued file **and** that file is large. Keeping this threshold low prevents that condition.)

Common PQ Settings (Source and Destination Sides)

Max file size: The maximum data volume to store in each queue file before closing it and (optionally) applying the configured **Compression**. Enter a numeral with units of KB, MB, and so forth. If not specified, Cribl Stream applies the default `1 MB`.

Max queue size: The maximum amount of disk space that Cribl allowa the queue to consume, on each Worker Process. Once th queue reaches this limit, this Source or Destination will stop queueing data; Sources

will block, and Destinations will apply your configured **Queue-full behavior**. Defaults to `5 GB`. Enter a numeral with units of KB, MB, GB, or TB. For details, see Optimizing Max Queue Size.

Queue file path: The location for the persistent queue files. Defaults to `$CRIBL_HOME/state/queues`. To this value, Cribl Stream will append `/<worker-id>/<output-id>`.

Compression: Codec to use to compress the persisted data, once a file closes. Defaults to `None`; `Gzip` is also available.

Optimizing Max Queue Size

When you upgrade Fleets, and customer-managed (hybrid or on-prem) Worker Groups, to Cribl Stream 4.4 and later: Any undefined PQ **Max queue size** values in pre-4.4 Source/Destination configs will be set to the new 5 GB default value. This is a guardrail to control queues' consumption of host machines' disk space.

Adjust this default to match your needs. If some of your integrations' persistent queues had an undefined **Max queue size**, queues larger than 5 GB will trigger PQ fallback behavior until you resize this limit.

Also, in Cribl Stream 4.4 and later, you can define this field's highest accepted value in the new **Group Settings** > **General Settings** > **Limits** > **Storage** > **Max PQ size per Worker Process** field. The corresponding `limits.yml` key is `maxPQSize`. Consult Cribl Support before increasing that limit's 1 TB default.

The changes here do not affect any existing config with a defined **Max queue size**, and do not affect the nonconfigurable 1 GB **Max queue size** for Cribl-managed Workers in Cribl.Cloud.

Max Queue Size with Compression

If you enable **Compression** and also enter a **Max queue size** limit, be aware of how these options interact:

- Cribl Stream currently applies the **Max queue size** limit against the **uncompressed** data volume entering the queue.
- With this combination, Cribl recommends that you set the **Max queue size** limit **higher** than the volume's total available disk space – again disregarding compression. This will maximize queue saturation and minimize data loss. (For details, see Known Issues.)

Destination-Side PQ Only

This section lists PQ configuration options on Cribl Stream Destinations.

Queue-Full Behavior

During a backpressure event, Cribl Stream will respond in one of the following ways, based on the Destination **Backpressure behavior** settings:

Setting	Description
Block	All data is blocked until the backpressure event has resolved. If set to Block, the output will refuse to accept new data until the receiver is ready. The system will return block signals back to the sender. If the sender also supports backpressure events, the sender may stop sending data. Consult the documentation for the sender to ensure you know how that specific sender handles a backpressure signal. In general, TCP-based senders support backpressure and stop sending data once Cribl Stream stops sending TCP acknowledgments back to it.
Drop Events	The Destination will discard all new events until the backpressure event has resolved and the receiver is ready.
Persistent Queue	If the Destination supports it, the Destination will engage the persistent queue behavior.

If the persistent queue behavior engages, Cribl Stream will respond in one of the following ways, based on its configured backpressure mode:

Mode	Description
Error	Queues and stores data on a disk only when the Destination is in an error state.
Backpressure	After the Destination has been in a backpressure state for a specified amount of time, Cribl Stream queues and stores data to a disk until the backpressure event resolves.
Always On	Cribl Stream immediately queues and stores all data on a disk for all events, even when there is no backpressure.

You can configure additional settings to determine the amount of data stored in memory and what happens to data when the queue reaches its capacity limit.

Clear Persistent Queue

Select this “panic” button if you want to delete the files that are currently queued for delivery to this Destination. A confirmation modal will appear - because this will free up disk space by permanently deleting the queued data, without delivering it to downstream receivers. (Appears only after you define the **Output ID**.)

This section's remaining controls are available in Cribl Stream 4.1 and later.

Strict Ordering

The default `Yes` position enables FIFO (first in, first out) event forwarding. When receivers recover, Cribl Stream will send earlier queued events before forwarding newly arrived events. Disabling Strict ordering prioritizes processing new events over those currently residing in the PQ. When you toggle this setting to off, it exposes the **Drain rate limit (EPS)** control.

Using Drain Limits

Disabling **Strict ordering** setting exposes the **Drain rate limit (EPS)** field. This setting allows you to throttle the rate at which events are drained from the PQ to the destination. The default `0` value disables throttling. This setting ensures that Cribl Stream can keep up with the incoming stream of live data and doesn't get bogged down processing events from the PQ. Additionally, throttling the queue's drain rate can boost the throughput of new/active connections, by reserving more resources for them.

The Drain rate limit (EPS) is set in Events Per Second (EPS). To determine an appropriate value, follow the steps below.

Find the Worker Process EPS

1. From Cribl Stream's top nav, select **Monitoring** to access multiple dashboards.
2. The initial view shows aggregate data for all Worker Groups and all @{nodes}. Use the drop-downs at the upper right to isolate a single Worker Node.
3. At the upper right, change the display's granularity from the default `15 min` to `1 day`.
4. Under **Events In and Out**, locate **THROUGHPUT IN (AVG)** and copy the EPS value. (Example: `31,000 EPS`)

Calculate Drain Rate Limit

1. Cribl recommends setting the **Drain Rate Limit** to 10% of the Worker Process EPS to prioritize live data.
2. Divide the Worker Process EPS by the number of Worker Processes (WPs).
3. Calculate 10% of the result from step 2. (Example: `31,000 EPS / 14 WPs = 2,200 EPS per WP; 10% of 2,200 EPS = 220 EPS`).

Enable and Set Drain Rate Limit

1. In the PQ settings, disable **Strict ordering**. This will expose the **Drain rate limit (EPS)** field.
2. Set the **Drain rate limit (EPS)** to the calculated value from step 2 (e.g., `220 EPS`).

Monitor and Adjust

Monitor the PQ drain rate. If the queue is draining too slowly, you can carefully increase the **Drain rate limit (EPS)**. However, be cautious not to set it too high, as this could impact processing live data streams.

You can further optimize Workers' startup connections and CPU load at **Group Settings** > Worker Processes.

Minimum Free Disk Space

For queuing to operate properly, you must provide sufficient disk space. In distributed mode, you configure the minimum disk space to support queues (and other features) on each Worker Group, at **Group Settings** > **General Settings** > **Limits** > **Min free disk space**. If available disk space falls below this threshold, Cribl Stream will stop maintaining persistent queues, and data loss will begin. The default minimum is 5 GB.

15.5. About Load Balancing

Cribl Stream will attempt to load-balance outbound data as fairly as possibly across all endpoints. For example, if FQDNs/hostnames are used as the Destination addresses, and each resolves to 5 (unique) IPs, then each Worker Process will have its # of outbound connections = {# of IPs x # of FQDNs} for purposes of the Destination.

Data is sent by all Worker Processes to a randomly selected endpoint, and the amount sent to each connection depends on these parameters:

1. Respective destination **weight**: If a **Load Weight** is set to `0`, Cribl Stream will not try to connect to that IP (nor to any IPs resolved for that FQDN). When a connection is blocked, Cribl Stream will apply a 10% penalty to the load weight, and will select the connection with the lower adjusted load.
2. Respective destination **historical data**: By default, historical data is tracked for 300s. Cribl Stream uses this data to influence the traffic sent to each destination, to ensure that differences decay over time, and that total ratios converge towards configured weights.

On Destinations that support load balancing, Cribl recommends enabling the feature, even if you only have one hostname – because this hostname can expand to multiple IPs. If you must disable load balancing, then to ensure robust connections, enable the alternative **Advanced Settings** > **Round-robin DNS** option. This will allow Cribl Stream to follow the DNS host's IP rotation, preventing connection pinning.

Example

Suppose we have two connections, A and B, each with weight of `1` (i.e., they are configured to receive equal amounts of data). Suppose further that the load-balance stats period is set at the default `300s` and – to make things easy – for each period, there are 200 events of equal size (Bytes) that need to be balanced.

Interval	Time Range	Events to be dispensed
1	*time=0s —> time=300s*	**200**

Both A and B start this interval with 0 historical stats each.

Let's assume that, due to various circumstances, 200 events are "balanced" as follows: `A = 120 events` and `B = 80 events` – a difference of **40 events** and a ratio of **1.5:1**.

Interval	Time Range	Events to be dispensed
2	*time=300s —> time=600s*	**200**

At the beginning of interval 2, the load-balancing algorithm will look back to the previous interval stats and carry **half** of the receiving stats forward. I.e., connection A will start the interval with **60** and connection B with **40**. To determine how many events A and B will receive during this next interval, Cribl Stream will use their weights and their stats as follows:

Total number of events: `events to be dispensed + stats carried forward = 200 + 60 + 40 = 300`. Number of events per each destination (weighed): `300/2 = 150` (they're equal, due to equal weight). Number of events to send to each destination `A: 150 - 60 = 90` and `B: 150 - 40 = 110`.

Totals at end of interval 2: `A=120+90=210`, `B=80+110=190`, a difference of **20 events** and a ratio of **1.1:1**.

Over the subsequent intervals, the difference becomes exponentially less pronounced, and eventually insignificant. Thus, the load gets balanced fairly.

If a request fails, Cribl Stream will resend the data to a different endpoint. Cribl Stream will block only if **all** endpoints are experiencing problems.

15.6. Configure Host Metadata

Cribl Stream can add a `__metadata` property to every event produced from every enabled Source. You can view the metadata collected for a Worker Node by selecting the Worker Node on the **Workers** page.

The metadata surfaced by a Worker Node can be used to:

- Enrich events (with an internal `__metadata` field).
- Display metadata to users as a part of instance exploration.

You can customize the type of metadata collected at **Group Settings** > **General Settings** > **Limits** > **Metadata**. Add and select metadata sources by selecting **Add Source** and choosing an option from the list.

In Cribl Stream, all the **Event metadata sources** are disabled by default.

The sources that you can select here include:

Source	Description
`os`	Reports details for the host OS and host machine, like OS version, kernel version, CPU and memory resources, hostname, network addresses, and so on.
`cribl`	Reports the Cribl Stream version, Distributed mode, Worker Nodes (for managed instances), and configuration version.
`aws`	Reports details on an EC2 instance, including the instance type, hostname, network addresses, tags, and IAM roles. For security reasons, we report only IAM role **names**.
`env`	Reports environment variables.
`kube`	Reports details on a Kubernetes environment, including the node, Pod, and container. For details, see __metadata.kube Property.

When these metadata sources are enabled (and can get data), Cribl Stream will add the corresponding property to events, with a nested property for each enabled source.

Some metadata sources work only in configured environments. For example, the `aws` source is available only when running on an AWS EC2 instance. And `kube` applies only to on-prem deployments.

If your security tools report denied outbound traffic to IP addresses like `169.254.169.168` or `169.254.169.254`, you can suppress these by removing `aws` from the metadata sources described

> above. If you have a proxy setup, Cribl recommends adding these IP addresses to your `no_proxy` environment variable.

`__metadata.kube` Property

For the `__metadata.kube` property (displayed as `kube` in the list of event metadata sources) to report details on a Kubernetes environment, Cribl Stream needs to know where it is running. Set the `KUBE_K8S_POD` environment variable to the name of the Pod in which Cribl Stream is running. This gives the `__metadata.kube` property the information it needs to report on the `node` and `pod` properties.

If `/proc/self/cgroup` is working, the `container` property information will be available, too.

15.7. Cribl Edge To Cribl Stream

Cribl Edge automatically discovers logs, metrics, application data, etc. – in real time – from your configured endpoints, and delivers them to Cribl Stream or any supported destination. Meanwhile, Cribl Stream can help collect, reduce, enrich, transform, and route data from Cribl Edge to any destination. And using a Cribl HTTP Source, you can collect and route data from Edge Nodes to Stream Worker Nodes connected to the same Leader, without incurring additional cost.

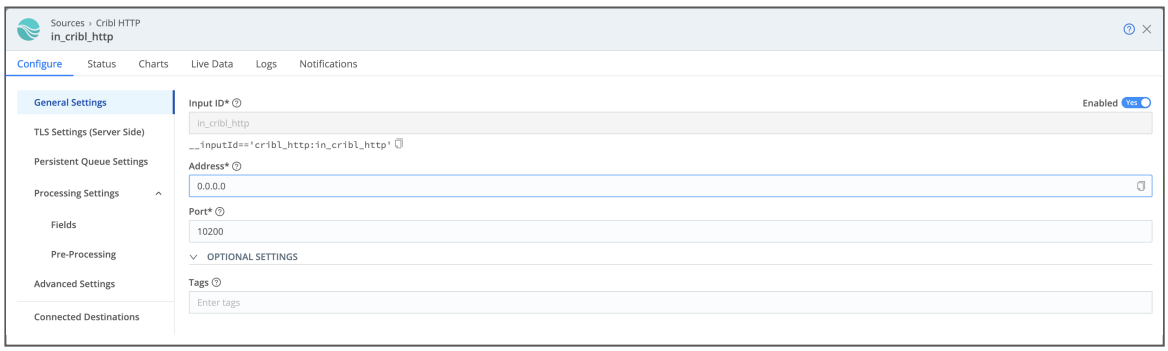
This guide outlines how to route data from an Edge Node (or an entire Fleet) to an existing Stream Worker Group for additional processing. We will walk you through the following:

- Configure Cribl HTTP Source on Cribl Stream to receive data from the Edge Node.
- Configure the Exec Source on Cribl Edge to collect data on the Edge Node.
- Configure the Cribl HTTP Destination on Cribl Edge to send data to Cribl Stream.
- Configure a Route to Send the Data.

And finally, we will confirm the data flow.

Configure the Cribl HTTP Source on Cribl Stream

In Cribl Stream, start by configuring and enabling a Cribl HTTP Source. The key requirement here is to set the **Port** to listen on. For this example, we'll use the default `10200`. (Optionally, you can also configure TLS, enable Persistent Queue, and/or a pre-processing Pipeline.)



Configuring a Cribl HTTP Source

When done, **Commit** and **Deploy** your changes. Before moving on to the next step, confirm that your Source is healthy.

Status of the Cribl HTTP Source

On Cribl-managed Worker/Edge Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl HTTP Source and the Cribl HTTP Destination it's receiving data from, or enabled on both. Otherwise, no data will flow. In the Source, TLS is enabled by default.

Configure the Exec Source on Cribl Edge

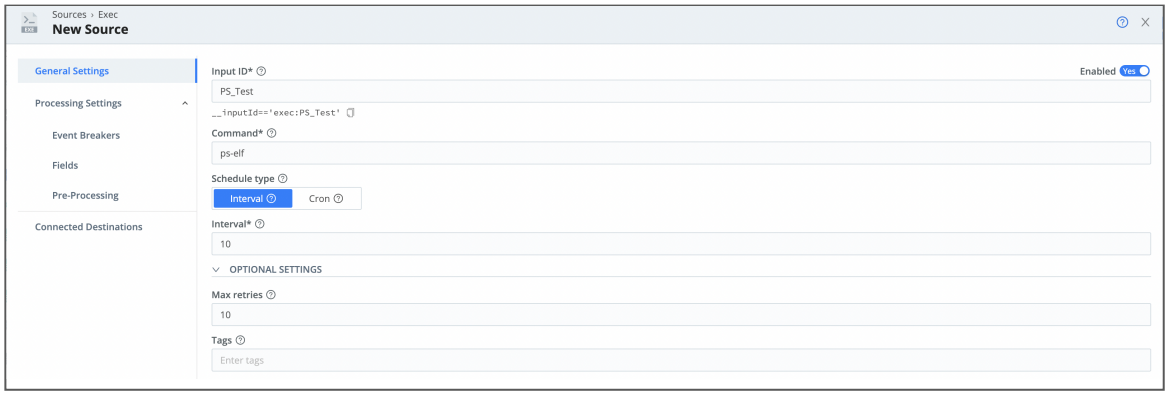
Next, we'll configure the Exec Source on your Edge Node. This Source will break the incoming streams of data into discrete events, and send them to Cribl Stream.

In this step, you can swap out the Exec Source by instead configuring a System Metrics or File Monitor Source. Or, configure multiple Sources to connect to the same Destination.

The Exec Source enables you to periodically execute a command and collect its `stdout` output. In the Exec Source's configuration modal, specify:

- Which command to execute.
- The number of times to attempt running the command.
- The interval between attempts.

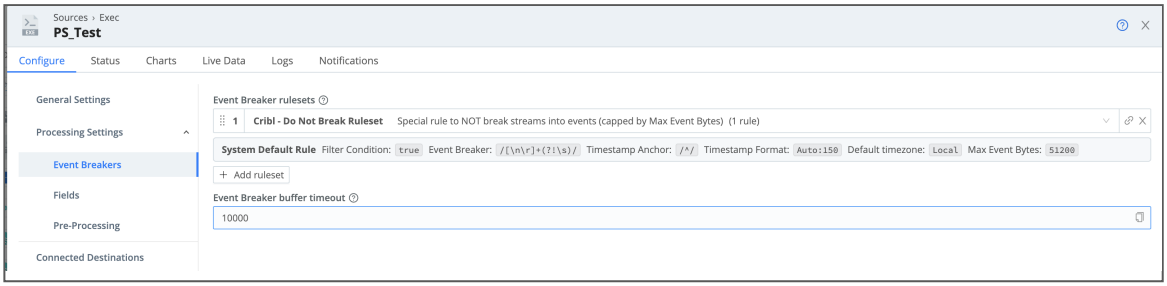
In our example, we are running the `ps` command to list and retrieve running processes every `10` seconds.



Configuring an Exec Source

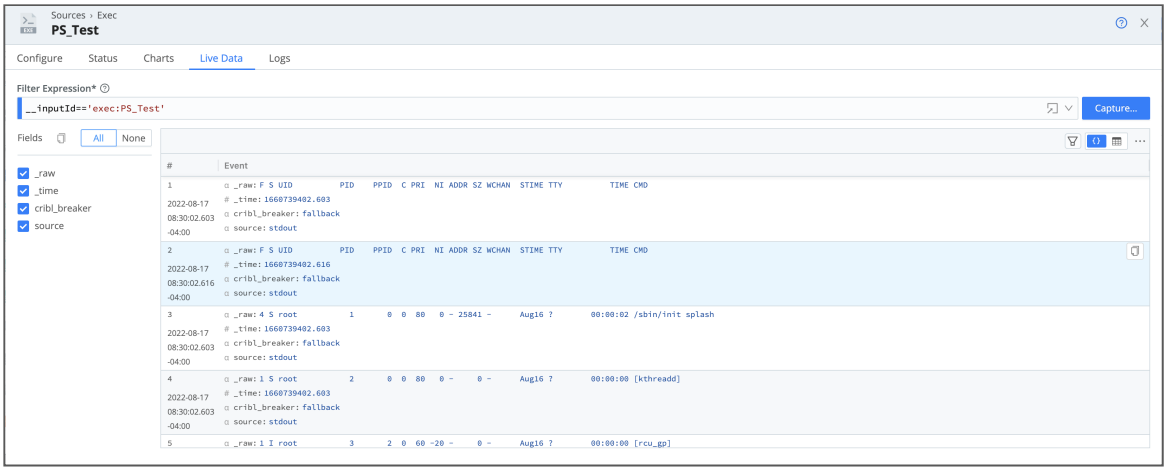
If we don't configure an Event Breaker, then with each capture we run on the dataset, each process will be ingested as its own event, without the header information. So to structure the data, we'll add an Event Breaker.

On the Exec Source configuration modal's left tab, select Event Breaker. In the **Event Breaker rulesets** drop-down, select `Cribl – Do Not Break Ruleset.`



Apply an Event Breaker

Next, preview your data on the modal's **Live Data** tab.



Preview Live Data

Configure the Cribl HTTP Destination on Cribl Edge

To get the data flowing, we'll configure the Cribl HTTP Destination on your Edge Node. A few things to note when configuring this Destination:

- This Destination's Cribl endpoint field must point to the **Address** and **Port** you've configured on its peer Cribl HTTP Source you configured in the first step.
- The Cribl HTTP Destination must be on a Node that is connected to the same Leader as the Cribl HTTP Source(s).
- Optionally, define your **Compression**, **Throttling**, and **Backpressure behavior** requirements.

- On Cribl-managed Worker/Edge Nodes in Cribl.Cloud, make sure that TLS is either disabled on both the Cribl TCP Destination and the Cribl TCP Source it's sending data to, or enabled on both. Otherwise, no data will flow. In the Destination, TLS is disabled by default.

Once you've configured your Destination, test it to verify that your Edge Node can communicate with the Stream Worker Group.

Configure a Route to Send the Data

Finally, configure a Route to send your data to Cribl Stream. For this example, we can use the `passthru` Pipeline.

Confirm the Data Flow

To confirm that your data is flowing, navigate back to Cribl Stream's Cribl HTTP Source. Run a **Live Data** capture on the Source.

You can also check the Monitoring page's **Data** submenu, to isolate the throughput on your Source.

15.8. Integrating With Other Services

15.8.1. Amazon

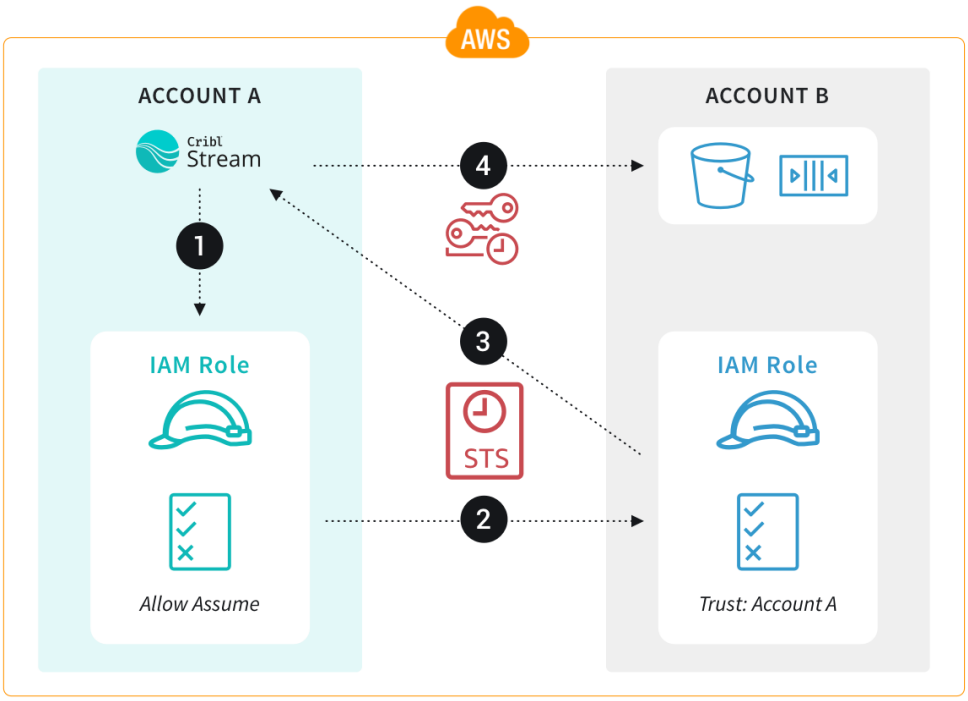
15.8.1.1. AWS Cross-Account Data Collection

Cribl uses multiple AWS accounts for different purposes, including our public Cribl.Cloud service (deployment details here). We built our account strategy from the ground up using the AWS Control Tower framework, as summarized in our Logging in a Multi-Account AWS Environment blog post.

However, some organizations use a legacy account structure that doesn't consolidate logs to a single account. This creates a challenge in collecting data or logs from peer accounts, as permission boundaries now need to be crossed. Whether you need to collect data from, or write data to, another account, the `AssumeRole` permission allows for cross-account access without the need to generate static IAM keys.

AssumeRole Example

A usage example is a central logging account that has access to other organization accounts to consume logs, but not to perform other actions. Let's say we have two AWS accounts, A and B. We want account A to be able to access resources in account B. We can build a policy inside account B that allows permissions to access the target resources. We can then specify, in account B, that we trust account A to be allowed to use this role. The diagram below illustrates how the `AssumeRole` action permits the Trusted Account (A) access to resources in the Trusting Account (B).



Here's how Cribl Stream would work with `AssumeRole` permissions inside AWS:

1. The Cribl Stream Worker has an EC2 instance role attached.
2. The IAM role in Account A permits the EC2 instance to assume the role in Account B (and Account B trusts Account A).
3. Temporary IAM credentials are returned to the EC2 instance.
4. Cribl Stream uses the temporary IAM credentials to access the resources in Account B.

Since this guide's original publication, we've updated `logstream` to `cribl-stream` in example ARNs below, to match our renamed product.

Configure IAM AssumeRole Permissions

First, in account A, we build a policy that allows only the ability to assume the role inside account B. This policy restricts users from being able to access any resources that they don't need to see. We can also revoke this trust relationship at any time, without having to worry about an account still having keys and (therefore) access to the data.

In our example, we want to access VPC Flow logs inside an S3 bucket in account B (ID 222222222222) from account A (ID 111111111111). We'll start building the two policies in account B, and then move to account A.

Account B Configuration

In account B, we build a policy to enable access to the S3 bucket (`vpc-flow-logs-for-cribl`) with the least privileges required for Cribl Stream. This policy is the one that changes depending on what you need to accomplish – e.g., reading from an S3 bucket, writing to Amazon Kinesis Data Streams, etc.

```
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Action": "s3:GetObject",
     "Resource": "arn:aws:s3:::vpc-flow-logs-for-cribl/*"
   },
   {
     "Effect": "Allow",
     "Action": "s3:ListBucket",
     "Resource": "arn:aws:s3:::vpc-flow-logs-for-cribl"
   }
 ]
}
```

Next, we need to attach a Trust Relationship to Account B's IAM role to permit the `AssumeRole` action from account A:

```
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Principal": {
       "AWS": "arn:aws:iam::111111111111:role/account-a-cribl-stream-assumerole-role
     },
     "Action": "sts:AssumeRole",
     "Condition": {
       "StringEquals": {
         "sts:ExternalId": "cribl-s3cre3t"
       }
     }
   }
 ]
}
```

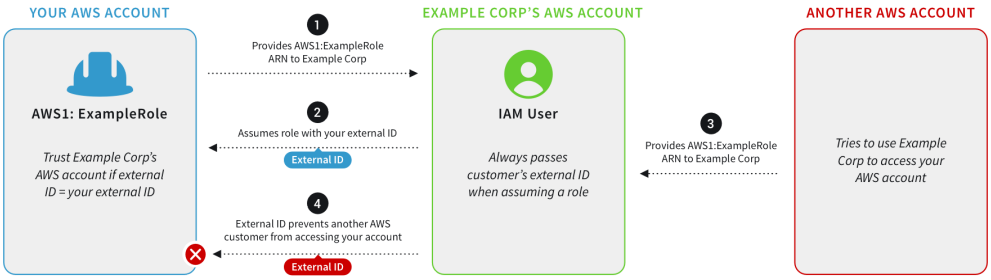
If you are creating a Trust Relationship for a Cribl.Cloud Worker managed by Cribl, you would instead paste the AWS Worker's role ARN in the format shown below. This option applies only to Cribl-managed

Workers, not to customer-managed (hybrid or on-prem) Workers:

```
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Principal": {
       "AWS": "arn:aws:iam::111111111111:role/main-default"
     },
     "Action": "sts:AssumeRole",
     "Condition": {
       "StringEquals": {
         "sts:ExternalId": "cribl-s3cre3t"
       }
     }
   }
 ]
}
```

Why an External ID Condition in the Trust Policy?

It is important to configure an AWS External ID, especially if you have third parties accessing your AWS accounts. The External ID protects from the confused deputy problem, where a third party obtains access through an intermediary. The External ID is not a password or secret, but it should still be protected from accidental sharing.



Mitigating the confused deputy vulnerability

Account A Configuration

In account A, we next configure a new IAM role with the following policy.

If you are creating a Trust Relationship for a Cribl-managed Cloud Worker, skip this section. Cribl has implicitly preconfigured Account A for you.

For our example, we only want the role to be able to use the `AssumeRole` action, but you can add additional statements to meet your needs:

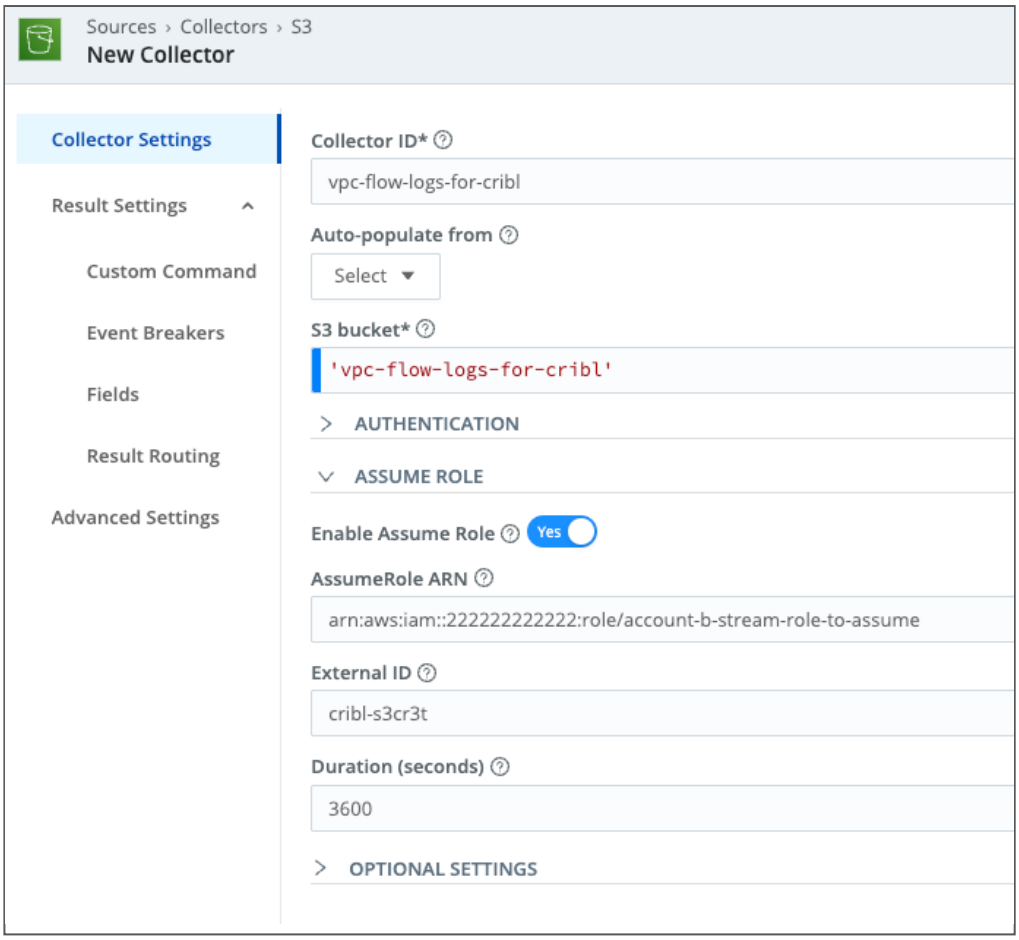
```
{
 "Version": "2012-10-17",
 "Statement": {
   "Effect": "Allow",
   "Action": "sts:AssumeRole",
   "Resource": "arn:aws:iam::222222222222:role/account-b-cribl-stream-role-to-assume"
 }
}
```

Since we need our EC2 instance to be able to assume this role, we will configure the Trust Relationship as follows:

```
{
 "Version": "2012-10-17",
 "Statement": [
   {
     "Effect": "Allow",
     "Principal": {
       "Service": "ec2.amazonaws.com"
     },
     "Action": "sts:AssumeRole"
   }
 ]
}
```

Configure Cribl Stream

Now that our `AssumeRole` policies have been built, we can configure Cribl Stream to assume the correct role to access the resources we need. Configure your Source, Collector, or Destination with the appropriate `AssumeRole` ARN and External ID. While this screenshot shows an S3 collector specifically, all AWS sources and destinations support Assume Role functionality.



Cribl Stream Assume Role configuration

15.8.1.2. Amazon S3 Better Practices

The “better practices” in this guide all apply to Cribl Stream’s Amazon S3-based Sources and Destinations. Many also apply to other object stores, like Azure Blob Storage, MinIO, and Google Cloud Storage.

View the AWS S3 with Cribl Best Practices video presentation from Cribl Community Office Hours.

Foundations: Cribl Stream and Object Storage

In this first section, we’ll lay out four basic factual underpinnings:

- How Cribl writes to object storage.
- Write to a Cribl Amazon S3 Destination.
- Read from Cribl’s Amazon SQS Source.
- Replay from Amazon S3 buckets, via Cribl’s S3 Collector.

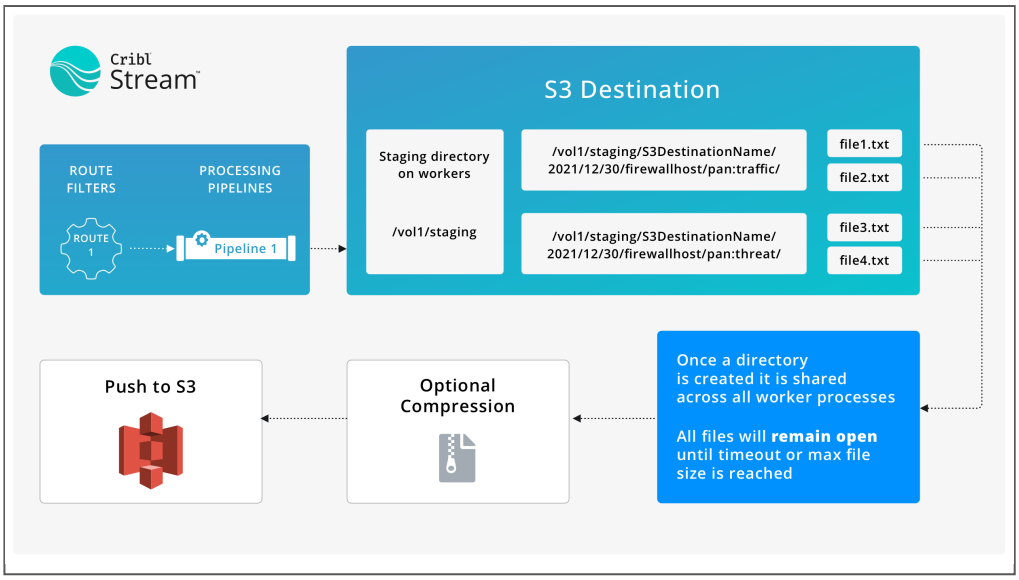
Then, this guide will go on to detail 10 “better practices” (and a bonus one!) as we cover four broad topics:

- Write to object storage, generically.
- Cardinality and partitioning expressions.
- Amazon S3–specific optimization.
- Better partitioning expressions.

How Cribl Writes to Object Storage

Cribl does not write data **directly** to its object storage Destinations, which include Amazon S3; any solution with an S3 API; and other object storage Destinations, like Azure Blob Storage, MinIO, and Google Cloud Storage.

Data persists locally to a “staging location” on the Workers. The Worker Processes append new data to the staging location based on partitioning expressions and configurations such as file size and max timeout settings. Each Worker Process, governed by its own specific settings, creates and maintains its own set of files.



Write to object storage – example

Write to a Cribl Amazon S3 Destination

When writing to our Amazon S3 Destination, or any object storage, consider two main settings: **File name prefix expression** and **Partitioning expression**.

Cribl allows a maximum of 2000 open files per Worker Process per S3 Destination. On a system with 14 Worker Processes, that translates to a maximum of 28,000 open files per S3 Destination. On a system with 30 CPUs, that translates to 60,000 open files.

When a specific Worker Process hits the maximum open files, it closes all open files, moves them to the final output location, and creates new ones. If you have multiple object storage Destinations configured in Cribl, ensure that the total maximum open files across all these Destinations is less than your system's configured maximum open files. To figure out this maximum, multiply the number of file-based Destinations by max open file limit for each such Destination and by number of Worker Processes (Destinations x max open file limit x Worker Processes).

The default maximum open file settings on many Linux systems are too low for Cribl Stream when writing to an object storage Destination. You'll need to increase your system max open files and/or process max open files settings, as explained below.

Additionally, to limit the number of files in each directory, **Partitioning expression** should specify dates down to the hour or minute.

Read from Cribl's Amazon SQS Source

When reading data using Cribl Stream's Amazon SQS Source, a few settings can greatly speed up data retrieval. These are:

- **General Settings** > **Queue**, a.k.a. the filename filter.
- **Advanced Settings** > **Max messages**.
- **Advanced Settings** > **Num receivers**.

Even more importantly, data retrieval speed is also governed by Destination settings and Pipeline efficiency.

Replay from Amazon S3 Buckets

When replaying from S3 via Cribl's S3 Collector, optimize your performance by adjusting the following:

- **Optional Settings** > **Path**, a.k.a. the filter.
- Pipeline efficiency.
- Destination settings.
- Destination health.

The **Path** should specify the time down to the hour, or in some cases, down to the minute.

Also, consider the API limits for your object storage bucket. AWS sets a limit of 3,500 writes/second and 5,500 reads/second per S3 prefix. An S3 prefix is a path on Amazon S3, including bucket name and any subdirectories up to but not including the object name. The S3 prefix always ends in (and includes) the slash before the object name. In its simplest form, the S3 prefix is just `BucketName/`.

AWS API limits apply to all attempted access to these prefixes, cumulatively. You probably won't hit the write limits while putting the "better practices" in this guide into effect. However, populating too many files in any one directory might trigger throttling when reading and performing replays.

Some Cribl Destinations have **File prefix expression** and/or **Partitioning expression** settings. Do not confuse these with the AWS prefix.

Write to Object Storage, Generically

When you deploy a Cribl Amazon S3 Compatible Stores Destination, start with a simple global **Partitioning expression** and the default **File name prefix expression**.

This will work as long as cardinality remains below 2,000 during the max timeout period. Also, apply the procedures to increase the system max open file settings, as described later in this guide.

Better Practice 1: Mind the Partitioning Expression

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}/${index ? inde
```

If cardinality exceeds 2,000, you can either:

- Remove the less-important fields from the expression; or
- Create different partitioning expressions for different event types, categories, etc.

On the **Advanced Settings** tab:

- Match the **Max open files** to cardinality, without exceeding 2,000.
- Toggle **Remove staging dirs** to `Yes`.
- Set the **Storage class** to `Intelligent Tiering`.

Still in **Advanced Settings**, keep the default settings for:

- **Max file size (MB)**: `32`.
- **Max file open time (sec)**: `300`.
- **Max file idle time (sec)**: `30`.

As you gain deeper understanding of the data, consider the following options:

- Create a set of different S3 Destinations, each with its own **Partitioning expression**. They can all point to the same S3 bucket. Be aware that doing so will increase the number of API requests becuase events will be spread over more files.
- If the numbers of open files becomes too large, discuss alternative architectures (e.g., creating additional Worker Groups) with your Cribl Account team or Support.

Better Practice 2: Optimize System Settings for Max Open Files

Consider the workflow for writing to Cribl S3 Destinations:

- Each Cribl Worker Process creates its own set of files in a staging directory based on **Partitioning expression** and **File name expression**.
- The maximum partitioning expression cardinality allowed is 2,000. This translates to a maximum of 2,000 open files per Worker Process per object storage Destination.
- Each Destination writes files to its staging directory until the number of files exceeds the configured maximum, or the Destination reaches any of the following limits: **Max file size (MB)**, **Max file idle time (sec)**, or **Max file open time (sec)**.

When writing to an object store, more Worker Nodes with fewer CPUs is better than fewer Worker Nodes with more CPUs (e.g., 5 Workers with 12 vCPUs is better than 2 systems with 32 vCPUs).

You should apply this principle to realize two benefits:

- To maximize the number of open files.
- To have more S3 Destinations with more precisely-focused partitioning expressions.

Linux defaults for maximum open files tend to be too low for writing to Cribl S3 Destinations, but the 65,536 limit recommended by Cribl is a good starting point. When setting the maximum open files substantially higher than 65,536, you should track system health.

You can further increase the maximum number of open files allowed by your system based on the number of S3 Destinations you are planning to use and the number of Worker Processes on each Node. The table below provides some examples:

# of S3 Destinations in Cribl	Max cardinality per Dest.	Max open files in Cribl Dest.	# Worker Process on each Worker Node	Min Linux per-process open file limit	Min Linux system plus Cribl user open file and 1k reserved for the system
1	2,000	2,000	10	3,000	21,000
1	2,000	2,000	14	3,000	29,000
1	2,000	2,000	22	3,000	45,000
2	2,000	2,000	10	5,000	41,000
2	2,000	2,000	14	5,000	57,000
2	2,000	2,000	22	5,000	89,000
5	2,000	2,000	10	11,000	101,000
5	2,000	2,000	14	11,000	141,000
5	2,000	2,000	22	11,000	221,000

Better Practice 3: Update Max Open File Settings on Hosts

Here are basic instructions that cover many Linux distributions. (Check the documentation for your specific Linux distribution and version for any variations required.)

Edit the following settings. You will be required to reboot.

```
# Update `fs.file-max` to a very large value run (as root):
sysctl -w fs.file-max=<open-files-limit>

# or edit sysctl.conf (as root):

vi /etc/sysctl.conf
fs.file-max = <open-files-limit>

# vi /etc/security/limits.conf (as Cribl user)
* soft nproc 65536
* hard nproc 65536
* soft nofile 65536
* hard nofile 65536
```

After you reboot, verify the settings:

```
# sysctl -p
# cat /proc/sys/fs/file-max
# sysctl fs.file-max
```

Cardinality and Partitioning Expressions

As we've seen, partitioning expressions and file expressions interact to determine cardinality. In this section, we'll examine this interaction more closely and learn better practices based on what we find.

Where Cardinality Begins

Partitioning expressions specify the directory structure that Cribl adds when writing to an object storage Destination.

For example, the following partitioning expression extracts the `year`, `month`, `day`, `hour`, `minute`, `index`, `host`, `sourcetype`, `server_ip`, `status_code`, and `Method`, and populates them as the directory structure.

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')
/${index ? index : 'no_index'}
/${host ? host : 'no_host'}
/${sourcetype ? sourcetype : 'no_sourcetype'}
/${server_ip}
/${status_code}
/${Method}/`
```

A file expression prefix comes into play next. The default file expression is just a random file name. However, an expression like this would create files that also include the hour and minute in each file name. This reflects the time the file was created, not the time of each event.

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%H%M')}
```

Together, the partitioning expression and the file expression must not produce a cardinality greater than 2,000.

Calculate Cardinality

Cardinality is the quantity of combinations of unique values, within a time period, for each parameter in the expressions.

For example, a partitioning expression could specify the following:

- Within an hour.
- 5 unique sourcetype values.
- 10 unique host values.
- 2 unique source values for each host.

For this example, we could calculate the maximum cardinality as `(5*10*2)=100`.

It's important to also consider the timeframe this is calculated within. That cardinality might be 100 over a 1-minute period, but might be 500 over a 5-minute period.

If we further add a file name prefix expression, this increases the cardinality. For example, let's add the method and top-level URI as file name prefix parameters. If there are 3 possible methods, and 10 URIs, the cardinality just went up from 100 to `100*3*10=3,000`.

Cardinality has the greatest impact on how you should configure an object storage Destination in Cribl Stream. For every combination of partitioning expressions, file prefix expressions, and Worker Processes, there can be an open file on the Worker Node's system.

A partitioning expression and file prefix expression should produce fewer than 2,000 potential combinations. When a Worker Process exceeds the configured **Max open files**, this generates errors; all open files for that Worker Process are simultaneously closed; and, new files will be created.

The Worker Process might experience some extra load while all files are processed. If this occurs infrequently, that's generally okay. But if it happens several times per hour, you should consider how to improve the combination of partitioning and file expressions.

As a starting point, consider these two strategies:

1. Write to one S3 bucket, incorporating parameters common to each event.

For example, here's a partitioning expression that specifies year, month, day, hour, minute, index, sourcetype, source, and host:

```
${C.Time.strftime(_time ? _time:Date.now()/1000,'%Y/%m/%d/%H/%M')/${index}/${host}/$
```

2. Dedicate different S3 Destinations to different event types. During replays, this makes searching specific data faster. However, this benefit comes at the expense of needing a larger number of open files. Should you pursue this option, test large numbers of open files on a test system in your environment. Such testing is especially crucial in virtualized environments with shared disk, CPU, and memory resources.

Better Practice 4: Select Files for Partitioning and File Expressions

The main factors to consider when selecting fields for a partitioning or filename prefix expression are:

- Configure Time-based filtering: All partitioning expressions should include `year`, `month`, `day`, `hour`, and optionally, `minute`. This facilitates filtering during replays. It also limits the files in any one directory, so that replays are not throttled when returning large volumes of files.
- Identify Universal fields: Fields that users will typically search on during replays across all datasets. Examples include `sourcetype`, `host`, `source`, `category`, and `index`.
- Optionally, configure specific fields for different datasets.
  Examples include:
  - Web logs: server IP, method, status code.
  - Firewall logs: source zone, destination zone, accept/deny status.
  - Flow logs: protocol, accept/deny status.

Be careful when pursuing this option as the number of open files can grow exponentially with too many multiple partition and file name prefix expressions.

Analyze Partitioning Expressions

Let's work through some examples of partitioning expressions, with hypothetical possible values for each parameter, to see what cardinalities they produce.

Example 1

This one produces reasonable results.

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}
/${sourcetype}/${host}/${AttackType}`
```

Possible values:

- `sourcetype`: 5.
- `host`: 100.
- `AttackType`: 5.

Potential cardinality: `5 x 100 x 5 = 2,500`.

Example 2

Here, too, cardinality is kept commendably low.

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}/${state}/${int
```

Possible values:

- `state`: 2.
- `interface`: 50.
- `dest_ip`: 20.

Potential cardinality: `2 x 100 x 10 = 2,000`.

Example 3

This is a bad partitioning expression which produces out-of-control cardinality. Back to the drawing board!

```
`${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}/${state}/${int
```

Possible values:

- `state`: 2.
- `interface`: 100.
- `src_ip`: 65,535.

Potential cardinality: `2 x 100 x 65,535 = 13,107,000`.

For more examples like these, see Better Partitioning Expressions.

See How Cardinality Changes Over Time

In the examples so far, we've assumed typical expected values for parameters. Another useful exercise is to estimate the maximum possible values of each parameter, and multiply each value to obtain maximum theoretical cardinality.

You should also investigate how cardinality changes depending on when and how long you measure it. To do this, query/search your analytic tool to determine cardinality for different durations over several days.

Run the searches over different duration spans (e.g., 1 minute, 3 minutes, 5 minutes) to determine the best timeout period. For example, your cardinality might be 2,000 over a 2-minute span, but 10,000 over a 5-minute span. In this case, it is most certainly beneficial to set the maximum file timeout to 2 minutes.

Below are examples of Splunk searches over different span periods, with maximum open file time set to 3 minutes. Change the fields to the ones you'd prefer to incorporate into a partition and/or file name prefix expression, and try running them in your environment.

Here's an example using a "traditional" search method:

```
earliest=-24h index=*
|bin _time span=3m
| stats dc(source) as dc by host, sourcetype _time
| stats sum(dc) by _time
```

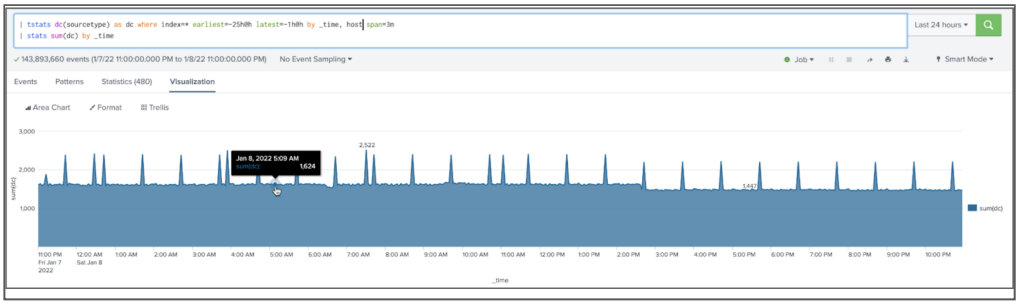
Here's an example using `tstats`:

```
| tstats dc(source) as dc where index=* earliest=-25h@h latest=-1h@h by _time, host,
| stats sum(dc) by _time
```

The `tstats` search produces the results shown in the diagram below.

- Cardinality mostly stays below 1,625.
- There are some hourly peaks around 2,500. These spikes, which exceed the max allowed cardinality of 2,000, are infrequent.

All of this is generally acceptable.



cardinality Check Results

Better Practice 5: Size a Separate Fast(er) Disk for Staging Location

The system's ability to handle enough open files is a key factor that drives performance. This requires:

- Setting **Max open files** high enough.
- Ensuring that the staging directory on the Workers can handle simultaneous writing tens of thousands of open files. The metric to use here is Input/Output Operations per Second (IOPS). A good starting point is 2,000 IOPS.

Cribl recommends that you allocate a separate disk for the staging directory on Workers, especially when you have configured multiple object storage Destinations. Follow these general, conservative guidelines:

- Toggle **Advanced Settings** > **Remove staging dirs** to `Yes`. This means that any empty directory that has not been written to for an hour, is deleted.
- Disk size of 500 GB should be adequate, since the Workers need only enough disk capacity for a few minutes' worth of data. 500 GB errs on the side of caution, allowing us to store as much as 4 hours of data to disk. See the formula and examples below.
- Because Cribl writes to the staging directory only when the object storage Destinations are healthy, disk size does not usually become an issue. If the Worker encounters or triggers a backpressure situation, it

stops writing to the staging directory.

- The staging directories are not intended for high availability, but rather to support creation of large-enough files to write to object storage.

Replay from a dedicated Worker Group. Do not compete for resources against production, real-time, streaming resources to perform replays!

Determine Staging Directory Disk Size

You can calculate an optimal size for your staging directory disk using the following formula:

- `Data Volume` (GB/day) you expect to ingest, times `1.25` metadata factor; divided by
- `1440` (minutes in a day), times
- `Duration` (minutes) you want to store data on disk; divided by
- `Number of Workers` writing to a staging directory.

The result will be disk size per Worker.

The figure below illustrates the formula.

$$\frac{Data\ Volume\ (GB/day) \times 1.25\ metadata\ factor}{1440\ mins/day} \times\ mins\ to\ store\ data\ to\ disk\ \div\ number\ of\ Workers$$

Here are some examples:

Data Volume	Number of Workers	Duration	Disk Size per Worker
1 TB/day	3	2	35 GB
10 TB/day	5	4	417 GB
50 TB/day	45	4	232 GB

Amazon S3 Optimization

Once you configure your Amazon S3 permissions, verify access, and (if applicable) discover your Cribl.Cloud Organization's AWS ARN, you can start applying some more better practices.

Amazon S3 Permissions

If your Workers are hosted outside AWS, you will need an access key and secret key to access the S3 bucket. If the Workers are EC2 instances or in AWS EKS, it's most ideal to assign an EC2 service role to the instances. The role will need access to the S3 bucket. For policies for reading and writing to/from Amazon S3, see AWS Cross-Account Data Collection.

Here's a policy to grant a role, or user access, with read and write permissions the S3 bucket. Just change the bucket name in this policy:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "s3:GetObject",
        "s3:PutObject"
      ],
      "Resource": "arn:aws:s3:::bucketname/*"
    },
    {
      "Effect": "Allow",
      "Action": [
        "s3:ListBucket",
        "s3:GetBucketLocation"
      ],
      "Resource": "arn:aws:s3:::bucketname"
    }
  ]
}
```

If `assumeRole` is required, here's a sample policy to assume the role that has access to the S3 bucket:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Principal": {
        "AWS": "arn:aws:iam::111111111111:role/account-a-cribl-stream-assumerole-rol
      },
      "Action": "sts:AssumeRole",
      "Condition": {
        "StringEquals": {
          "sts:ExternalId": "cribl-s3cre3t"
        }
      }
    }
  ]
}
```

Test your policy with AWS's IAM policy simulator to ensure there are no boundary policies that might conflict with this policy.

Verify S3 Access

To troubleshoot access to your S3 bucket, install the AWS CLI on one of the Workers. Log in using your AWS user and Region. Assume the role if necessary. Then, attempt to download a file from the bucket or write a new file to the bucket.

Example of assuming a role:

```
aws sts assume-role --role-arn "arn:aws:iam::123456789012:role/example-role" --role-s
```

Example of validating the role you'll use to run subsequent commands:

```
aws sts get-caller-identity
```

Example of listing files in a bucket:

```
aws s3 ls s3://s3-bucket-name
```

Example of sending stdin to a specified bucket:

```
aws s3 cp - <target> [--options]
```

Example of writing a local file to the bucket:

```
aws s3 cp localfilename.txt s3://bucket-name
```

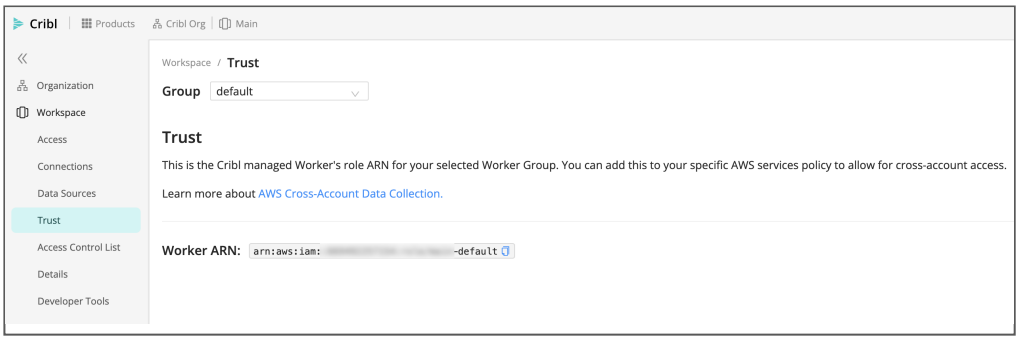
Example of reading a file from S3:

```
aws s3 cp s3://bucket-name localfilename.txt
```

Access Amazon S3 from Cribl.Cloud

Every Cribl.Cloud Organization exposes its own unique AWS ARN.

From the main Cribl.Cloud portal, navigate to the **Workspace** you are working in, and select **Trust** from the sidebar to expose the Cribl.Cloud ARN.



Cribl.Cloud ARN

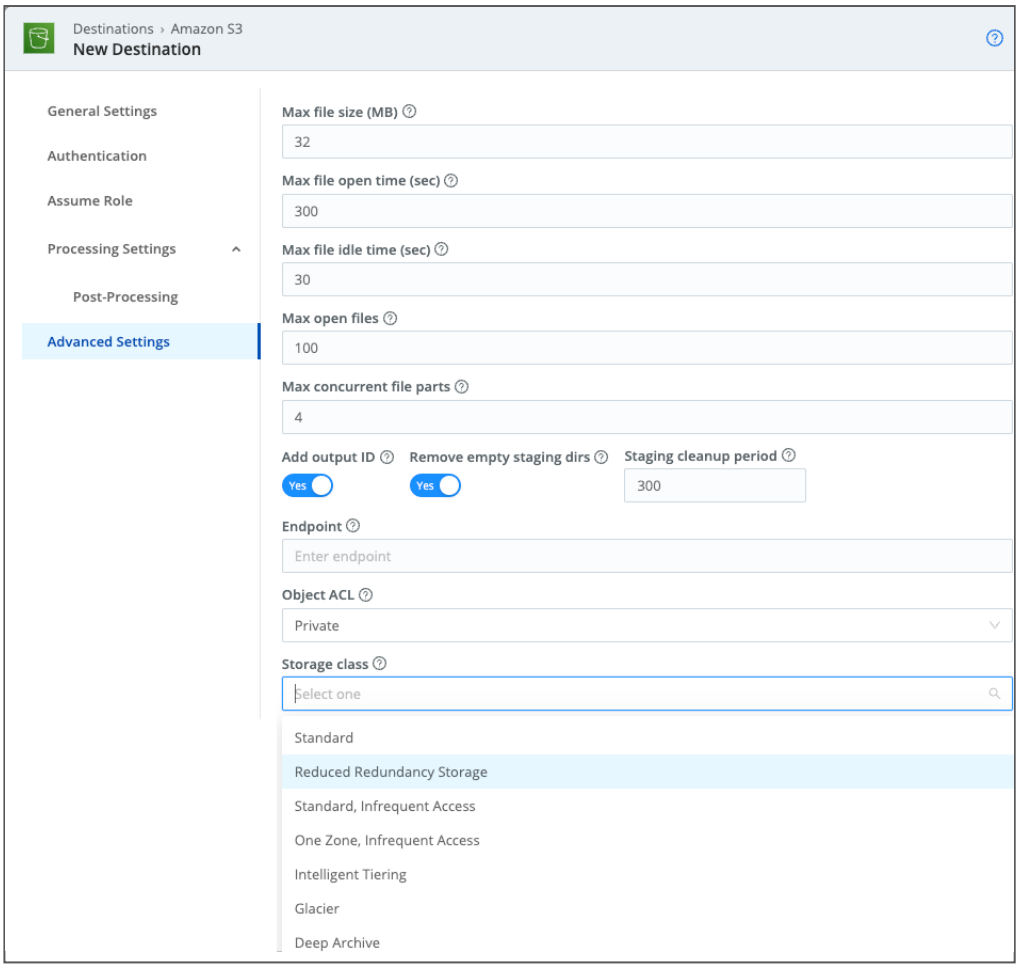
Configure your AWS account with access to the S3 bucket, to allow Cribl.Cloud to assume that role, as illustrated above in Amazon S3 Permissions.

Better Practice 6: Tuning Amazon S3 Destination Settings

Under the Amazon S3 Destination's **General Settings** and **Advanced Settings** tabs are several settings for tuning your Amazon S3 Destination. Below are some recommendations for tuning those settings, in order of

importance:

1. **Staging Location**: Change this to a directory on the Workers with increased IOPS, to accommodate thousands or tens of thousands of simultaneous open files. (Cannot be configured on Cribl.Cloud-managed Workers.)
2. **Remove staging dirs**: This setting must be enabled, so as not to leave millions of empty directories on the system over time.
3. **Compress**: Always enable compression, to reduce the size of files uploaded and downloaded from S3. This can reduce your S3 bill by 8–15x. Note that compression does add to the processing time – but transfer time will be substantially faster.
4. **Max open files**: Adjust this to be slightly larger than the data's cardinality, but not greater than 2,000. Also, ensure that the system can support the number of open files for all Worker Processes, and across all configured S3 Destinations. This value is set per process. 32CPUs*100 - 3200 max open files. Increase this value to avoid "Too many open files" errors. Default open file limit on Linux is 1024/process.
5. **Max file size (MB)**: If you have a separate S3 Destination for high-volume data sources, such as VPC Flow Logs or firewall logs, consider raising this value in order to create fewer files. Start with 64 MB. Otherwise, the default 32 MB setting is generally acceptable.
6. **Max file open time (sec)**: First, determine your cardinality over 1 minute, 3 minutes, 5 minutes, and 10 minutes. Adjust this setting to match the lowest-cardinality period. E.g., if cardinality is 10,000 over 5 minutes, but 2,000 over 90 seconds, change this setting to 90 seconds. If cardinality is 2,000 over 5 minutes, then the default 5 minutes (300 seconds) is acceptable.
7. **Max idle time (sec)**: The default 30 seconds is generally acceptable. In cases with high cardinality, lowering this setting can result in fewer open files when processing bursty data.
8. **Data format**: If using a Passthru Pipeline, change this setting to `Raw`. Otherwise, leave it at the JSON default to preserve all metadata added to the events.
9. **Storage class**: For Amazon S3 Destinations, consider the "infrequent access tier" or "intelligent tier" to reduce overall cost if the data will be rarely searched. Examples of rarely-searched data include threat-hunting or compliance-reporting use cases. "Standard, Infrequent Access" and "Intelligent Tiering" options should be used on low-access use cases such as threat hunting or compliance audit.
10. **AWS Region**: Leave this field blank for non-AWS Destinations, unless instructed otherwise. For AWS, set this to the nearest geographic location to the Workers.

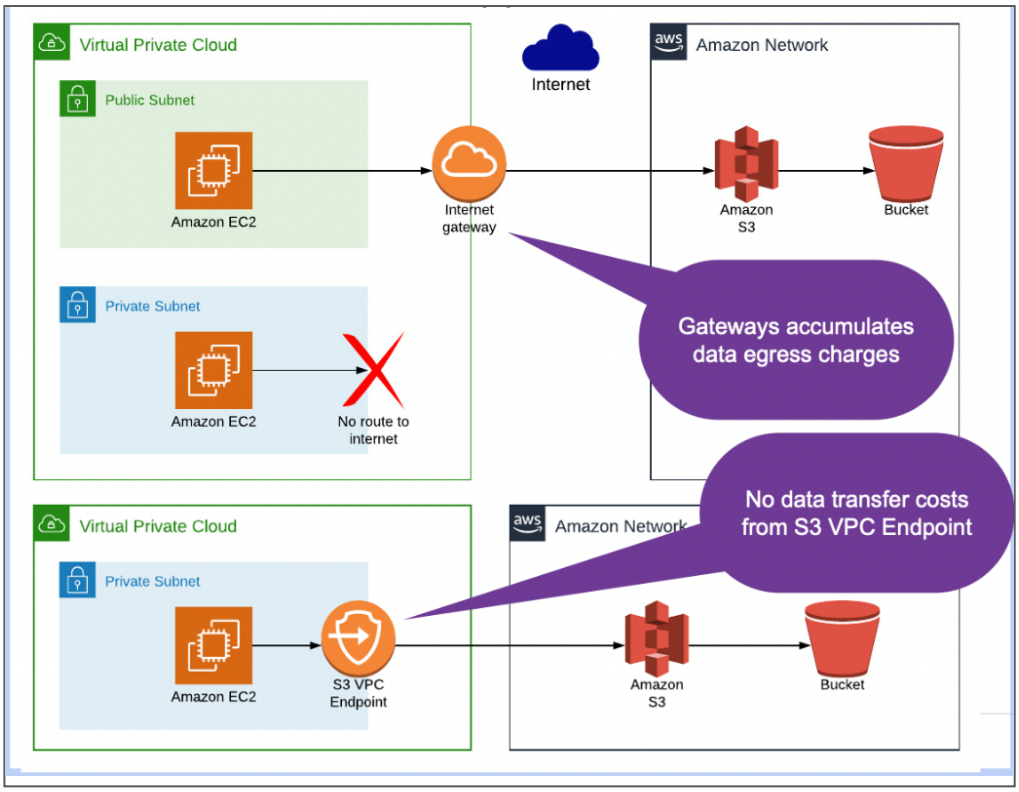


Configuring S3 Destination Settings

Better Practice 7: Lower AWS Costs

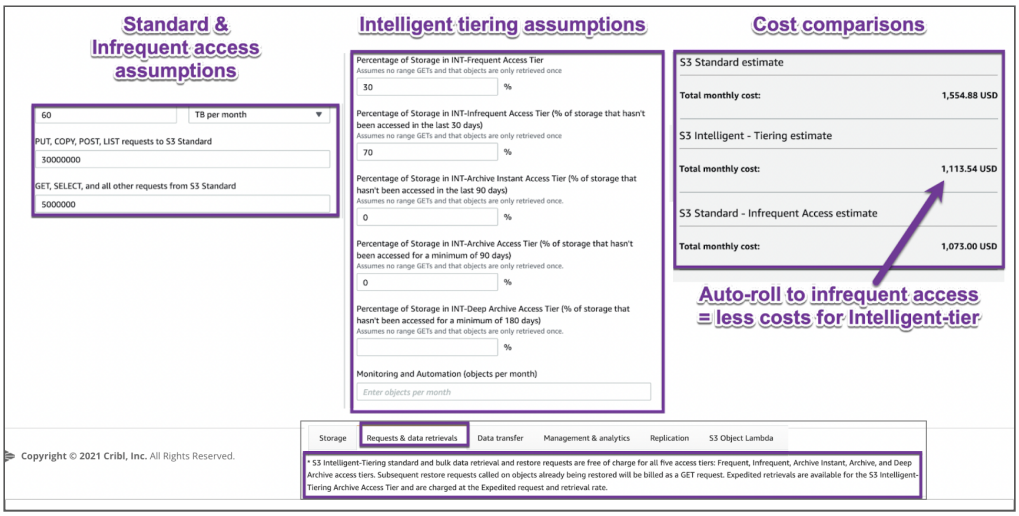
Lowering AWS costs can be achieved by a few means. First and foremost, ensure that compression is enabled on your Cribl S3 Destination and set to `gzip`. This will reduce both egress costs and S3 storage costs.

To eliminate egress costs from your Workers to S3, map a VPC endpoint on the S3 bucket to the VPC where your Workers reside.



Mapping a VPC endpoint to an S3 bucket

Writing to S3's Intelligent storage class, or infrequent access tier, can reduce long-term costs. Intelligent storage automatically routes data to cheaper S3 tiers when it is not searched or touched for certain periods of time. Consult the AWS Cost Estimator to calculate the differences. Old data can also be rolled off to a much cheaper option such as Glacier Instant Retrieval or Glacier Deep Archive. Below are sample cost comparisons:



AWS Cost Comparison

Cribl Stream Collectors and Replay features don't support S3 Glacier or S3 Deep Glacier due to long retrieval times for those storage classes.

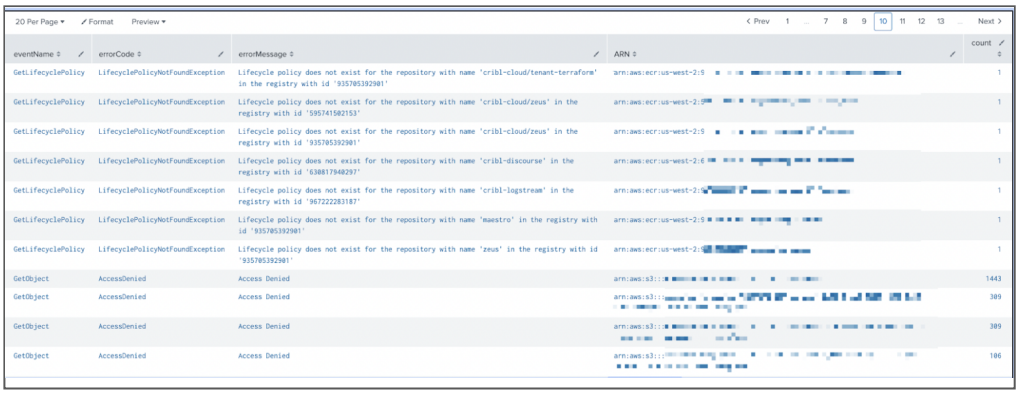
> Collectors and Replay features do support S3 Glacier Instant Retrieval when you're using the S3 Intelligent-Tiering storage class.

Better Practice 8: Monitor Amazon S3 Buckets

AWS may limit S3 access if cumulative API writes are greater than 3,500 writes/second, or cumulative API reads are greater than 5,500 reads/second for a prefix (a.k.a., directory within S3). While it would be impossible to track every single AWS prefix's API requests, Cloudtrail offers "rate exceeded" events if you are ever over the API request limits.

Here's a Splunk search to report on all Cloudtrail events for S3. Filter or look for rate exceeded within the `errorMessage` field:

```
index=aws sourcetype=aws:cloudtrail errorCode=* "resources{}.ARN"=* | rename "resources{}.ARN" as ARN | stats count by eventName errorCode errorMessage ARN
```



Cloudtrail Logs Search

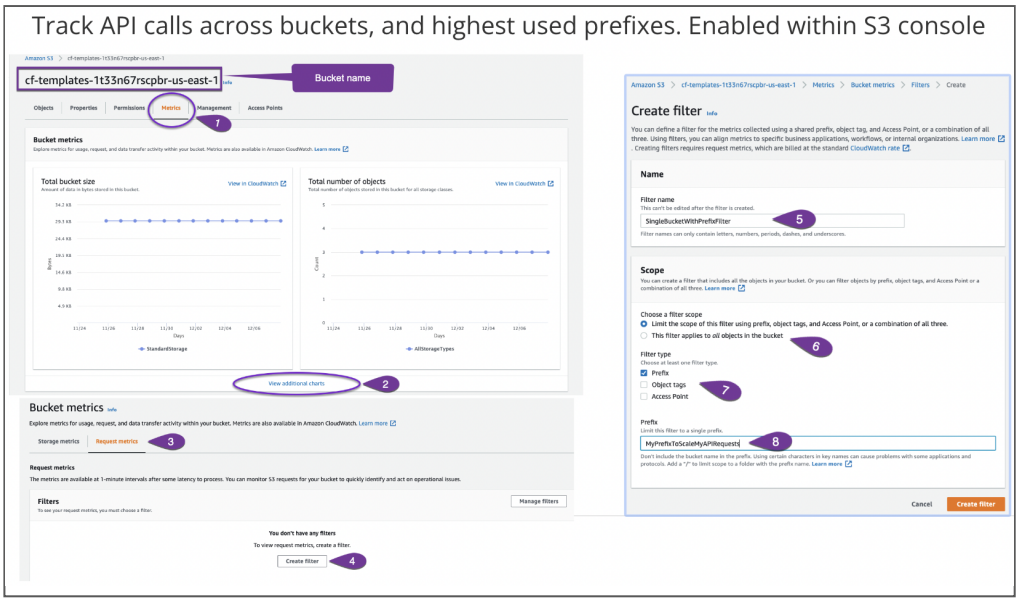
If there are `rate exceeded` messages from writing to Amazon S3, then a new strategy for partition and filename prefix expressions might be warranted. You will want to create fewer files, so consider one or more of the following options:

- Increasing timeouts.
- Eliminating file name expression prefixes.
- Updating partitioning expressions.

If there are rate exceeded messages on reading from Amazon S3, then you should likely apply better filtering. This might also warrant a new strategy for how files are written to S3.

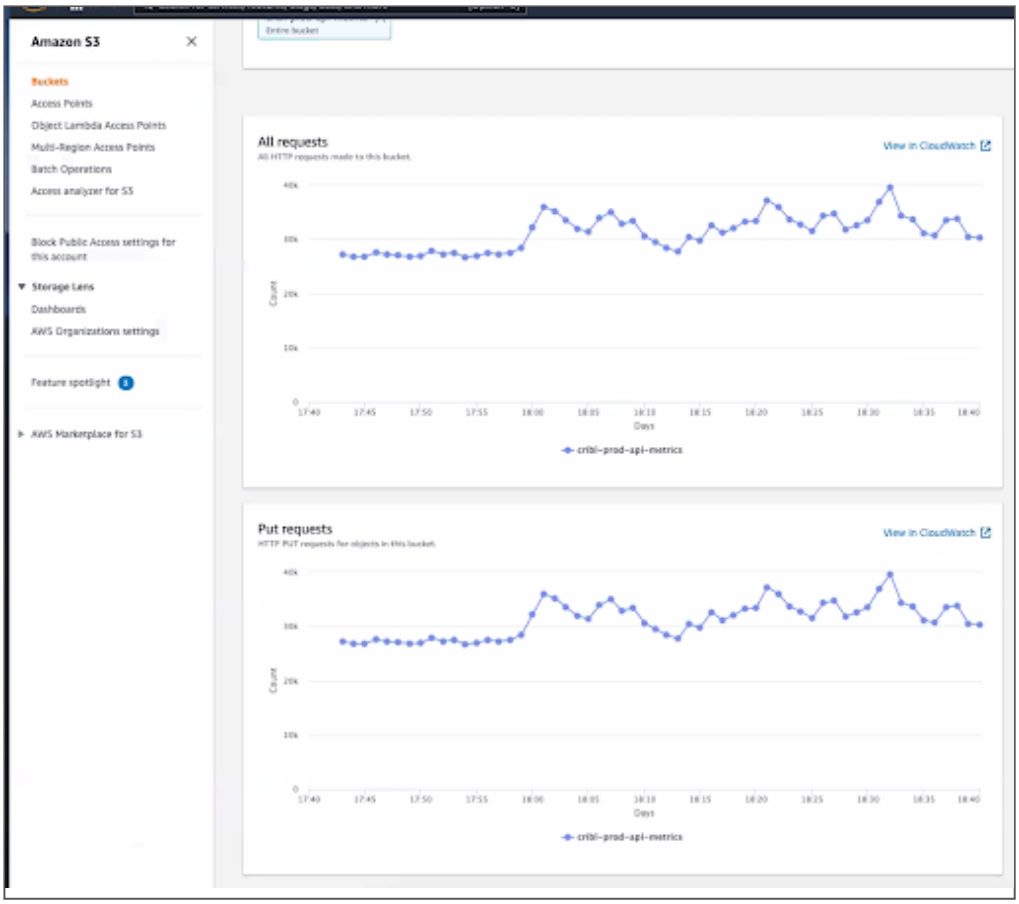
For trending API calls, you'll need to focus on a specific prefix. This might be useful for specific AWS prefixes, as there will be hundreds of thousands or millions. API calls can be tracked via AWS Cloudwatch, but first need to be enabled for tracking within the S3 bucket. See AWS' Creating a Metrics Configuration that Filters by Prefix, Object Tag, or Access Point topic.

The screenshot below illustrates the locations to enable tracking API calls for a specific prefix:



Enable Monitoring in S3

Here's a Cloudwatch chart trending all requests, and write requests, for an S3 prefix. This is granular to 1 minute. Because the API limits are per second, some extrapolations are necessary to estimate per-second values.



Cloudwatch Chart

Consider both the write and read behavior when designing your partitioning expressions and file name prefix expressions.

Better Practice 9: Monitor Worker Node Performance, and Enable Notifications

Aside from the standard CPU load, disk space, memory usage metrics, consider tracking some additional metrics. If the Worker Nodes are deployed as EC2 instances, track the Cloudwatch metrics for the EC2 instances and associated disks. Cribl Support will ask for these metrics to track Amazon S3 issues:

- `BurstBalance`
- `VolumeReadBytes`
- `VolumeWriteBytes`
- `VolumeReadOps`
- `VolumeWriteOps`
- `VolumeQueueLength`

On the Linux host, the following command allows you to track the number of open files. This would be another useful metric to track over time:

```
lsof | grep <common_upperlevel_staging_dir> | wc -l
```

You can also configure Notifications in Cribl Stream when the S3 Destination is unhealthy or triggering backpressure. Once the S3 Destination is enabled, and a Notification target is set, you need to:

- Edit Cribl Stream's S3 Destination to configure Notifications.
- Add Notifications for different conditions.

Better Practice 10: Dedicate a Separate Worker Group for Replays

Execute Replays from a dedicated Worker Group. Streaming real-time data needs dedicated Worker Groups. You do not want CPU or memory conflicts on production systems that are streaming mission-critical, real-time machine data. Kubernetes or AWS spot instances are good options for on-demand Worker Processes that are needed only for infrequent replays.

Bonus Better Practice: Tune Amazon S3 Source Settings

For Cribl Stream's SQS-based Amazon S3 Source (as opposed to our S3 Collector), a few settings can speed up processing of new files added to an S3 bucket:

1. Under **General Settings**, apply a **Filename filter** if you want to pull only a subset of files from the S3 filter. The value is a regular expression (e.g., *suricata*)
2. Under **Advanced Settings**, set **Max messages** as high as 10 to fetch more SQS messages from the queue at once.
3. Under **Advanced Settings**, set the **Num receivers** to vertically scale the number of simultaneous processes pulling SQS messages and downloading S3 files. For S3 buckets with centralized Cloudtrail logs, or VPC flows across multiple accounts, raise the setting to 5 or 10.

Improve Partitioning Expressions

Creating partitioning expressions is an art. To get a sense of the possibilities and risks, let's consider both positive and negative examples.

Partitioning Expression 1: The Good

```
${C.Time.strftime(_time ? _time : Date.now()/ 1000, '%Y/%m/%d/%H/%M')}
```

Key Questions	Answers
Potential cardinality every *minute*?	1
How many open files if there are 30 Worker Processes?	30 open files
How many files in the S3 prefix, if the timeout is the default 60 seconds (assuming no file size limit)?	30 * 1 = 30 files
What if there are 10 Nodes in the Worker Group? How many files in each S3 prefix?	30 * 10 = 300 files
What happens when a replay fetches data for this hour?	Under API limit of 5,500 reads/sec

Result

- A good partitioning expression.

Partitioning Expression 2: The Ambiguous

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}
/${index ? index : 'no_index'}
/${host ? host : 'no_host'}
/${sourcetype ? sourcetype : 'no_sourcetype'}
```

Key Questions	Answers
Potential cardinality every 3 minutes?	3,000
How many active subdirectories in the staging dir?	3,000
What is the excess cardinality?	3,000 - 2,000 = 1,000
What are maximum open files if there are 14 Worker Processes on a Worker ?	14 * 2,000 = 28,000 open files
What happens when maximum open files of 2,000 is reached for any one Worker Process? What happens if it happens too frequently?	All files closed & written to S3 at once = 2,000 writes. Potential for backpressure if Cribl Stream takes long enough to write the files.
What's the maximum number of files in any S3 prefix?	14 * 10 Worker Process * (60min/3min) = 2800 files max in any S3 prefix

Additional assumptions:

- Cardinality of 3,000 every 3 mins.
- File write timeout of 3 minutes.
- Max file size never reached.
- 10 Worker Process in group.

Result

- Proceed with caution.

Solution

- Track the occurrences of `max open files reached` messages
- If the `max open files reached` message occurs too frequently, consider reducing the cardinality. You might achieve this by lowering the timeout period to 2 minutes or 1 minute.

Partitioning Expression 3: The Bad

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d/%H')}
```

Key Questions	Answers
Potential cardinality every hour?	1
How many open files if there are 30 Worker Processes?	30 open files.
How many files in the S3 prefix, if the timeout is the default 60 seconds (assuming no file size limit)?	(30 * 60) = 1800 files
What if there are 10 Nodes in the Worker Group? How many files in each S3 prefix?	(1,800 * 10) = 18,000 files
What happens when a replay fetches data for this hour?	Could exceeed the API limit of 5,500 reads/sec.

Result

- A bad partitioning expression.

Solution

- Change the timeout to 1800 seconds to allow files to grow in size.

Partitioning Expression 4: The Terrible

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%Y/%m/%d')}
/${index ? index : 'no_index'}
/${host ? host : 'no_host'}
/${sourcetype ? sourcetype : 'no_sourcetype'}
```

Filename Prefix Expression:

```
${C.Time.strftime(_time ? _time : Date.now() / 1000, '%H%M')}
```

Key Questions	Answers
What are max open files on any one Worker Process?	Answer: `2,000`, because that is the lower of: `[(500 directories * 5 filename prefix files = 2,500 open files per process]` and `[2,000 open files]`

Key Questions	Answers
How many active subdirectories in the staging dir?	Around 400
What happens when max open files of 2,000 is reached for any one Worker Process?	All files closed and written to S3 at once (2,000 writes at once). Happens every 4 minutes. There's potential for backpressure if Cribl Stream takes long enough to write the files.
What's the max number of files in any S3 prefix?	14 processes * 1440 mins * 10 Worker Process = 202K files! API issues on read are likely.

Additional Assumptions

- Reduced cardinality of 200 every 2 minutes, and 500 every 5 minutes.
- Introduction of a file prefix partition.
- Max open files within Cribl Destination set to 2,000.
- Max file open time of 5 minutes.
- Assume max file size is never reached.
- 10 Worker Processes in Group.
- 14 Worker Processes/Worker.

Result

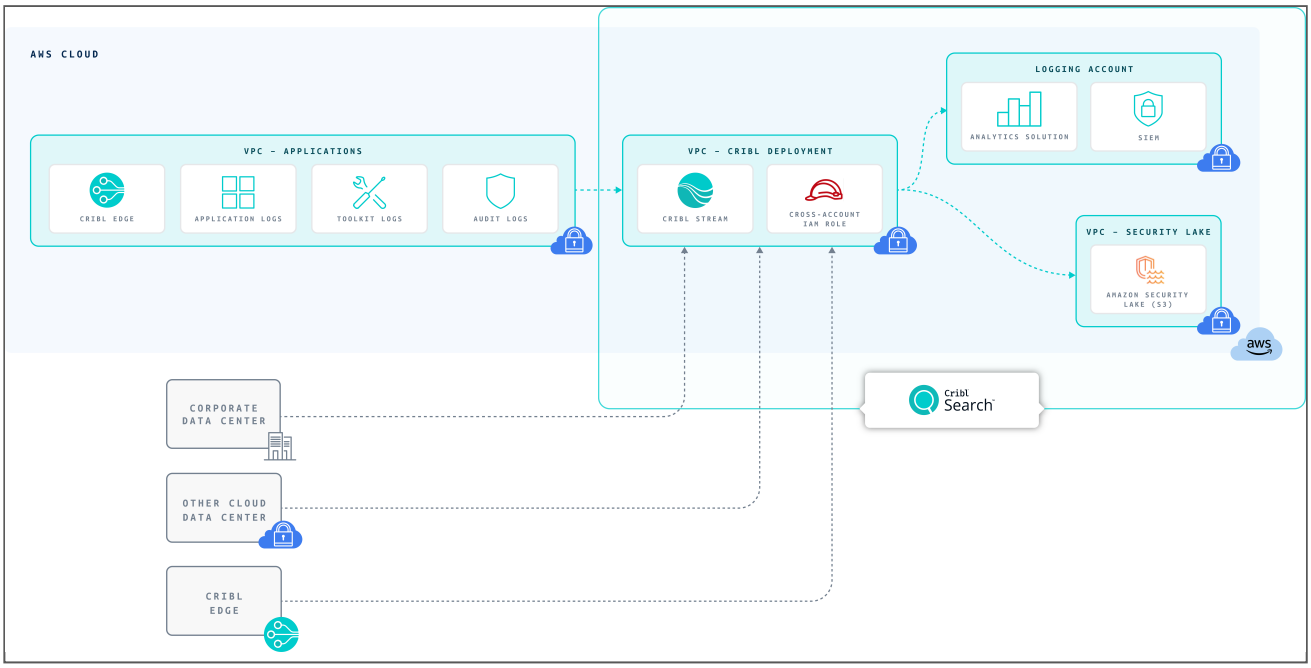
- A terrible partitioning expression.

Solution

- Don't use the file prefix expression; consider expanding the partitioning expression instead.
- Reduce timeout to 2 minutes, as cardinality will be lower over a 2-minute span.

15.8.1.3. Amazon Security Lake Integration

Cribl Stream supports sending data to Amazon Security Lake as Parquet files that adhere to the Open Cybersecurity Schema Framework (OCSF). The diagram below illustrates the all-AWS variant of this architecture.



Integrating Cribl Stream with Amazon Security Lake

This guide walks you through an example where Cribl Stream, running in Cribl.Cloud, sends Palo Alto Networks logs to Amazon Security Lake. The workflow starts with a Cribl Stream Syslog Source, which ingests the Palo Alto data and routes it to a Cribl Stream Amazon Security Lake Destination, which then writes Parquet files to Amazon Security Lake. These Parquet files organize the data according to the OCSF schema for the appropriate OCSF Event Class, in this case Network Activity [4001].

You can work with other data sources besides Palo Alto Networks, and other OCSF Event Classes besides Network Activity [4001]. See Going Beyond This Example below.

If you want to use Amazon Security Lake with a Cribl Stream instance deployed on-prem or in your private cloud, the setup procedures will differ from those documented here. Please contact Cribl via the `#packs` channel of Cribl Community Slack.

Set Up Amazon Security Lake

Complete the Amazon Security Lake Getting Started instructions, paying particular attention to the following actions:

1. Enable Amazon Security Lake for your AWS account.

2. Define the **collection objective** and **target objective**.
3. Select the regions where you want to create S3 buckets to store the data in OCSF format.

Note your Amazon Security Lake S3 bucket name for use later in the setup process.

Set Up Cribl Stream

Complete the procedures in this section before doing anything else in Cribl Stream.

First, find and note the Amazon Resource Name (ARN) that enables AWS to locate your Cribl Stream instance.

1. Log in to Cribl.Cloud.
2. In the sidebar, select **Workspace**, and then select **Trust**.
3. Select the copy icon next to the **Worker ARN**, and paste the ARN into a local text editor.
4. Copy the 12-digit number in the middle of the ARN. This is the AWS Account ID you'll need later in the setup process.

For example:

- If your ARN is `arn:aws:iam::222233334444:role/main-default`, then …
- Your AWS Account ID will be `222233334444`.

Next, install the Cribl Pack that Cribl Stream will use to send data to Amazon Security Lake in the required OCSF format. (As the reference shows, the Palo Alto Networks data chosen for this example requires the **OCSF Post Processor Pack**.)

1. On the top bar, select **Products**, and then select **Cribl Stream**.
2. Select the name of the Worker Group whose Worker Nodes you want to send data to Amazon Security Lake. (For this example, we'll use the `default` Worker Group.)
3. Navigate to **Processing** > **Packs** (Stream) or **More** > **Packs** (Edge) and select **Add Pack**. From the drop-down, select **Import from Git**.
4. For the **URL**, enter:

   ```
   https://github.com/asc-me-cribl/cribl_ocsf_postprocessing
   ```

5. For the **New Pack ID**, enter:

   ```
   Cribl-OCSF_Post_Processor
   ```

6. Select **Import** to close the modal. Cribl Stream will take a little time to finish importing the Pack.

At the bottom of the list of Packs, you should now see your newly imported Pack, listed with the display name of **OCSF Post Processor**.

Finally, you will need the Parquet schema that supports the OCSF Event Class you're working with. In this example, that's OCSF Event Class 4001, so as shown in the reference below, you'll need the `OCSF 4001 Network Activity` Parquet schema.

- First, download the Parquet schema from this GitHub repo.
- Then, upload the schema to the Cribl Stream Parquet schema library as described here.

Once this is done, the Parquet schema you need should be available when you configure the **Parquet Settings** for your Cribl Stream Amazon Security Lake Destination.

Please post any questions you have about these procedures to the `#packs` channel of Cribl Community Slack.

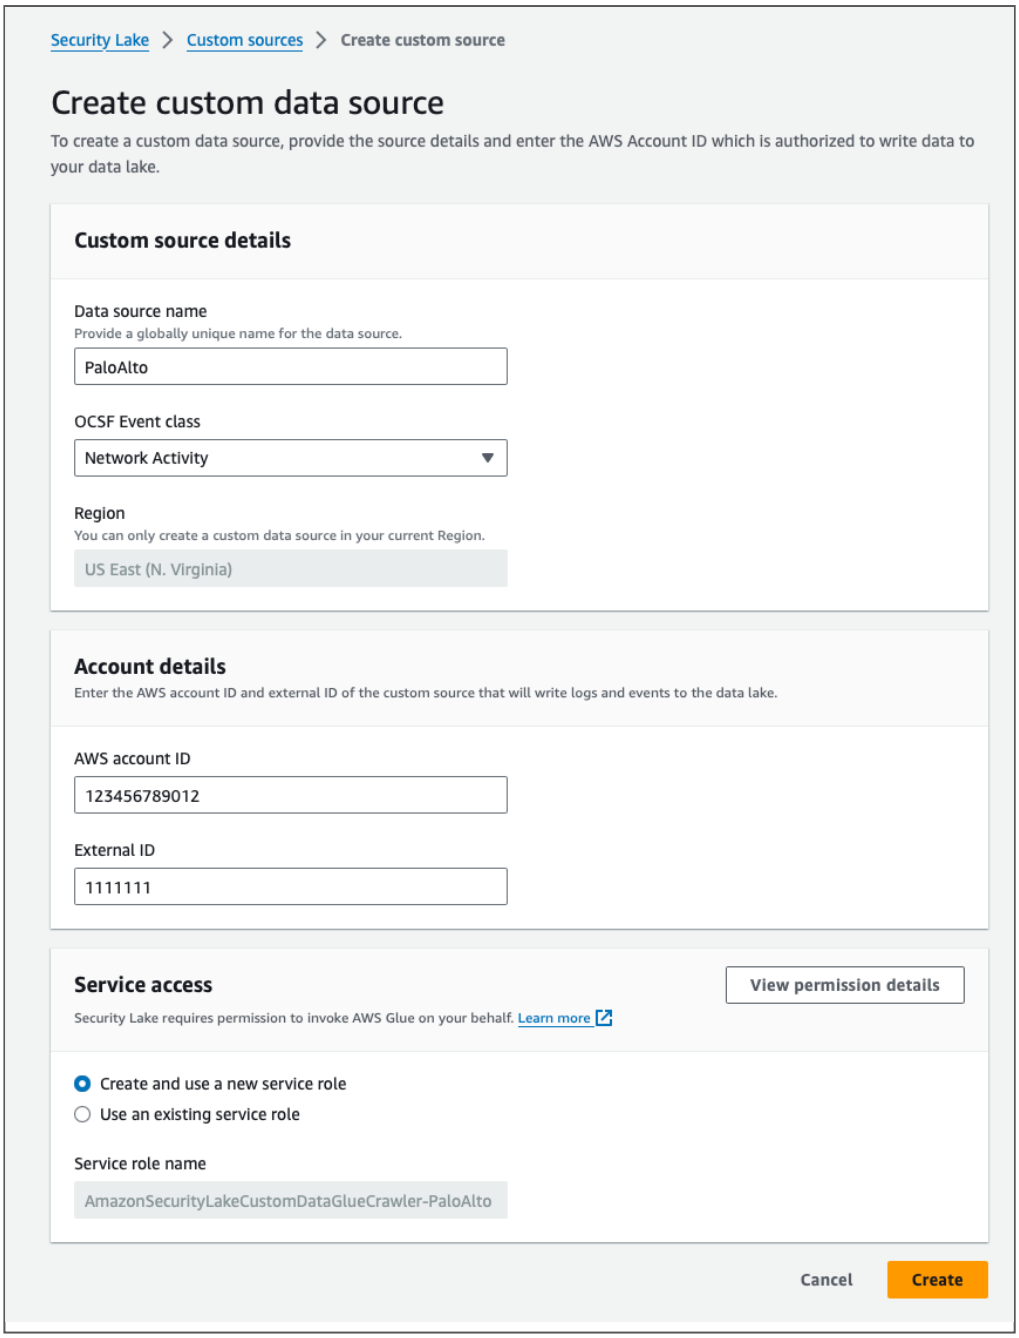
Create an Amazon Security Lake Custom Source

Because Cribl is not a native Amazon service, you'll configure what Amazon calls a **Security Lake custom source**, and the Cribl Stream Amazon Security Lake Destination will write to that.

Before you begin:

1. Have your Cribl.Cloud AWS account ID, which you identified earlier, handy.
2. Ensure that you have permissions in AWS Lake Formation to create AWS Glue databases and tables. For more information, see Granting and revoking permissions using the named resource method in the AWS docs.

Then complete the instructions here in the AWS docs. These docs will take you through the **Create custom data source** template show below.



Creating an Amazon Security Lake custom source

Once the custom source has been created, still in AWS, navigate to **Security Lake** > **Custom sources** and you should see your new custom source in the list.

Now locate the **Provider role ARN**. This is the ARN that Cribl Stream will use to declare its role to AWS.

1. Select the copy icon next to the **Provider role ARN** to add it to your clipboard. Keep the ARN handy for use later in the setup process.
2. Navigate to the **Identity and Access Management (IAM)** screen.
3. From the left menu, select **Access management** > **Roles**.
4. In the **Roles** search box, paste the part of the ARN that begins `AmazonSecurityLake` and ends with the region.

5. When the role name appears below, select the link.
6. In the **Trust relationships** tab, view the `ExternalId` element in the JSON object that appears there.

This is the External ID for the trust relationship, which you created when went through the template. You will need this ID later in the setup process.

Create a Cribl Amazon Security Lake Destination

Back in Cribl Stream, create a new Amazon Security Lake Destination in the Routing UI as described in the Destination topic. In the **New Destination** modal, configure the settings specified below. For all settings **not** mentioned in the following notes, you can keep the defaults.

General Settings

S3 Bucket name: The S3 bucket name you noted when setting Up Amazon Security Lake.

Region: Select the region where the S3 bucket is located.

Optional Settings

File name prefix expression: Keep the default (`CriblOut`) if it satisfies your requirements; otherwise, edit to suit your needs.

Authentication

Authentication method must be set to `Auto` (the default).

Assume Role

Cribl strongly recommends using the **Auto** authentication method in conjunction with the **Assume Role** settings as described below. Both Cribl and Amazon discourage the use of other approaches.

When using Assume Role to access resources in a different region than Cribl Stream, you can target the AWS Security Token Service (STS) endpoint specific to that region by using the `CRIBL_AWS_STS_REGION` environment variable on your Worker Node. Setting an invalid region results in a fallback to the global STS endpoint.

AssumeRole ARN: This is the **Provider role ARN** you copied after creating your custom source in Amazon Security Lake.

External ID: Enter the ID that you specified when creating your Amazon Security Lake custom source.

Processing Settings

Post-Processing

Pipeline: From the drop-down, select the Pack you installed earlier:

```
PACK Cribl-OCSF_Post_Processor (OCSF Post Processor)
```

System fields: Remove any fields specified here.

Parquet Settings

Parquet schema: From the drop-down select `OCSF 4001 Network Activity`, since OCSF Event Class 4001 describes the events coming from Palo Alto Networks in this example.

At this point, you can select **Save**; the defaults for **Advanced Settings** should work fine for this example. Then, **Commit** and **Deploy**.

You must create one Cribl Stream Amazon Security Lake Destination for **each unique pairing** of a data source with an OCSF Event Class.

- In this example, we're ingesting Palo Alto Networks Threat and Traffic data, which requires the OCSF Network Activity [4001] Event Class. That's one pairing.
- If you also wanted to ingest CrowdStrike Network Activity data, that would be a new data source paired with the same OCSF Event Class – such as, **that would be a second unique pairing**. You would need to create a **separate** Cribl Stream Amazon Security Lake Destination for that pairing.

The reference below shows all the possible pairings of data sources and OCSF Event Classes.

Connect a Cribl Source to the S3 Destination

We'll now configure a Cribl Stream Syslog Source to ingest Palo Alto Networks system logs, using the QuickConnect UI. (The reference below shows what Cribl Stream Source to use for each supported data source.)

Navigate to QuickConnect as described here. After selecting the Syslog Source tile, select **Select Existing**, then select the pre-configured `in_syslog` Source. When prompted to `Switch in_syslog to send to QuickConnect instead of Routes?`, select `Yes`.

Select + and drag the connection line to the S3 Destination you created above.

The connection between the Syslog Source and the S3 Destination should now be enabled.

Commit and **Deploy** the changes.

Send Data to Amazon Security Lake

Return to your AWS Console. You should see Parquet files landing in the S3 bucket. These files should contain the Palo Alto Networks syslog data you sent through Cribl Stream.

Troubleshooting and Testing

Good things to double-check:

- Are you sending the events to your Amazon Security Lake in Parquet format?
- Are your permissions set properly for your IAM role to write to the S3 bucket?

If the answer to either question is "No," your data will not make it into Amazon Security Lake.

To send sample events from the GitHub repo, using netcat:

1. Download the `oYLbFU.json` sample file.
2. Run the following command, replacing `<cribl_org_id>` with your Cribl.Cloud Organization ID:

```
cat oYLbFU.json | nc default.main.<cribl_org_id>.cribl.cloud 10070
```

With a Cribl.Cloud Enterprise plan, generalize the above URL's `default.main` substring to `<group-name>.main` when sending to other Worker Groups.

Beyond This Example

If you want to send data from sources other than Palo Alto Networks, you can adapt the above instructions to use the appropriate Source and Pack (and/or modifications to the OCSF Post Processor Pack) in Cribl Stream. This holds true as long as the OCSF Event Classes you want to work with are among those supported by Cribl Stream. For each unique pairing of a data source with an OCSF Event Class, you'll need to create a separate Amazon Security Lake Destination.

In the next section is a list of the supported data sources, what OCSF Event Classes they handle, and what Packs and Parquet schemas you need to work with them.

Reference: Supported Data Sources

Data Source	OCSF Event Classes Handled	Cribl Source	Cribl Pack Display Name	Parquet Schema(s)

Azure Audit Logs	3002, 3004	REST Collector against Microsoft Graph API	Azure Audit Logs to OCSF	`OCSF 3002 Authentication`
				
				`OCSF 3004 Entity Management`

Azure NSG Flow Logs	4001	Azure Blob Storage Source, run as scheduled jobs, not as a Pull Source	Azure NSG Flow Logs	`OCSF 4001 Network Activity`
Cisco ASA	4001	Syslog	Cisco ASA	`OCSF 4001 Network Activity`
Cisco FTD	4001	Syslog	Cisco FTD	`OCSF 4001 Network Activity`
CrowdStrike Account Change	3001	CrowdStrike FDR	Crowdstrike FDR Pack	`OCSF 3001 Account Change`
CrowdStrike Authentication	3002	CrowdStrike FDR	Crowdstrike FDR Pack	`OCSF 3002 Authentication`
CrowdStrike Network Activity	4001	CrowdStrike FDR	Crowdstrike FDR Pack	`OCSF 4001 Network Activity`
GCP Audit Logs Account Activity	3001	Google Cloud Pub/Sub	Google Cloud Audit Logs	`OCSF 3001 Account Change`
Palo Alto Networks (PAN) Threat and Traffic	4001	Syslog	OCSF Post Processor Pack	`OCSF 4001 Network Activity`

SentinelOne	1001, 2001, 3002, 4001	Amazon S3	SentinelOne Cloud Funnel	`OCSF 1001 File System Activity`
				
				`OCSF 2001 Security Finding`
				
				`OCSF 3002 Authentication`

Data Source	OCSF Event Classes Handled	Cribl Source	Cribl Pack Display Name	Parquet Schema(s)
				`OCSF 4001 Network Activity`
Windows Logon Activity	3002	Splunk TCP	Splunk Forwarder Windows Classic Events to OCSF	`OCSF 3002 Authentication`
ZScaler Firewall and Weblogs	4001	Syslog	OCSF Post Processor Pack	`OCSF 4001 Network Activity`

15.8.1.4. Collecting Logs From Amazon ECS Containers

When using the Amazon Elastic Container Service (ECS), Cribl Stream can eliminate the additional expense of CloudWatch Logs by selecting an alternative Docker logging driver.

By default, the `awslogs` driver will forward all container logs to CloudWatch Logs. This requires an additional Amazon service, such as Amazon Data Firehose or AWS Lambda, to export logs to the desired destination.

But by using Docker's `splunk` logging driver, you can forward the ECS container logs directly to a Cribl Stream Worker Group, bypassing CloudWatch Logs.

For example, when using Cribl.Cloud, you can forward logs to your Organization's Splunk HEC endpoint. This endpoint information can be found in your Cloud Organization's Data Onboarding configuration.

Example Task Definition

Below is a sample JSON task definition with the required `logConfiguration` section configured to forward Splunk HEC payloads to Cribl Stream:

```
{
    "containerDefinitions": [
        {
            "name": "my-example-container",
            "essential": true,
            "image": "public.ecr.aws/my/containerimage:latest",
            ...
            "logConfiguration": {
                "logDriver": "splunk",
                "options": {
                    "splunk-url": "https://main-default-<org>.cribl.cloud:8088",
                    "splunk-token": "176FCEBF-4CF5-4EDF-91BC-703796522D20",
                    ...
                }
            }
        }
    ],
    ...
}
```

Additional Details

For additional configuration options on the `splunk` logging driver, see Docker's documentation.

For additional details on the `LogConfiguration` section, see the Amazon ECS documentation.

15.8.2. Azure

15.8.2.1. Preparing The Azure Workspace

Currently, Cribl Stream supports sending data only to custom tables and certain native tables. For details, see Azure's Supported Tables topic.

To send data to custom tables from Cribl Stream, you must update a DCR Template with Stream definitions. We've provided an example DCR Template file.

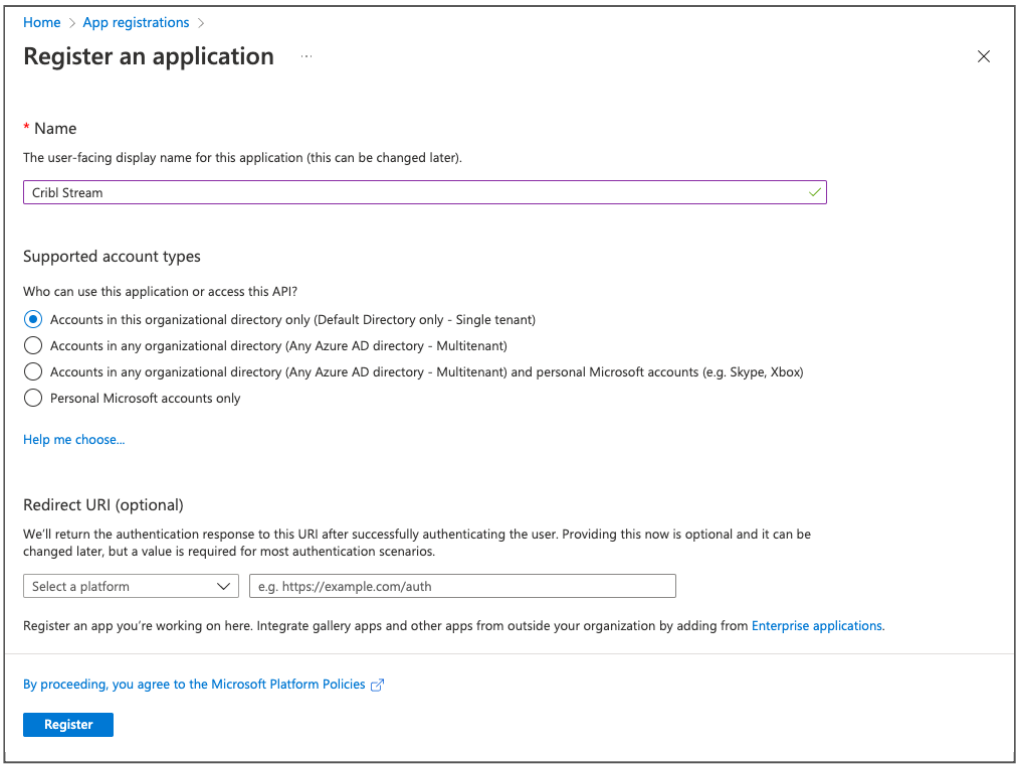
Prepare the Azure Workspace

First, you must prepare the Azure Workspace to receive data from Cribl Stream, by registering Cribl Stream as an authorized application with the Microsoft Identity Platform.

Use Copy buttons, where available, to copy complete values for later use without truncation.

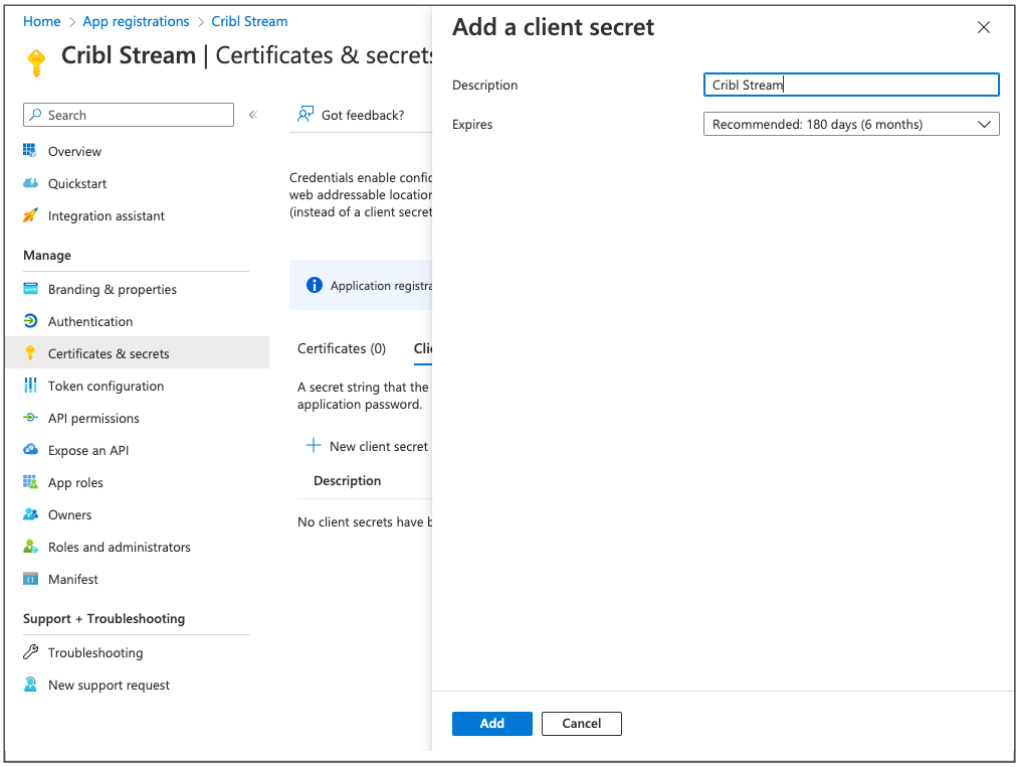
Create Credentials for a New Azure Application

1. Log into the **Azure** portal as an `Administrator`.
2. Navigate to the portal's **App registration** section.
3. Click **New registration** to register an application.
4. Register a new application with the name `Cribl Stream`.



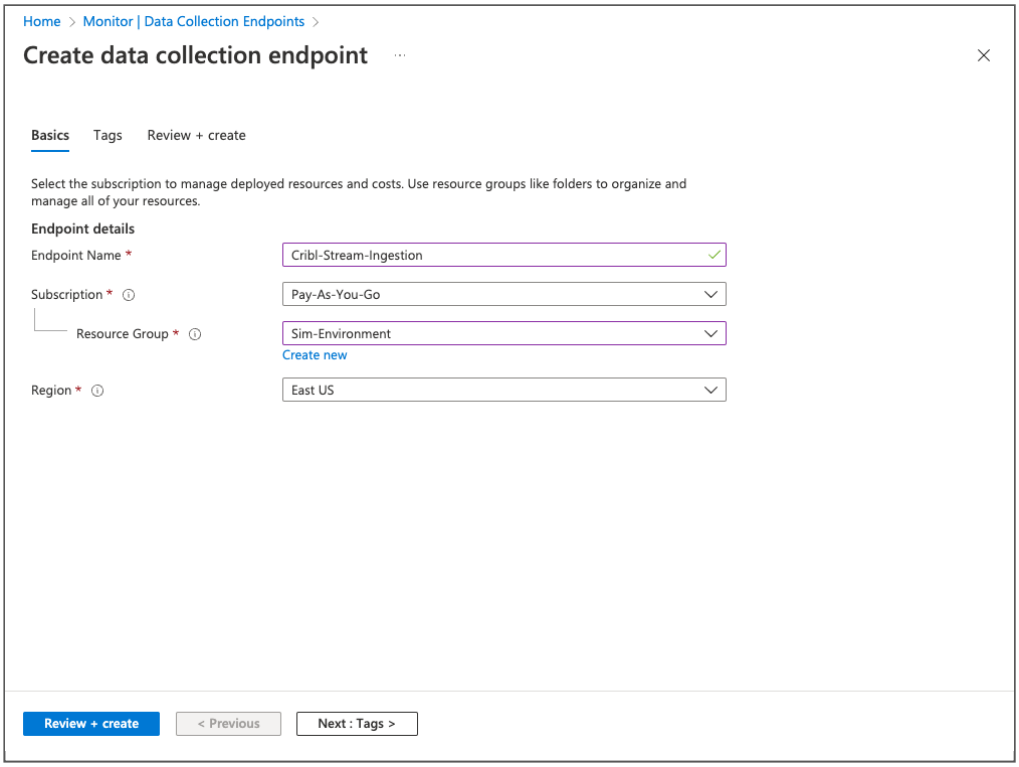
Registering an Application

5. Click **Register**.
6. Store the **Application (client) ID** and **Directory (tenant) ID** for later steps.
7. In your newly registered application, select the **Certificates & secrets** tab.
8. Create a **New client secret**.
9. Store the secret **Value** for later steps.



Create a Data Collection Endpoint

1. Navigate to the Azure portal's **Monitor** service.
2. Under **Settings**, select **Data Collection Endpoints**.
3. Select **Create** to add a new endpoint named `Cribl-Stream-Ingestion`.
4. Select the appropriate Subscription and Resource Group used by your organization.
5. Select **Review + create**, review your changes, then select **Create**.
6. In the list of **Data Collection Endpoints**, open the newly created endpoint. (You might need to refresh the page to see it.)



Creating a Data Collection Endpoint

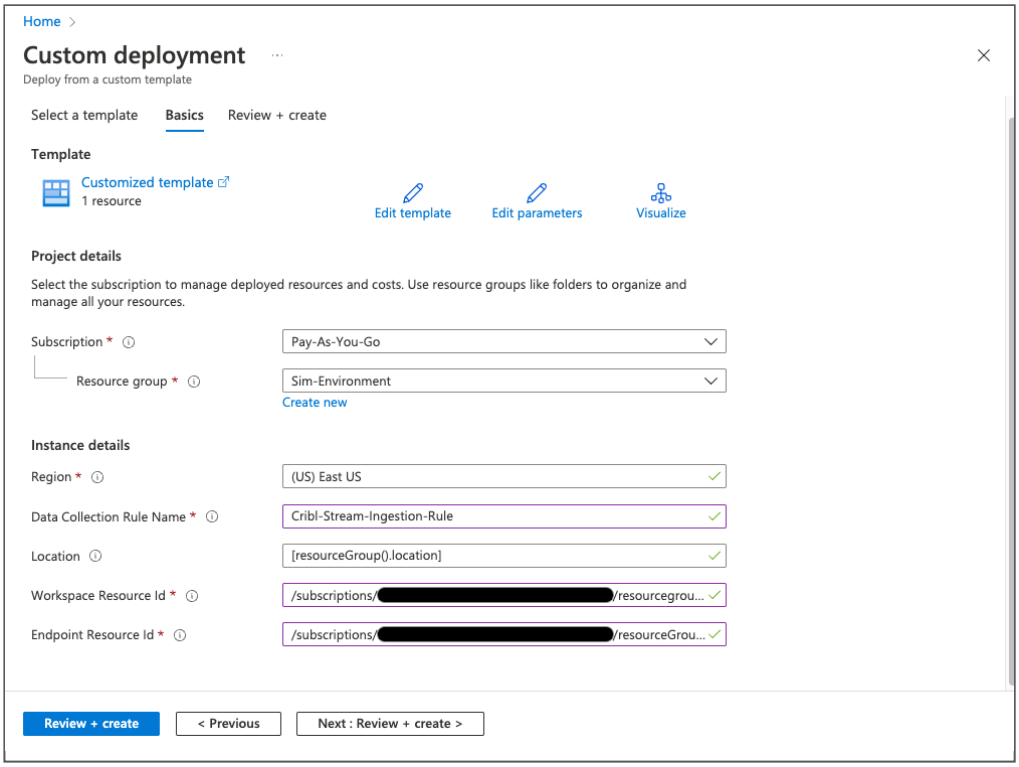
7. Navigate to the **Overview** page, and copy and store the **Logs Ingestion** URL.
8. Select **JSON view**, and store the value of the **Resource ID** (gray box at the top) for later use.

Find the Log Analytics Workspace Resource ID

1. Navigate to the Azure portal's **Log Analytics workspaces** service.
2. Select the workspace that will receive data.
3. From the **Overview** page, select **JSON view**, and store the value of the **Resource ID** (gray box at the top) for later use.

Create Data Collection Rule

1. Navigate to the Azure portal's **Deploy a custom template** service.
2. Select **Build your own template in the editor**.
3. Select **Load file** and upload the DCR Template.
4. Click **Save**.
5. Select the appropriate Subscription and Resource Group used by your organization.
6. Name the new Data Collection Rule `Cribl-Stream-Ingestion-Rule`.
7. Enter the Log Analytics **Workspace Resource ID**, and the Data Collection **Endpoint Resource ID**, that you stored in the previous steps.
8. To create the Data Collection Rule, click **Review + create**, followed by **Create**.

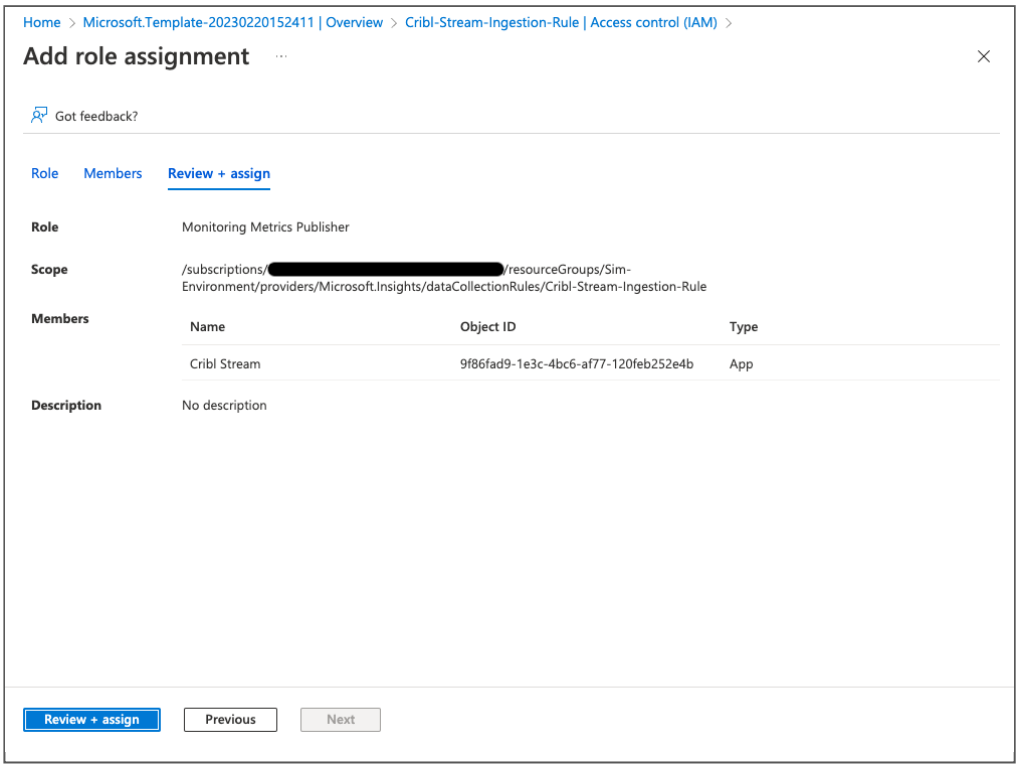


Registering an Application

Add Role Assignment

1. Once the template has been deployed, click **Go to resource**.
2. From the Overview page, select the **JSON view**, and store the **immutableId** from the JSON body (without quotes) for later use.
3. Click the Data Collection Rule's **Access control (IAM)**.
4. Click **Add role assignment**.

5. Select the **Monitoring Metrics Publisher** role, then click **Next**.
6. Click **+ Select members**.
7. Search for and select `Cribl Stream` (the app you created earlier), then click **Select** to confirm the selection.
8. Click **Review + assign** to review changes.
9. Click **Review + assign** again to implement the permissions update.



Adding a Role Assignment

15.8.2.2. Azure Event Hubs Integrations

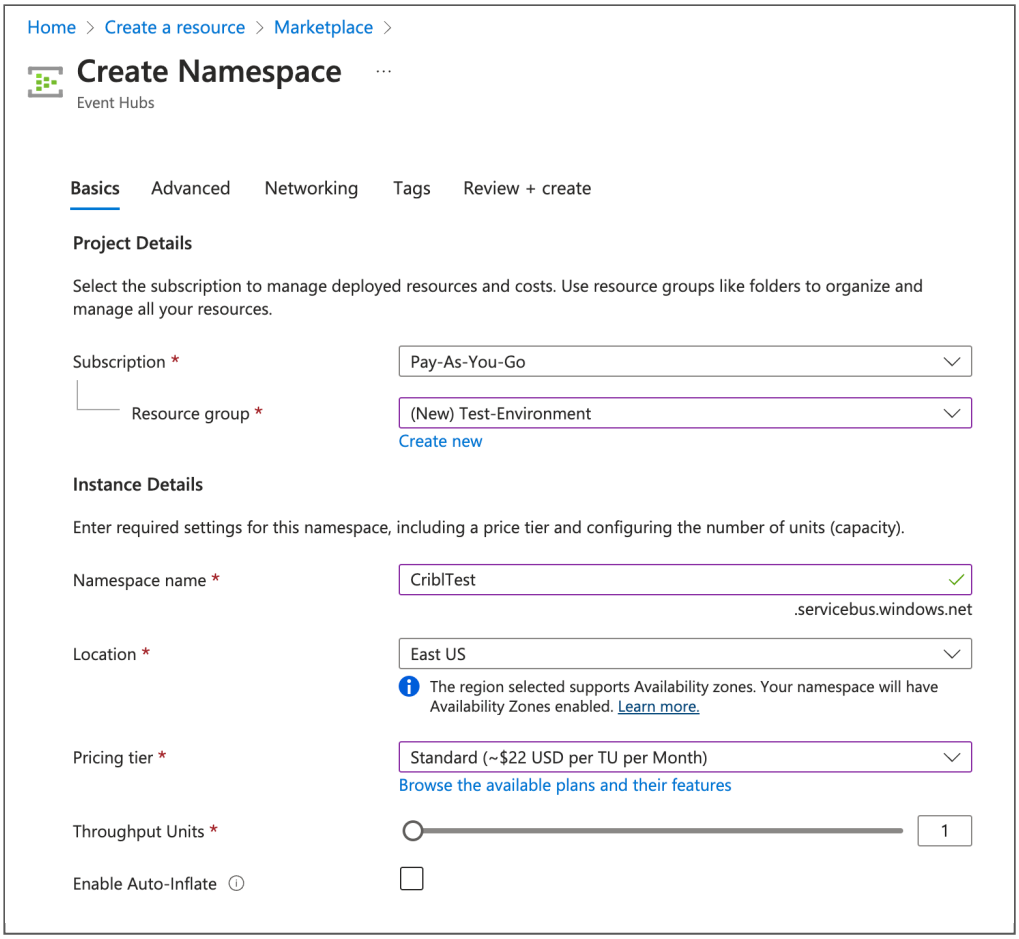
To ingest data from an Azure Event Hub, you can create an Event Hub and a Cribl Stream Azure Event Hubs Source configured to consume data from the Event Hub. This page documents that integration.

Your Azure Event Hubs account must be at the Standard (or a higher) pricing tier, because the Basic pricing tier does not support the PLAIN authentication method Cribl Stream uses for Event Hubs.

Prepare Azure Event Hubs to Send Data to Cribl Stream

First, create an Azure Event Hub as described in the Azure documentation.

In this tutorial, we use `CriblTest` as the **Namespace name**. You can use any **Namespace name** you like, as long as it is unique across Azure.

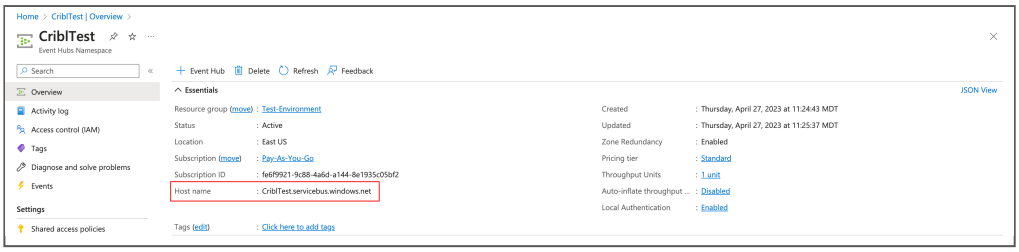


Creating an Event Hubs Namespace

Collect the information you will need when configuring Cribl Stream:

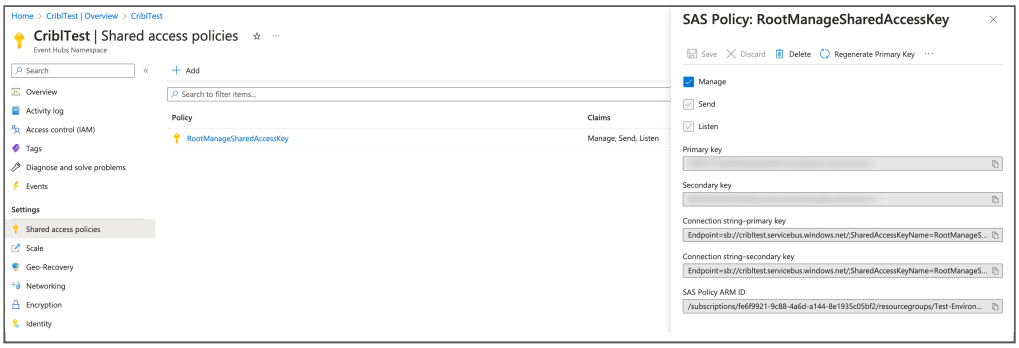
1. In the **Deployment** page, click **Go to Resource**.

2. Copy the **Host Name** and store it.



Finding the Host name and Shared access policies

3. Click **Shared Access Policies** to open the page where you can select policies for your Event Hubs Namespace, and then click `RootManageSharedAccessKey` to show details for that policy.



Viewing Shared access policies

4. Copy and securely store the **Connection String-primary key**.
5. Click on Event Hubs on the left-hand column and copy the Event Hubs name you want to ingest.

Restricting Public Network Access for Cribl.Cloud Deployments

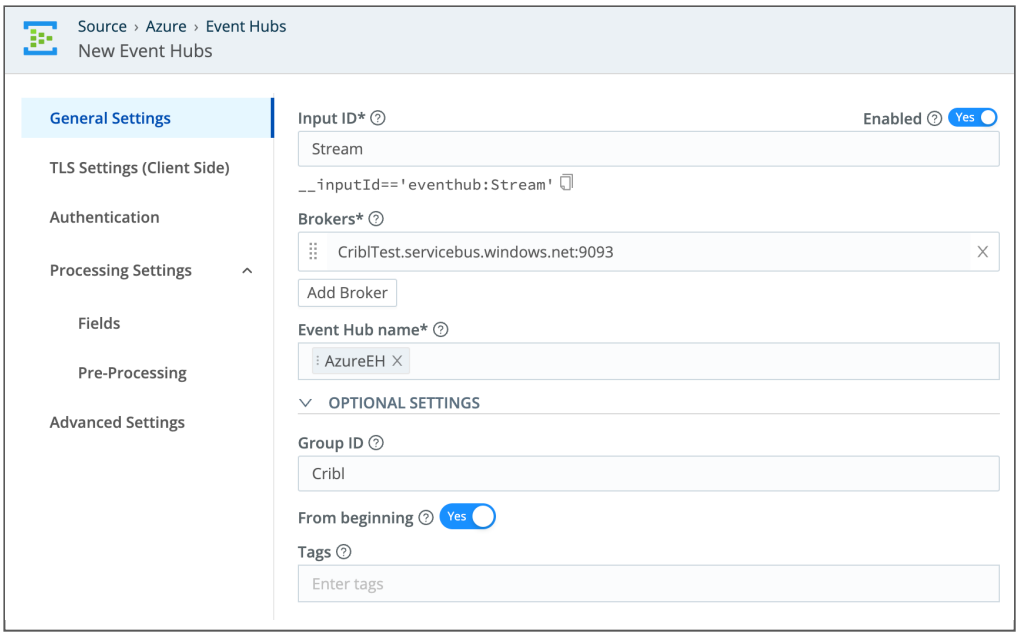
If you are using a Cribl.Cloud deployment, you have the option of restricting public network access to the Event Hubs environment.

To restrict access, you will need to obtain the egress IP in your Cribl.Cloud portal, then use it to configure public network access in the Event Hubs environment.

1. To obtain the egress IP, click **Access Details** and copy the **Egress IP** of your Cribl.Cloud Organization.
2. In the Azure Event Hubs environment, select **Networking** > **Public network access** > **Selected networks**.
3. On that same page, paste the Cribl.Cloud egress IP into the **Address range** field in the Event Hubs environment.

Configure the Azure Event Hubs Source in Cribl Stream

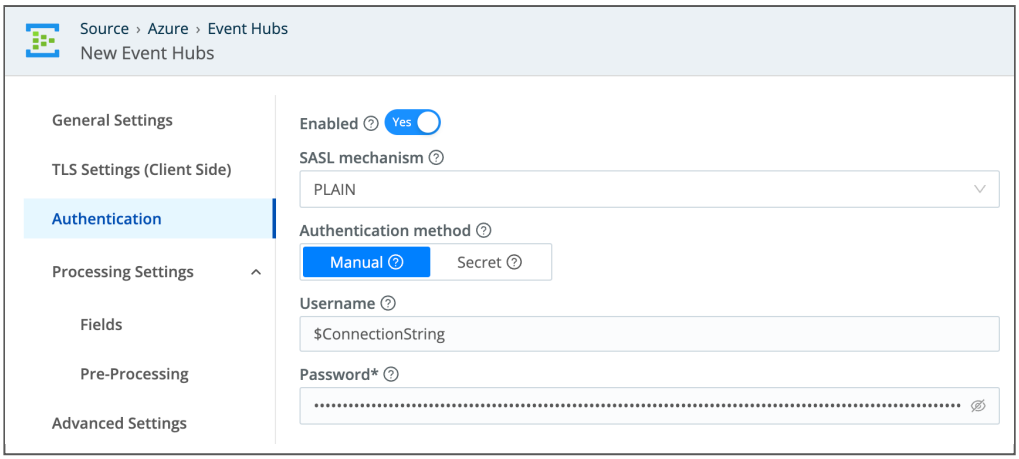
1. From a Cribl Stream instance's or Group's **Manage** submenu, select **Data** > **Sources**, then select **Azure Event Hubs** from the **Manage Sources** page's tiles or left nav. Click **New Source** to open the **Azure Event Hubs** > **New Source** modal.
2. In the **General Settings** tab, enter the following values:
    - **InputId**: An **InputId** of your choice. For example: `Stream`.
    - **Brokers**: End the Host Name you wrote down earlier and append port `9093`. For this example: `CriblTest.servicebus.windows.net:9093`.
    - **Event Hub Name**: The name of your Azure Event Hub. For this example: `AzureEH`. The **Event Hub Name** is equivalent to a Kafka topic. It should not be the same as the Azure Event Hubs namespace value you created above.
    - **Group ID**: This value can be `Cribl`, but the **Group ID** cannot be shared with other technologies. Sharing this value across technologies may cause unexpected behavior, such as failing to collect logs reliably.



The General Settings tab

3. In the **Authentication** tab, enter or select the following values:
    - **SASL mechanism**: Options include `PLAIN` and `OAUTHBEARER`.
    - **Username**: `$ConnectionString` (the default generated by Azure).
    - **Authentication Method**: Select `Manual` to use the Connection String Key generated by Azure Event Hubs.

- **Password**: Enter the **Connection String-primary key** that you copied earlier.



The Authentication tab

Verify that Data is Flowing from Your Azure Event Hub to Cribl Stream

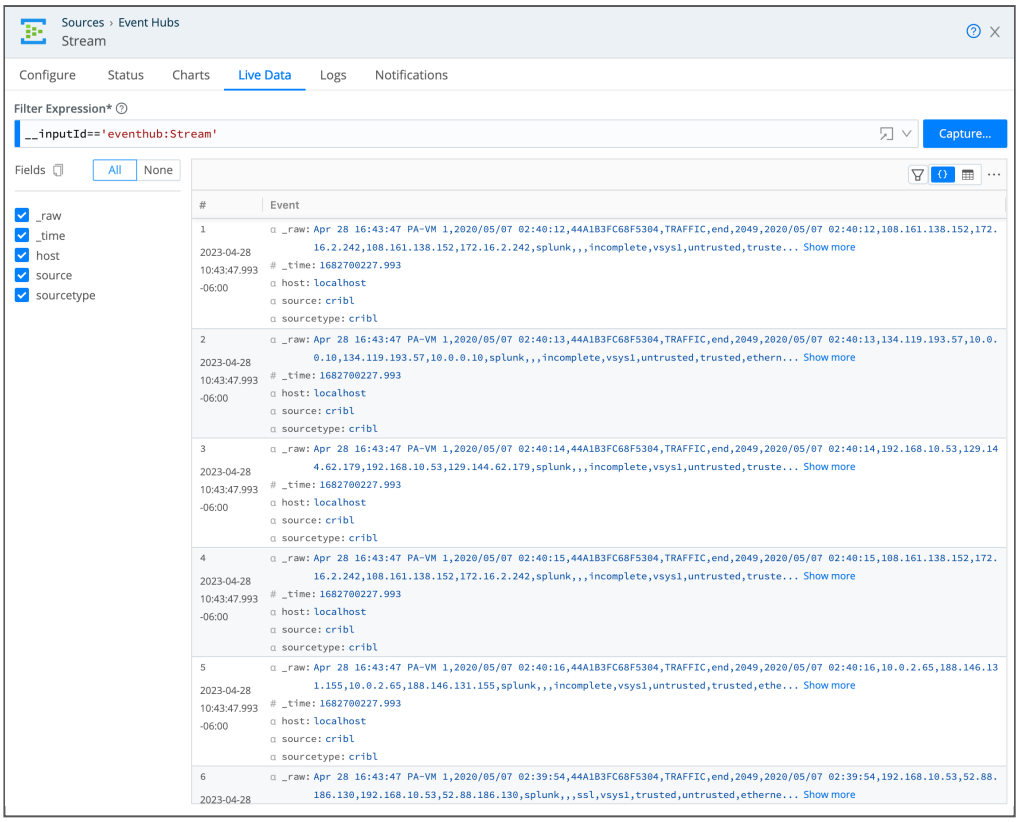
Before you can verify that data is reaching Cribl Stream, you must ensure that it is flowing out of your Azure Event Hub in the first place.

One option is to configure a Datagen and a Route to send data to the Event Hub destination. We'll assume you have done that, or gotten data flowing from your Azure Event Hub in some other way.

1. In Cribl Stream, open the **Sources** > **Azure Event Hubs** > **Cribl Stream** page. This should show your Source, with a message confirming that it is working properly.

A working Source

2. Open the **Live Data** tab. You should see the data that is flowing from your Azure Event Hub to Cribl Stream.



Viewing Live Data

15.8.2.3. Microsoft Sentinel SIEM Integration

You can send events through Cribl Stream Microsoft Sentinel Destinations to the Microsoft Sentinel SIEM in Azure.

This use case demonstrates how to send data from Cribl Stream to Microsoft Sentinel in various Azure environments, including Azure Public Cloud, Azure US Government Cloud, and Microsoft Azure operated by 21Vianet. While we'll cover key points about the Cribl Stream Microsoft Sentinel Destination here, you should refer to the Sentinel Destination topic for complete UI details.

Before You Begin

Ensure that you have prepared your Azure Workspace. You must complete this step before you can send events through the Microsoft Sentinel Destination to the Microsoft Sentinel SIEM.

If you do not yet have Microsoft Sentinel up and running, please join us on Cribl's Community Slack at https://cribl-community.slack.com/ and let us know; very likely, a wise goat will offer time-saving suggestions.

Event Types

Of the many event types (also called "tables") present in the Microsoft ecosystem, this topic provides what you need to get started quickly with any or all of the following four:

- CommonSecurityLog
- SecurityEvent
- Syslog
- WindowsEvent

We'll also explain how you can bring additional event types into your deployment.

To plan your Cribl/Sentinel integration, start by deciding which event types (a.k.a. tables) you want to send to Sentinel.

If the answer is "more than one," you should use an Output Router and multiple Destinations. You'll configure one Destination per table, but a single URL will ingest all the data. The Output Router can then route a given event type to the correct Destination.

The four event types above belong to the much larger set of event types that the Azure Monitor provides in its Logs Ingestion API. You can work with any of these event types as you would the four types above. See the Appendix below for the full list.

Creating Data Collection Rules

The Sentinel SIEM can have multiple ingestion endpoints, called Data Collection Endpoints (DCEs). In turn, each DCE can have multiple Data Collection Rules (DCRs). A DCR can dictate the structure of the data flowing into one table, or multiple tables.

Cribl's template is an example of a custom DCR that sends data to four different tables, one for each of the four event types enumerated above.

Alternatively, you could populate one table with different kinds of data. For example, you could define a table for the Syslog event type, and then create a **separate** DCR for Windows, Linux, and Mac system logs, respectively, all of which would populate that single table.

Besides the Azure documentation, you can study the Cribl template to understand how DCRs are structured. For example, each table's columns are defined in a sub-element of the `resources` > `properties` > `streamDeclarations` element. The `dataFlows` element – at the same level as `streamDeclarations` – specifies the table that a given type of data should populate, via the `outputStream` sub-element. It also specifies the query that will translate incoming fields into values in the table's columns, via the `transformKql` sub-element.

Read more about DCRs in the Microsoft Sentinel documentation.

Custom DCR Template Errors

If you get an error such as `Table for output stream 'Microsoft-CommonSecurityLog' is not available for destination 'logAnalyticsWorkspace'`), it is probably because you don't have Sentinel assigned to your Log Analytics workspace. Please add Microsoft Sentinel to your Log Analytics Workspace to correct this error.

Obtaining Your URL

To configure your Cribl Stream Microsoft Sentinel Destination, you must know the ingestion URL to send data to. This is in **General Settings** > **Endpoint configuration**, where you choose between the **URL** and **ID** options. The **ID** option is just a somewhat roundabout method for generating the URL – in this section, we'll ignore **ID** in favor of an easier way to obtain the URL.

In your Azure portal:

1. Navigate to the Azure Resource Graph Explorer. The Resource Graph Explorer queries across your whole Azure cloud.

2. Run the following query in the Explorer to list all your Data Collection Endpoints (DCEs) and Data Collection Rules (DCRs).

```
Resources
| where type =~ 'microsoft.insights/datacollectionrules'
| mv-expand Streams= properties['dataFlows']
| project name, id, DCE = tostring(properties['dataCollectionEndpointId']), Immu
 | join kind=leftouter (Resources
| where type =~ 'microsoft.insights/datacollectionendpoints'
| project name,  DCE = tostring(id), endpoint = properties['logsIngestion']['enc
| project name, StreamName, Endpoint = strcat(endpoint, '/dataCollectionRules/',
```

3. If you are using all four of the tables mentioned above, the output should look something like this:

Azure Resource Graph Explorer query output

Problems with Resource Graph Explorer Queries

If you get zero returns or the query returns unexpected data, be sure you have properly prepared your Azure workspace. This step is a preprequisite.

4. Click a DCE of interest to open its **Details** drawer.
5. Find the **Endpoint** field and click its **Copy to clipboard** icon.
    - Microsoft defines the Endpoint URI as follows:

```
{Data Collection Endpoint URI}/dataCollectionRules/{DCR Immutable ID}/streams/{S
```

6. In your Cribl Stream Microsoft Sentinel Destination, paste the copied Endpoint URI into the **URL** field.

Configuring Your Destinations, Continued

In most respects, Cribl Stream's Microsoft Sentinel and Webhook Destinations are alike. This section notes the few differences, while highlighting key points about configuring Microsoft Sentinel Destinations.

In Microsoft Sentinel Destination, **General Settings** > **Authentication** offers fewer options than the Webhook Destination. This is because OAuth is Cribl Stream's only supported option for Microsoft Sentinel, for now. Some fields that present in other Destinations always have the same values for Microsoft Sentinel, and Cribl Stream fills those out for you without exposing them in the UI.

The Microsoft Sentinel Destination does not support client-side TLS.

The value for **Advanced Settings** > **Max body size (KB)** value defaults to `1000`. The intent here is to keep request bodies from exceeding Microsoft Sentinel's limit of 1 MB, meaning 1024 KB including headers. If necessary, you can lower **Max body size (KB)** even further.

Appendix: Azure Monitor Logs Ingestion API Event Types

Here's the whole list – note that this includes event types for AWS and for Google Cloud Platform (GCP).

Category	Event Type
Active Directory	ADAssessmentRecommendation
	ADSecurityAssessmentRecommendation
Advanced Security Information Model (ASIM)	ASimAuditEventLogs
	ASimAuthenticationEventLogs
	ASimDhcpEventLogs
	ASimDnsActivityLogs
	ASimDnsAuditLogs
	ASimFileEventLogs
	ASimNetworkSessionLogs
	ASimProcessEventLogs
	ASimRegistryEventLogs
	ASimUserManagementActivityLogs
	ASimWebSessionLogs
AWS	AWSCloudTrail
	AWSCloudWatch
	AWSGuardDuty
	AWSVPCFlow

Category	Event Type
Azure	AzureAssessmentRecommendation
Common Event Format (CEF)	CommonSecurityLog

        {
            "name": "TemplateOID",
            "type": "string"
        },
        {
            "name": "TemplateSchemaVersion",
            "type": "string"
        },
        {
            "name": "TemplateVersion",
            "type": "string"
        },
        {
            "name": "TimeCollected",
            "type": "datetime"
        },
        {
            "name": "TimeGenerated",
            "type": "datetime"
        },
        {
            "name": "TokenElevationType",
            "type": "string"
        },
        {
            "name": "TransmittedServices",
            "type": "string"
        },
        {
            "name": "UserAccountControl",
            "type": "string"
        },
        {
            "name": "UserParametersUserParameters",
            "type": "string"
        },

15.8.3. Splunk

15.8.3.1. Splunk Cloud Platform And BYOL Integrations

The Splunk HTTP Event Collector (HEC) is the preferred method for integrating with the Splunk Cloud Platform. It's easy to set up, offers superior compression, and efficiently load balances data across multiple indexers in a distributed Splunk environment. While Splunk-to-Splunk (S2S) can be used for specific scenarios, such as legacy integrations or granular data distribution, HEC generally provides a more straightforward and efficient integration process.

Cribl Stream provides multiple integrations for sending data to the Splunk Cloud Platform. The following table outlines the supported Cribl Stream Destinations and Splunk protocols for different Splunk Cloud Platform deployment scenarios:

Cribl Stream Destination	Splunk Protocol	Splunk Deployment
Splunk HEC Destination	Splunk HEC	- Distributed Splunk Cloud Platform - Bring Your Own License (BYOL) deployment (either in a non-Splunk cloud or on-prem)
Splunk Load Balanced Destination	S2S	- Distributed Splunk Cloud Platform - BYOL deployment
Splunk Single Instance Destination	S2S	- Single-instance Splunk Cloud Platform (trial or smaller deployments)

For BYOL deployments, leverage the `.pem` and `outputs.conf` files already in use on your Splunk Universal Forwarders to maintain consistency and simplify the security setup. The Splunk documentation has detailed instructions on securing your Splunk indexers to ensure the overall security of your deployment.

15.8.3.2. Switch Cribl Stream Destinations From S2S To Splunk HEC

This guide is for users that want to change their Splunk data flow from using Splunk to Splunk (S2S) to HTTP Event Collector (HEC). The guide will provide step-by-step instructions for making this change.

Prerequisites

You must have the following prerequisites before following this guide:

- A Cribl Stream instance
- A Splunk instance

Configure the queue Setting

If you have numerous index-time extractions in Splunk Technology Add-ons (TAs), be aware of potential data quality impacts. By default, Splunk HEC sends data through a queue that might apply these extractions, altering your data.

To bypass index-time extractions and send data directly to the `indexQueue`, configure the `queue` setting in Splunk's `inputs.conf` file **for the Cribl integration only, on a per-token stanza level**. Changing the `queue` setting in the **global** stanza of `inputs.conf` will impact all HEC tokens and may have negative consequences for other HEC-based integrations.

1. Locate and open the `inputs.conf` file on your Splunk instance. This file is typically located in the `$SPLUNK_HOME/etc/system/local` directory.
2. Add or modify the following within the file:

```
[http://cribl]
disabled = 0
index = main
token = ${SPLUNK_HEC_TOKEN}
queue = indexQueue
```

3. Replace `${SPLUNK_HEC_TOKEN}` with your actual HEC token.
4. Save the `inputs.conf` file and restart the Splunk instance for the changes to take effect.

If you are using Splunk Cloud, you must open a ticket with Splunk to request a change to the `inputs.conf` file. Make sure you request that they change the `queue` setting only for the Cribl

integration, not on a global level.

Create the Splunk HTTP Event Collector Token

Once you complete this section, you will have a new HEC token in Splunk that can receive data from Cribl Stream.

1. Log in to Splunk.
2. Navigate to **Settings** then **Add Data**.
3. Select **Monitor** from the **Add Data** menu.

Select a Source

1. Choose **HTTP Event Collector**.
2. Enter a name for your token (`cribl-HEC` for example).
3. Click **Next**.

Validate Input Settings

1. For **Source type**, select **Automatic** (unless you are setting this token for a specific Sourcetype).
2. For **Index**, select your desired Allowed Indexes.

If you want to send Splunk logs such as data from `_internal`, set the Allowed Indexes to `N/A`. You may want different tokens for different types of data.

3. Click **Next**.

Review HEC Settings

1. Ensure that **Allowed indexes** it set to `N/A`, unless you want to restrict users to only send data to specific indexes using this token.
2. Click **Submit**.

You should now have a new, valid HTTP Event Collector (HEC) token that you can use with Cribl Stream. This token allows Cribl Stream to receive events for any index that is available in Splunk.

Create a Splunk HEC Destination in Cribl Stream

Using the token you just created in Splunk, create a Splunk HEC Destination in Cribl Stream.

1. Log in to Cribl Stream.
2. Click **Data** then **Destinations**.
3. From the resulting page's tiles or the **Destinations** left nav, select **Splunk**, then > **HEC**
4. Click **Add Destination** to open a **New Destination** modal and fill in the required fields:

Field	Configuration
Output ID	Enter a descriptive name for your Destination.
Load balancing	Decide whether to enable Load Balancing for this Destination.
Splunk HEC Endpoints	Enter the endpoint for your Splunk instance, in the following format: `https://http-inputs-<CLOUD_ORG>.splunkcloud.com/services/collector/event`
Authentication method	Set to **Manual**.
HEC Auth token	Enter the Splunk HEC API access token from the Create the Splunk HTTP Event Collector Token section.

5. Depending on your data volume and event size, you may also want to tune Advanced Settings (**Max body size**, **Request concurrency**, **Flush period (sec)**). See Splunk HEC Advanced Settings for specific guidance.
6. Click **Save**.
7. In a Distributed deployment, you'll also need to **Commit & Deploy** to push the configurations to your Workers.

Test the Destination Connection

1. Open the Splunk HEC Destination you just created and click the **Test** tab.
2. Add the index field to **Test input** and click **Run test**.
3. Check the bottom of the **Test** tab. If the banner shows a green Success indicator, your endpoint and token are valid.

Switch from S2S to Splunk HEC

Now, you can switch from Splunk S2S to HEC Destination.

1. In Cribl Stream, navigate to **Data** then **Destinations**.
2. Choose either **Splunk Single Instance** or **Splunk Load Balanced** depending on which applies to you.
3. Open the Splunk S2S Destination and check for any **QuickConnects** Sources.

4. Click directly on a Source in this column to it.
5. Switch all **QuickConnects** Sources from the Splunk S2S Destination to the Splunk HEC Destination.

Check Routes and Packs

Once you've switched all QuickConnects references to Splunk HEC:

1. Navigate to **Processing**, **Packs** and **Routing**, **Data Routes** and look for references to the Splunk S2S Destinations:
    - On the **Data Routes** page.
    - On the **Routes** page for the Pack.
2. Change the Splunk S2S Destinations you find to the Splunk HEC Destination.
3. Once you're finished, **Commit & Deploy** the changes. In standalone instances, the changes take place as soon as you save them.

We recommended that you make these changes incrementally and validate each change inside of your Splunk instance for any data irregularities before you move on.

Now, you've successfully switched all Splunk S2S Destinations in Cribl Stream to the Splunk HEC Destination.

15.8.3.3. Splunk To Elasticsearch

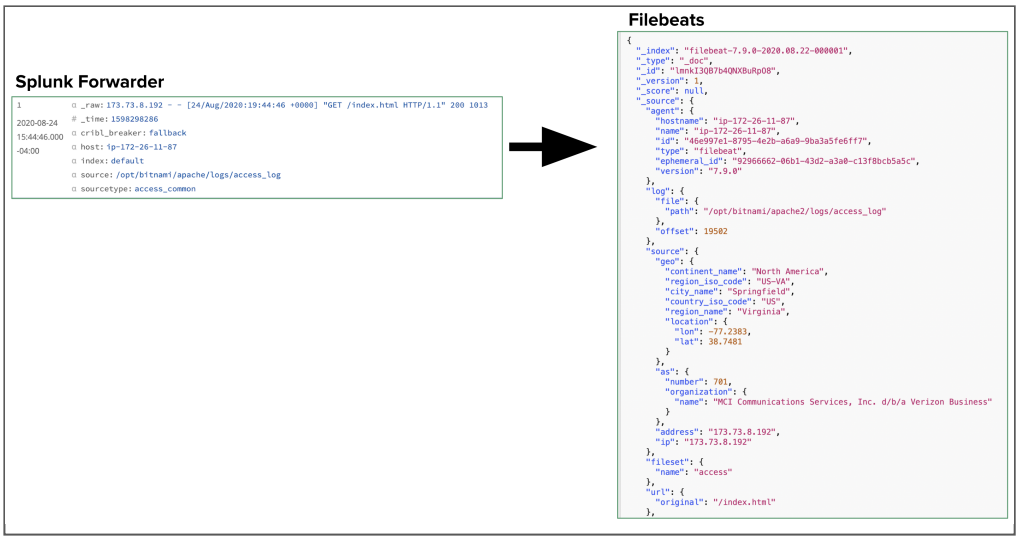
To route data from existing Splunk infrastructure to Elasticsearch services, you might face a daunting task: re-architecting your entire forwarding tier. This could require retooling lots of servers – up to hundreds, or thousands – to uninstall their Splunk forwarders, and swap in Elastic-compatible agents.

Cribl Stream can reduce this effort to just a few hours: Configure one Splunk `outputs.conf` stanza to output to Cribl Stream, and propagate that across all your Splunk servers. Done!

Next, you can easily configure Cribl Stream to listen for Splunk data on one port, and to route that data to all the Elasticsearch destinations you want to feed.

Transforming Data from Splunk to Elastic Format

Also, in Cribl Stream's core, you can easily design a Pipeline that modifies the original Splunk event into Elastic's Common Schema – making it look exactly like an event generated by an Elastic agent. These transformations help you make the most of Elastic's offerings, like Filebeats, etc.



Transforming to Elastic Common Schema

Some of the Cribl Stream Functions useful in transforming Splunk-generated events into Elastic's format are:

- Regex Extract: Extract a portion of the raw event, and place it into a specified field.
- Lookup: key off the host IP to add fields like `hostname`, `name`, `id`, and `type`.
- Eval: Turn key-value pairs into nested JSON objects.
- GeoIP: Correlate source IP to a geographic database.

We'll show all four in our example Pipeline below, although you might need only a subset.

Goat Rid of Some Guesswork

Cribl Stream will offer you further time savings as you configure the internal data transformation. Cribl Stream's Data Preview features enable you to test transformations' results as you build your Pipeline, before you commit or run it.

This eliminates blind guesswork in Splunk configuration files to specify source -> index transformations, check the results, and then start all over again. In particular, Cribl Stream's Regex Extract Function provides a regex101-like UI, to facilitate precisely designing and debugging your regex expressions.

Let's goat started on the example.

Configure Splunk Forwarder

First, in a Splunk App, configure a Splunk forwarder (UF or HF) to specify your Cribl Workers as destinations. Use outputs.conf stanzas of this form:

.../outputs.conf

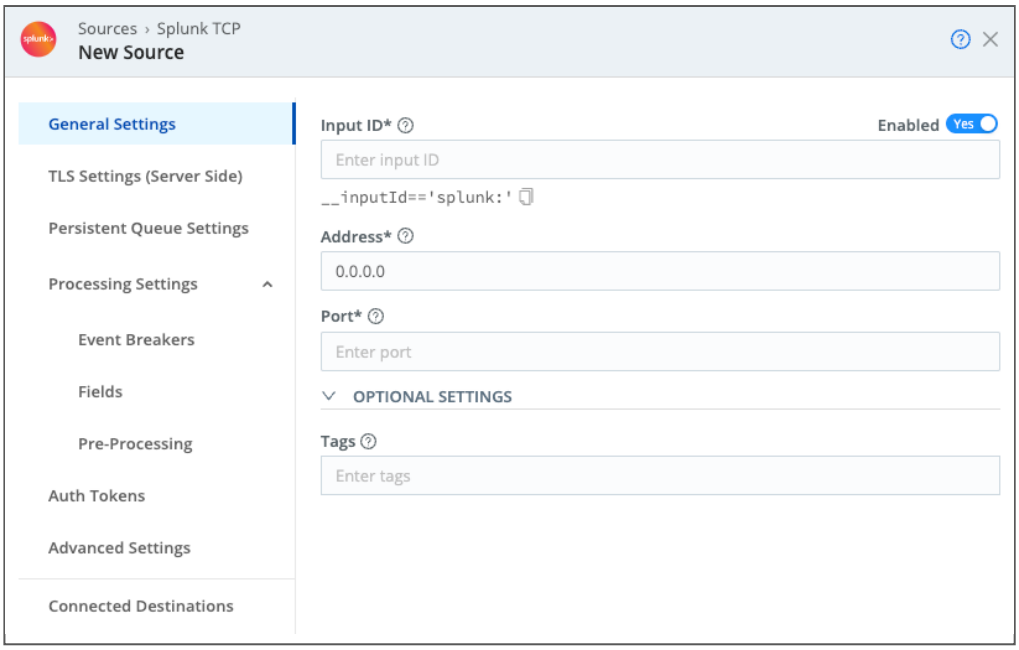
```
[tcpout]
disabled = false
defaultGroup = cribl, <optional_clone_target_group>, ...

[tcpout:cribl]
server = [<cribl_ip>|<cribl_host>]:<port>, [<cribl_ip>|<cribl_host>]:<port>, ...
sendCookedData=true
```

Push the app using the deployment server.

Configure Splunk Source in Cribl Stream

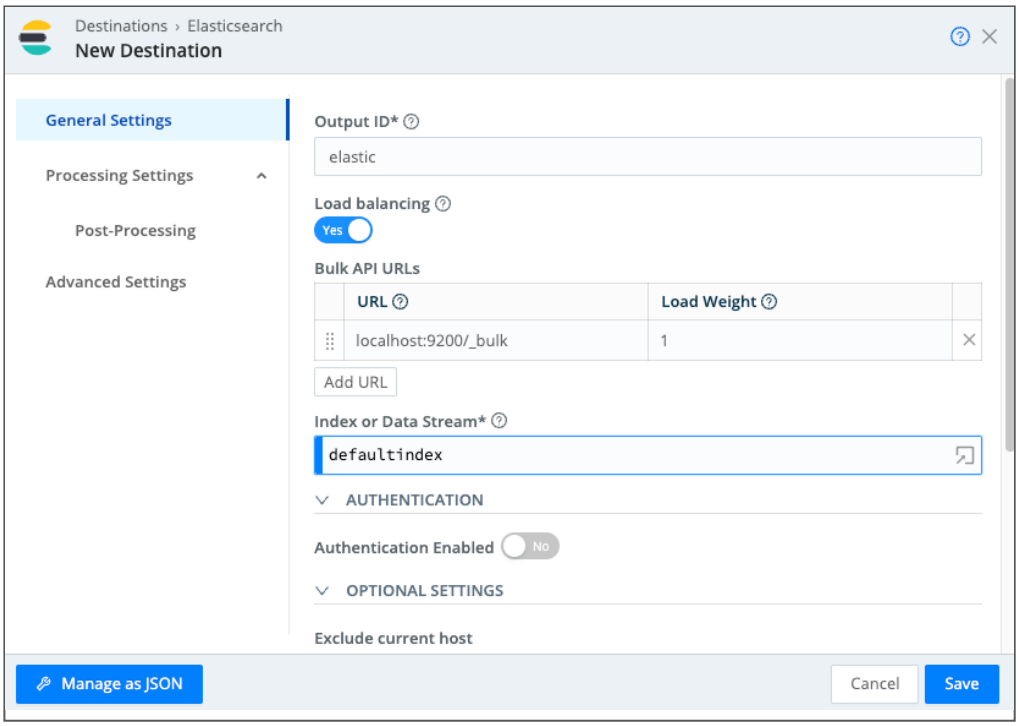
Next, in Cribl Stream, configure a Splunk Source. The key requirement here is to set the **Port** to listen on. (Optionally, you can also configure TLS, Event Breakers, metadata fields, and/or a pre-processing Pipeline.)



Splunk Source configuration

Configure Elasticsearch Destination

To configure Cribl Stream's output, set up an Elasticsearch Destination by specifying the **Bulk API URL** and **Index**.



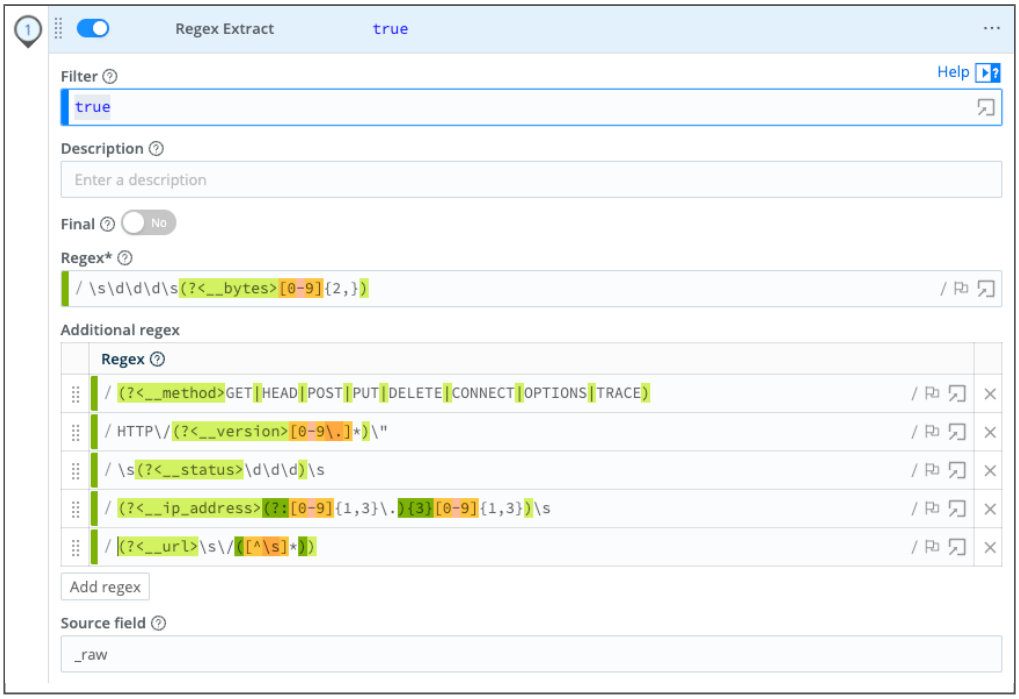
Elasticsearch Destination configuration

Configure Pipeline

Next, this section shows several Functions that you can assemble into a Pipeline to transform incoming Splunk events to match the Elastic Common Schema.

Regex Extract Function

First, use a Regex Extract Function to break the Splunk events into fields. Try the sample configuration shown below:



Regex Extract Function

Here are the six rows of regex in this example:

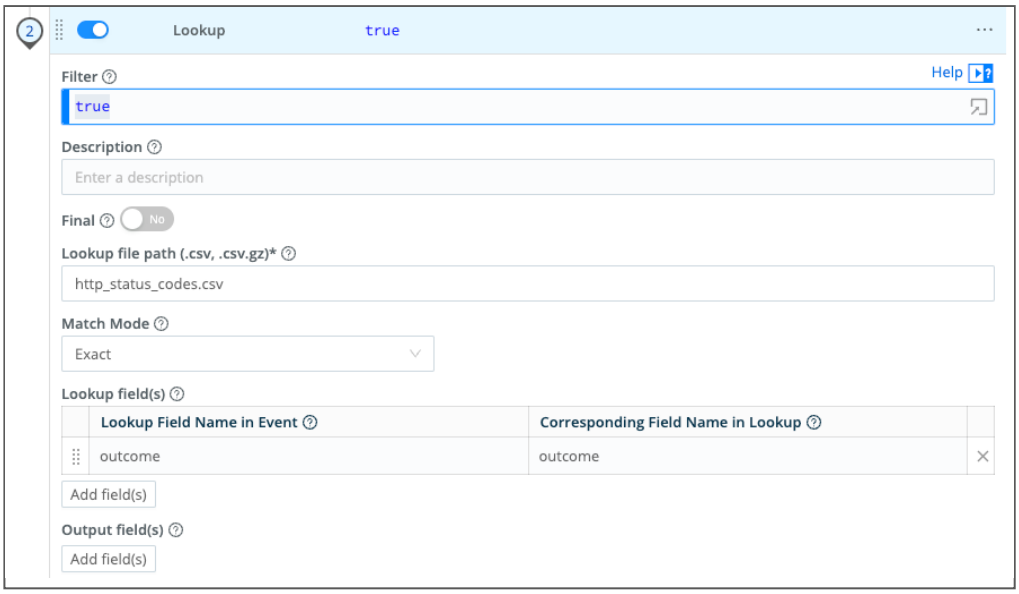
Regex; Additional Regex

```
/\s\d\d\d\s(?<__bytes>[0-9]{2,})/
/(?<__method>GET|HEAD|POST|PUT|DELETE|CONNECT|OPTIONS|TRACE)/
/HTTP\/(?<__version>[0-9\.]*)\"/
/\s(?<__status>\d\d\d)\s/
/(?<__ip_address>(?:[0-9]{1,3}\.){3}[0-9]{1,3})\s/
/(?<__url>\s\/([^\s]*))/
```

As you refine your expression, capture a sample of incoming Splunk data to test your regex's results in Cribl Stream's right Preview pane.

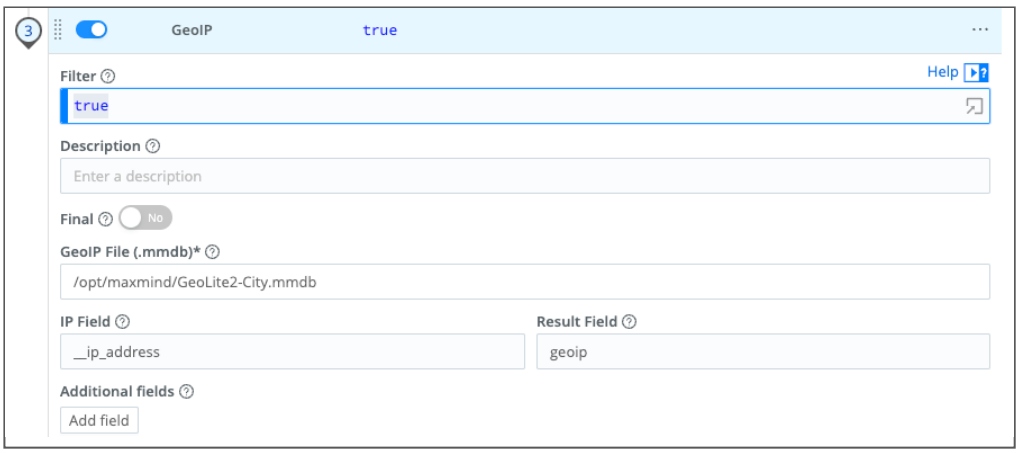
Lookup Function

In this example, we next add a Lookup Function, to translate HTTP error codes to readable text. Note this Function's optional **Reload Period** field, in which you can define a reload interval for a lookup file whose contents refresh frequently.



GeoIP Function

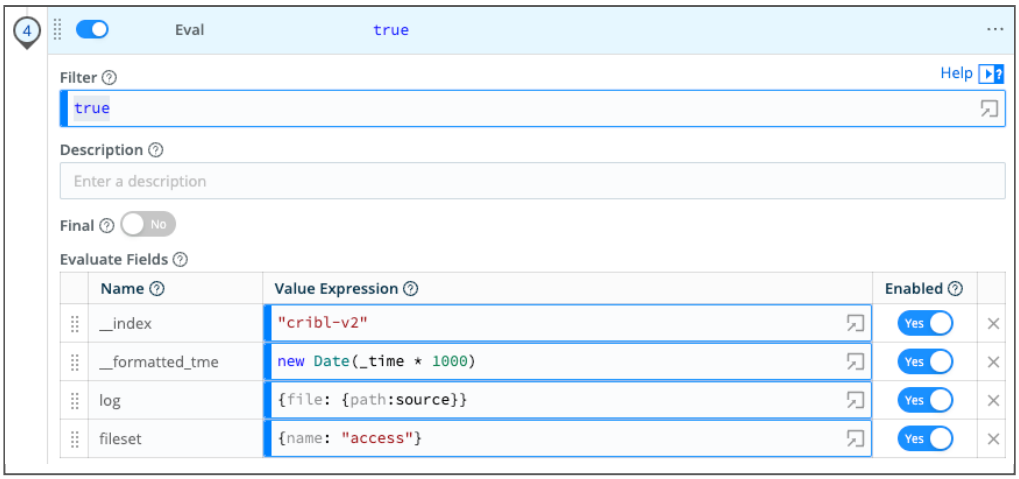
To enrich the Splunk data, we next use a GeoIP Function. This a specialized lookup against a database of IP addresses by geographic location. This Function's output can provide Elasticsearch with `location` fields like `lat` and `long`.



GeoIP specialized lookup

Eval Function

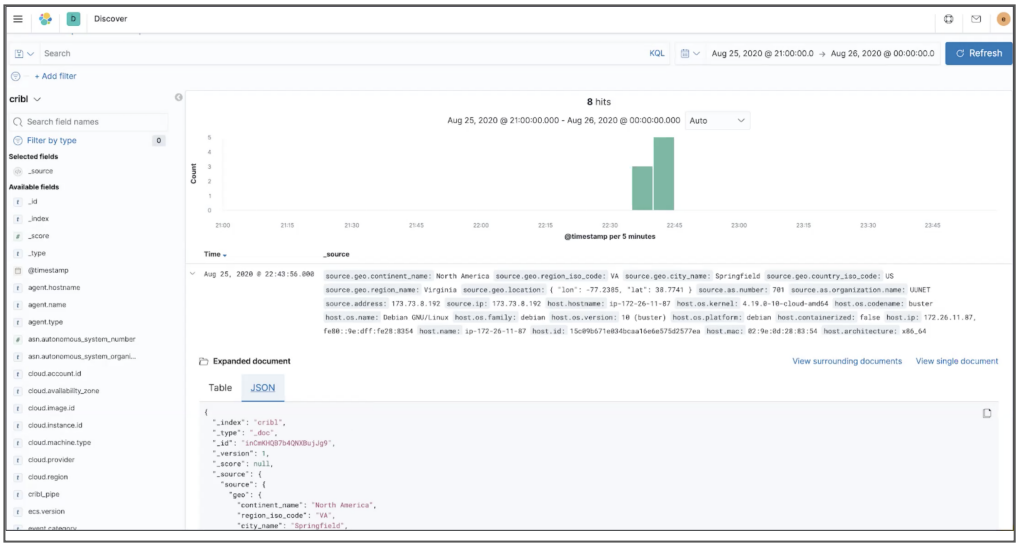
Finally, to further enrich the outbound events, the Pipeline uses an Eval Function. This adds multiple key-value pairs that define and populate fields conforming to the Elastic Common Schema.



Eval Function

Results

After attaching your Pipeline to a Route, here's an an exported event, all happy in Elasticsearch with nested JSON.



Event as exported to Elasticsearch

For More Info

For additional details on configuring Splunk forwarders for Cribl Stream, see this related documentation:

- Configuring a Splunk (TCP) Forwarder
- Configuring Cribl App for Splunk on an HF

15.8.3.4. Splunk To Exabeam

In many organizations, the IT department uses a tool like Splunk for operational logging, while the Security team relies on Exabeam to prevent insider threats. These tools use separate agents to access the same data, leading to some data-sharing conundrums:

- Installing the Exabeam agent in parallel with Splunk would duplicate the data.
- Some servers, like domain controllers, allow only a single agent. In this case, you can't feed two platforms with the same data.
- Querying Splunk for the data would introduce extra latency and overhead costs.
- Forwarding data directly from Splunk Universal Forwarders (UFs) is a nonstarter. Classic logs from Splunk UFs embed newlines and special characters, which break Exabeam's parser.

Cribl Stream can help you unblock these issues: Ingest data directly into Cribl Stream from Splunk UFs running on the domain controller, and transform the events in Stream before routing them to Exabeam.

While this example is written around a Splunk-to-Exabeam scenario, you can use the same general techniques to connect and transform data between several other upstream and downstream services.

Transform Data from Splunk to Exabeam's Format

In Cribl Stream's core, you can easily design a Pipeline that modifies the original Splunk event to fit the format that Exabeam expects. Some Cribl Stream Functions useful for this transformation are:

- Serialize: Remove all of the newlines and spaces, and then transform the data into `JSON` format.
- Mask: Remove the special characters, and replace them with space.
- Eval: Create a new field called `Message`, and remove everything else using the **Remove Fields** option.

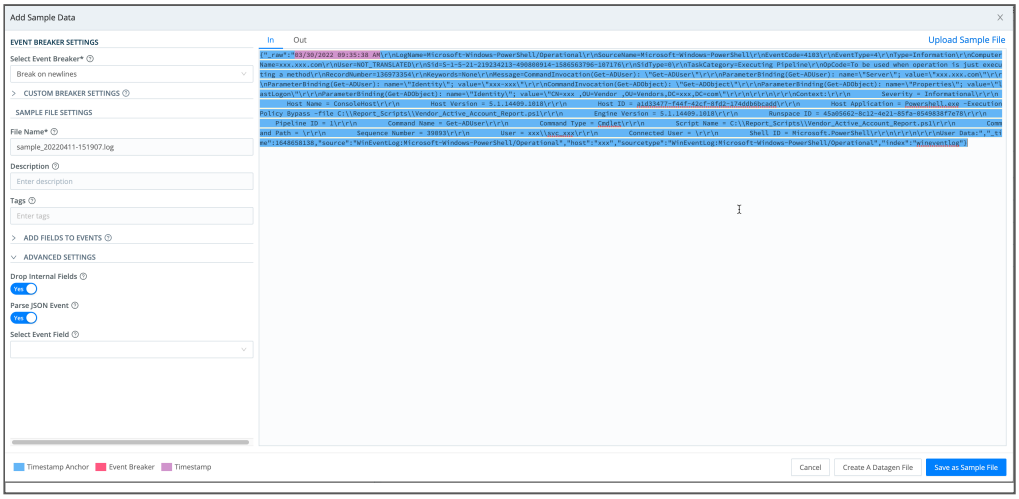
In this guide, we'll show you how to:

1. Capture sample logs.
2. Apply the Functions (outlined above) to transform the sample log into Exabeam's expected format.
3. Validate your fields with Exabeam Parsers.
4. Stream your event to Exabeam to test the entire sequence.

Capture Sample Logs

Start with sample logs of the event data you plan to work with. In our example, we'll copy and paste the log sample straight into Cribl Stream.

Once you've pasted the log sample, enter a unique **File Name** on the modal's left side, then select **Save as Sample File** at right.



Saving captured data

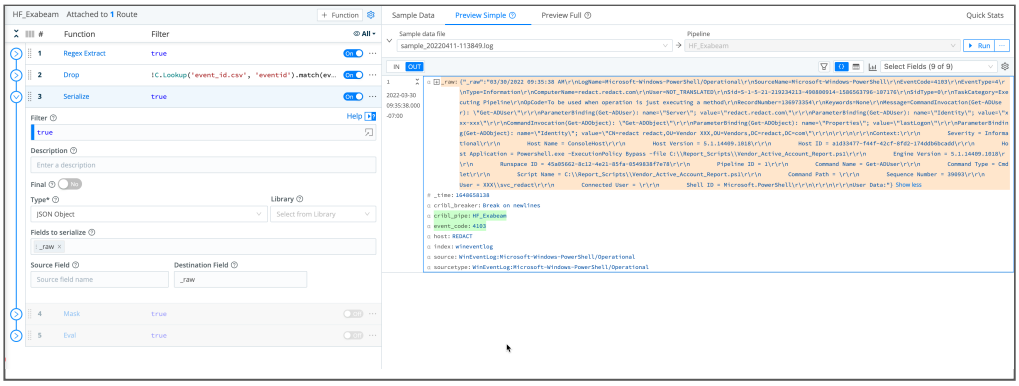
In your production environment, you can filter incoming events in real time (e.g., using a filter expression like `Windows Security logging`) to identify your in-scope Exabeam data.

Configure Pipeline

Next, this section shows relevant Functions that you can assemble into a processing Pipeline to transform the sample log into Exabeam's expected format.

Serialize Function

First, use a Serialize Function to change the event's format into `JSON`. Then, remove the extra lines and spaces, because Exabeam treats each newline as a separate event.

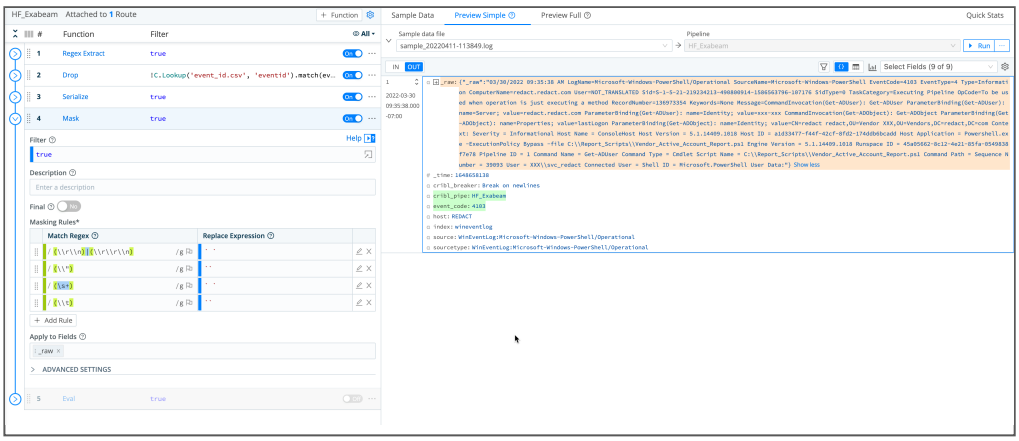


Reformatting the event

Mask Function

Next, use a Mask Function to remove extra `\n` and `\r` characters. (Otherwise, Exabeam's regex filter would reject the characters and drop whole fields that need to be matched and extracted.)

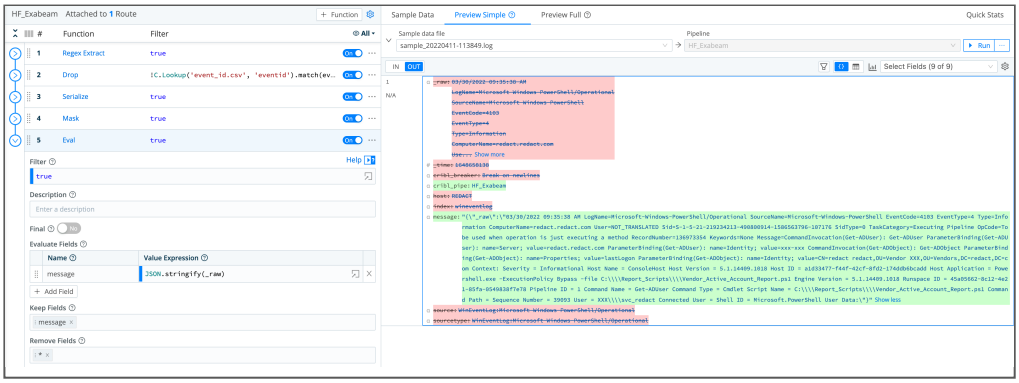
In this example, we are using a Mask Function to remove these special characters and replace them with spaces.



Extraneous newlines/returns to remove

Eval Function

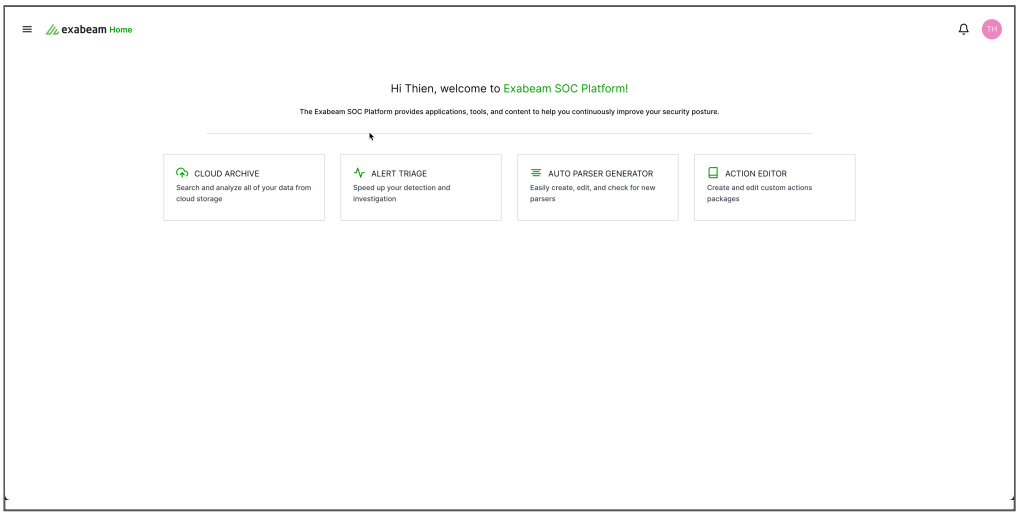
As the last step in Cribl Stream, use an Eval Function to enrich the outbound events, by adding key-value pair that defines and populates a field conforming to the Exabeam schema. Name the new field `Message`. (The `Message` field will populate `Raw Message` in the Exabeam Data Lake.) Remove everything else using **Remove Fields**.



Eval Function to add an Exabeam-specific field

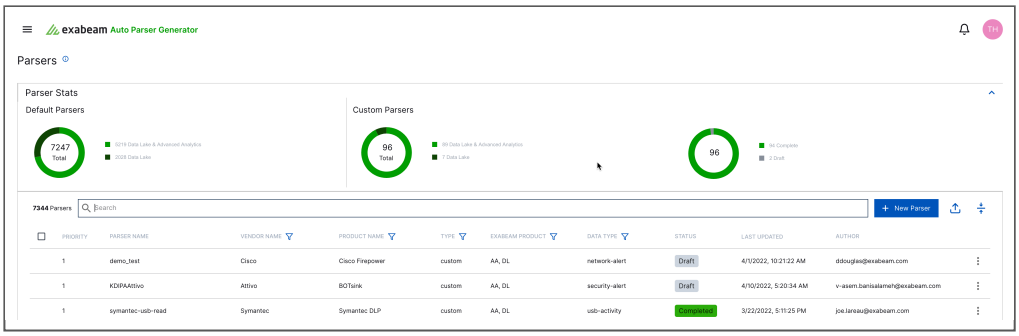
Goat the Fields?

Use Exabeam's Auto Parser Generator (APG) tool to validate your fields. If you don't have the APG tool, contact Exabeam support to request access via your ECP account. This tool validates matching parsers based on your event.



APG tool access in Exabeam

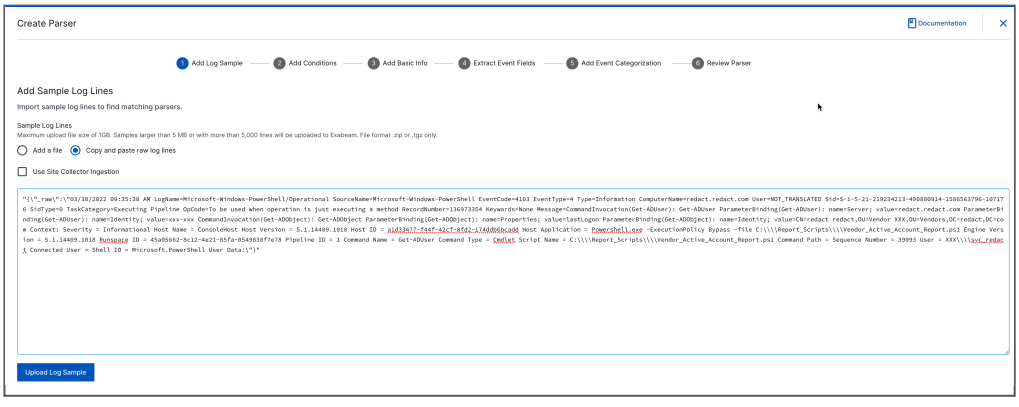
In the APG tool, select **New Parser**.



New Parser option

On the **Create Parser** page, select **Copy and paste raw log lines**.

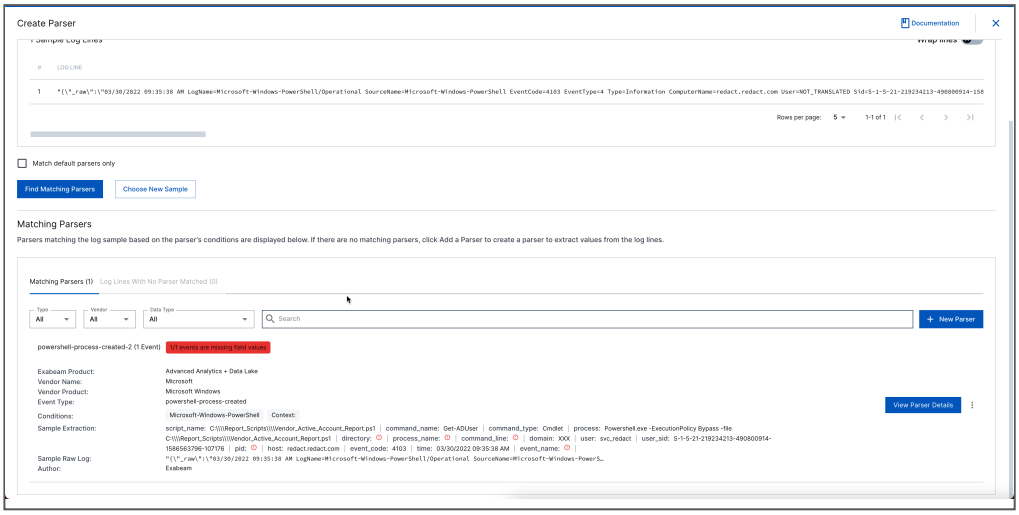
In the text box, paste the **Message** field value from the your sample file and select **Upload Log Sample**.



Paste Message Field

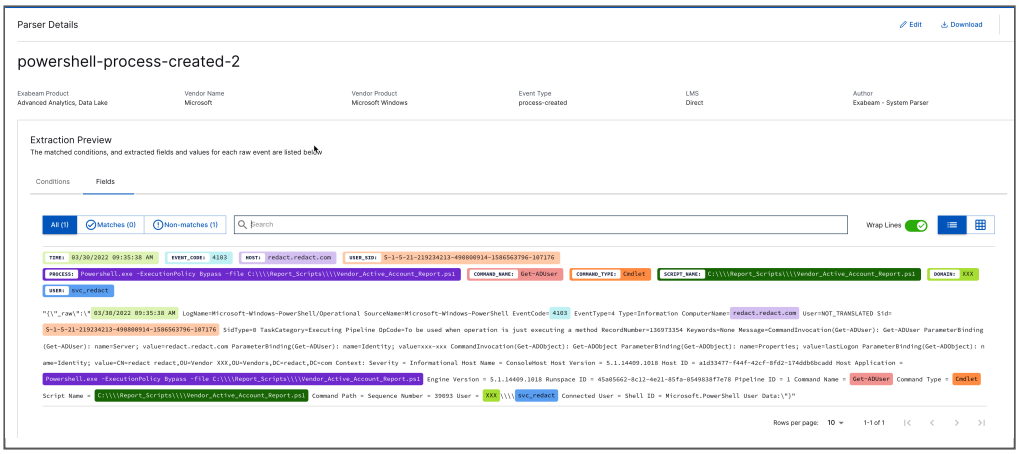
Copy the *Message** field value to your clipboard for a later step in Stream it to Exabeam.

Select **View Parsing Details** to view parsers matching this event type.



New Parser option

Validate that all the fields you need are populated: `src_ip`, `dest_host`, `user`, etc.



Paste Message Field

Do not change Field Names in Exabeam (e.g., `src_ip` to `source_IP`). Exabeam has its own Field Name format that matches its Advanced Analytics template.

At the bottom of the **Extraction Preview** page, select **Configuration Files** to inspect the parsers. If required, you can download the parser to change the regex configurations.

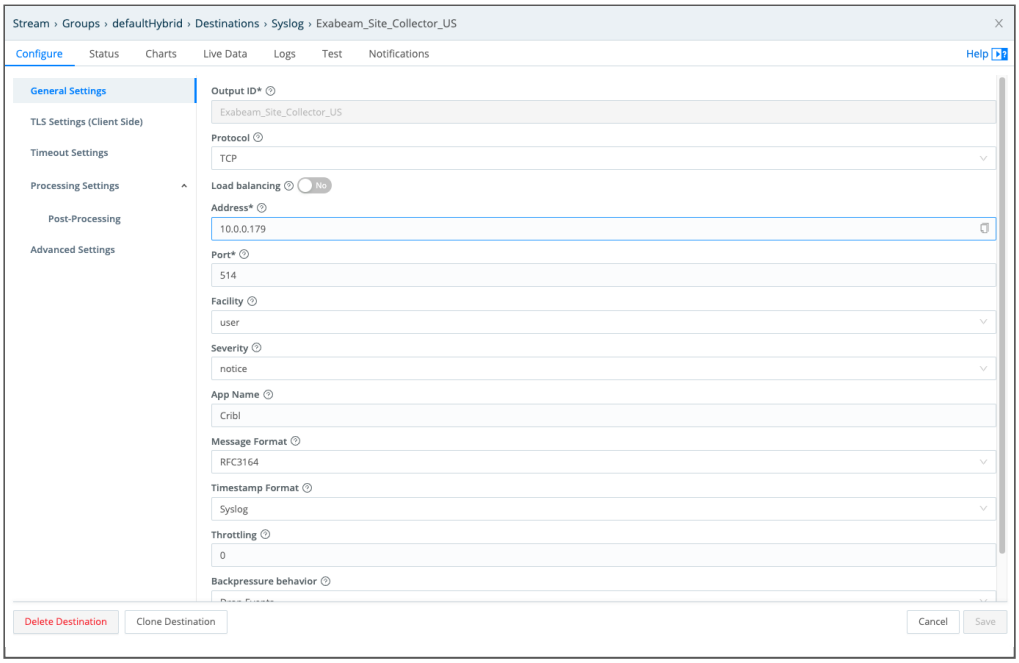
Parser Details

Stream It to Exabeam

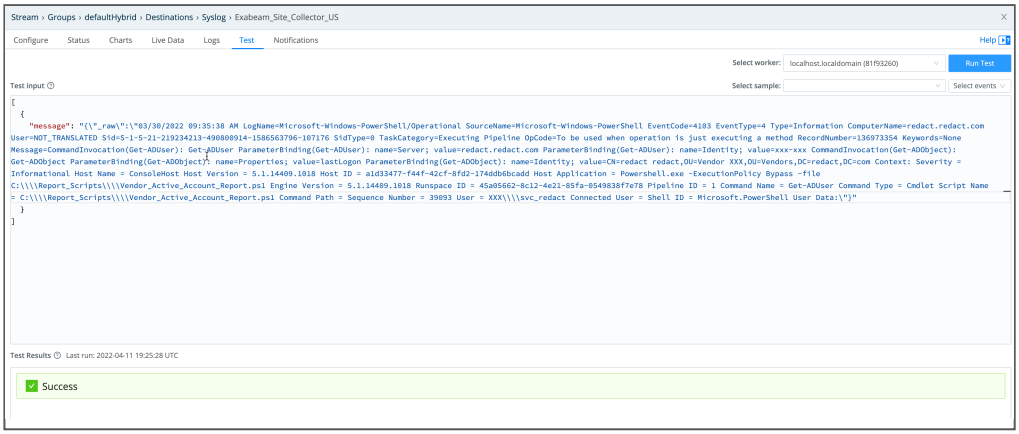
Our final test is to send a single event to Exabeam, and validate the results in Exabeam's Data Lake or Advanced Analytics.

Before testing, configure your Exabeam implementation's `Asset Name` and `Username` to a dummy account. Exabeam's Advanced Analytics has hundreds of models out of the box, and you do not want to ruin these models while testing out your data.

1. From Cribl Stream Home, select a Worker Group, and then select **Data** > **Destinations** > **Syslog**.
2. Select **Add Destination** to configure and save a new Syslog Destination to export data to Exabeam. Configure the **Address**, **Port**, **Message format**, **Timestamp format**, and other options to match your Exabeam implementation.

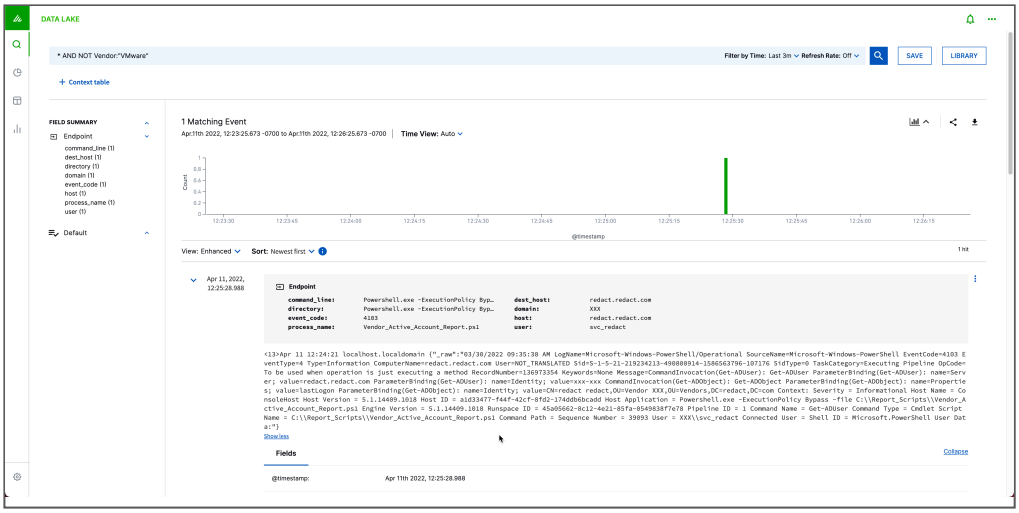


3. Reopen the Syslog Destination. On its **Test** tab, copy and paste the **Message** field's value you copied onto your clipboard above.



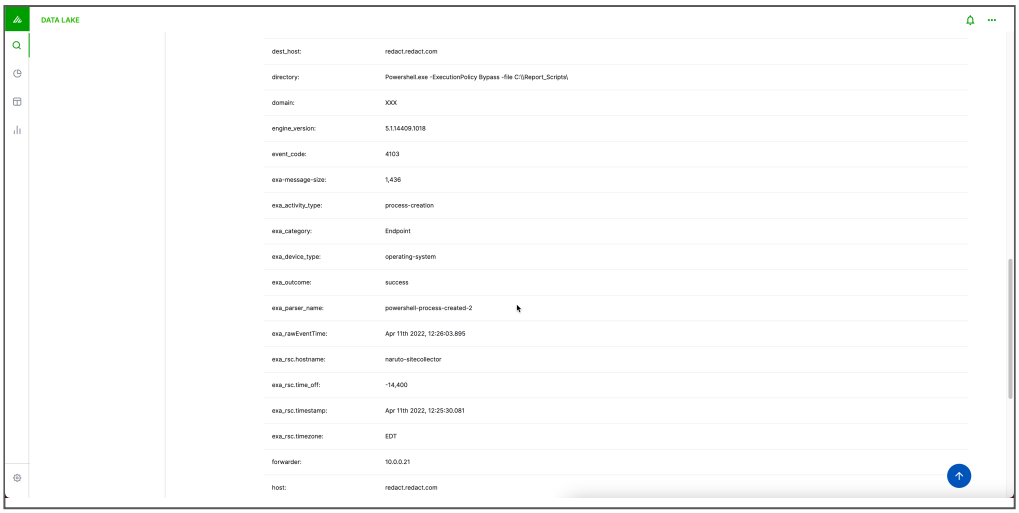
Syslog Test tab

4. Within a few seconds, you should see your event display in the Exabeam Data Lake. Search for your forwarder IP/Host (Example syntax: `Forwarder:"IP/host`).



Validating event in Exabeam

5. You can validate that you have the right parser by matching the `exa_parser_name` with the parser in the Auto Parser Generator.



Validating parser in Exabeam

15.8.3.5. Splunk Stream To Cribl Stream

Splunk Stream is a set of three Splunk packages that, combined, enable you to capture and work with streams of network event data. This adds up to a collector for streaming data. You can deploy Splunk Stream in either of two forms:

- As part of a Splunk Universal Forwarder (we'll call this the forwarder-based config), sending data to a Cribl Stream Splunk TCP Source; or
- As an independent stream forwarder (we'll call this the ISF config), running on a compatible Linux machine, and sending data to a Cribl Stream Splunk HEC Source.

In either case, the collector process (not to be confused with a Cribl Stream Collector) will need to call home to a Splunk Enterprise process with the Splunk Stream app installed. You'll manage the collector's settings in Splunk Enterprise.

For the broader Splunk configuration story, see Splunk's documentation. Here, we'll explain one small part of the Splunk configuration process: how to configure Splunk Stream to send the data it captures to Cribl Stream. See the section below – either Forwarder-based or ISF – that corresponds to your use case.

Setting Up the Forwarder-Based Config

Install the Stream TA on the Universal Forwarder targets, either manually or via the deployment server. You'll need to add a new `inputs.conf` stanza pointing to your Splunk Stream App management instance. Adapt the example stanza below, replacing the placeholder with the hostname or IP address of your management host.

New stanza in config file

```
[streamfwd://streamfwd]
splunk_stream_app_location = https://<your_management_host>:8000/en-us/custom/splunk_
disabled = 0
```

The `outputs.conf` for the Universal Forwarder with Splunk Stream App is the same as for a Universal Forwarder with a non-streaming collector. See these examples.

To verify that your setup is working, run a Live Capture in your Cribl Stream Splunk TCP Source with appropriate filters. Once the Universal Forwarder is sending data to your Cribl Stream Workers, you're ready to begin working with sample captures, Routes, and Pipelines.

If no data seems to be coming through, check the logs located at `/opt/splunkforwarder/var/log/splunk/splunkd.log` on each machine where your Forwarder is running.

Setting Up the ISF Config

Splunk Stream as an independent stream forwarder (ISF) can run only on Ubuntu- or RHEL-based x64 Linux machines that have bzip2 installed.

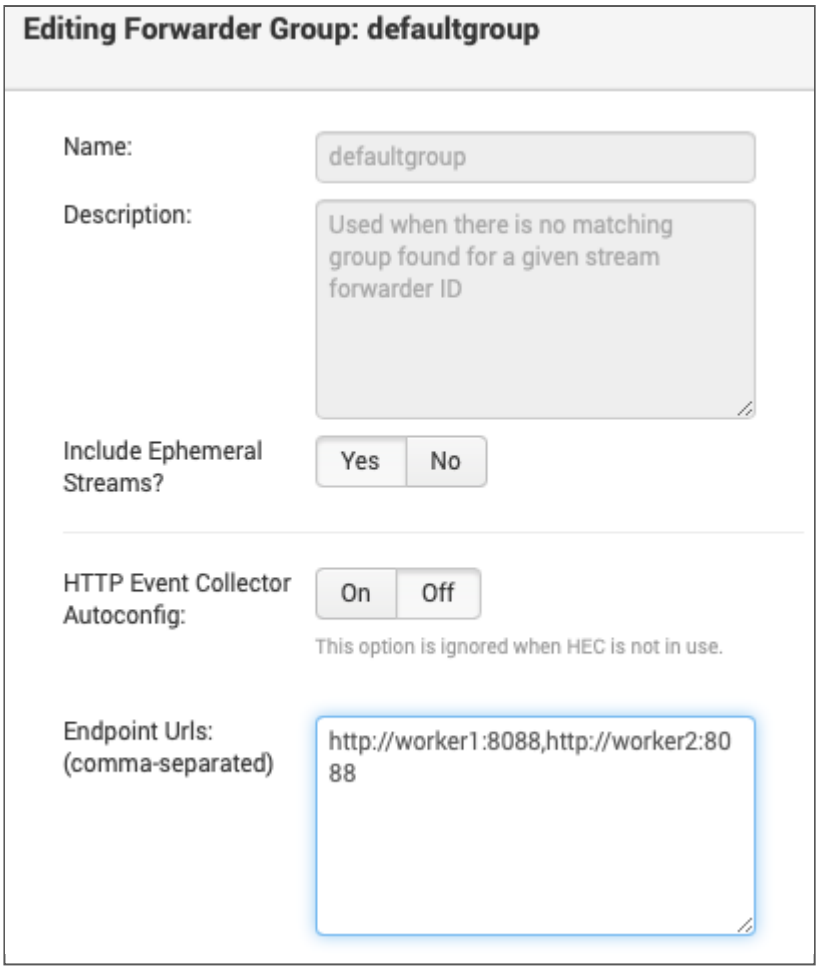
To install Splunk Stream, begin in the Splunk UI:

- In the Stream App, navigate to **Configuration** > **Distributed Forwarder Management**.
- Click the **Install Stream Forwarders** button.
- In the resulting modal, under the text `To get data from other machines, run this command on your data source machine`, copy the `curl` command. E.g.:
  `curl -sSL http://DellT20:8000/en-us/custom/splunk_app_stream/install_streamfwd | sudo bash`

On each Linux machine where you want to install Splunk Stream, run the `curl` command that you copied. Installation will fail if the machine lacks `bzip2`.

Once installation is complete, return to the Splunk UI.

1. To update the HEC endpoint URL, navigate to **Actions** > **Edit Forwarder Group** for the desired group.
2. Toggle **HTTP Event Collector Autoconfig** to `Off`.
3. In the **Endpoint URLs** field, list your Cribl Stream Worker URLs, as shown here:



Editing forwarder group to specify Cribl Worker URLs

4. Click **OK**.

Finally, on each Linux machine where you're running Splunk Stream, update the ISF settings with the proper HEC token. (While it is technically possible to run without a token, Cribl strongly recommends against this practice.)

1. In Cribl Stream, copy the HEC token from your Cribl Stream Splunk HEC Source definition (the value of the `__hecToken` internal field).
2. On the desired Linux machines, open `/opt/streamfwd/local/streamfwd.conf` in a text editor.
3. Add the following stanza, substituting your HEC token for the placeholder:

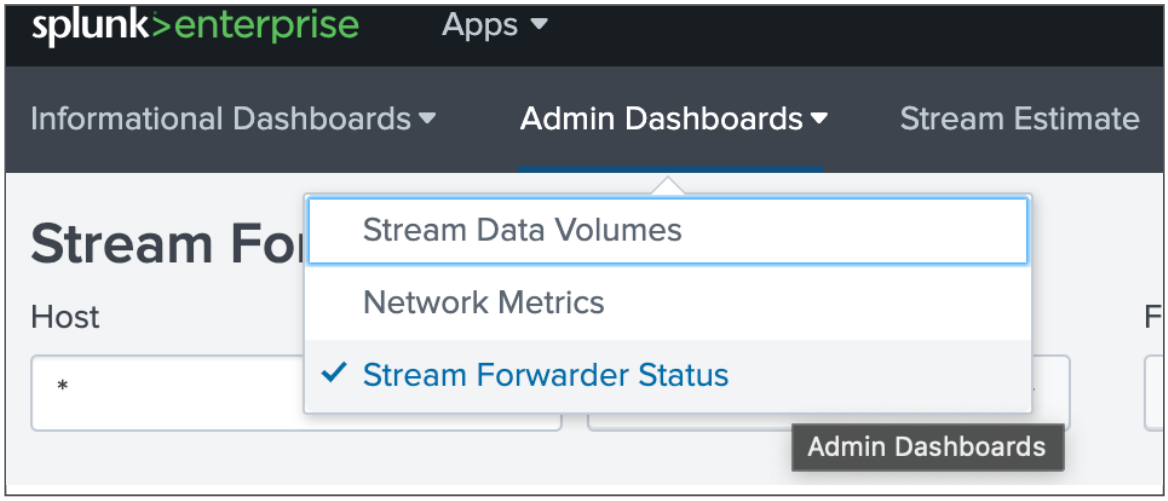
```
[streamfwd]
httpEventCollectorToken = <HEC_token_from_your_Cribl_Stream_Source>
```

4. Run the following command to restart the ISF:

```
systemctl restart streamfwd
```

To verify that your setup is working, run a Live Capture in your Cribl Stream Splunk HEC Source with appropriate filters.

You can also check ISF status in Splunk. Navigate to **Apps** > **Splunk Stream** > **Admin Dashboards** > **Stream Forwarder Status**:



Verify ISF status in Splunk

If no data seems to be coming through, check the logs located at `/opt/streamfwd/var/log/streamfwd.log` on each machine where your ISF is running.

15.8.3.6. Decryption Of Data In Splunk

Currently, Cribl Stream supports decryption only when Splunk is the end system. In Splunk, decryption is available to users of any role with permissions to run the `cribldecrypt` command that ships with Cribl App for Splunk. Further restrictions can be applied with Splunk **capabilities**. This page provides details.

For clarity, Cribl introduced the `cribldecrypt` as an alias to the original `decrypt` command. Use this alias to avoid conflicts with Splunk's internal commands. (We show it in the examples below.) Both are, in fact, aliases to the actual command: `/path/2/cribl --splunk-decrypt`. You can use both aliases.

Usage

The `cribldecrypt` command is used to display Cribl-encrypted fields in cleartext. It is an alias to the `decrypt` command. This command decrypts fields only for the encryption keys that the user can access.

The example below retrieves data from a Splunk index with Cribl-encrypted data, and pipes it to the `cribldecrypt` command:

```
index=index_with_encrypted_fields | cribldecrypt
```

Decrypting in Splunk

Decryption in Splunk is implemented via a custom command called `cribldecrypt`. To use the command, users must belong to a Splunk role that has permissions to execute it. Capabilities, which are aligned to Cribl Key Classes, can be associated with a particular role to further control the scope of `cribldecrypt`.

Decrypt Command Is Search Head ONLY

To ensure that keys don't get distributed to all search peers – including peers that your search head can search, but you don't have full control over – `cribldecrypt` is scoped to run locally on the installed search head.

Restricting Access with Splunk Capabilities

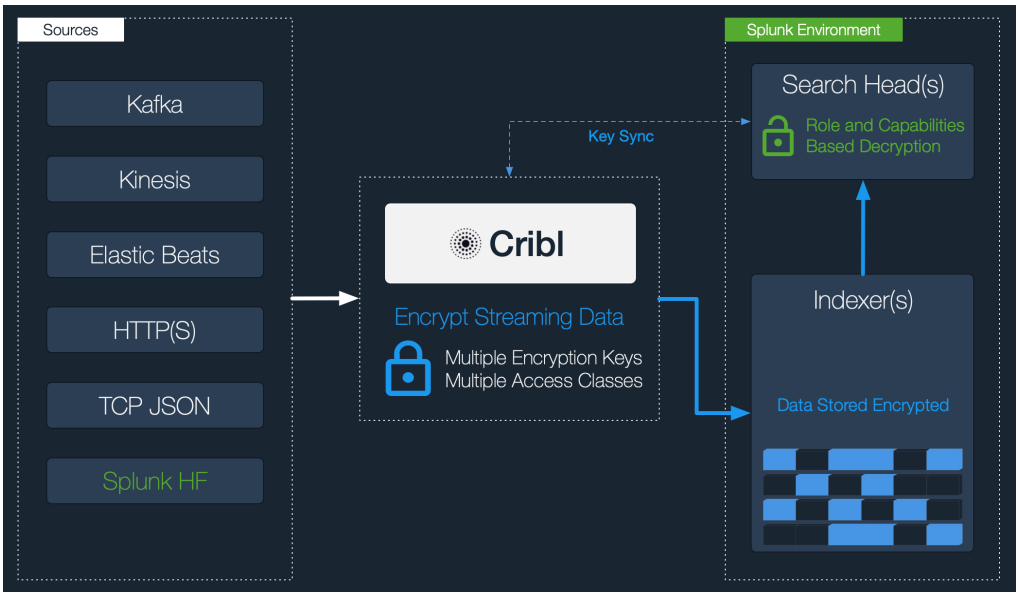
In Splunk, capability names should follow the format `cribl_keyclass_N`, where `N` is the Cribl Key Class. For example, a role with capability `cribl_keyclass_1` has access to all key IDs associated with key class `1`.

Capability Name	Corresponding Cribl Key Class

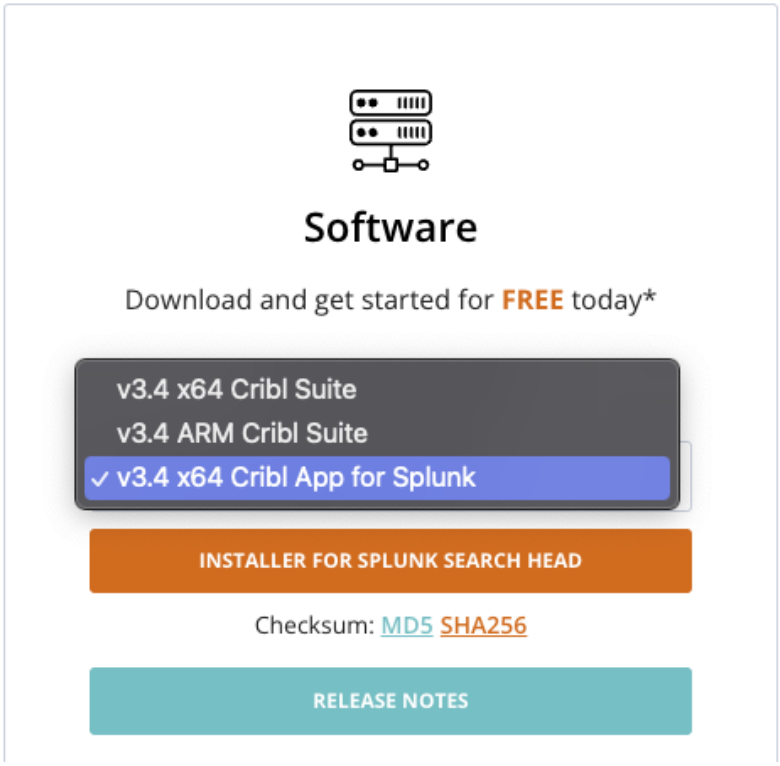
`cribl_keyclass_1`
`cribl_keyclass_2`
`...`
`cribl_keyclass_N`
	`1`
	`2`
	`...`
	`N`

Configuring Splunk Search Head to Decrypt Data

You set up decryption in Splunk according to this schematic:



1. Download the Cribl Stream App for Splunk from Cribl's Download Cribl Stream page: In the **On Prem** section, select the Splunk app from the drop-down list, as shown. Clicking the orange button downloads a file named: `cribl-splunk-app-<version-#>-<hash-#>-linux-x64.tgz`.



Downloading Cribl's Splunk app

2. To install the Cribl/LogStream App for Splunk on your search head, untar the package into your `$SPLUNK_HOME/etc/apps` directory.
   The app will run in search head mode by default. If the app has previously been installed and later modified, you can convert it to search head mode with the command: `$CRIBL_HOME/bin/cribld mode-searchhead`. (When installed as a Splunk app, `$CRIBL_HOME` is `$SPLUNK_HOME/etc/apps/cribl`.)
3. Assign permissions to the `cribldecrypt` command, per your requirements.
4. Assign capabilities to your roles, per your requirements. If you'd like to create more capabilities, ensure that they follow the naming convention defined above.
5. In the `$SPLUNK_HOME/etc/apps/cribl/local/cribl/auth/` directory, sync `cribl.secret` | `keys.json`. (To successfully decrypt data, the `cribldecrypt` command will need access to the same keys that were used to encrypt, **in the Cribl instance where encryption happened**.)

- In a single-instance deployment, the `cribl.secret` and `keys.json` files reside in: `$CRIBL_HOME/local/cribl/auth/`.
- In a distributed deployment, these files reside on the Leader Node in: `$CRIBL_HOME/groups/<group-name>/local/cribl/auth/`.
- When using Cribl Stream's UI, you can download these files by clicking the **Get Key Bundle **button.

Sync/copy these files over to their counterparts on the search head (decryption side). In a non-Splunk integration, you would copy these assets to wherever decryption will take place.

Modifying Keys

When you update keys by editing the `keys.json` file, you must add them back to the directories above (respectively, on a single instance or on a distributed deployment's Leader Node).

15.8.3.7. Stream-To-Splunk Encryption

Encrypt at Ingest-Time and Decrypt in Splunk

With Cribl Stream, you can encrypt your sensitive data in real time before it's forwarded to and stored at a destination. Using the out-of-the-box Mask function, you can define patterns to encrypt with specific key IDs or key classes. To decrypt in Splunk, you will need to install Cribl App for Splunk on your search head. (The app will default to `mode-searchhead`.)

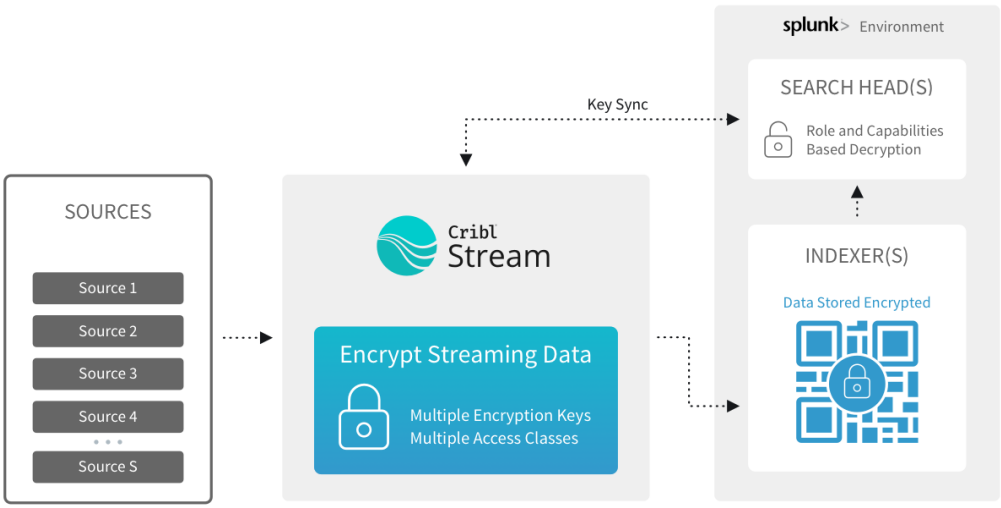
Keys and Key Classes

Symmetric encryption keys can be configured through the CLI or the UI. They're used to encrypt the patterns, and users are free to define as many keys as required.

Key classes are collections of keys that can be used to implement multiple levels of access control. Users (or groups of users) that have access to data with encrypted patterns can be associated with key classes. You can use these classes to provide more-granular access rights, such as read versus decryption permissions on a dataset.

Encrypt in Cribl Stream and Decrypt in Splunk

1. Define one or more keys and key classes on Cribl Stream. (See UI- and CLI-based instructions.)
2. Sync `auth` with the decryption side (Splunk Search Head). (The Splunk-side directory is `$SPLUNK_HOME/etc/apps/cribl/local/cribl/auth/`.)
3. Apply the Mask function to patterns of interest, using C.Crypto.encrypt().
4. Decrypt on the Splunk search head, using Role-Based Access Control on the `decrypt` command.

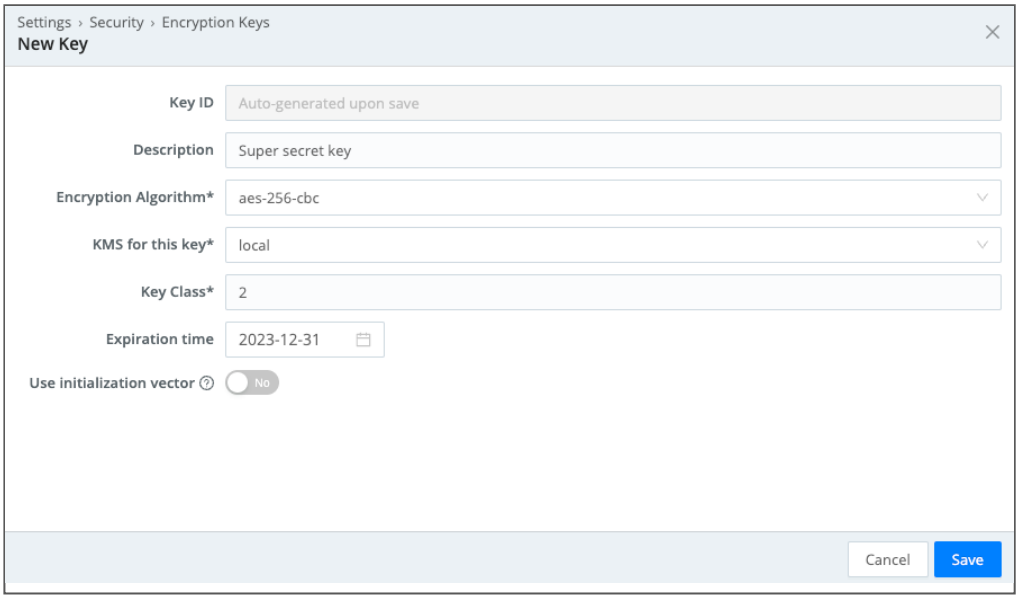


Examples

Encryption Side

You can generate keys via the UI or the CLI.

To generate keys via the UI, access **Group Settings** > **Security** > **Encryption Keys**:



Adding a new encryption key

To generate one or more keys via the CLI, pattern your commands after these examples.

In a single-instance deployment:

```
$CRIBL_HOME/bin/cribl keys add -c 1 -i ... $CRIBL_HOME/bin/cribl keys add -c <N> -i
```

In a distributed deployment, to generate keys on a Worker Group named `uk`:

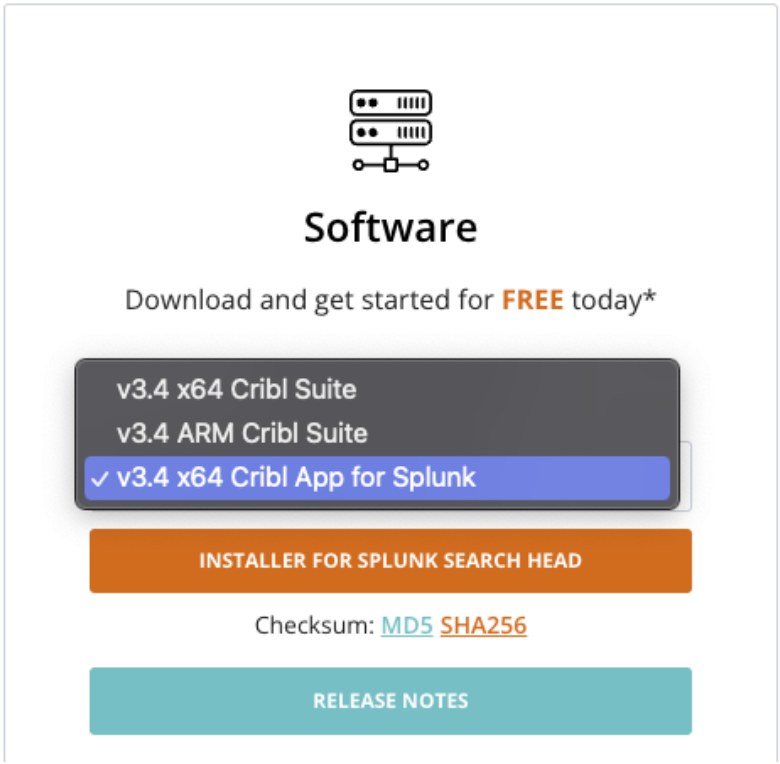
```
$CRIBL_HOME/bin/cribl keys add -c 1 -i -g uk ... $CRIBL_HOME/bin/cribl keys add -c <N>
-i -g uk
```

Add `-e <epoch>` to the above commands if you'd like to set expiration for your keys.

For all command/syntax options, see Adding Keys.

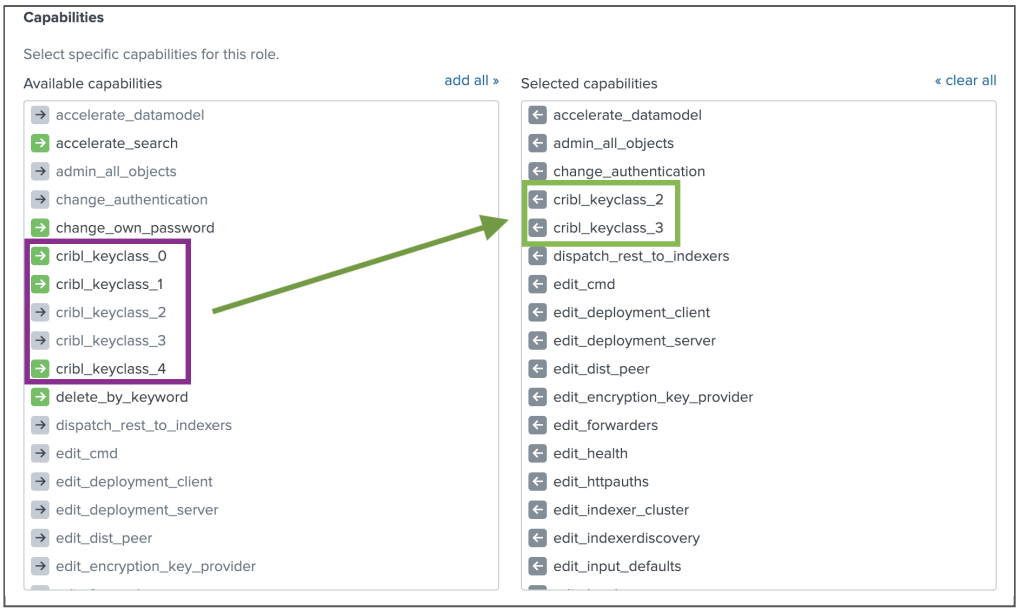
Decryption Side

- Download the Cribl Stream App for Splunk from Cribl's Download Cribl Stream page: In the **On Prem** section, select the Splunk app from the drop-down list, as shown. Clicking the orange button downloads a file named: `cribl-splunk-app-<version-#>-<hash-#>-linux-x64.tgz`.



Downloading Cribl's Splunk app

- To install the Cribl Stream App for Splunk on your search head, untar the package into your `$SPLUNK_HOME/etc/apps` directory. The app will default to `mode-searchhead`.
- Assign permissions to the `decrypt` command, per your requirements.
- Assign capabilities to your Roles, per your requirements. Capability names should follow the format `cribl_keyclass_N`, where `N` is the Cribl Key Class. For example, a role with capability `cribl_keyclass_1` has access to all key IDs associated with key class `1`. You can use more capabilities, as long as they follow this naming convention.



Selecting capabiities

- In the `$SPLUNK_HOME/etc/apps/cribl/local/cribl/auth/` directory, sync `cribl.secret` | `keys.json`. (To successfully decrypt data, the `decrypt` command will need access to the same keys that were used to encrypt, **in the Cribl instance where encryption happened**.)
    - In a single-instance deployment, the `cribl.secret` and `keys.json` files reside in: `$CRIBL_HOME/local/cribl/auth/`.
    - In a distributed deployment, these files reside on the Leader Node in: `$CRIBL_HOME/groups/<group-name>/local/cribl/auth/`.
    - When using Cribl Stream's UI, you can download these files by clicking **Get Key Bundle**.

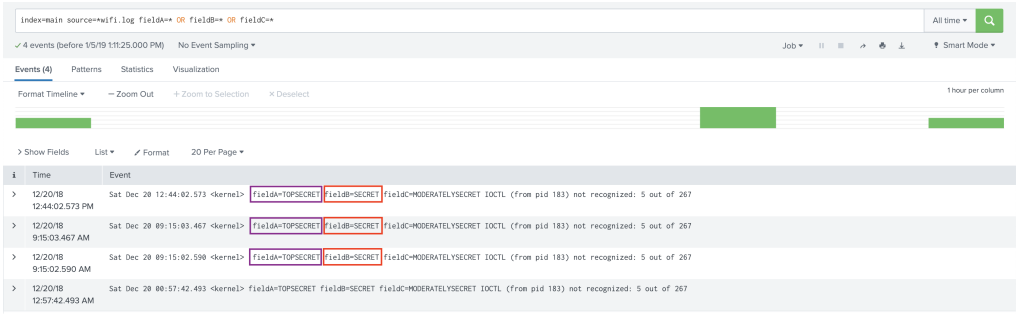
  Sync/copy these files over to their counterparts on the search head (decryption side). In a non-Splunk integration, you would copy these assets to wherever decryption will take place.

Modifying Keys

When you update keys by editing the `keys.json` file, you must add them back to the directories above (respectively, on a single instance or on a distributed deployment's Leader Node).

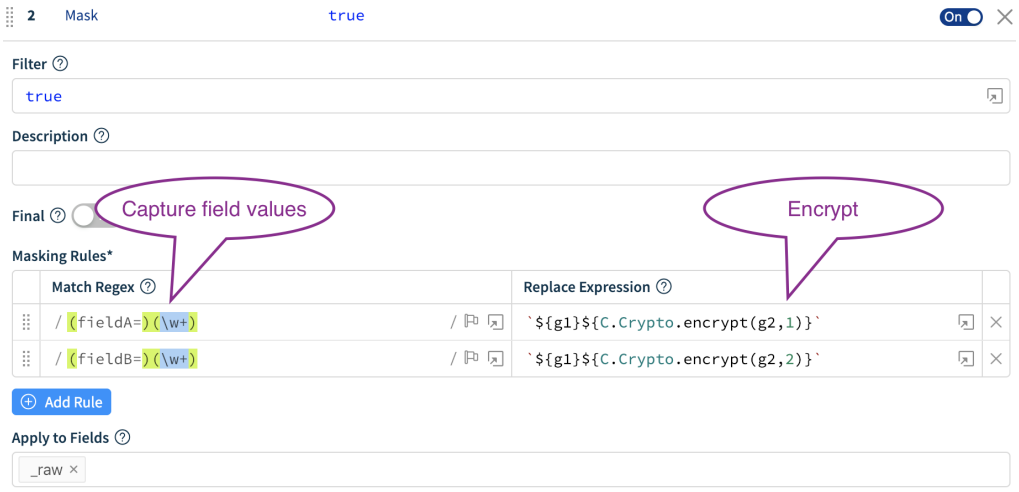
Usage

Before Encryption: Sample un-encrypted events. Notice the values of `fieldA` and `fieldB`.



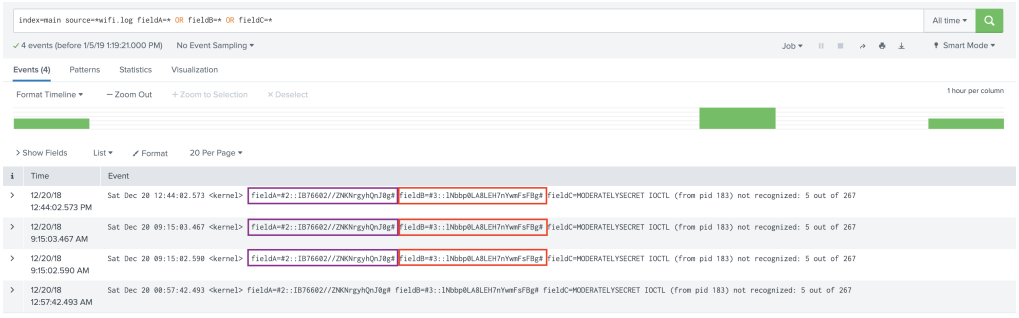
Events before encryption

Next, encrypt `fieldA` values with key class `1`, and `fieldB` with key class `2`.



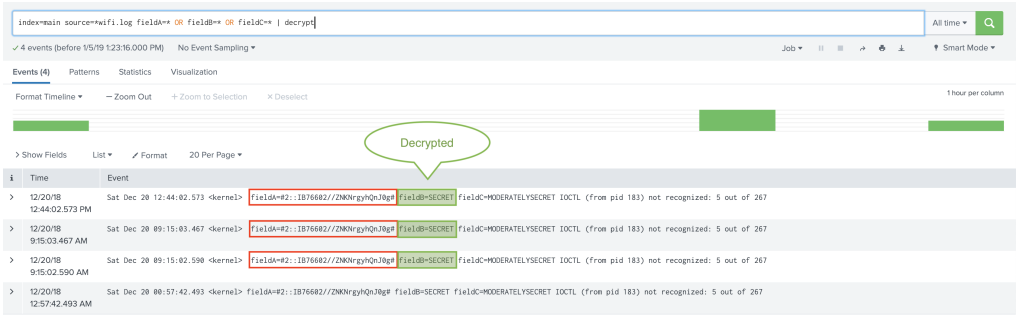
Encrypting two fields with separate key classes

After Encryption: again, notice the values of `fieldA` and `fieldB`.



Both fields encrypted

Here, we've decrypted `fieldB` but not `fieldA`. This is because the logged-in user has been assigned the capability `cribl_keyclass_2`, but not `cribl_keyclass_1`.



One field decrypted

15.8.4. Syslog

15.8.4.1. Syslog Best Practices

Cribl Stream can process a syslog stream directly. Moving to Cribl Stream from existing syslog-ng or rsyslog servers fully replaces those solutions with one that is fully supported and easily managed.

Processing syslog in Cribl Stream allows you to readily address these common challenges of ingesting data from syslog senders:

- **Architecture**: Cribl Stream routes the syslog stream directly, immediately, and securely to the destinations of your choice, reducing latency and management overhead.
- **Volume**: Removing redundant data and unnecessary fields in Cribl Stream typically reduces volume 20–30% overall. It also optimizes the data for downstream services like Splunk or Elasticsearch.
- **Timestamp handling**: Cribl Stream intelligently processes events sent from different time zones. It can embed a new, consistent timestamp, and can auto-correct timestamps that are off by an exact number of hours.
- **Severity/Facility accuracy**: Each syslog event begins with a bracketed integer that represents Facility and Severity, as defined in the Syslog Protocol. Cribl Stream translates this code (e.g., `<165>`, `<0>`) into the correct Facility and Severity values.
- **Metadata**: Cribl Stream can automatically set metadata fields, including `sourcetype` and `index`.

This tutorial outlines best practices for replacing your syslog server with Cribl Stream. To go even a bit deeper, check out this Cribl Office Hours video.

The Goal: Optimizing Syslog Events

By default, a Cribl Stream Syslog Source produces eight fields: `_time`, `appname`, `facility` (numeric), `facilityName` (text), `host`, `message`, `severity` (numeric), and `severityName` (text).

Default, parsed syslog event

While this default parsing makes the output much more readable, we haven't saved any volume – and we now have redundant pairs of fields (numeric versus text) that represent facility and severity.

Our next logical step is to streamline syslog events to something more like this:

Default, parsed syslog event

This accomplishes all of the following:

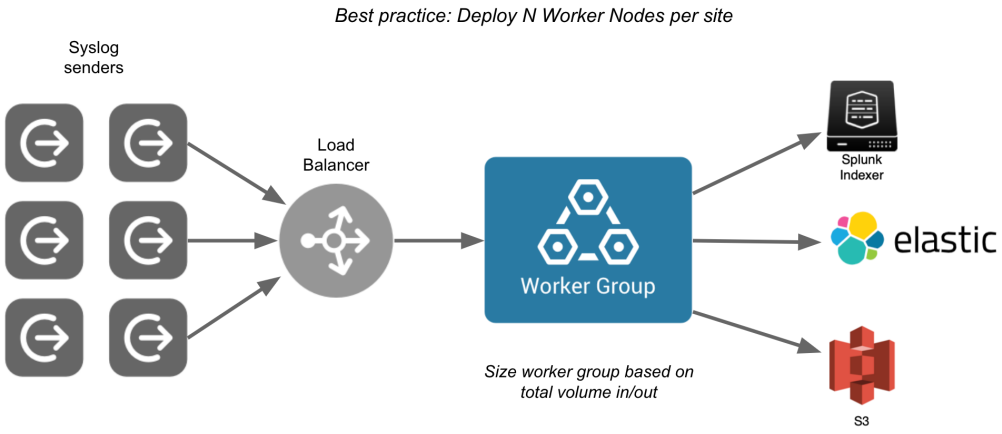
- Extracts the essentials.
- Removes the redundancies.
- Adds a new field to identify the Cribl Stream Pipeline (which we're about to build).
- Adds metadata that the Destination needs.
- Shrinks the outbound `_raw` payload to just its `message` component.

Once we optimize syslog in this way, we can achieve still further efficiencies by dropping or downsampling frequent events, and by balancing high-volume syslog inputs across Cribl Stream worker processes.

Overall Architecture

Syslog data, especially when sent via UDP, is best collected as close to the source as possible. Ideally, you should capture syslog data **at its origin**. (This is true of syslog in general, not just syslog processed in Cribl Stream.)

Also, because syslog senders have no built-in load balancing, Cribl strongly recommends using a load balancer to distribute the load across multiple Worker Nodes.



Example architecture for a single site or location

The load balancer shown above is dedicated only to communication between the syslog senders and the Stream Worker Nodes. Any load balancing between the Worker Group and its Stream Leader would be handled by a separate load balancer.

Load Balancing

When configuring a load balancer to be fed by syslog senders, start with these basic principles:

Avoid Stickiness

In this context, **stickiness** is when traffic from a given source is always sent to the same destination IP. The optimal configuration of the load balancer avoids "sticky" behavior, and instead spreads the workload across Cribl Stream Worker Nodes as evenly as possible.

Use API Calls to Do Health Checks

If UDP data is being sent, the load balancer has no way to automatically detect whether the destination is up. Configure the load balancer to use API calls to the Worker Nodes to check the health status of each Node (see Health Endpoint).

Listen on Port 514

If possible, configure the load balancer to listen on port 514, and then relay traffic to the Worker Nodes on port 9514. Here's why:

- Many syslog senders are hard-coded to send only to port 514, so you need to support them.

- Cribl Stream itself should not run as root, and therefore cannot listen on ports lower than 1024 without additional OS-level steps (like SETCAP).

A Port for Each Device Class

As explained above, for syslog devices that can send only to port 514, you can configure the load balancer to relay to destination port 9514. But what about the many syslog senders that **do** support sending to ports other than 514? It's a best practice among Cribl customers to use a dedicated receiving port for each class of device in their environment. While this takes a little more effort to set up, it enables you to hard-code metadata (and optionally, Pipelines) for the events from that data source. Examples include:

- 1517: VMware ESXi logs.
- 1521: Palo Alto Firewall.
- 1522: F5 load balancers.

We'll see how to set per-port metadata in the Adding Processing Pipelines section.

UDP Versus TCP

For any given syslog device, you might need to choose between using UDP or TCP. Which is best depends on the characteristics of the sender. Here are some basic guidelines:

- For single, high-volume senders (over 300GB/day), use UDP if possible. For both the sender and Cribl Stream, UDP imposes lower overhead than TCP. The stateless nature of UDP allows each log event to be directed to a different worker thread than the last. This ensures maximum utilization of the Worker Nodes. See Sizing and Scaling for more details.
- For lower-volume senders, use TCP if the sender supports it.
- For all other use cases, use UDP.

Pipeline Planning

In Cribl Stream, we speak of **pre-processing Pipelines**, **processing Pipelines** (or just plain **Pipelines**), and **post-processing Pipelines**. Cribl recommends combining the first two in an arrangement that we've found to be optimal for syslog.

Pre-Processing Syslog Sources

Attach a pre-processing Pipeline to most (or all) of your Syslog Sources. Use the pre-processing Pipeline to apply the same set of ingest-time processing that all syslog events will need, regardless of what subsequently happens on different subsets of the data.

Syslog data is a classic example of where a pre-processing Pipeline is useful: Unlike processing Pipelines, pre-processing Pipelines attach directly to a Source, enabling you to standardize or normalize what comes in. This way, you avoid having to implement that same functionality and logic separately in each processing Pipeline associated with a Syslog Source.

Pipeline for Selected Syslog Data Subsets

Configure dedicated Pipelines (and Routes!) for each distinct subset of data that arrives via syslog senders. These subsets might include DHCP logs from the router, traffic logs from the firewall, operational logs from load balancers, and virtualization logs from on-prem virtualization hypervisors.

Certain kinds of subset-specific processing have become Cribl Stream best practices. These include:

- For ESXi or other hypervisor logs, use the Drop Function to drop `debug`-level logs.
- For firewall logs, enrich with DNS names, GeoIP fields, and lookups from a threat list.
- For load balancer logs, use the Suppress Function to reduce volume.

Unless you're new to Cribl Stream, you've already created your own Pipelines, so we're not going to review that here. (If you are new to Cribl Stream, consider running through the free Cribl Stream Fundamentals sandbox course ASAP.)

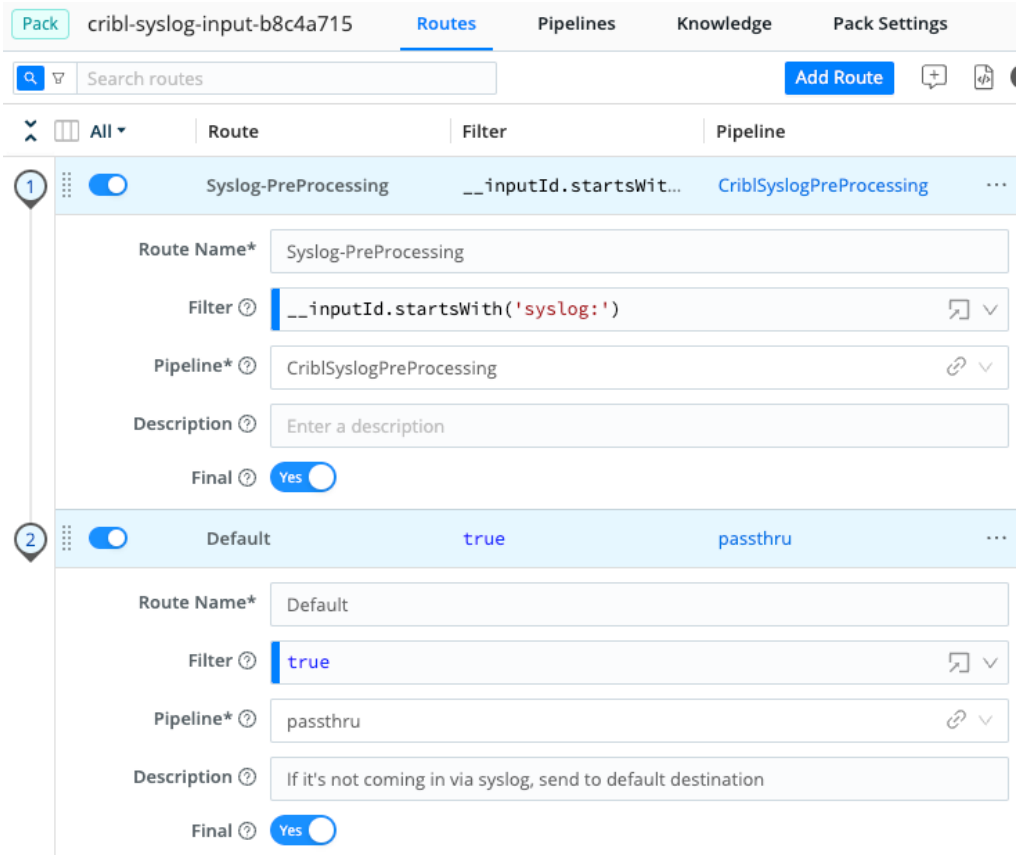
Importing the Pre-Processing Pipeline

Even before setting up a Cribl Stream Syslog Source, you'll want to install the Cribl Pack for Syslog Input (a.k.a. `cribl-syslog-input` Pack), which provides the required pre-processing Pipeline.

If this is your first time installing from the Cribl Dispensary, see the full directions with screenshots. Otherwise:

1. Open the Cribl Pack Dispenary's Cribl Pack for Syslog Input page.
2. Under **Releases** at right, click the link for the latest release.
3. In the resulting **Assets** section, right-click the `.crbl` file to download it locally.
4. In Cribl Stream, select a Worker Group, then select **Processing** > **Packs**.
5. Click the **Add New** button, and select **Import from file**.
6. Select the Pack you downloaded, and follow the prompts from there. In most cases, when installing a Dispensary Pack, you should not enter an override value for **New Pack ID**.
7. Review the Pack's `README` file, available in the Pack's **Settings** link and also online.

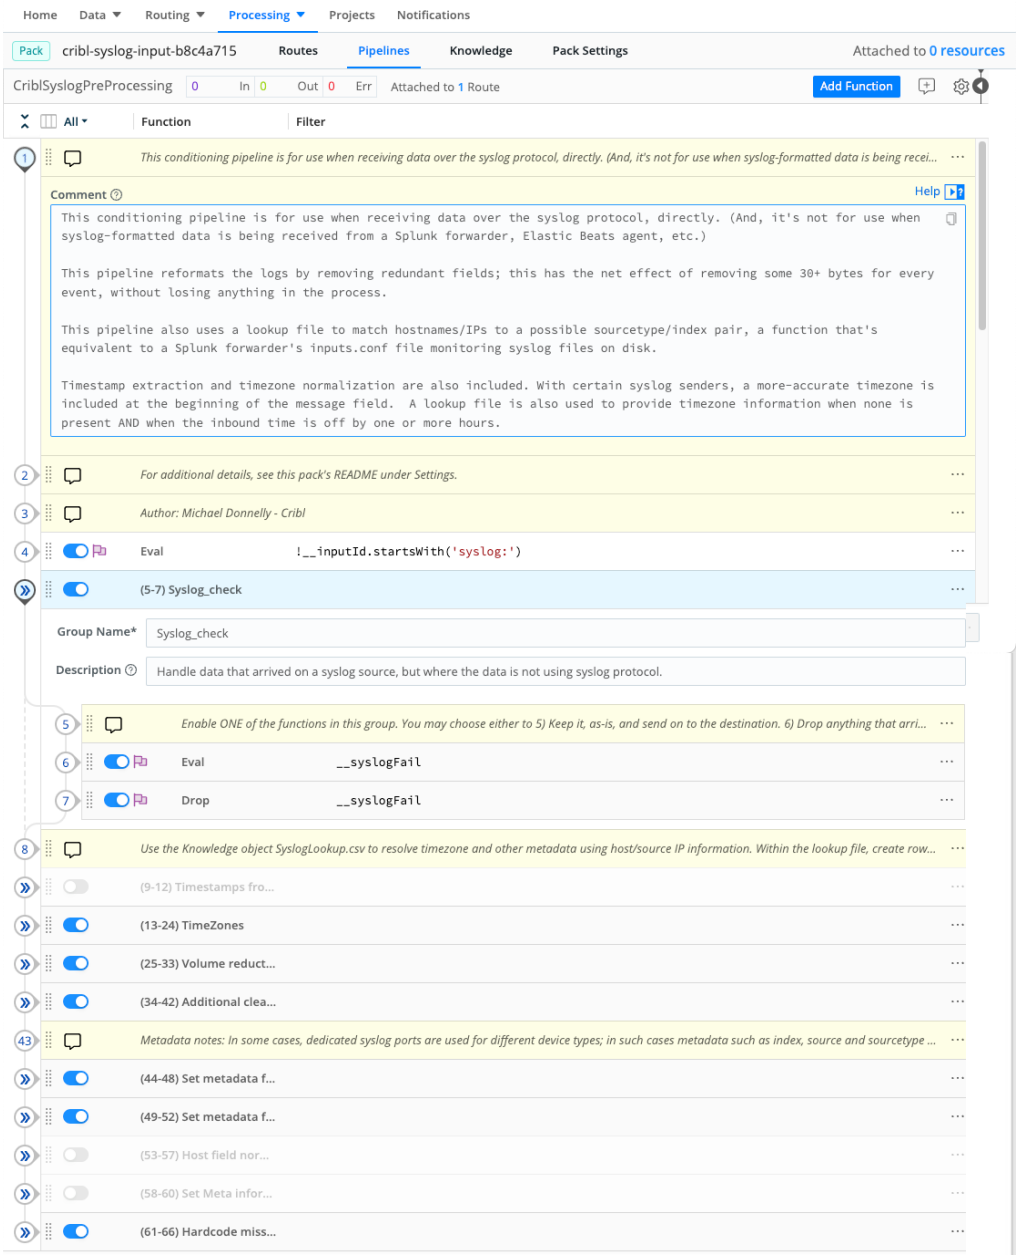
Let's examine what this Syslog Input Pack provides, starting with the Routes page.



Routes page in the Cribl Pack for Syslog Input

The first Route matches based on `inputId`. Anything arriving via a Cribl Stream Syslog Source will match this filter, as long as you've configured the Source to use the Pack, as shown below.

On first installation of the Pack, the Pipeline defaults to commonly used configurations. Cribl **strongly** recommends reviewing the Pipeline's internal documentation to understand which features are enabled. This documentation consists of Comments for each section, and a Description for each Function to explain what's happening in that step.

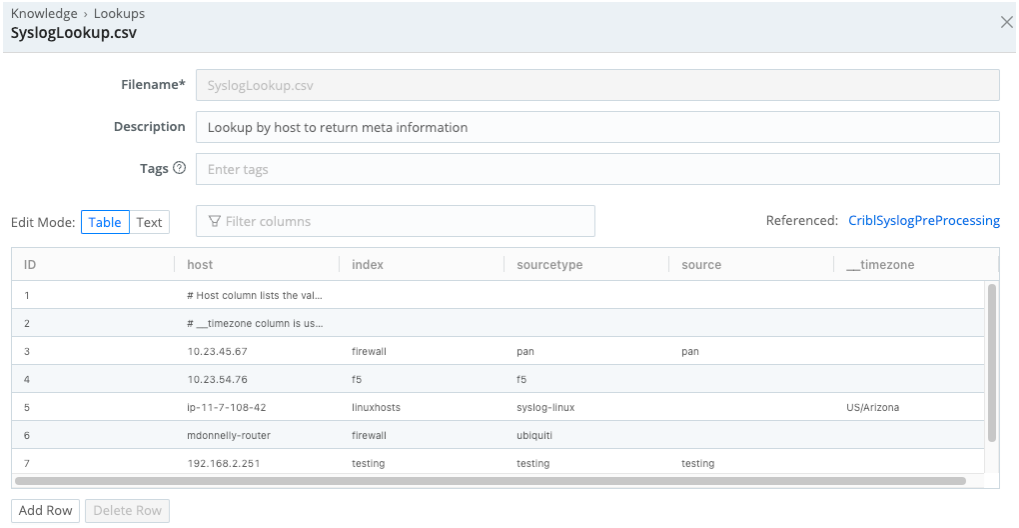


The Pipeline's internal documentation

Examining this documentation should make it clear what changes (if any) are needed to suit your deployment environment. Go ahead and make those changes now.

The Lookup File

The Pack ships with a lookup file called `SyslogLookup.csv`, whose contents you should replace as necessary. To access the file, navigate to **Processing** > **Packs**, select the `cribl-syslog-input` Pack, and click **Knowledge**.



Stock `SyslogLookup.csv` file, to be filled with customer data

Creating Syslog Sources

Now that you've imported the pre-processing Pipeline, the next step is to ensure that you have the Syslog Sources you need.

Configure the `in_syslog` Source

Cribl Stream ships with a Syslog Source named `in_syslog`, which is preconfigured to listen for both UDP and TCP traffic on Port 9514. You can clone or directly modify this Source to further configure it, and then enable it.

Use the `in_syslog` Source for syslog senders that are hard-coded to send to port 514, as described above. In the **QuickConnect** UI: Click **Add Source**. From the resulting drawer's tiles, select [**Push** >] **Syslog**. Click **Select Existing**, then `in_syslog`.

Or, in the **Data Routes** UI: From the top nav of a Cribl Stream instance or Group, select **Data** > **Sources**. From the resulting page's tiles or the **Sources** left nav, select [**Push** >] **Syslog**. In the **Manage Sources** page, click `in_syslog`.

Configure the fields and options as follows:

General Settings

- **Enabled**: Toggle to `Yes`.

- **UDP Port** and **TCP Port**: Assuming you're following the guidelines in this tutorial, you'll have a load balancer relaying incoming traffic from port 514 to port 9514. Therefore, leave the `in_syslog` Source configured to listen on its default port, 9514, for both TCP and UDP.

TLS Settings (TCP Only)

- Enabling TLS is strongly recommended if the Source will be receiving data across the Internet.

Processing Settings

- **Metadata**: There is no need to add fields here, because for generic senders coming in on 9514, the Pack will set the meta-information via the `SyslogLookup.csv` file. What you need to do is edit the lookup file to add content appropriate to your deployment.
- **Pre-processing**: From the **Pipeline** drop-down, select `PACK: cribl-syslog-input (Syslog Preprocessing)`.

Create a Source for Each Device Class

As explained above, you should now create a Syslog Source for each vendor/class of syslog sender. Create each Syslog Source as follows:

In the QuickConnect UI: Click **Add Source**. From the resulting drawer's tiles, select [**Push** >] **Syslog**. Click **Add New**.

If you use QuickConnect, remember that each Source/Destination pair will be parallel and independent.

Or, in the **Data Routes** UI: From the top nav of a Cribl Stream instance or Group, select **Data** > **Sources**. From the resulting page's tiles or the **Sources** left nav, select [**Push** >] **Syslog**. Click **New Source** to open a **New Source** modal.

Configure the fields and options as follows:

General Settings

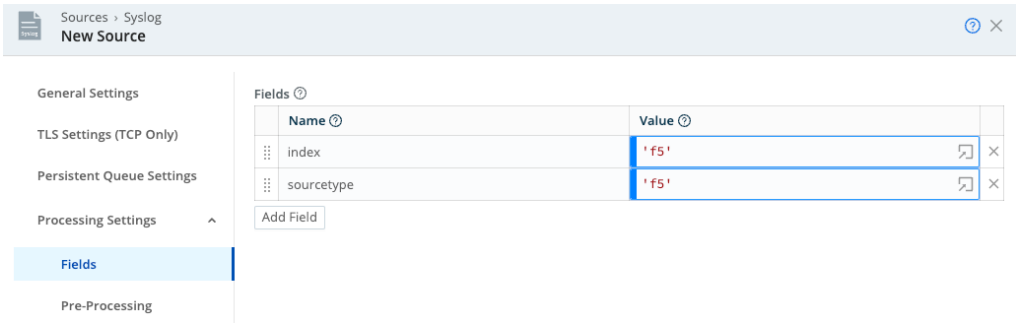
- **Input ID**: This field specifies the name for the Source, which will appear in the `__inputId` field as well as on Monitoring pages that show Source information. Common examples include `in_syslog_cisco_switch` for Cisco switches, `in_syslog_f5` for F5 load balancers, and so on.
- **UDP Port** and **TCP Port**: Enter the dedicated port you have chosen for the device class, and use UDP or TCP according to the recommendations above.

TLS Settings (TCP Only)

- Enabling TLS is strongly recommended if the Source will be receiving data across the Internet.

Processing Settings

- **Metadata**: Select **Fields (Metadata)** and add the fields appropriate for the intended Destination(s), such as `sourcetype`, `index`, `__timezone`, and any other meta-information you want to tie to the sender's hostname or IP address.



Metadata fields tied to a dedicated-port Syslog source

- **Pre-processing**: From the **Pipeline** drop-down, select `PACK: cribl-syslog-input (Syslog Preprocessing)`.

Adding Processing Pipelines

Congratulations! You've gotten a nice grounding in syslog processing, and you've seen methods with which you can:

- Properly architect the deployment environment, where syslog sender data travels through a load balancer, which then distributes it across a Cribl Stream Worker Group.
- Import a Pack from the Cribl Pack Dispensary.
- Create new Cribl Stream Syslog Sources which use the **Cribl Pack for Syslog Input**.
- Hard-code meta-information for specific ports, or use the lookup file to map meta-information for specific hosts.

Your logical next step: using Pipelines and Routes, transform syslog data in a way that makes sense for your particular syslog sender(s).

We'll look at two use cases:

- QuickConnect a Syslog Sender to a Source

- Route Multiple Syslog Senders to a Source

The point is to see how Cribl Stream offers different approaches for different scenarios. For configuring one dedicated Source to receive a given, single dataset, QuickConnect is ideal. But to accommodate a mix of data arriving on the same Source and port, and needing to be divided into subsets, and processed differently by different Pipelines – that is where we need Routes.

Use Case A: QuickConnect a Syslog Sender to a Source

Of the many possible examples, we'll focus on reducing the volume of VMware ESXi syslog data by dropping events of `debug` severity.

Data reduction will be significant, because `debug` severity events can make up 80-90% of syslog data sent from ESXi servers. Not only that: Reducing the data volume reduces the CPU load and storage used to process the data, and searches will respond faster. In a world where we're searching for needles in a haystack, dropping 80% of the hay makes everything better.

To set this up:

1. In your Worker Group, navigate to **Pipelines**, click **Add Pipeline**, then click **Add Pipeline**.
2. Name the new Pipeline `DropNoisySyslog` or something similar.
3. Click **Comment** and enter a good description of what you're doing. (This is an important best practice!)
4. Add a Drop Function with filter `severityName=='debug'`. (You could also use sampling, or dynamic sampling if you wanted to be fancy about this.)
5. Click **Save** and we're done.

Next, we need to direct VMware ESXi data to our Pipeline. We'll do this using QuickConnect, which is the fastest way to configure a new Source, tie it to a Destination, and assign pre-processing and processing Pipelines to that Source. (We could also do this with Routes; that simply requires a few more configuration steps.)

In the **QuickConnect** UI:

1. Click **Add Source**.
2. From the resulting drawer's tiles, select [**Push** >] **Syslog**.
3. Click **Add New**.
4. Configure the fields and options as follows:
    - **Name**: `in_syslog_ESXi`.
    - **TCP**: `1517`. This is the TCP port on which ESXi servers send their logs.
    - **Pre-Processing** > **Pack**: Select `cribl-syslog-input`.

- **Fields (metadata)**: Add a `sourcetype` field with value `esxilogs`, and an `index` field with value `vmware-esxi`.

Adding metadata appropriate for ESXi

5. Click **Save**.
6. On the main **QuickConnect** page, drag a connector from `in_syslog_ESXi` to each Destination you want to receive these events. When prompted, select **Pipeline**, select your `DropNoisySyslog`, and click **Save**.
7. Commit and deploy, and you're all set!

Use Case B: Route Multiple Syslog Senders to a Source

Let's imagine you have incoming data from a router. This data is tagged with `sourcetype=myrouter`, and it includes a mix of DHCP actions, login/authentication attempts, and firewall traffic logs.

Our goal is to send each of the three data subsets of data – DHCP, login, and firewall – to its own Pipeline.

We know that the **Cribl Pack for Syslog Input** has a Lookup Function that – for data arriving on the default port – should return meta-information such as `sourcetype` or `index`. We can combine this metadata with some matching of strings within the data, in Route filters that direct the right data to the right Pipeline.

Although in reality, the `myrouter` firewall does not exist, the example that follows shows the art of the possible. We'll spell out the procedures as if the scenario were real. Perhaps one day you'll use it as a template for an actual deployment.

Create a Pipeline for Each Data Subset

- Create three Pipelines, naming each one for a data subset: `myrouter-dhcp`, `myrouter-auth`, and `myrouter-fw-traffic`.

- Leave the Pipelines empty for now; we'll add Functions later on.

Create a Route for Each Data Subset

1. Navigate to **Routing** > **Data Routes**.
2. Click **Add Route**.
3. Configure a Route as specified in the table below:

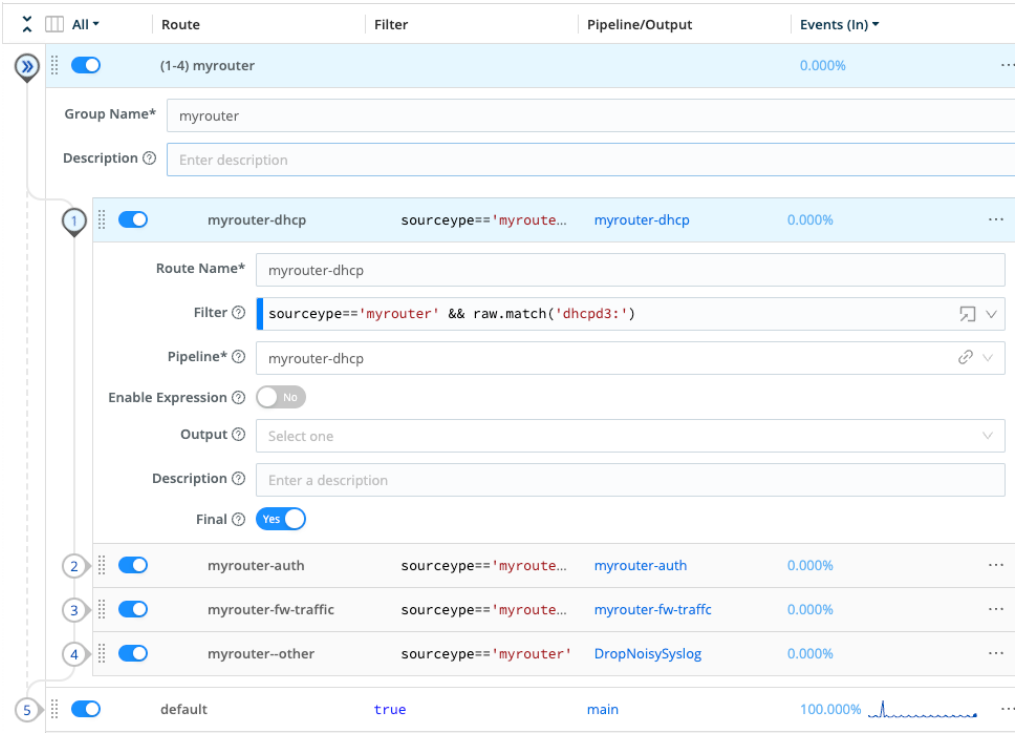
Name	Filter	Pipeline
`myrouter-dhcp`	`sourcetype=='myrouter' && raw.match('dhcpd3:')`	`myrouter-dhcp`
`myrouter-auth`	`sourcetype=='myrouter' && raw.match('login')`	`myrouter-auth`
`myrouter-fw-traffic`	`sourcetype=='myrouter' && raw.match('TRAFFIC')`	`myrouter-fw-traffic`
`myrouter-other`	`sourcetype=='myrouter'`	`DropNoisySyslog`

4. Repeat the preceding steps until you have configured four new Routes – one for each of the three data subsets, plus a final Route to drop events that don't match our Filters (i.e., noise).

All Routes should have the **Final** flag to `Yes`, and the output set to whatever Destination you think is appropriate for the given data subset.

5. Click the `myrouter-dhcp` Route's ••• (Options) menu, then select **Group Actions** > **Create Group**.
6. Name new Group `myrouter`.
7. Drag the Routes you created above into the new Group. (Be sure that `myrouter-other` is listed last.)
8. Drag the new Group to whichever vertical position makes the most sense for your deployment.

Once you've completed all the above steps, then after collapsing your new Routes, you should see something like this:



Example of Routes in a Group, each tied to the same sender

Next, edit each of the `myrouter-<data-subset>` pipelines:

- Use an Eval Function to modify the `sourcetype` (and perhaps other metadata.)
- Use appropriate Functions to accomplish the enrichment, suppression, volume reduction, and/or other transformations that the data needs.

Takeaways from This Routing / Pipeline Use Case

- Routing provides the flexibility needed when dealing with multiple datasets from a single sender, or when a single Source receives multiple datasets.
- Ensure that you have a dedicated Pipeline (and Route) for each discrete dataset that you want to manipulate in some way (e.g., `fw-traffic`).
- Ensure that you have a final Route that matches the general data from the overall sourcetype.
- Use the Routing page's Groups option to create logical containers for sets of Routes that belong together.

15.8.4.2. Palo Alto Syslog To Cribl.Cloud

Panorama management appliances give you insights into what is happening behind your Palo Alto Networks firewalls, including details about applications, URLs, threats, data files, and patterns. By forwarding logging data directly from Palo Alto firewalls or Panorama management appliances to your Cribl.Cloud instance, you can shape, process, search, and route the data to the analytics platform of your choice.

In this example, we will show you how to configure your devices so that you can connect to your Cribl.Cloud instance.

Obtain Cribl.Cloud CA Certificates

The first step is to obtain the CA chain from your Cribl.Cloud Organization. This script automates the process.

The `HOST` domain in this example uses the `default` Worker Group. Modify this substring, as needed, to query other Cribl.Cloud-managed Worker Groups.

```
#!/bin/bash
mkdir certstmp
if ! cd certstmp; then
   echo failed to cd into certstmp dir
   exit 1
fi

HOST=default.main.<OrganizationID>.cribl.cloud
PORT=6514
echo | openssl s_client -servername $HOST -showcerts -connect $HOST:$PORT 2> /dev/nu

for cert in $(ls -1); do
  newname=$(openssl x509 -noout -subject -in $cert | sed -nE 's/.*CN ?= ?(.*)/\1/; s,
  echo "${newname}"; mv "${cert}" "${newname}"
done
```

Example output:

```
thegoat@in certs % ls -la
total 24
drwxr-xr-x   5 thegoat  staff   160 Sep 13 21:45 .
drwx------@ 44 thegoat  staff  1408 Sep 13 20:45 ..
-rw-r--r--   1 thegoat  staff  2472 Sep 13 21:44 logstream_<OrganizationID>_cribl_cl
-rw-r--r--   1 thegoat  staff  1968 Sep 13 21:44 usertrust_rsa_certification_authori
-rw-r--r--   1 thegoat  staff  2431 Sep 13 21:44 zerossl_rsa_domain_secure_site_ca.p
```

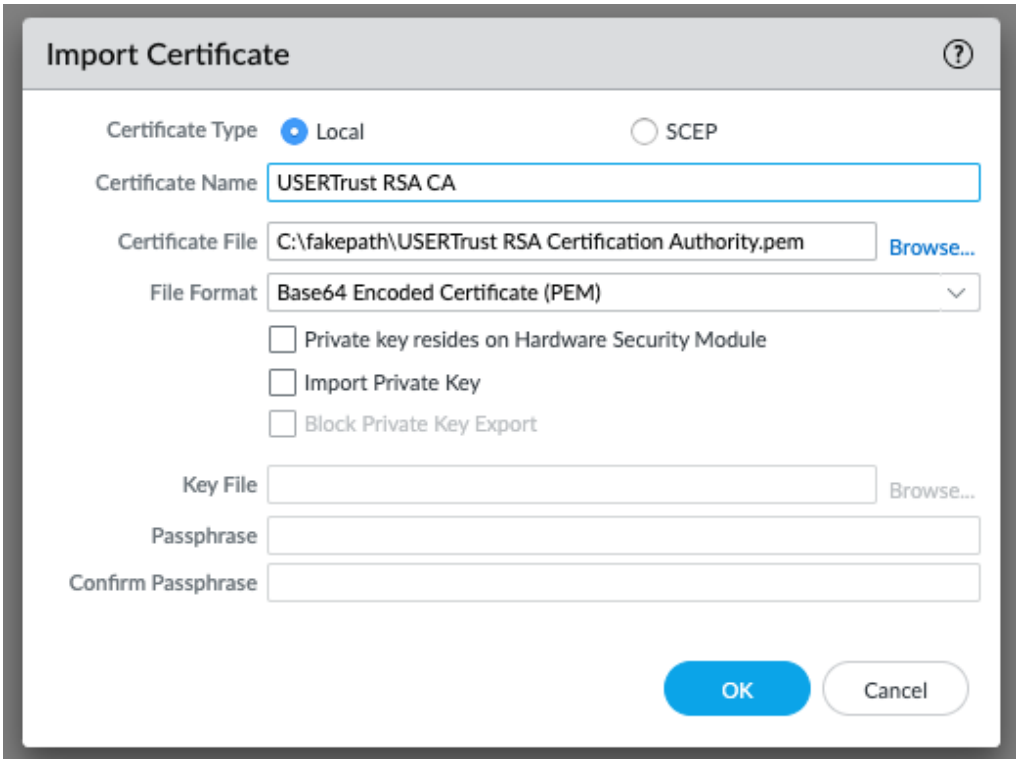
Import the `usertrust` and `zerossl` certs in the next section.

Import Trusted Roots into PAN

Next, you need to import the certificates into PAN. In the PAN OS:

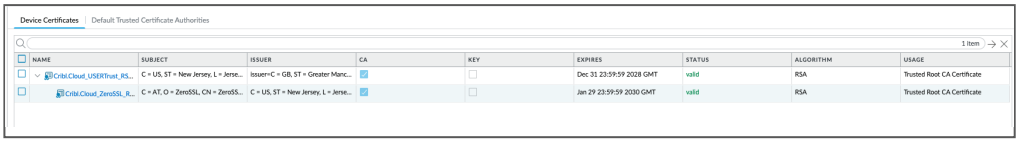
- Go to **Device** > **Certificate Management** > **Certificates**.
- Click the **Import** button at the bottom.
- The **Import Certificate** configuration modal (below) appears. Import the two certificates obtained in the previous section.

We configured the steps below on PAN OS `10.2.2`. The screenshots might vary depending on your software version, and on whether you are using PAN OS vs. Panorama.



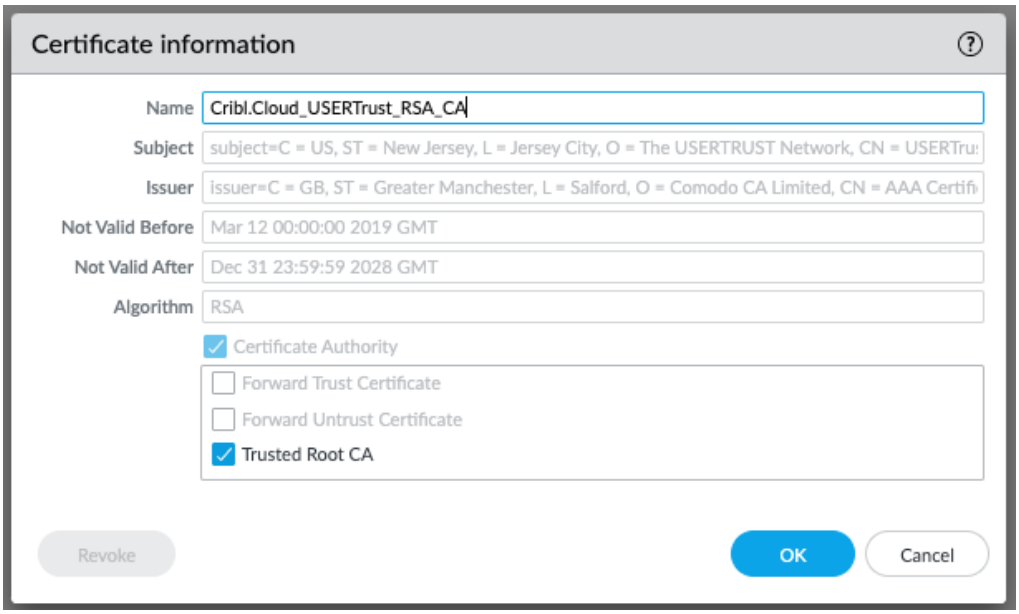
Import Certificate

- Once you have imported both certificates, go to the **Device Certificates** table and click on the blue link for each certificate you just imported.



Device Certificates

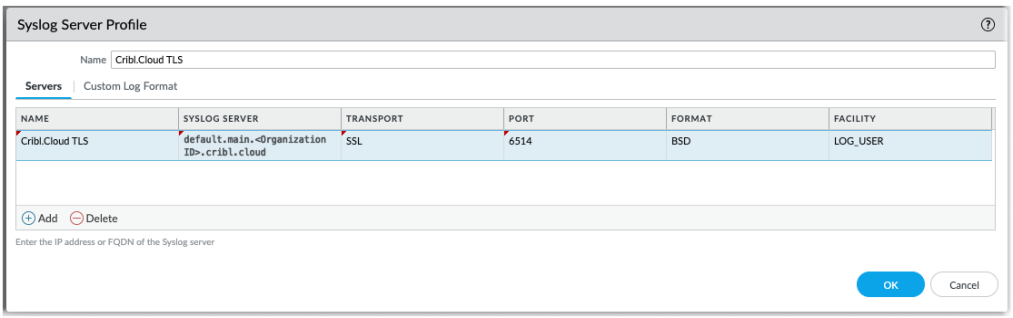
- Select the **Trusted Root CA** check box for each certificate.



Certificate information

Configure the Syslog Server Profile

After importing the certs, create a new Syslog Server Profile in **Device** > **Server Profiles** > **Syslog**.



Syslog Server Profile

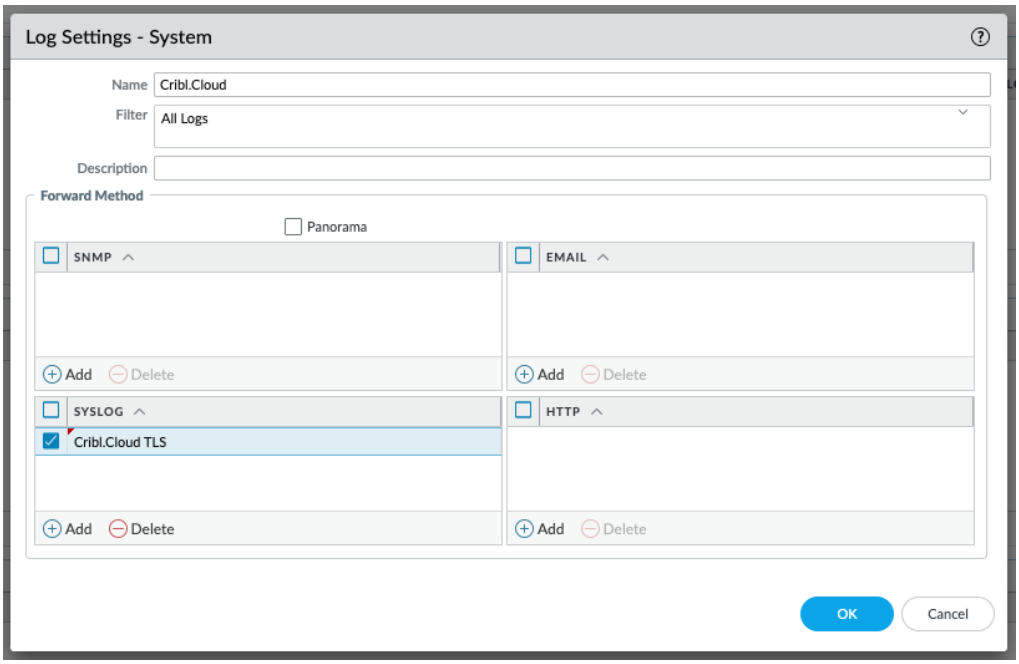
The Syslog server is the ingest address to your Cribl.Cloud Organization. To find your ingest address, click **Network Settings** at the top of your Organization's portal and select the Worker Group you're sending to. For example, sending to the `default` Group your ingest address would look like:

```
default.main.<OrganizationID>.cribl.cloud
```

Configure Log Settings to Use the Syslog Profile

Next, configure your log settings to use the Syslog Profile.

Go to **Device** > **Log Settings** and configure each relevant section with the appropriate settings.

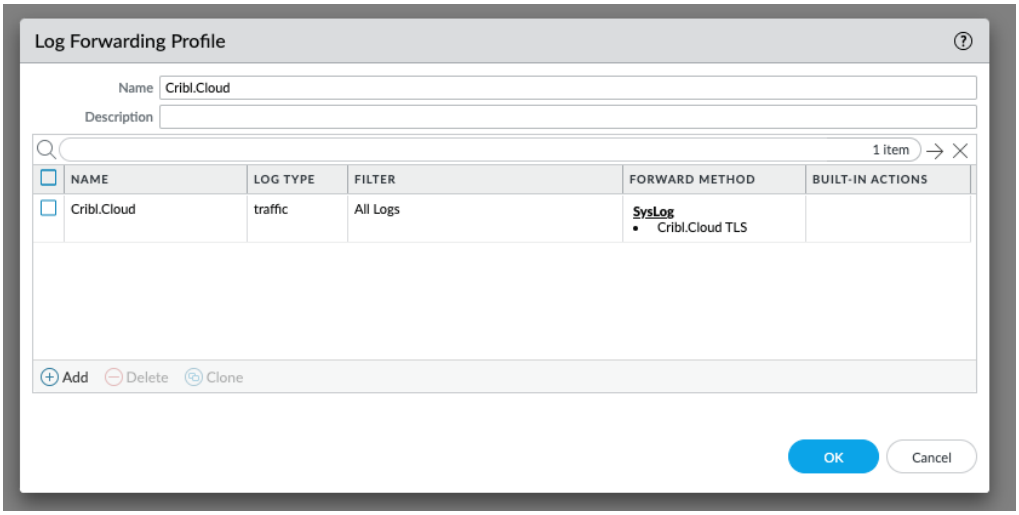


Log Settings

Configure Firewall Rule Log Forwarding

Use the **Log Forwarding Profile** to create a ruleset and configure the appropriate log types to be forwarded.

Go to **Objects** > **Log Forwarding** and configure each relevant section with the appropriate settings.



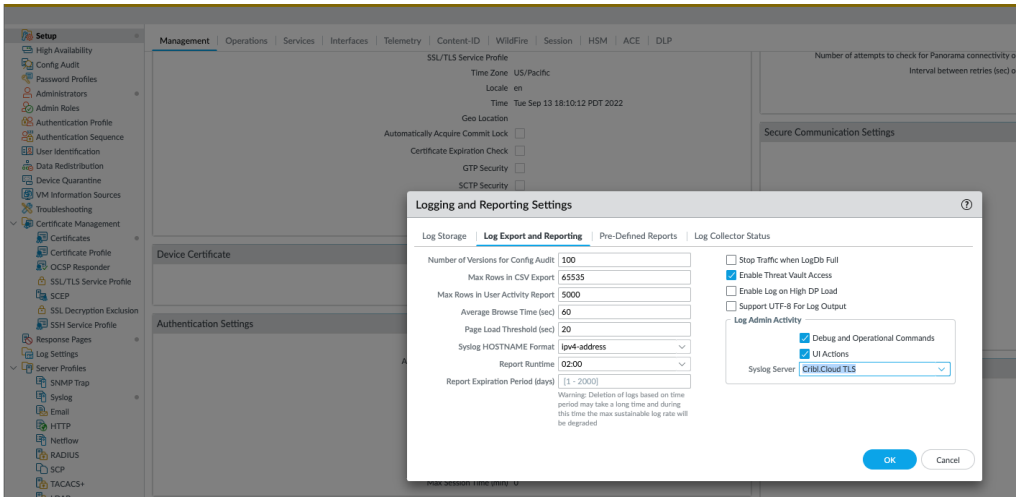
Log Forwarding Profile

Forward Admin Activity Logs

Admin activity logs can provide more context to your logs. To forward your admin activity logs:

Go to **Device** > **Setup** > **Management**, and click the gear icon in the **Logging and Reporting** settings.

Enable the **Debug and Operational Commands** and **UI Actions**, and choose the appropriate Syslog server.



Forwarding admin activity logs

Customize OCSP Validation Settings for the `syslog-ng` Process

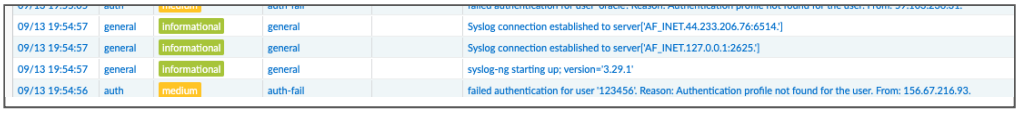
If the certificate validation fails, follow these steps to customize the validation settings for the `syslog-ng` process. You'll need to shell into the box to perform them.

These commands are for an individual PAN OS device, and might be different for Panorama:

```
set syslogng ssl-conn-validation all-conns skip
set syslogng ssl-conn-validation explicit OCSP skip CRL skip EKU skip
```

Validation

To validate whether you have successfully set up the TLS-encrypted Syslog, check the logs on your PAN OS.



09/13 19:54:57	general	informational	general		Syslog connection established to server['AF_INET.44.233.206.76:6514.']
09/13 19:54:57	general	informational	general		Syslog connection established to server['AF_INET.127.0.0.1:2625.']
09/13 19:54:57	general	informational	general		syslog-ng starting up; version='3.29.1'
09/13 19:54:56	auth	medium	auth-fail		failed authentication for user '123456'. Reason: Authentication profile not found for the user. From: 156.67.216.93.

Validating syslog setup

Troubleshooting

If you run into issues not anticipated above, you can use some of the following commands to further diagnose them:

```
# restart the syslog-ng process
debug syslog-ng restart

# see syslog-ng process logs
tail follow yes mp-log syslog-ng.log

# get stats for processes
debug log-receiver statistics
debug syslog-ng stats

# tcpdump activity on the syslog port and view the results
# note: control-c to exit the tcpdump, it will not show anything on the cli when runi
tcpdump filter "port 6514" snaplen 0
view-pcap mgmt-pcap mgmt.pcap
```

15.8.5. Configure Upstream Logging Agents

This page explains how to quickly connect a wide selection of common logging agents and other log sources to Cribl Stream. The examples below are equally valid for Cribl.Cloud and on-prem Cribl Stream instances.

Whichever source you choose, start by doing a live capture on the corresponding Source in Cribl Stream. Verify that data is coming in. Then save your capture to a sample file, which will help you build your Pipelines.

Fluent Bit and Fluentd

Both Fluent Bit (written in C) and fluentd (written in Ruby) are open-source log collectors, processors, and aggregators.

Fluent Bit to HEC

Of Fluent Bit's many output options, several work with Cribl Stream. Here's how to connect a Cribl Stream Splunk HEC Source to Fluent Bit with the Splunk HEC formatting option.

You'll need to copy and paste the following:

- From the Cribl.Cloud sidebar, select **Workspace** > **Data Sources** and copy the `in_splunk_hec` ingest address.
- From a Cribl Stream instance or Worker Group, select **Data** > **Sources** > **Splunk HEC** > `<source_name>` > **Auth Tokens**, and copy the HEC token.

Decide how to adjust the `match` parameter for your use case. For example, an asterisk (wildcard) value will send **all** events to Cribl Stream.

Edit the Fluent Bit settings accordingly. They're usually in `/etc/td-agent-bit/td-agent-bit.conf`, in a form similar to this:

```
[OUTPUT]
    name         splunk
    match        *
    host         in.main-default-<organization>.cribl.cloud
    port         8088
    splunk_token <HEC_token>
    tls          on
    # optional
```

Save the changes and restart the `td-agent-bit` service.

Fluent Bit to Elastic Sources

You can also connect Cribl Stream to Fluent Bit, using an Elastic Source.

```
[OUTPUT]
    name         es
    match        *
    host         10.0.21.134
    port         9200
    index        my_index
    type         my_type
```

Fluentd to HEC

If you don't already have it, install the `splunk_hec` fluentd mod:

```
sudo gem install fluent-plugin-splunk-hec
```

You'll need to copy and paste the following:

- From the Cribl.Cloud sidebar, select **Workspace** > **Data Sources** and copy the `in_splunk_hec` ingest address.
- From a Cribl Stream instance or Worker Group, select **Data** > **Sources** > **Splunk HEC** > `<source_name>` > **Auth Tokens**, and copy the HEC token.

Decide how to adjust the `match` parameter for your use case. Use an asterisk (wildcard) if you want to send **all** events to Cribl Stream.

Edit the `<match` section of the fluentd settings accordingly. They could be in `/etc/fluent/fluent.conf` or another location, as described in the fluentd docs.

```
<match **>
  @type splunk_hec
  @log_level info
  hec_host in.main-default-<organization>.cribl.cloud
  hec_port 8088
  hec_token <HEC_token>
  index <index_name>
  source_key <file_path>
  <format>
    @type json
  </format>
</match>
```

Save the changes and restart fluentd.

Splunk

Cribl Stream can directly ingest the native Splunk2Splunk (S2S) protocol. As a result, both Splunk universal and heavy forwarders can send log data to Cribl Stream.

Splunk Forwarder (Universal or Heavy) to Splunk TCP

See how to configure a Splunk Forwarder in the Splunk TCP Source document.

Elastic

In the Elastic ecosystem, Elastic Filebeat is an agent that functions as a lightweight shipper for forwarding and centralizing log data.

Elastic Filebeat

Cribl Stream can ingest the native Elasticsearch streaming protocol directly.

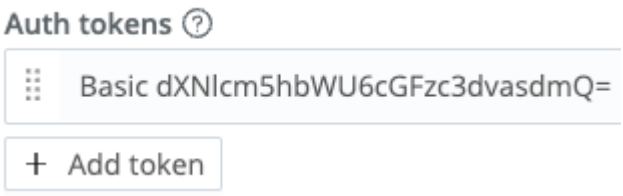
Cribl recommends setting an authorization token so that your receiver will accept only your traffic. This setting is in the **Auth Tokens** field of Cribl Stream's **Sources** > **Elasticsearch API** > **General Settings** tab.

If you want to enable Basic authentication:

- Concatenate your username and password with a colon in between, like this: `username:password`.

- Encode the `username:password` string using base64.
- Prepend the string `Basic ` (including the trailing space) to the encoded string.
- Enter the resulting string in the **Auth tokens** field as described above.

You'll see something like this:



Basic auth in the Cribl Stream Elasticsearch API Source

```
output.elasticsearch:
  hosts: ["in.main-default-<organization>.cribl.cloud:9200/search"]
  protocol: "https"
  ssl.verification_mode: "full"
  username: <some_username>
  password: <some_password>
```

syslog

To receive syslog data in Cribl Stream, create a native Syslog Source. See Cribl's best practices for working with syslog data.

Cribl recommends not using UDP over the public internet. UDP examples are included here for test purposes only.

UDP, by definition, does not guarantee delivery. While TCP mitigates this problem, using either UDP or TCP without TLS over the public internet exposes unencrypted data.

syslog-ng (TLS over TCP)

Cribl recommends using TLS over TCP to send data from syslog-ng to Cribl Stream.

Here's an example of `syslog-ng.conf` edited such that all event data will be encrypted on the way to Cribl.Cloud. Adapt the snippet to your use case and edit `syslog-ng.conf` accordingly.

```
destination d_syslog {
    syslog("in.main-default-<organization>.cribl.cloud"
        transport("tls")
        port(6514)
        tls(
            peer-verify(required-trusted)
            ca-dir("/etc/syslog-ng/ca.d")
        )
    );
};

log {
    source(s_network);
    destination(d_syslog);
};
```

Save the changes and restart the syslog-ng service.

syslog-ng (UDP or TCP)

Here's an example of `syslog-ng.conf` – for test purposes only, because it does not use TLS.

Adapt the snippet to your use case, and edit `syslog-ng.conf` accordingly. You can change `tcp` to `udp` to switch protocols.

```
destination d_syslog {
    syslog("in.main-default-<organization>.cribl.cloud"
        transport("tcp")
        port(9514)
    );
};

log {
    source(s_network);
    destination(d_syslog);
};
```

Save the changes and restart the syslog-ng service.

syslog-ng with Load-Balanced Outputs

You can forward logs from syslog-ng to multiple Cribl Stream Workers through a redundant, load-balanced output by using the syslog-ng `elasticsearch-http` output module. With this arrangement, syslog-ng receives syslog messages over TCP and/or UDP and outputs events over the Elasticsearch HTTP Bulk API to Cribl Stream Workers.

Forwarding to Cribl Stream from the syslog-ng `elasticsearch-http` output module requires syslog-ng version 3.19 or higher.

To check your syslog-ng version, run the following command:

```
syslog-ng -V
```

Adapt the snippet to your use case, and edit `syslog-ng.conf` accordingly. To learn more about syslog-ng destination flags, see the syslog-ng Administration Guide.

```
@version: 3.33
@include "scl.conf"

# Inputs
source s_network {
    # flags(no-parse) disables syslog-ng parsing of syslog messages (raw passthru)
    network(transport("tcp") port("9514") flags(no-parse));
    network(transport("udp") port("9514") flags(no-parse));
};

destination d_elasticsearch_tls {
    # https://www.syslog-ng.com/technical-documents/doc/syslog-ng-open-source-editio
    elasticsearch-http(url("https://worker1:9200/_bulk" "https://worker2:9200/_bulk"
        batch-lines(100)
        batch-bytes(512Kb)
        batch-timeout(2500)
        persist-name("d_elasticsearch-http-load-balance")
        type("")
        index("syslog")
        # Auth token
        #headers("Authorization: <token from Stream>")
        # or Basic Auth
        #user("username")
        #password("password")
    );
};

log {
    source(s_network);
    destination(d_elasticsearch_tls);
};
```

Save the changes and restart the syslog-ng service.

rsyslog (TLS over TCP)

You'll need to install the `rsyslog-gnutls` package if it's not already on your system. E.g.:

```
apt install rsyslog-gnutls
```

If the `rsyslog-gnutls package` is not already on your system, run the following command (or equivalent) to install it:

```
apt install rsyslog-gnutls
```

Cribl recommends using TLS over TCP to send data from rsyslog to Cribl Stream.

Here's an example of `rsyslog.conf`, edited such that all event data will be encrypted on the way to Cribl.Cloud. Adapt the snippet to your use case, and edit `rsyslog.conf` accordingly:

```
# path to the crt file.
# You will need a valid ca cert file. Most linux distros come with this
$DefaultNetstreamDriverCAFile /etc/ssl/certs/ca-certificates.crt

*.*     action(
         type="omfwd"
         target="in.main-default-<organization>.cribl.cloud"
         port="6514"
         protocol="tcp"
         action.resumeRetryCount="100"
         queue.type="linkedList"
         queue.size="10000"
         StreamDriver="gtls"
         StreamDriverMode="1" # run driver in TLS-only mode
)
```

Save the changes and restart the rsyslog service.

rsyslog (UDP or TCP)

Here's an example of `rsyslog.conf` – for test purposes only, because it does not use TLS.

Adapt the snippet to your use case, and edit `rsyslog.conf` accordingly. You can change `tcp` to `udp` to switch protocols.

```
*.*     action(
         type="omfwd"
         target="in.main-default-<organization>.cribl.cloud"
         port="9514"
         protocol="tcp"
         action.resumeRetryCount="100"
         queue.type="linkedList"
         queue.size="10000"
)
```

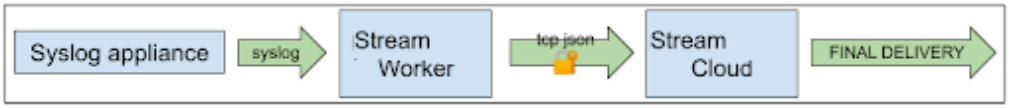
Save the changes and restart the rsyslog service.

Appliances that Send syslog

Many appliances emit syslog data. At a minimum, configure your appliance(s) to send syslog over TCP with TLS enabled, if possible.

Even better, stand up a Cribl Stream instance close to the appliances in your network topology. Have the appliances send syslog to the nearby Cribl Stream, which can optionally transform, filter, and/or enhance the data, and then send it to a more centralized Cribl Stream cluster in Cribl.Cloud or an one-prem location.

The Cribl Stream worker that's closest to the appliance will use TCP JSON, with TLS enabled, to send syslog to the second Cribl Stream instance:



Sending syslog from an appliance to Cribl Cloud

The benefits of placing the first Cribl Stream instance close to the log producer include:

- Since there are fewer network hops, UDP becomes a more viable option, if you want it.
- If you're using TCP, that can be more performant here than it would be across the internet.
- The first Cribl Stream instance can do data reduction and/or compression. These operations reduce the volume of the data hitting the wire on the way to the next hop.
- This can help keep data egress costs under control.

Vector

Vector is Datadog's tool for building observability pipelines.

Vector to HEC

Vector supports Splunk's HTTP Event Collector (HEC). Here's how to connect a Cribl Stream Splunk HEC Source to Vector.

For Cribl.Cloud especially, Cribl recommends setting an authorization token so that your receiver will accept only your traffic. This setting is in Cribl Stream's **Sources** > **Splunk HEC** > **Auth Tokens** tab.

The snippet below references a random syslog generator called `dummy_logs` for testing purposes. Adapt the snippet to your use case and edit `vector.toml` (or `vector.yaml` or `vector.json`) accordingly.

```
[sinks.my_sink_id]
type           = "splunk_hec"
inputs         = [ "dummy_logs" ]
endpoint       = "https://in.main-default-<organization>.cribl.cloud:8088"
compression    = "gzip"
token          = "<optional-but-recommended>"
encoding.codec = "json"
```

Vector to Elasticsearch

Vector supports Elasticsearch API. Here's how to connect a Cribl Stream Elasticsearch API Source to Vector.

The snippet below references a random syslog generator called `dummy_logs` for testing purposes. The snippet also specifies Basic authentication. Follow the procedure for enabling Basic authentication described in the Elastic Filebeat example above.

Adapt the snippet to your use case and edit `vector.toml` (or `vector.yaml` or `vector.json`) accordingly.

```
[sinks.elastic_test]
type          = "elasticsearch"
inputs        = [ "dummy_logs" ]
endpoint      = "https://in.main-default-<organization>.cribl.cloud:9200/search"
compression   = "gzip"
index         = "my_es_index"
auth.user     = "<some_username>"
auth.password = "<some_password>"
auth.strategy = "basic"
```

Pull-based Sources

All the above data sources **push** data into Cribl Stream. Here are brief notes on configuring some popular Cribl Stream-native Pull Sources:

Amazon Kinesis

You can create an Amazon Kinesis Source in Cribl Stream. This is straightforward for on-prem Cribl Stream instances.

Cribl.Cloud sits behind an network load balancer, which Amazon Data Firehose does not support. For this reason, the best option for connecting Amazon Kinesis to Cribl.Cloud is to (1) have Amazon Data Firehose write to an Amazon S3 bucket, and (2) set up a Cribl Stream Amazon S3 Source to pull data from there, as described in the next section.

Amazon S3

Configuring an S3 Source is virtually the same for Cribl.Cloud as it is for on-prem Cribl Stream instances.

See this in-depth article about the Cribl Stream S3 Source, whose content also applies to Cribl.Cloud. Here's an overview of the process:

- Configure an S3 bucket to send `s3:ObjectCreated:*` events to an SQS queue.
- Configure a Cribl Stream S3 (Pull) Source (not Collector) to subscribe to the SQS feed from step 1.
    - Be sure to properly configure permissions for the Secret/Access keys you use for authentication.
- Set up Event Breaker rules as required based on the contents of your log files.

Office 365 Service, Activity, or Message Trace

Configuring an Office 365 Services, Activity, or Message Trace Source is virtually the same for Cribl.Cloud as it is for on-prem Cribl Stream instances. Note that you need to start your Office 365 Content subscription from within Office 365, or there will be no data available to pull.

AppScope

Integrating AppScope with Cribl Stream is simple and fast. The easiest way is to just set the `$SCOPE_CRIBL` environment variable to define a connection between Cribl Stream and AppScope.

For example, you could "scope" the `nginx` command, and send the captured data using TLS over TCP:

```
SCOPE_CRIBL=tcp://in.main-default-<organization>.cribl.cloud:10091 scope nginx
```

15.8.6. BigPanda/Webhook Integration

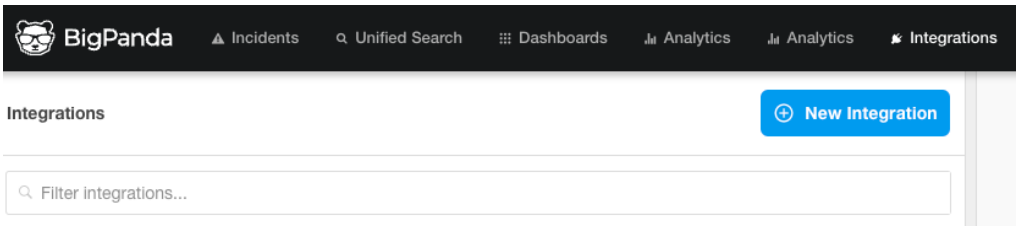
You can configure Cribl Stream to send Webhook notifications to the BigPanda IT Ops platform. These notifications arrive in BigPanda as Alerts, which BigPanda correlates into Incidents.

Before you begin, you should have an Admin account on a BigPanda Cloud instance.

Prepare BigPanda to Receive Data from Cribl Stream

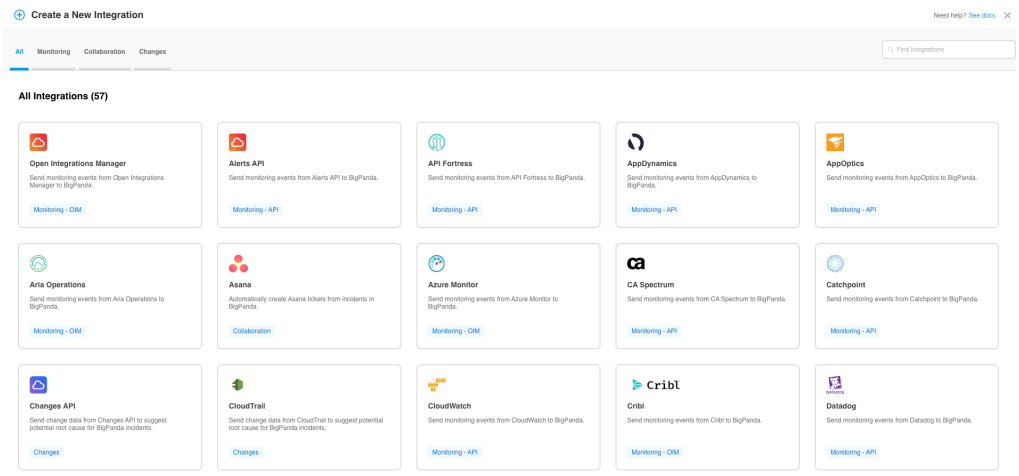
The BigPanda **App Key** and **Access Token** are separate and independent. The **Access Token** is a 32-character string that is part of the value that BigPanda generates for the `Authorization` HTTP header. (It functions like an auth token or bearer token.)

1. Log into your BigPanda Cloud instance as an Admin.
2. In the **Integrations** tab, select **New Integration**.



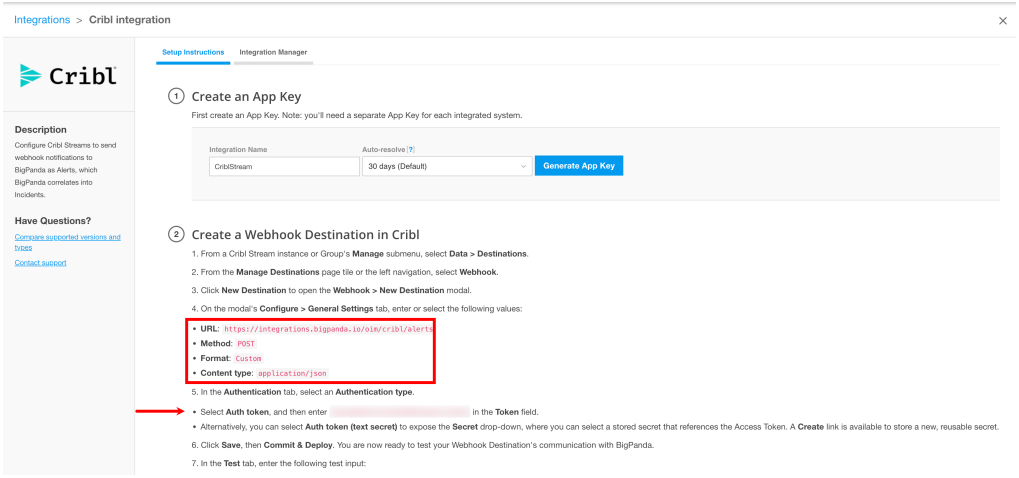
The **Integrations** tab

3. In the **Create a New Integration** modal, select the Cribl tile.



The **Create a New Integration** modal

- This opens the **Cribl Integration** page.



The **Cribl Integration** page

4. In the **Create an App Key** section, generate an App Key named `Cribl Stream`. You'll need the App Key when configuring Cribl Stream in the next section. Cribl Stream will insert the App Key into every event it sends to BigPanda.
5. BigPanda will generate a page containing setup instructions for the Cribl Stream Webhook Destination. Store the following information:
    - **URL**: `https://integrations.bigpanda.io/oim/cribl/alerts`.
    - **Method**: `POST`.
    - **Format**: `Custom`.
    - **Content Type**: `application/json`.
    - **Authentication token**: A 32-character `<auth-token>`.

The BigPanda page will also contain test code. You'll need the preceding information and the test code when configuring Cribl Stream in the next section.

Configure the Webhook Destination in Cribl Stream

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Destinations**. Then select **Webhook**. Next, select **Add Destination**.
2. On the modal's **Configure** > **General Settings** tab, enter or select the following values:
    - **URL**: Enter the Alerts API endpoint URL, for example: `https://integrations.bigpanda.io/oim/cribl/alerts`.
    - **Method**: `POST`.
    - **Format**: `Custom`.
    - **Content type**: `application/json`.

3. In the **Authentication** tab, select an **Authentication type**.
    - You can select **Auth token**, and then enter the Access Token (the 32-character string you wrote down earlier) in the **Token** field.
    - Alternatively, select **Auth token (text secret)** to expose the **Secret** drop-down, in which you can select a stored secret that references the Access Token. A **Create** link is available to store a new, reusable secret.
4. Select **Save**, then **Commit & Deploy**. You are now ready to test your Webhook Destination's communication with Big Panda.
5. In the **Test** tab, enter the test code from the BigPanda setup instructions. It will look like this:

```
[
        {
                "app_key": "<your_app_key>",
                "status": "critical",
                "host": "production-database-1",
                "timestamp": 1402302570,
                "check": "CPU overloaded",
                "description": "CPU is above upper limit (70%)",
                "cluster": "production-databases",
                "my_unique_attribute": "myUniqueValue987654321"
        }
]
```

6. Select **Run Test**.

This should send an alert to BigPanda.

BigPanda Alerts API Requirements

HTTP payloads sent to the BigPanda Alerts API must satisfy rules that are beyond the scope of this topic. For details, see the BigPanda documentation about Alert Properties and Integration Diagnostics.

However, at at minimum, three fields are required:

1. `app_key`.
2. `status`.
3. `host` OR `service` OR `application` OR `device`.

Thus, the test input shown above works even if you omit all but the first three fields.

There are other possibilities for the third field, but they require understanding how BigPanda determines the `primary_property` of an Alert, plus some additional BigPanda configuration. See the BigPanda links above for details.

BigPanda Alert Deduplication

BigPanda processes an alert's Primary and Secondary properties on ingestion. These properties default to `host` and `check`.

When an alert has the same Primary and Secondary properties as those received in previous alerts, the Incident Console shows only the timestamp from the initial event.

For more information on this functionality, see the BigPanda pages Deduplication and Incident_identifier.

Verify that BigPanda is Receiving Notifications and Events

In the BigPanda **Incidents** tab, you should see an Incident whose Source is `Cribl Stream`. The details of the test input you sent from the Webhook Destination should appear in an Alert within that Incident. If so: It works!

15.8.7. Gigamon To Cribl Stream

Gigamon and Cribl have integrated the Gigamon GigaVUE Cloud Suite with Cribl Stream to optimize telemetry intelligence delivery across hybrid cloud infrastructures. This integration enables seamless data formatting and routing, enhancing the value of existing tools by providing comprehensive observability and security.

Gigamon's Deep Observability Pipeline, with GigaVUE Cloud Suite, delivers deep visibility into hybrid cloud traffic, improving security and performance by addressing East-West application traffic blind spots. Cribl's data management solution enhances threat detection and incident response through seamless access, enrichment, and routing of telemetry data from multiple sources.

In this integration, data is sent from the Gigamomn Application Metadata Exporter to a Cribl Stream HTTP Raw Source.

Prerequisites

- Your Gigamon GigaVUE Cloud Suite has the AMI module enabled.
- You've enabled the appropriate Application Metadata Intelligence attributes.
- You know your Cribl Stream Worker Group ingress address, shown on the **Overview** page under **Group Information**.

Configuring Cribl Stream

1. In your Cribl Stream account, select the Worker Group that will receive the data.
2. Select **Processing**, then **Packs**. Add the **Gigamon** Pack from the Dispensary to your Worker Group.
3. Select **Routing**, then **QuickConnect**. Select **Add Source** and add a new **Raw HTTP** Source.
4. Configure the new Raw HTTP Source as follows:
    - **General Settings**:
        - **Input ID**: Enter a unique name to identify this Raw HTTP Source definition. Such as `Raw HTTP`.
        - **Address**: Enter the address to bind on. Use `0.0.0.0` to bind on all addresses.
        - **Port**: Enter `20001`. This port number is used in the Cribl Stream Worker Group ingress address you'll provide to Gigamon.
    - **Authentication**:
        - Select **Add token** and **Generate** an **Auth token**. You'll provide this token to Gigamon when configuring your **Monitoring Session**.
5. Click **Save**.

6. Use QuickConnect to connect your new Raw HTTP Source to Cribl Destinations. Be sure to use the Gigamon Pack for the connection configuration.
7. **Commit & Deploy** your changes.

Configuring Gigamon to Export Data to Cribl Stream:

1. In your Gigamon instance, navigate to the **Traffic** section from the FM instance.
2. Select the location of your deployment, like `AWS`.
3. Choose and edit your **Monitoring Instance**.
4. Select the **Details** for your AMX instance.
5. Create a new Cloud Tool Export as follows:
    - **Alias**: `Cribl`
    - **Cloud Tool**: `Other`
    - **Endpoint**: Provide your Cribl Stream Worker Group ingress address with port `20001`. For example, `https://workergroup.main.orgname.cribl.cloud:20001`.
    - **Headers**:
        - **Authorization**: Provide the **Auth token** you generated when configuring the Cribl Stream **Raw HTTP Source**.
        - **Content-Type**: `application/json`
    - **Enable Export**: Check the box to enable.
    - **Format**: `JSON`
6. Click **Save** and **Deploy** the changes.

Verifying Data Flow

There are many ways to monitor the status of your Source. Navigate to the Source and use the available tabs.

- Use the **Live Data** tab to capture metadata received by Cribl Stream.
- The **Charts** tab displays throughput details.
- The **Status** tab provides details about the Workers in the group and their status.

You can also monitor Source throughput on the Monitoring page.

15.8.8. System Metrics To Grafana

Cribl Stream can collect metrics from the host on which it is running, and can populate some standard metrics dashboards right out of the box. For metrics details, see Linux System Metrics Details. While, Grafana is a multi-platform open source analytics and interactive visualization web application. It provides charts, graphs, and alerts for the web when connected to supported data sources.

Cribl has configured a Prometheus dashboard to display Cribl Stream System Metrics, and shared the dashboard in the Grafana library, which is public. This is a relatively simple dashboard suitable for showing aggregate metrics.

Another useful dashboard is the one that's commonly used with Prometheus and their Node Exporter agent, found here. This dashboard can handle the highly detailed metrics.

In this guide, we will show you how to route system metrics to a Grafana dashboard for both basic and highly detailed metrics visualizations.

We will walk you through the following:

- Configure System Metrics Source on Cribl Stream to receive metrics from the host.
- Configure the Prometheus Destination to send data to Grafana Cloud.
- Access Grafana Cloud to see the metrics and visualizations.

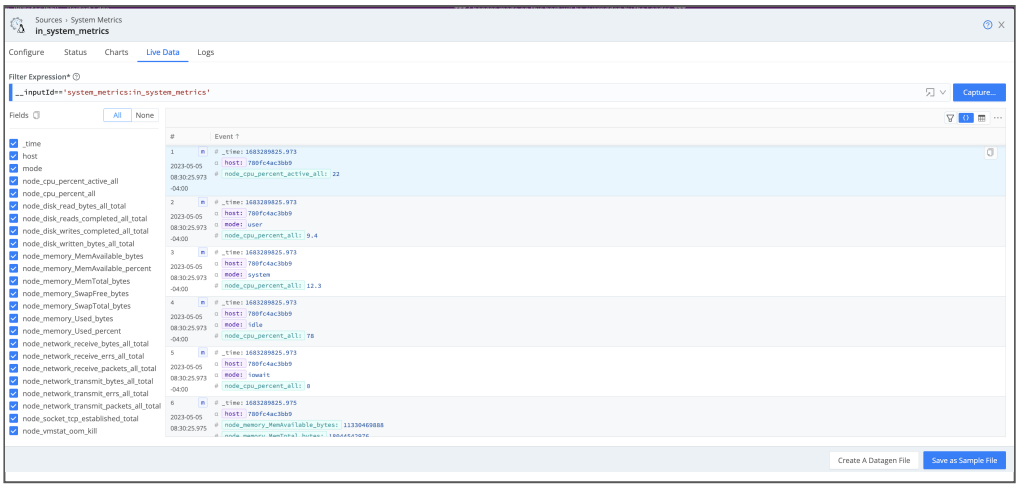
Configure the System Metrics Source on Cribl Stream

In Cribl Stream, start by configuring and enabling a System Metrics Source. The key requirement here is to to decide on the level of details for the metrics you want to collect. In the **Host Metrics** and **Container Metrics** tabs:

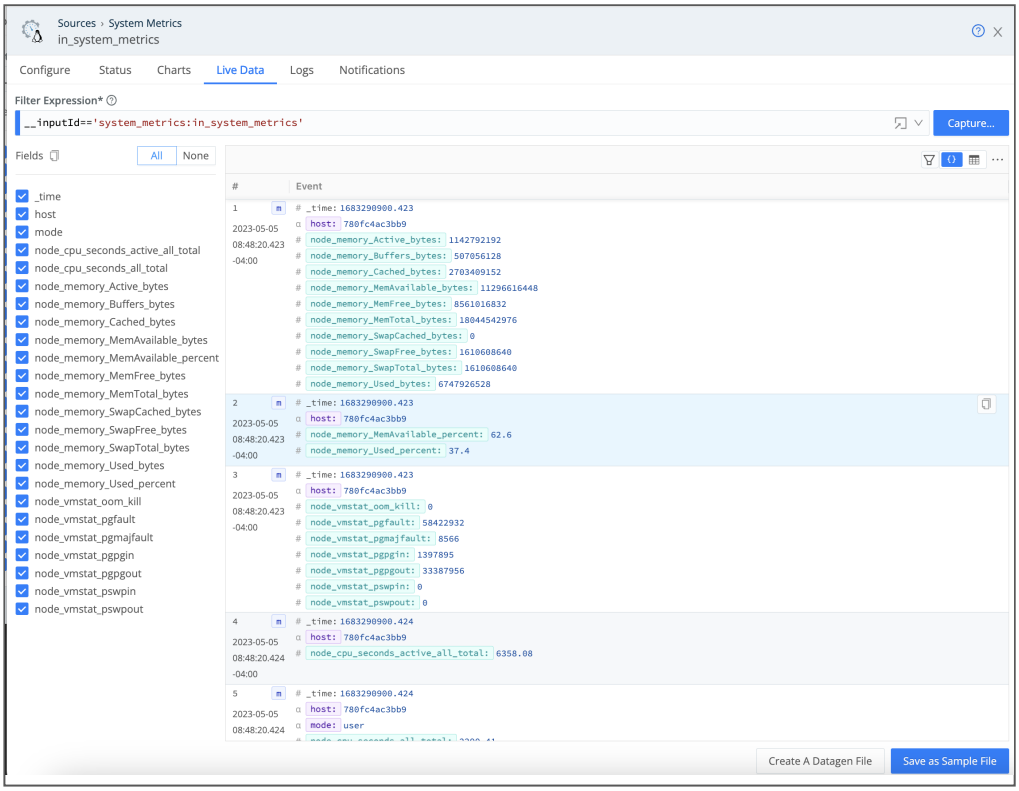
- For the relatively simple dashboard showing aggregate metrics, choose the **Basic** mode for most of your metrics.
- For the highly detailed metrics visualizations dashboard, choose the **All** mode for all of your metrics.

In the **Pre-Processing** tab, select the `prometheus_metrics` **Pipeline**.

When done, **Commit** and **Deploy** your changes. Before moving on to the next step, check the **Live Data** tab to make sure the metrics are generated.



Basis System Metrics

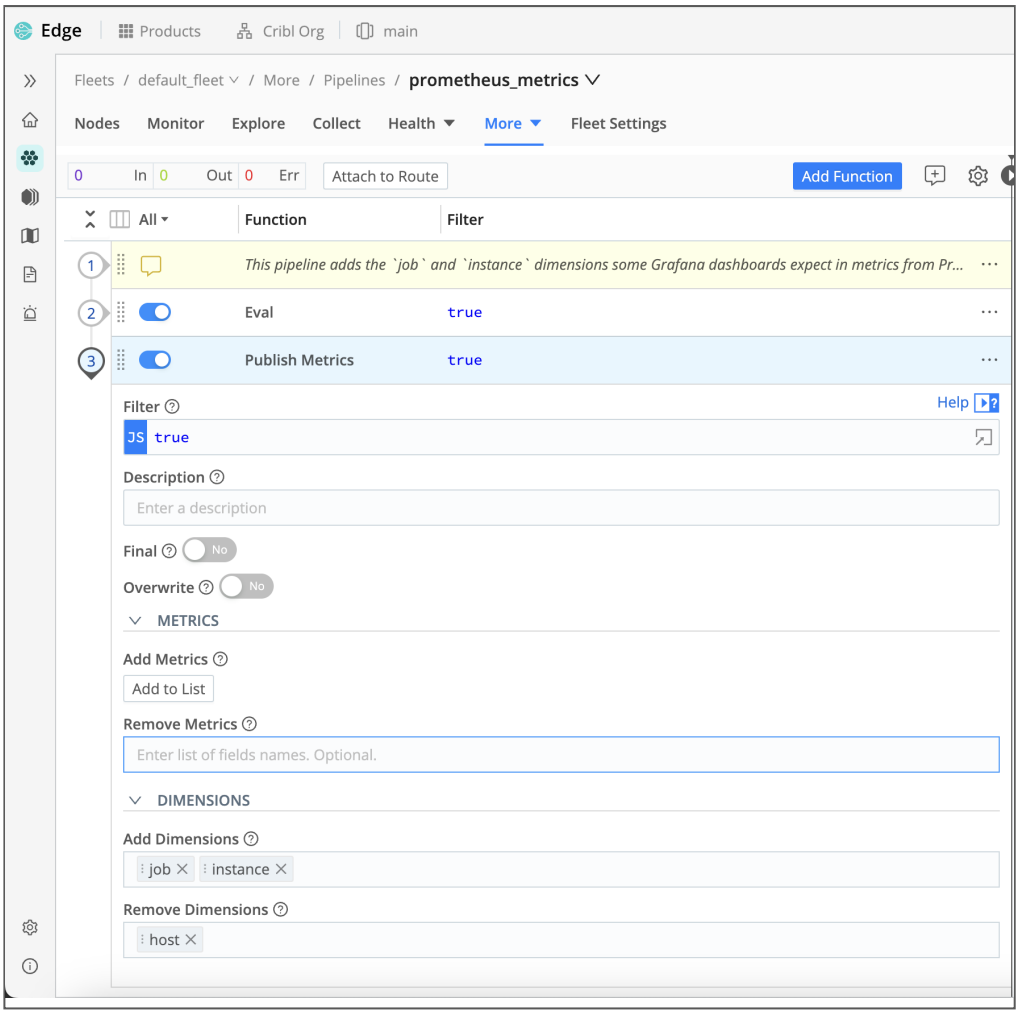


Detailed System Metrics

(Optional) Adjust the `prometheus_metrics` Pipeline

Optionally, you can adjust the `prometheus_metrics` Pipeline to include the `host` dimension or add/remove more dimensions.

Select a **Fleet** to configure. From the Fleet's submenu, select **More** > **Pipelines**.

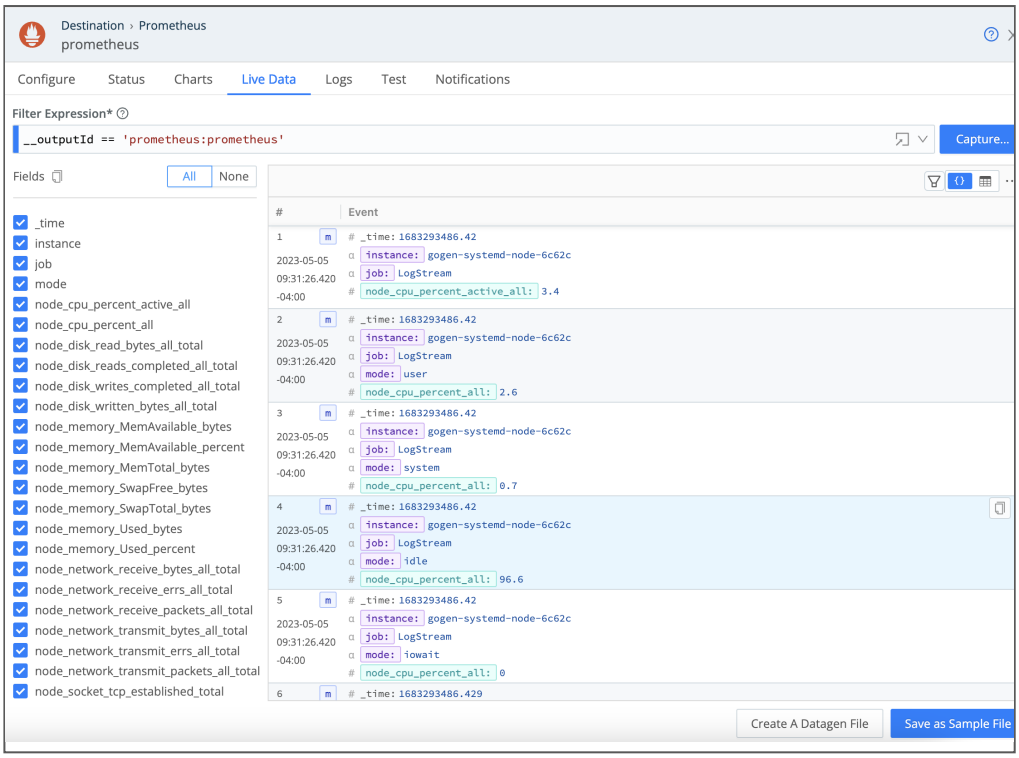


Adjust the Pipeline

Configure the Prometheus Destination

Next, we'll configure the Prometheus Destination to send data to Grafana Cloud.

Next, preview your data on the modal's **Live Data** tab.

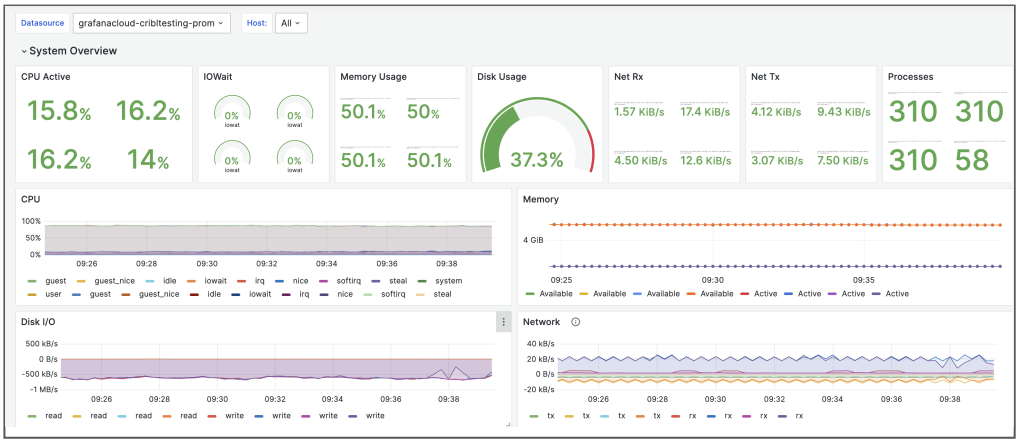


Preview Live Data

Visualize the Data in Grafana

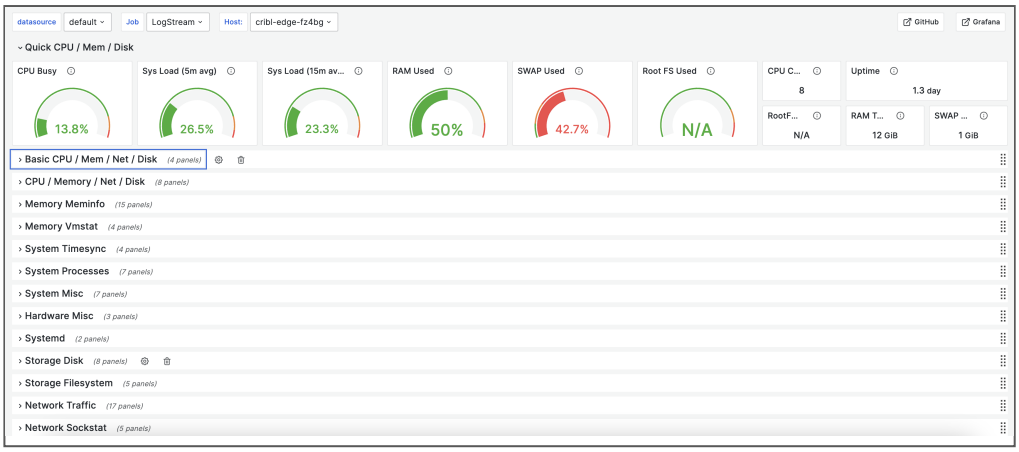
Navigate to your Grafana Cloud instance, and select **Explore** on the left panel to review the node metrics. Selecting metrics and running the query will produce a chart and table of metric events that can be added to new or existing dashboards for analysis. If you are missing some expected metrics, you might need to adjust the variables in your Grafana Cloud instance. For details, see Variables.

Use the Grafana **Filter** option to browse the dashboards for your Prometheus data. Below are the Cribl dashboards with the basic and detailed metrics shown.



Cribl Node Observability

To view the detailed panels, select the arrow for each category:



Node Exporter Full

15.8.9. Kafka Authentication With Kerberos

This page describes how to configure a Kafka Source and Destination to use Kerberos authentication. It also documents the verification steps required to test your setup.

Availability:

- Kerberos is available only on Linux, so you'll have to use a Linux host or Linux container to work through this procedure.
- Kerberos is not supported for Cribl-managed Cribl.Cloud Workers, but it is enabled for customer-managed (hybrid or on-prem) Worker Groups, whether the Leader is based in Cribl.Cloud or on-prem.

For additional information on Kafka configuration, see also our Kafka Source or Kafka Destination reference topics.

Setting up the Cribl Stream Host

Once you have set up an instance of Kafka with Kerberos, perform the following steps on the same host where Cribl Stream is running:

1. Install `krb5-user` (or the equivalent for non-Ubuntu systems) on your Worker Node.
2. Ensure that you have a valid `/etc/krb5.conf` file. Consult your Kerberos admin if you don't have one. Kerberos authentication with Kafka specifically requires `rdns = false` in this config, but no other special settings. Cribl Stream supports the file and directory cache types.
3. Ensure that the keytab path in your configuration points to a valid keytab on each Worker Node.

Configuring the Kafka Destination

Create a new Kafka Destination with the following settings:

General Settings

- **Brokers**: `broker.kerberos-demo.local:9092`
- **Topic**: `Cribl`

Authentication Settings

- **Enabled**: `Yes`
- **SASL mechanism**: `GSSAPI/Kerberos`

- **Keytab location**: `/<path-to-client-keytab>/kafka-client.key`. This path to the valid keytab file must be available on all Worker Nodes.
- **Principal**: `kafka_producer@TEST.CONFLUENT.IO`
- **Broker service class**: `kafka`

Configuring the Kafka Source

Create a new Kafka Source with the following settings:

General Settings

- **Brokers**: `broker.kerberos-demo.local:9092`
- **Topic**: `Cribl`
- **Group ID**: `Cribl`

Authentication Settings

- **Enabled**: `Yes`
- **SASL mechanism**: `GSSAPI/Kerberos`
- **Keytab location**: `/<path-to-client-keytab>/kafka-client.key`
- **Principal**: `kafka_producer@TEST.CONFLUENT.IO`
- **Broker service class**: `kafka`

Verifying the Setup

1. Open the **Live Data** tab and start a capture with **Capture Time (sec)** and **Capture Up to N Events** set to high values (e.g., `1000`).
2. In a separate browser tab, navigate to the Destination's **Test** tab and click **Run Test** a few times.
3. Return to the Source's **Live Data** tab and verify that the Source is capturing events.
4. When you're done testing, run `./stop.sh` from the same directory where you ran `./start.sh` to set up your environment.

15.8.10. Moogsoft/Webhook Integration

Written for Cribl by Douglas Bothwell, formerly of Moogsoft.

You can configure Cribl Stream to send Webhook notifications to Moogsoft, using custom integrations. A custom integration is a user-defined Moogsoft endpoint that ingests JSON payloads, and converts them to Moogsoft events or metrics.

Note these options:

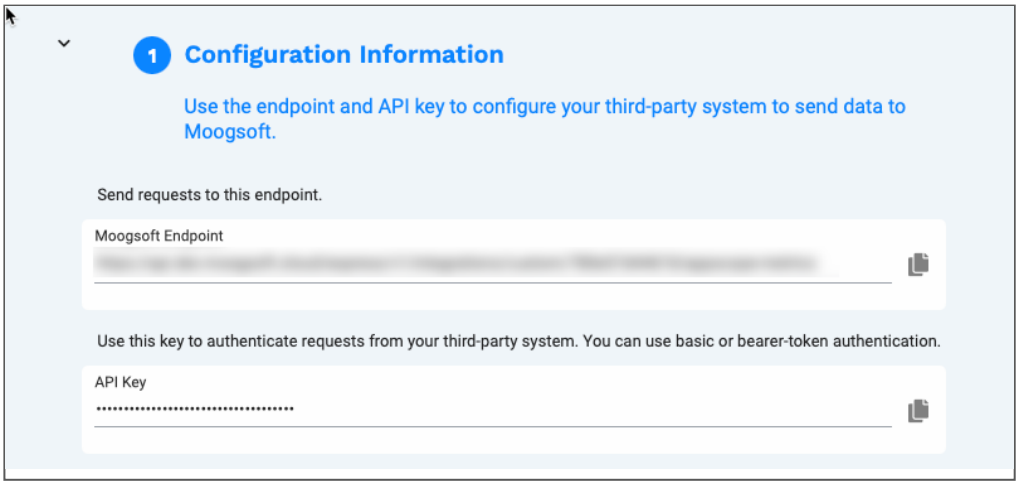
- A Moogsoft custom integration can ingest either events or metrics. Each custom integration has its own separate API key, and its own Cribl-to-Moogsoft mappings.
- There is no limit to the number of custom integrations you can create.
- The examples below illustrate simple event and metric mappings. You can define your own mappings for each endpoint, based on the data types and payloads you want to send. For details, see Moogsoft's Create Your Own Integration documentation.

Create the Moogsoft Custom Integration

Log into your Moogsoft SaaS instance as an Owner or Administrator, and then:

1. Choose **Data Config** > **Ingestion Services** > **Create Your Own Integration**.
2. Select **Add New Integration**.
3. Specify an integration endpoint and description.
4. Specify the data type to send to the endpoint: **Events** or **Metrics**.

The integration setup screen appears, with the URL and the API key for the new endpoint.



The Moogsoft integration setup screen

Configure the Webhook Destination

Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Data** > **Destinations**. Select **Webhook**. Next, select **Add Destination** to open the **Webhook** > **New Destination** modal, and configure the following.

General Settings

URL: The URL for the new custom integration (copy this from the Moogsoft UI).

Method: `POST`.

Format: `Custom`.

Content type: `application/json`.

Advanced Settings

Extra HTTP Headers: Select **Add Header** to define this extra header:

Name	Value
`apiKey`	The API key for the new custom integration (copy this from the Moogsoft UI).

Select **Save**, then **Commit** and **Deploy**. Now you are ready to map your events and/or metrics.

Mapping Cribl Data to Moogsoft

Your mappings will differ, depending on the data you want to send. However, the simple examples below, in which we map a Cribl Stream payload to a Moogsoft custom integration, illustrate principles that apply to all custom mappings:

- Moogsoft has a defined event schema and metric schema. Each schema includes a set of required fields. Your custom integration must include mappings for all required fields.
- You can define custom tags for Cribl Stream fields that do not have Moogsoft equivalents.
- You can also specify default values in case Cribl Stream sends an object with a missing field.

- The Moogsoft event schema includes a `severity` field. You can map Cribl Stream fields and values to Moogsoft severities, or define a default severity if a payload does not include this information.

Define and validate your mappings based on the type of data you plan to send to Moogsoft:

- Event Mapping
- Metric Mapping

Event Mapping

To illustrate how to map Cribl Stream payloads to Moogsoft events, we'll walk through an example with a payload of Cribl Stream syslog messages. You'll follow the same overall workflow for any events payload.

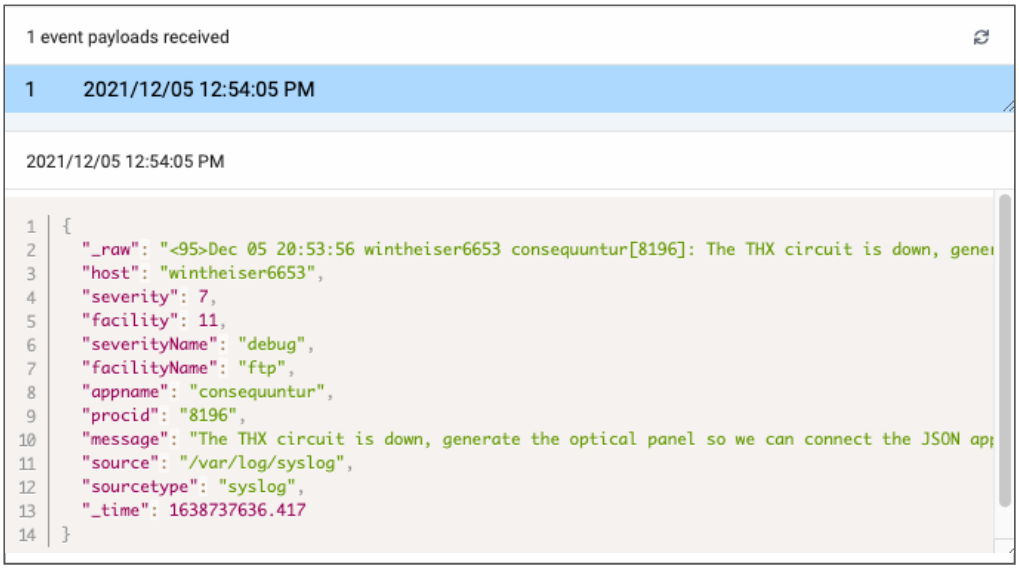
Send a Sample Payload to Moogsoft

In Cribl Stream, navigate to your Webhook Destination's configuration modal, select the **Test** tab, then:

1. In the **Test input** field, define one or more JSON payloads for the Cribl data you want to send. To map syslog events, set the **Select sample** drop-down to **syslog.log**.
2. Select **Test**.

Map the Event Fields

In Moogsoft, view the custom integration's config screen. Under **Map Your Data**, you should now see the payload you just sent.



The event payload appears in Moogsoft

Select the payload, and then define your Cribl-to-Moogsoft mappings. Your Cribl Stream data will largely determine the mappings you want. See Events Object in the Moogsoft API docs.

Here are some reasonable mappings for the syslog payload in this example:

Cribl Source Field(s)	Moogsoft Target Field
`message`	`description`
`appname`	`service`
`facilityName`	`check`
`severity`, `severityName`	`severity`
`procid`	`tag.process-id`

Map the Severities

The Moogsoft event schema has a severity field. You can specify integers or strings, from `0`, meaning Clear, to `5`, meaning Critical. Here are some reasonable mappings.

Syslog Severities	Moogsoft Severities
Emergency (`0`), Alert (`1`), Critical (`2`)	Critical (`5`)
Error (`3`)	Major (`4`)
Warning (`4`)	Warning (`2`)
Informational (`6`), Debug (`7`)	Unknown (`1`)
Notice (`5`)	Clear (`0`)

Verify your Mappings

Once you save and apply your mappings in Moogsoft, do the following:

1. In Cribl Stream, return to the **Test** tab for the Webhook Destination. Select **Test** again to send another payload.
2. In Moogsoft, go to the **Alerts** screen. You should now see a new alert based on the payload you just sent.

Metric Mapping

To illustrate how to map Cribl Stream payloads to Moogsoft events, we'll walk through an example with a payload of Cribl Stream syslog messages. You'll follow the same overall workflow for any metrics payload.

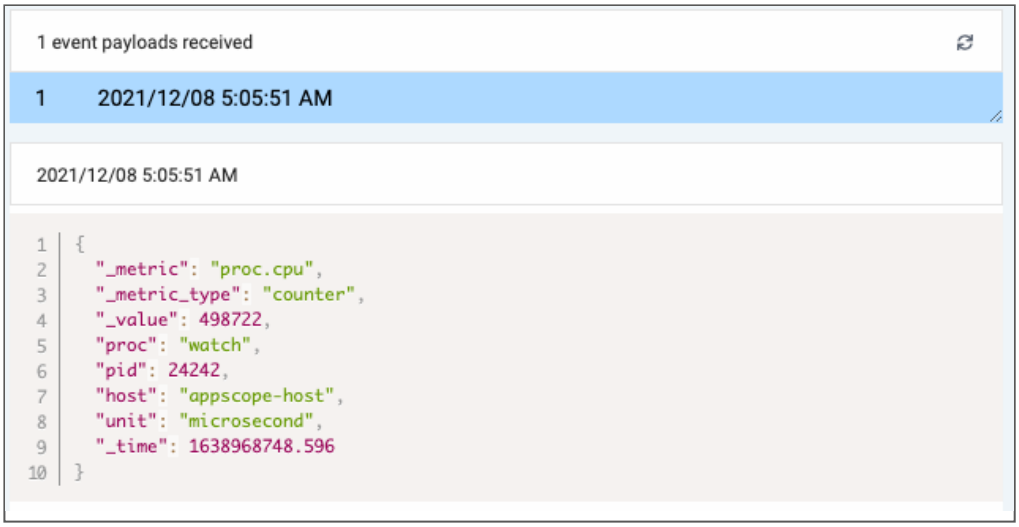
Send a Sample Payload to Moogsoft

In Cribl Stream, navigate to your Webhook Destination's configuration modal, select the **Test** tab, then:

1. In the **Test input** field, define one or more JSON payloads for the Cribl data you want to send. To map syslog events, set the **Select sample** drop-down to **appscope-metrics.log**.
2. Select **Test**.

Map the Metrics Fields

In Moogsoft, view the custom integration's config screen. Under **Map Your Data**, you should now see the payload you just sent.



The metrics payload appears in Moogsoft

Select the payload and then define the Cribl-to-Moogsoft mappings you want. Your Cribl data will largely determine these mappings. See Metric Datum Object in the Moogsoft API docs.

Here are some reasonable mappings for the AppScope payload you just sent:

Cribl Source Fields	Moogsoft Target Field
`_metric`	`metric`

Cribl Source Fields	Moogsoft Target Field
`_value`	`data`
`host`	`source`
`unit`	`tag.unit`
`pid`	`tag.pid`

Verify Your Mappings

After you save and apply your mappings in Moogsoft, test them like this:

1. In Cribl Stream, return to the Webhook Destination's **Test** tab. Select **Test** again to send another payload.
2. In Moogsoft, go to the **Metrics** screen. You should now see a new alert, based on the payload you just sent.

15.8.11. Nightfall Integration

Thanks to Nightfall for contributing this page and the corresponding Nightfall Pack, which you can install in Cribl Stream and customize as described below.

The Nightfall Pack relies on Nightfall's Data Loss Prevention (DLP) engine, which uses machine learning to detect sensitive information in events streamed through Cribl. The Pack enables you to monitor your Pipelines in real time for PII, PHI, PCI, and other sensitive data. Nightfall discovers and automatically redacts the sensitive content before it can reach any Destination. Aside from redaction, you can use the Pack to automatically label problematic event data.

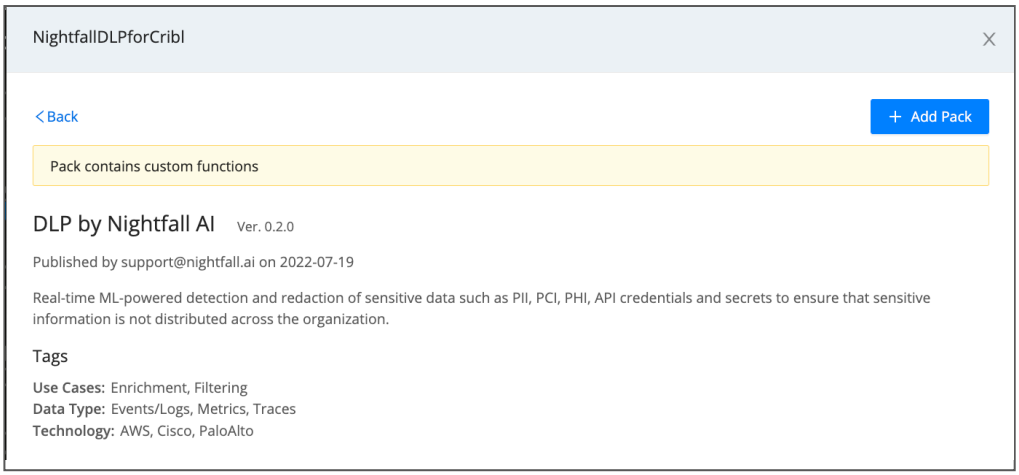
The risk of sensitive data spreading across data pipelines grows as organizations work with data from more sources. Nightfall can help ensure that sensitive data doesn't accumulate in the first place, facilitating compliance with data-security regulations. This is important for Cloud-first organizations that must scale observability while complying with regional or industry-specific compliance regimes.

Configure the Detection Engine

1. Sign up for a free Nightfall Developer Platform account, if you have not already done so. This entitles you to scan up to 3GB of event data per month for free.
2. Log in to the Nightfall Dashboard.
3. Create an API Key.
4. Create the Detection Rules and/or Policy that you want Nightfall to scan with.
   Detection Rules enable you to specify which Detectors will scan each event. A Detection Rule simply redacts sensitive information from events.
   A **Policy** governs alerts, which Nightfall can send via email, Slack, or webhook. (Assuming that you want to send data to a Cribl Stream Destination and/or a SIEM, use a webhook.) A Policy can include up to 20 previously defined Detection Rules. It can also turn redaction off, if desired.

Install the Nightfall Pack

1. Navigate to **Products** > **Stream** > **Worker Groups**. Select a Worker Group, then go to **Processing** > **Packs**.
2. Select **Add Pack**, then select **Add from Dispensary** to open the Packs Dispensary drawer.
3. Navigate to the **DLP by Nighfall AI** Pack's tile.
4. Select the Nightfall Pack's tile to display its details page.

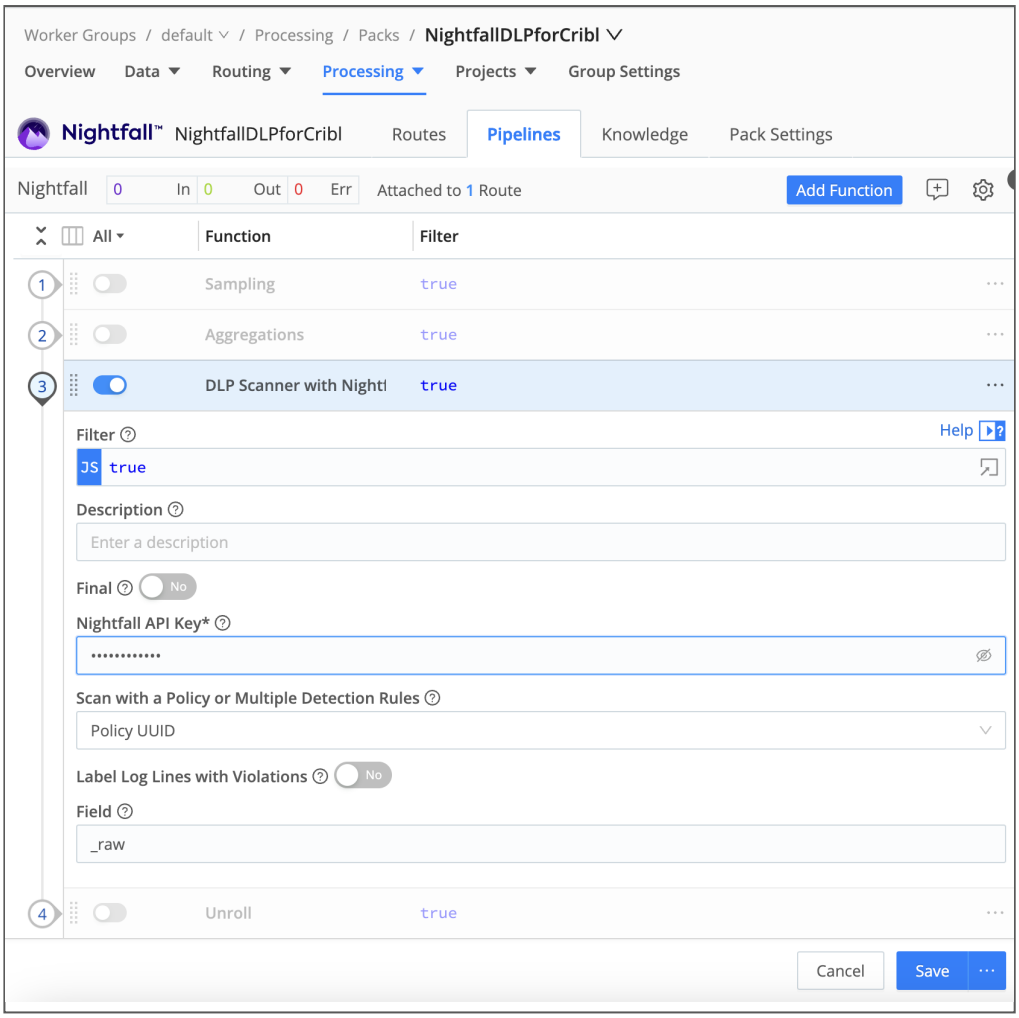


The Nightfall Pack details page

5.Select **Add Pack**. Shortly, you'll see a banner confirming that the Pack is installed.

Configure the Nightfall Pack

1. From the **Packs** page, select the new Pack. This opens the Pack's **Routes** tab.
2. In the **Pipeline** column, select `Nightfall`.
3. From the resulting Nightfall Pipeline configuration, expand the **DLP Scanner with Nightfall AI** Function.



Selecting the Nightfall Pipeline

4. In the **Nightfall API Key** field, enter the API key you created in the Nightfall Dashboard.
5. Set the **Scan with a Policy or Multiple Detection Rules** drop-down to match your detection engine configuration.
   Selecting **Policy UUID** exposes a corresponding field to enter the single UUID.
   Selecting **Detection Rule UUID** exposes a **Add Rule**. Click this to enter as many Detection Rule UUIDs as you want to specify.
6. (Optionally:) Label sensitive events. If you toggle **Label Log Lines with nightfall_violations** to `Yes`, each event where Nightfall has detected sensitive information will have an added `nightfall_violations: true` field.

Advanced Features

The Nightfall Pipeline also includes three limiting Functions, described here. These are disabled by default, but you can enable them as needed.

Sampling

To reduce the data usage that's billed against your Nightfall plan, you can enable the Sampling Function. This way, Nightfall will scan only a subset of each streamed file, instead of every event.

Log Batching

To reduce the number of requests that Cribl Stream makes to the Nightfall API, you can enable log batching. To do so, enable both the Aggregations and Unroll Functions, then configure the Aggregation Function's **Time window**.

The Nightfall DLP plugin will automatically detect the aggregations, and unroll the batches, only after Cribl Stream sends them to the Detection Engine. Then, Nightfall will process each event separately, as it normally does.

15.8.12. Managing QRadar Licenses

If you're using a SIEM (security information and event management) system like QRadar that's subject to an events-per-second (EPS) licensing model, managing license costs can be an issue. Cribl Stream enables you to proactively manage your license by slowing EPS growth.

Cribl Stream does so by offering fine-grained control over what events to send to the QRadar Event Processor, without breaking the expected LEEF (Log Event Extended Format) data format. You can report on event codes, and make decisions about what to drop, based on the data in the events. Some of what we discuss here also applies to SIEMs generally, not just QRadar.

Confronting QRadar Constraints

QRadar imposes constraints on data through several of its components:

- QRadar Event Collectors can send data only to QRadar. Elastic and other systems of retention or analysis are not an option.
- QRadar Event Collectors can send data only in LEEF format. The pipeline cannot provide additional streams of data in different formats such as JSON or syslog.
- Incoming data must adhere to a predefined schema, based on IBM LEEF format. You can't reformat events, nor reduce the size of an event, without breaking the correlation rules within the QRadar Event Processor.
- When incoming data exceeds the EPS license limits, QRadar will drop or stop ingesting data. Meanwhile, since the license is based on EPS event velocity, license costs increase linearly: the higher the EPS count, the higher the cost.

If your event velocity approaches the license limit, your options are unappealing:

- You can try to exclude some data, but the correlation rules and constraints on data formatting restrict your ability to be selective. You can drop only broad categories of data, such as an entire Windows Event ID, leaving you at a risk of missing something important.
- You can hope that you never actually exceed the EPS limit, but if you guess wrong, QRadar dropping or not ingesting data can be disruptive and compromise your enterprise security posture.

Cribl Stream enables you to surgically minimize these risks, and get the most out of your existing licenses.

Dropping Events Selectively

A common tactic to avoid exceeding an EPS license limit is to start dropping an entire class of events. This is a crude approach that carries its own risks. With Cribl Stream, you can analyze the data within the event, and

decide what to keep based on your priorities.

Analyzing a Windows Event

Here's an example of how to analyze and selectively drop Windows Security Event ID 4674. This event documents operations attempted on a privileged object. While it's commonly discarded when admins are feeling pressed to drop events, 4674 is actually a critical ID that should be kept some, or most, of the time.

Event ID 4674 includes the logon types shown in the table below.

Logon Type	Logon Title	Description
2	`Interactive`	Activity on the system's keyboard and screen.
3	`Network`	Connection to a shared folder on this computer from elsewhere on the network.
4	`Batch`	Processes might be executing on behalf of a user without their direct intervention.
5	`Service`	Service startup by the Service Control Manager.
7	`Unlock`	An unattended workstation with password-protected screen saver.
8	`NetworkCleartext`	Logon with credentials sent in cleartext. Most often indicates a logon to IIS with "basic authentication".
9	`RemoteInteractive`	Logon with RunAs, or mapping a network drive with alternate credentials.
10	`CachedInteractive`	Logon with cached domain credentials, such as when logging on to a laptop when away from the network.

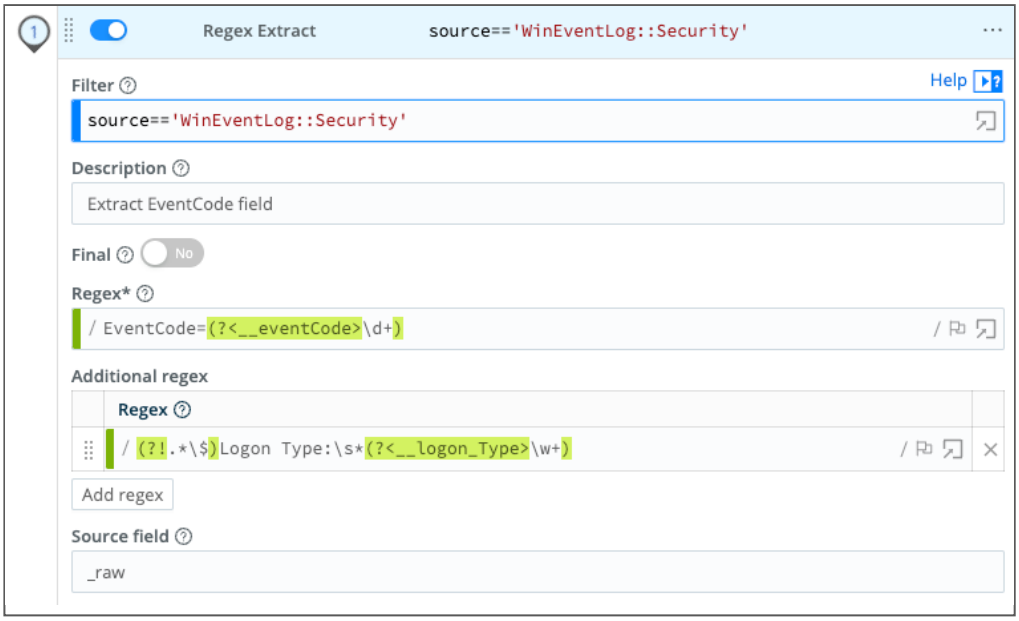
Each logon type is assigned a different security value.

Let's suppose that your QRadar deployment is in an enterprise where inbound file sharing is disabled. In that case, you don't need logon type 3 events. So let's see how to use Cribl Stream to keep all ID 4674 events except logon type 3 events, which we'll' drop.

Dropping the Excess Baggage

Use sample data to validate the reduction methods described below. Don't apply these methods to your production SIEM until you are confident they won't interfere with the usability of your system.

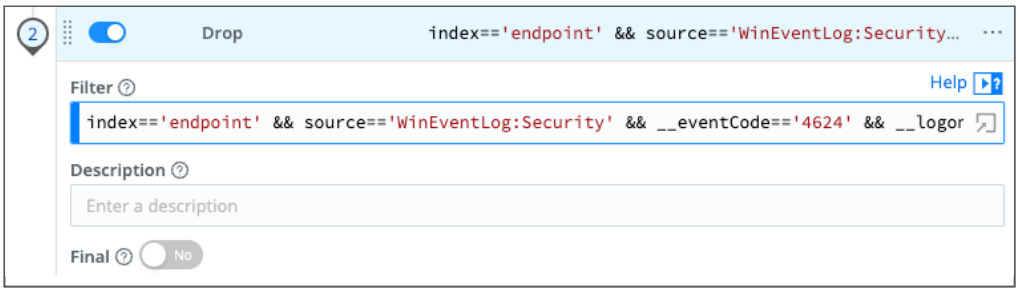
1. Save your Windows Events to Cribl Stream using Live Capture.
2. Create a Pipeline and name it `Windows_Event_Reduction`.
3. Add the Regex Extract Function to your Pipeline to create fields for `EventCode` and `Logon Type`. These fields will be the foundation for a Filter that drops only Windows events of ID 4624, logon type 3.



Regex Function on Pipeline

4. Add the Drop Function to your Pipeline using the Filter below.

```
index=='endpoint' && source=='WinEventLog:Security' && __eventCode=='4624' && __logo
```



Drop Function

5. Apply the Pipeline to your Windows Sources. Cribl Stream will then start dropping the unneeded events.

Other Reduction Examples

Apply the options in this section only after careful analysis of your own environment and priorities. Even if you choose to exclude these events from QRadar, you might want to send them to an object store for

> later auditing and/or replay.

WinEvents

- Event ID 4624: Look for Subtypes (Logon Type) that can be dropped.
- Event ID's 4634 and 4674: An account was logged off. Most security use cases don't require Logoff events.
- Event ID 4673: A privileged service was called. This event rarely contains actionable intel. It's a large-volume data source that can be dropped, in exchange for other, more-valuable event IDs.
- Event ID 4674: An operation was attempted on a privileged object. Similar to Event ID 4673, this event is largely considered "noise," providing little value. Consider dropping.
- Event ID 4689: A process was exited. This source, when paired with Event ID 4688, can tell you "how long a process was running." Typically, this is unimportant information, and can be omitted from your event collection.

Palo Alto

The following filters can be helpful to reduce the noise:

- All external-to-internal traffic AND `action=deny`: `Ingress traffic && action=deny`
- `PAN Traffic logs && application=ping|ibm-bigfix|outlook-web-online|google-base|traceroute|ms-teams|ic mp|outlook-web-online|ms-office365-base|crowdstrike`

Cisco ASA

- All external-to-internal traffic AND `action=deny`: `Ingress traffic && action=deny`
- Teardown UDP Connection && Event ID 302016
- Teardown TCP connection && Event ID 302014
- Teardown ICMP connection && Event ID 302021
- Teardown Translation && Event ID 305010|305012

15.8.13. Slack/Webhook Integration

You can configure Cribl Stream to send simple Notifications to Slack via a Webhook URL. These Notifications arrive in Slack as messages in a channel that you choose. For more information, see our Slack Notifications topic.

However, if you have specific event data such as alert-based or conformance data that you want to route to Slack for prompt attention, you can use Cribl Stream's Webhook Destination to route or filter this data.

You can also enhance your messages with more advanced formatting. Consult the Slack documentation for detailed information.

Cribl Stream does not currently support the use of special characters in Slack notifications sent via a Webhook Destination.

Creating a Slack/Webhook integration is a three-step process:

1. Create a Slack demo app.
2. Configure the Webhook Destination.
3. Verify that Slack is receiving messages.

Create a Slack Demo App

1. Create a Slack app by following these Slack instructions on sending messages with incoming webhooks.
2. Test the cURL command supplied by the app setup. For example:

```
curl -X POST -H 'Content-type: application/json' --data '{"text":"Hello, World!"}' h
```

Configure a Webhook Destination

Configure a Webhook Destination in Cribl Stream as described in Webhook. However, you must override some of the default settings:

- In **General Settings**, use the **URL** provided for your Slack demo app.
- In **General Settings** > **Optional Settings**, set **Format** to `Custom`.
- In **General Settings** > **Optional Settings**, set **Source expression** to `` `{"text":"${_raw}"}` `` (with literal backticks).

- In **Advanced Settings**, set:
  - **Validate server certs** to `No`.
  - **Compress** to `No`.
  - **Max events per request** to `1`.

Verify That Slack Is Receiving Messages

To verify that Slack is receiving message, send a test message, using the **Test** UI. For example:

```
[
  {
    "_raw": "Hello, World!"
  }
]
```

If the integration is working correctly, this test message will arrive in the Slack channel you're using for your demo app.

15.8.14. Tanium To Cribl Stream

Tanium is a security platform that provides rapid searches across multiple endpoints. Tanium integrates with a finite number of tools using its Tanium Connect module, but this can still leave gaps in conforming Tanium output to the specific data formats required by unsupported tools and destinations.

Cribl Stream can help collect, reduce, enrich, transform, and route data from Tanium to any destination. This includes SIEM (Security Information and Event Management) tools, logging tools, or other analytics platforms. In this guide, we'll explain how to configure Tanium Connect to send Tanium-captured data to Cribl Stream. For further details, see Tanium's Configuring SIEM Destinations topic.

Configure Tanium Connect

A Tanium Connection is essentially a scheduled search/collection of data linked to a destination. Tanium translates queries into **Questions**. It formats the Questions into the Tanium Search Language for a search, providing near real-time results.

The first step in configuring Tanium Connect is to set up a Question. A Question can be a Saved Search, Question Log, Client Status, or an Event.

To configure a new connection, go to the **Tanium Module** page and click **Tanium Connect**. On the **Connect Overview** page, scroll to the **Connections** section, and click **Create Connection**.

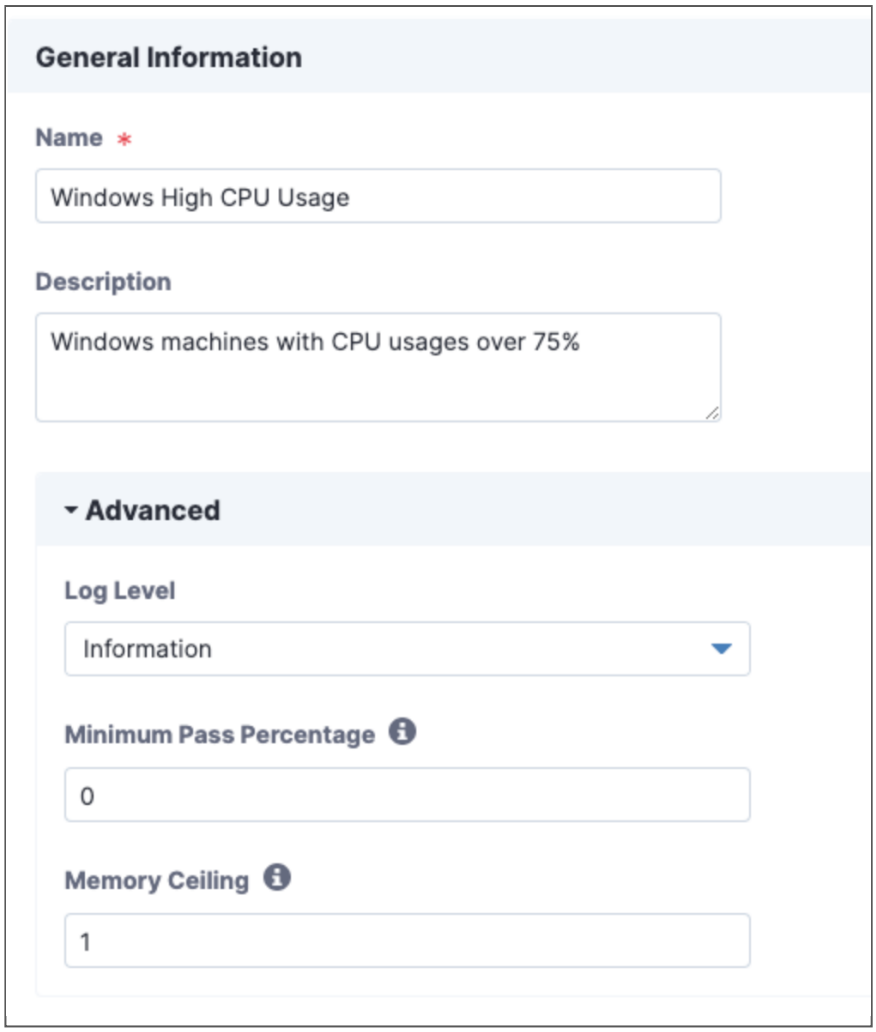
Specify General Connection Information

Name: A unique name for your connection.

Description: An optional description for this connection.

Advanced Settings: Optionally, configure the following fields:

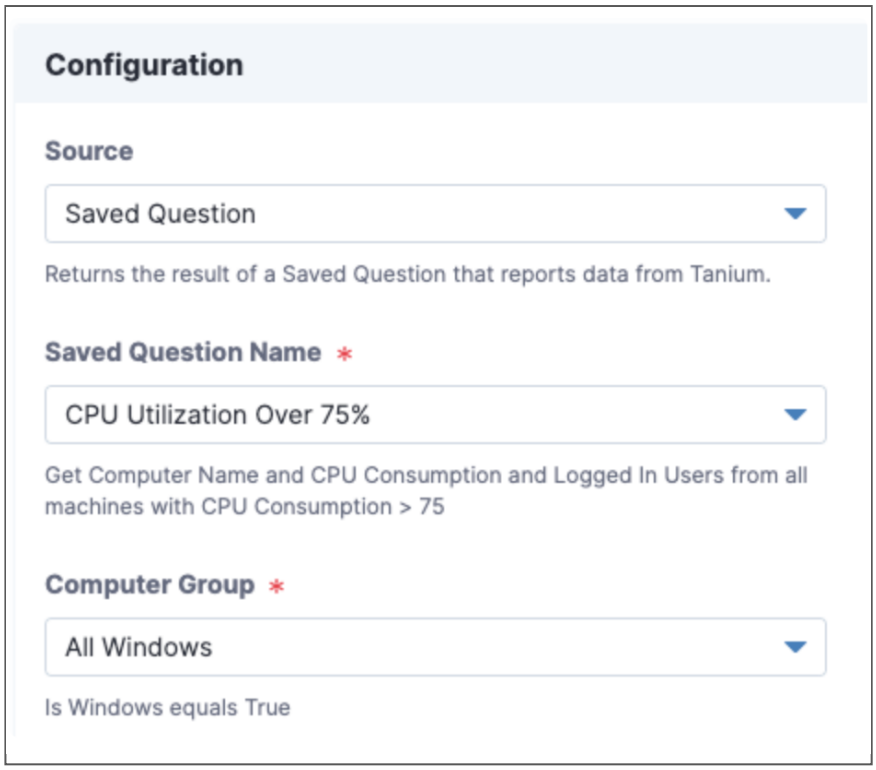
- **Log Level**: Defaults to **Information**. Change the **Log Level** to **Trace** or **Debug** if plan to debug the connection. Alternatively, set the **Log Level** to **Warning**, **Error**, or **Fatal** to reduce the amount of logging.
- **Minimum Pass Percentage**: Minimum percentage of the expected rows to process for the connection to succeed.
- **Memory Ceiling (GB)**: Maximum memory for the node process to run the connection.



General Connection Information tab

Configure the Connection Source

This section enables you to specify the type of data you are sending to your destination. The data is usually information from Tanium, such as a Saved Question, Question Log, Client Status, or Event. The settings vary depending on the Source.



Connection Source Configuration

When sending logs to Cribl Stream, you must create a network egress rule in Tanium for port 10060. See Tanium's Configure a new network egress rule topic.

Configure Your Destination

In this section, we'll configure Cribl Stream as the destination, using the following fields.

Destination: Select the destination type. For our example, we'll configure it as a `Socket Receiver`.

New: Configure a new destination.

Name: Specify a unique name for your new destination. (This field is displayed only when configuring a **new** destination.)

Existing: Update the settings on an existing destination. (Note that this will affect all the connections that use this destination.)

Destination Name: Drop-down list where you can specify a preconfigured destination. Displayed only when updating an **existing** destination.

Copy Settings: Copy settings from a preconfigured destination.

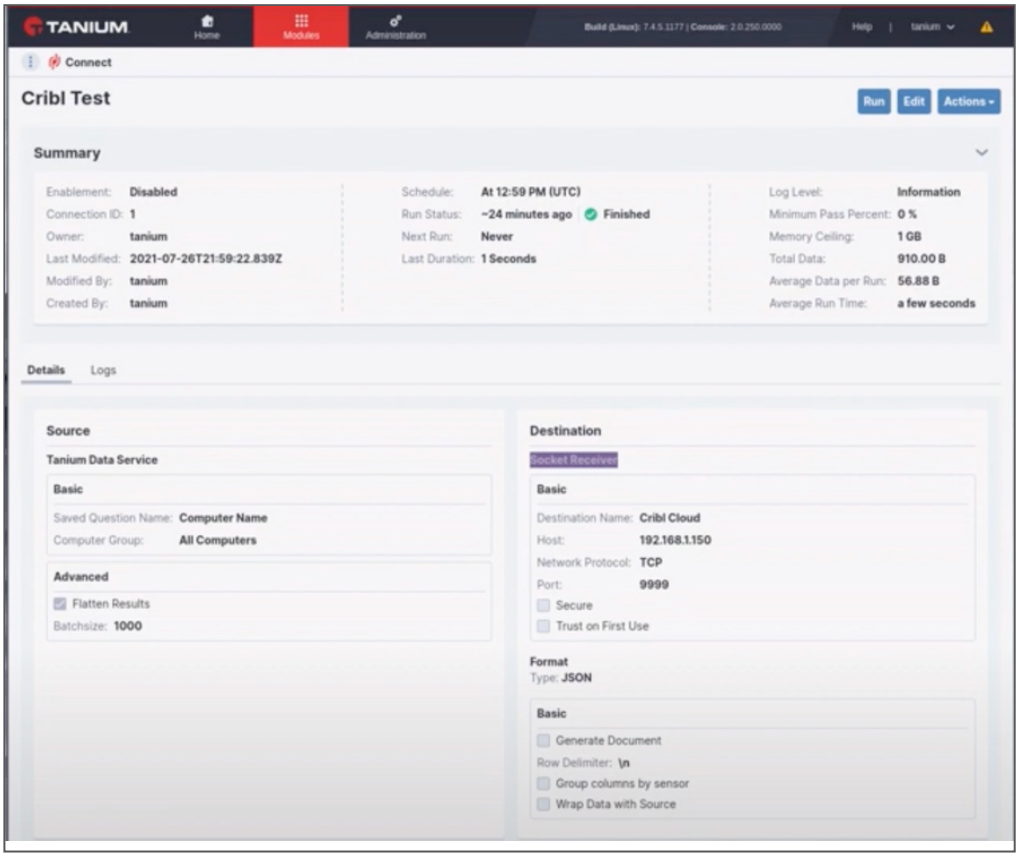
Host: Specify the destination'server host.

Network Protocol: Specify how to connect to the server (e.g., `TCP`).

Port: Enter the port number to listen on.

Secure: Select this option to use TLS encryption.

Trust on First Use: Select this option to accept the certificate presented from the server, and to trust **only** that certificate for future connection runs.



Sample Cribl Stream Configured Destination

Format the Data

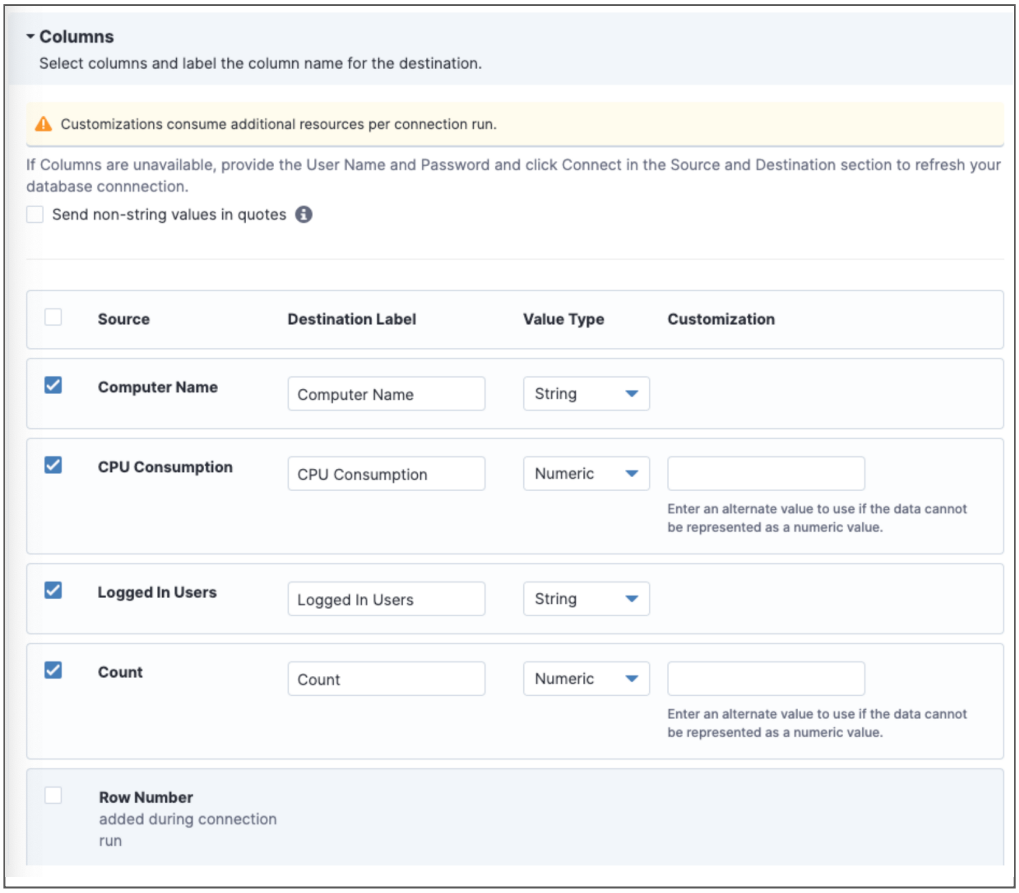
When you select a destination, the expected data format is displayed by default. For example, if you select Splunk, the `Syslog RFC 5424` automatically pre-populates the **Format Type** field. However, you can customize the format as needed. (For details, see Tanium's Format Types topic.)

Format Type: When sending to Cribl Stream, select the `JSON` data format for best results.

In the **Columns** section, configure the columns that you want to pass on to your Destination. (For details, see Tanium's Column Customizations topic.)

- **Source**: Check the box next to each **Source** to include the columns in your Destination.
- **Destination Labels**: You can optionally assign a new column heading. Defaults to the **Source** name.

- **Value Types**: You can change the data type to `String`, `Numeric`, or `Data/Time` value.
  - If you select a `Numeric` value, you must specify a default value. It can be any integer.
  - If you select a `Data/Time` value, specify the format to apply for the column. R(For details, see Tanium's Time Stamp Variables topic.)



Configure your columns

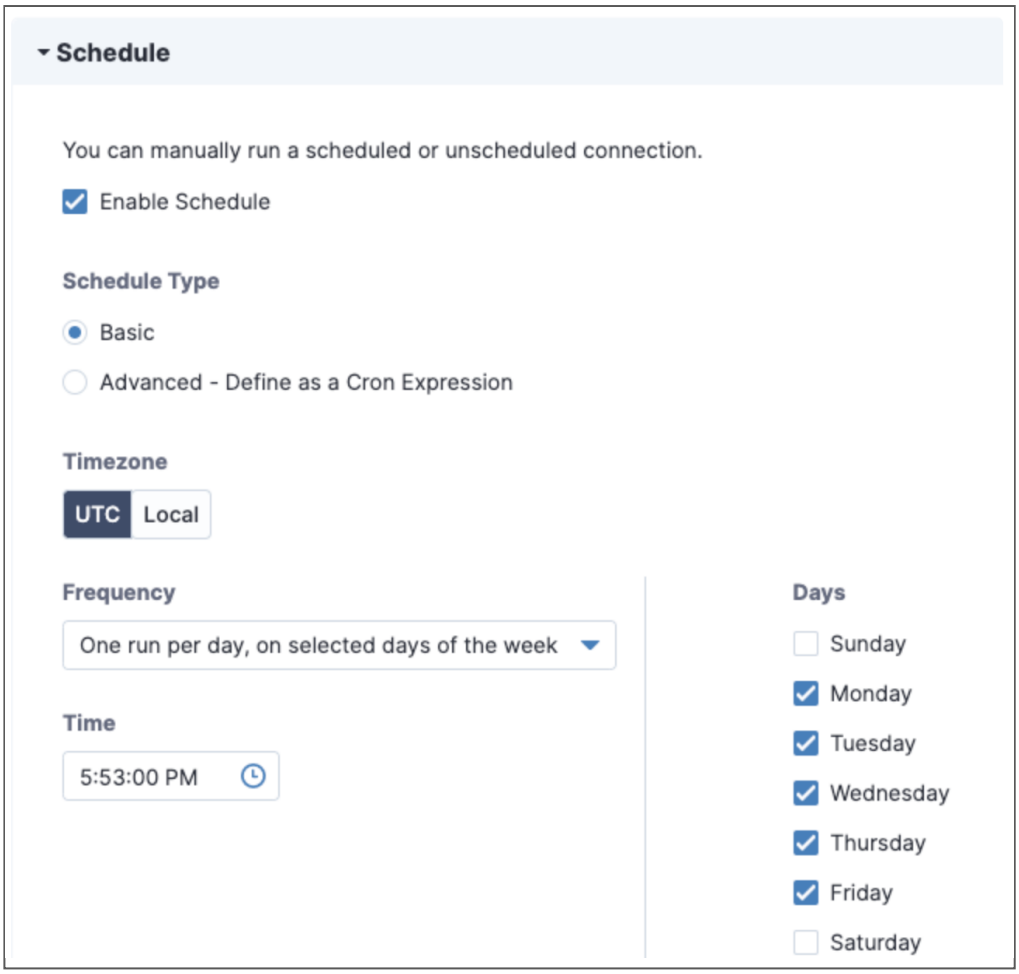
Schedule the Connection

Connections can run at a highly configurable time interval – anywhere from multiple times per hour, to daily, weekly, or monthly intervals. The **Schedule** section allows you to enable and configure the scheduler.

Enable Schedule: If you do not enable the scheduler here, the connection will run only when you explicitly run it.

Schedule Type: Select **Basic** to build a schedule with the provided controls.

Advanced – Define as a Cron Expression: Select this field to view or edit the cron expression directly.



Configure your columns

If the user who owns a connection is deactivated, future instances of a scheduled connection will not run. For details, see Tanium's Deleted User Troubleshooting topic.

Save and Verify the Connection

When you are done configuring your connection, click **Save**.

To view details when the connection runs, select the **Logs** tab. To inspect an individual run log, expand the row table.

For help on resolving errors, see Taniuum's Troubleshooting topic.

You can also click **Run and Save** to save and immediately run the connection. Connection details will be displayed for successful connections.

Configure Cribl Source

On your Cribl Stream instance, configure a TCP Source to receive the data from your configured Tanium connection. For a video demo of this step, see this Tanium blog post.

15.8.15. Zscaler NSS Integration

Zscaler Nanolog Streaming Service (NSS) uses a VM to stream traffic logs in real time from the Zscaler Nanolog to a SIEM. Cribl Stream can take the place of the SIEM in this arrangement. Then you can use Cribl Stream to greatly reduce the size of ZScaler logs.

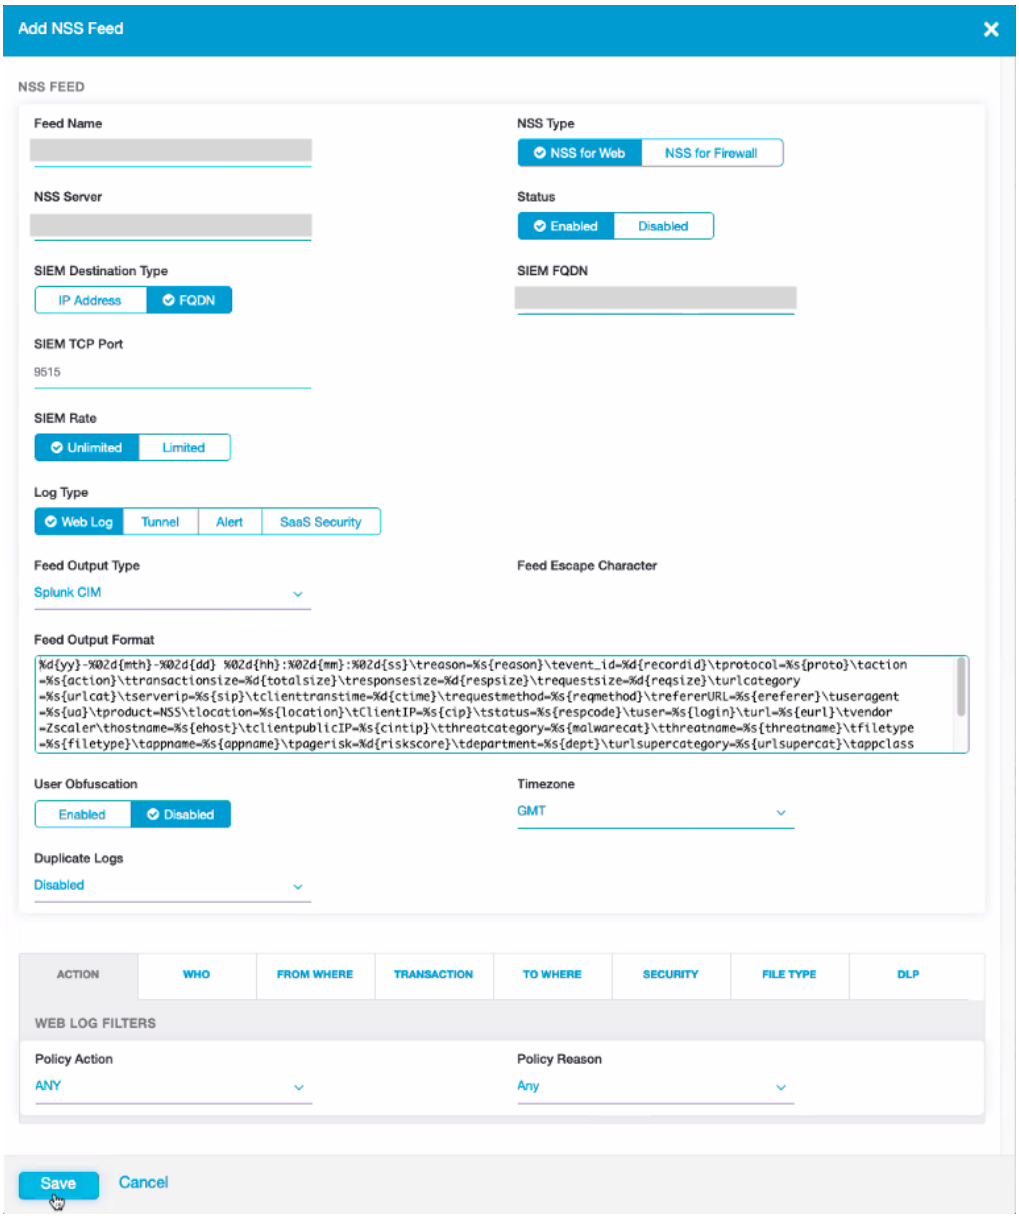
Configuring NSS to Send Data to Cribl Stream

Since Nanolog forwards data to a single IP address or FQDN, Cribl recommends that you use a load balancer to distribute data among Cribl Stream Workers.

Nanolog delivers data using a raw TCP connection.

In Zscaler:

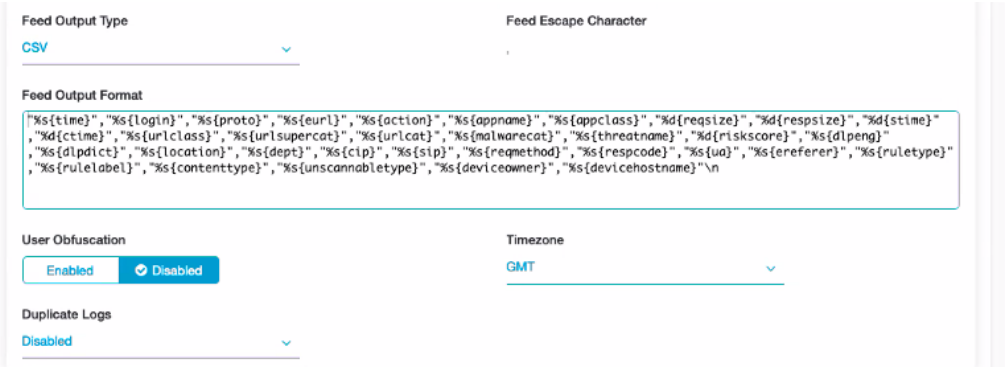
- Go to **Administration** > **Nanolog Streaming Service**.
- In the **NSS Feeds** tab, click **Add NSS Feed** to open the following configuration window:



Adding a Zscaler NSS feed

- Enter a **Feed Name** that identifies this feed as one that sends data to Cribl Stream.
- Enter the IP address or FQDN for either your Cribl Stream instance, or the load balancer you're using with your Cribl Stream instances.
- Select a **Feed Output Type**. `Splunk CIM`, a tab-delimited key/value format, is a typical choice.

Alternatively, you choose a different option, such as CSV:



Choosing a CSV output format

Example Pipeline

Cribl Stream can reduce Zscaler log size by (1) reformatting and reshaping the data, and (2) suppressing, sampling, and dropping appropriate fields.

The following code block shows how to correctly parse tab-delimited key-value pairs.

```
let temp = {};

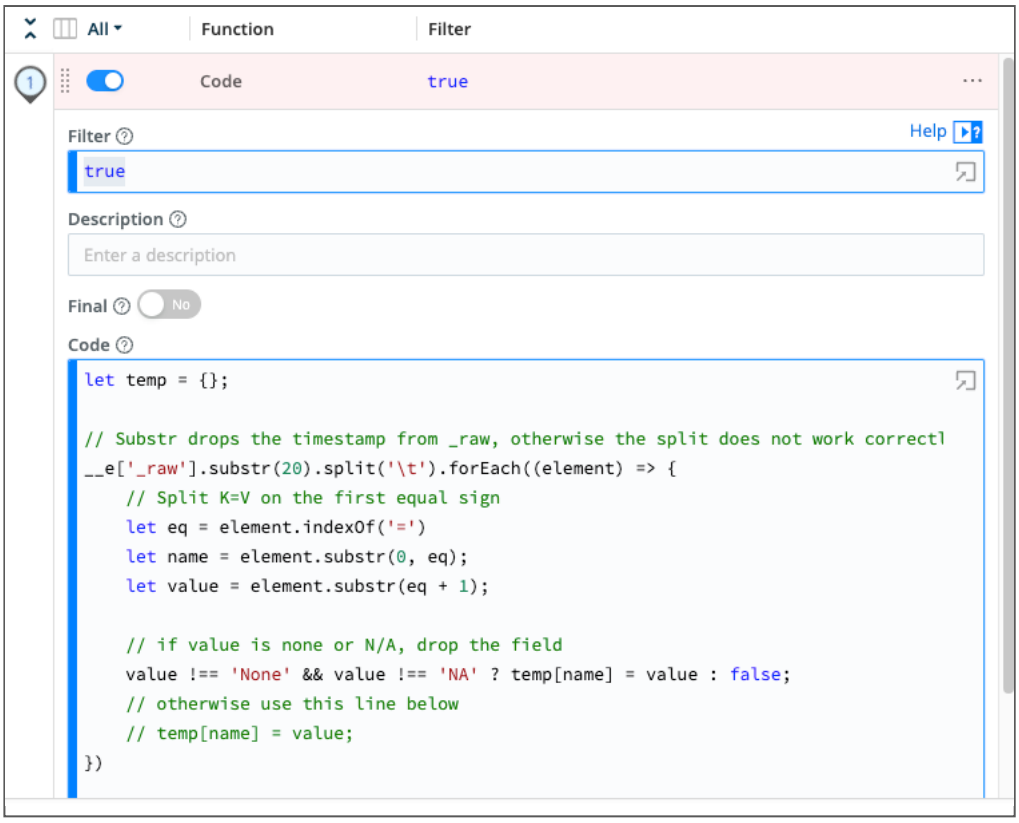
// Substr drops the timestamp from _raw, otherwise the split does not work correctly
__e['_raw'].substr(20).split('\t').forEach((element) => {
    // Split K=V on the first equal sign
    let eq = element.indexOf('=')
    let name = element.substr(0, eq);
    let value = element.substr(eq + 1);

    // if value is none or N/A, drop the field
    value !== 'None' && value !== 'NA' ? temp[name] = value : false;
    // otherwise use this line below
    // temp[name] = value;
})

__e['_raw'] = temp;
```

Here's an example Pipeline that uses the parsing code above. (You can directly import this Pipeline in JSON form.)

A Code Function parses the data:

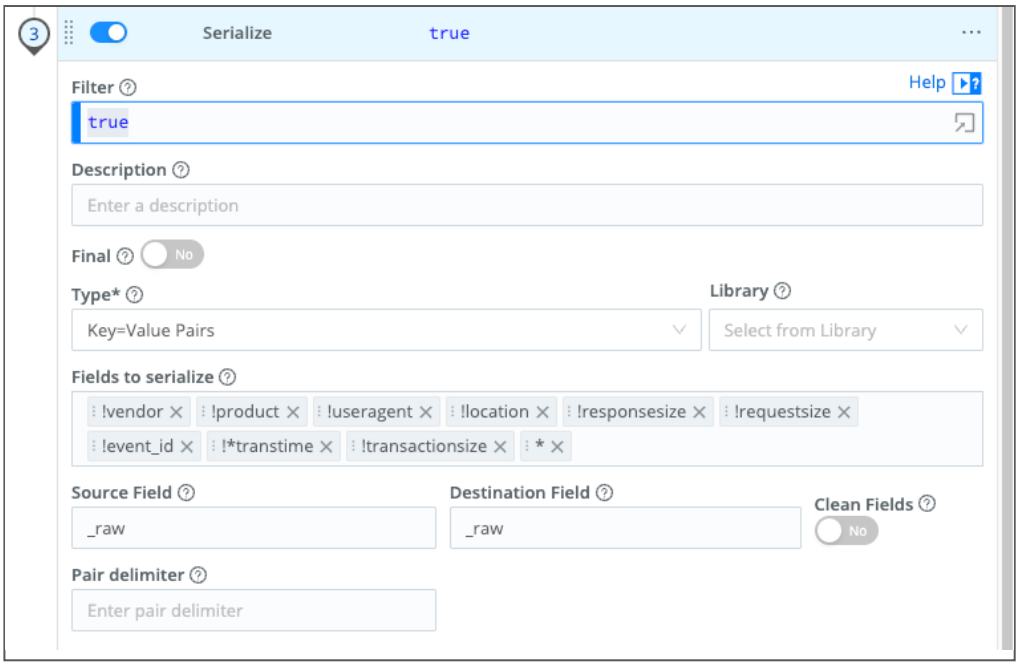


Parsing with a Code Function

An Eval Function reshapes the data:

Reshaping with Eval

And finally, a Serialize Function drops unwanted fields:



Dropping fields with Serialize

Example Pipeline JSON

To import the example Pipeline directly, copy and save the JSON below, then follow these instructions.

Zscaler Example Pipeline

```
{
  "id": "zscaler",
  "conf": {
    "output": "default",
    "groups": {},
    "asyncFuncTimeout": 1000,

    ]
  }
}
```

16. Knowledge Libraries

Select **Processing** > **Knowledge** to access Cribl Stream's libraries of default Lookup tables, Event Breaker rulesets, Parsers, Global Variables, Regex expressions, Grok patterns, Schemas, Database Connections, and AppScope config templates. You can customize these libraries by adding your own Knowledge objects.

From the **Processing** > **Knowledge** top nav, you can select:

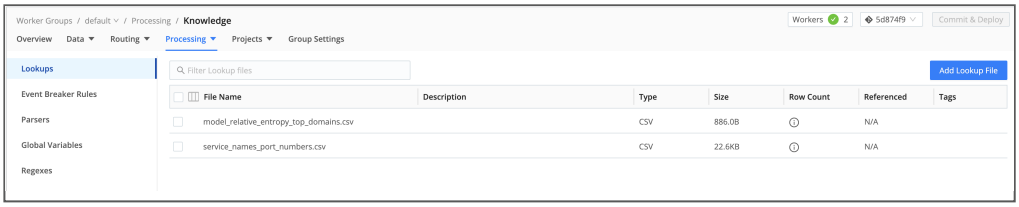
- Lookups
- Event Breakers
- Parsers
- Global Variables
- Regexes
- Grok Patterns
- Schemas (JSON)
- Parquet Schemas
- Database Connections (Cribl Stream only)
- HMAC Functions (Cribl Stream only)
- AppScope Configs

16.1. Lookups Library

What Are Lookups

Lookups are data tables that can be used in Cribl Stream to enrich events as they are processed by the Lookup Function. To access the Lookups library, which provides a management interface for all lookups, navigate to **Products** > **Cribl Stream** > **Worker Groups**. Select a Worker Group, then go to **Processing** > **Knowledge** > **Lookups**.

This library is searchable, and each lookup can be tagged as necessary. There's full support for `.csv` files. Compressed files are supported, but must be in gzip format (`.gz` extension). You can add files in multimedia database (`.mmdb`) binary format, but you cannot edit these binary files through Cribl Stream's UI.



Lookups Library

How Does the Library Work

In single-instance deployments, all files handled by the interface are stored in `$CRIBL_HOME/data/lookups`. In distributed deployments, the storage path on the Leader Node is `$CRIBL_HOME/groups/<groupname>/data/lookups/` for each Worker Group.

For large and/or frequently replicated lookup files, you might want to bypass the Lookups Library UI and instead manually place the files in a different location. This can both reduce deploy traffic and prevent errors with Cribl Stream's default Git integration. For details, see Managing Large Lookups.

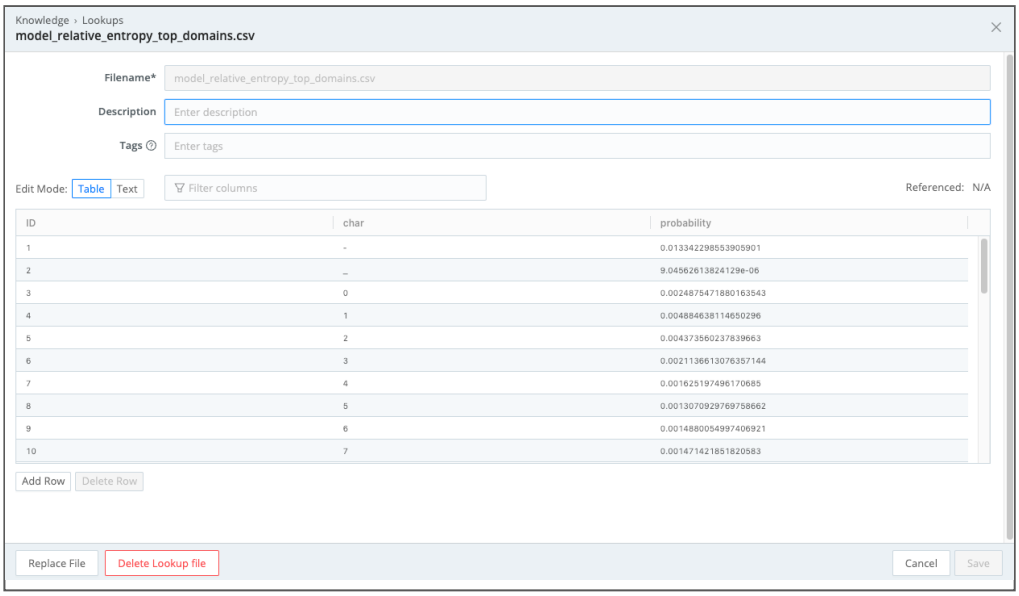
Add Lookup Files

To upload or create a new lookup file, select **New Lookup File**, then select the appropriate option from the drop-down.

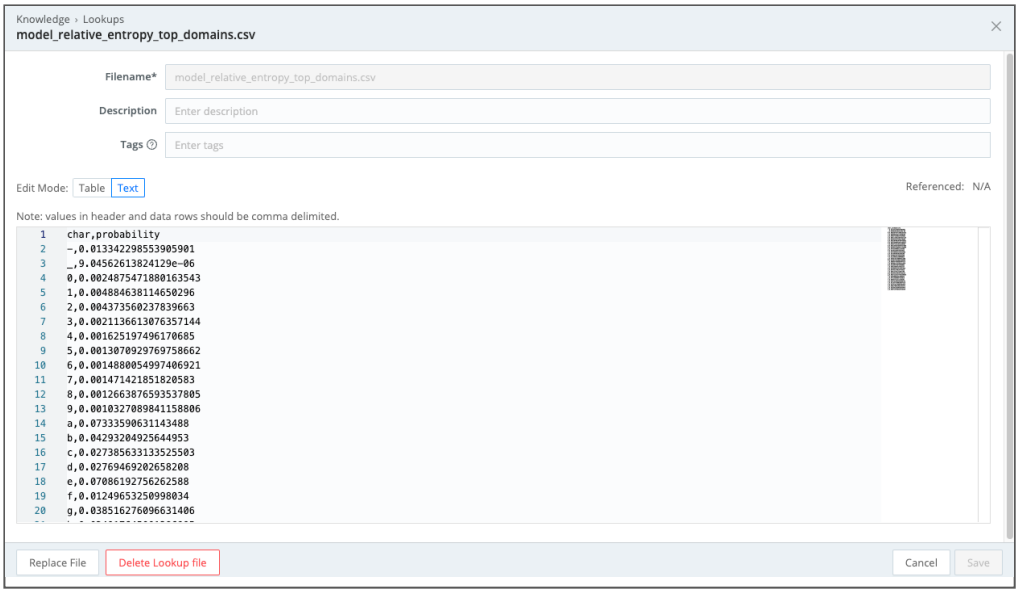
Modify Lookup Files

To re-upload, expand, edit, or delete an existing `.csv` or `.gz` lookup file, select its row on the Lookups page. (No editing option is available for `.mmdb` files; you can only re-upload or delete these.)

In the resulting modal, you can edit files in **Table** or **Text** mode. However, **Text** mode is disabled for files larger than 1 MB.



Editing in **Table** mode



Editing in **Text** mode

Edit Regex with Quotation Marks

When a regex contains quotes, edit it in **Text** mode. Do not edit it **Table** mode, which can cause the regex to behave in unexpected ways.

Memory Sizing for Large Lookups

For large lookup files, you'll need to provide extra memory beyond basic requirements for Cribl Stream and the OS. To determine how much extra memory to add to a Worker Node/Edge Node for a lookup, use this formula:

```
Lookup file's uncompressed size (MB) * 2.25 (to 2.75) *  numWorkerProcesses = Extra RAM required for lookup
```

For example, if you have a lookup file that is 1 GB (1,000 MB) on disk, and three Worker Processes, you could use an average 2.50 as the multiplier:

```
1,000 * 2.50 * 3 = 7,500
```

In this case, the Node's server or VM would need an extra 7,500 MB (7.5 GB) to accommodate the lookup file across all three worker processes.

What's with That Multiplier?

We've cited a squishy range of 2.25–2.75 for the multiplier, because we've found that it varies inversely with the number of columns in the lookup file:

- The fewer columns, the higher the extra memory overhead (2.75 multiplier).
- The more columns, the lower the overhead (2.25 multiplier).

In Cribl's testing:

- 5 columns required a multiplier of 2.75
- 10 columns required a multiplier of only 2.25.

These are general (not exact) guidelines, and this multiplier depends only on the lookup table's number of columns. The memory overhead imposed by each additional row appears to decline when more columns are present in the data.

Maximum Table Size

Aside from the memory requirements above, the Node.js runtime imposes a hard limit on the size of lookup tables that Cribl Stream can handle. No table can contain more than 16,777,216 (i.e., 2^{24}) rows. If a lookup exceeds this size, attempting to load the lookup will log errors of the form: `failed to load function...Value undefined out of range...`.

Other Scenarios

See also:

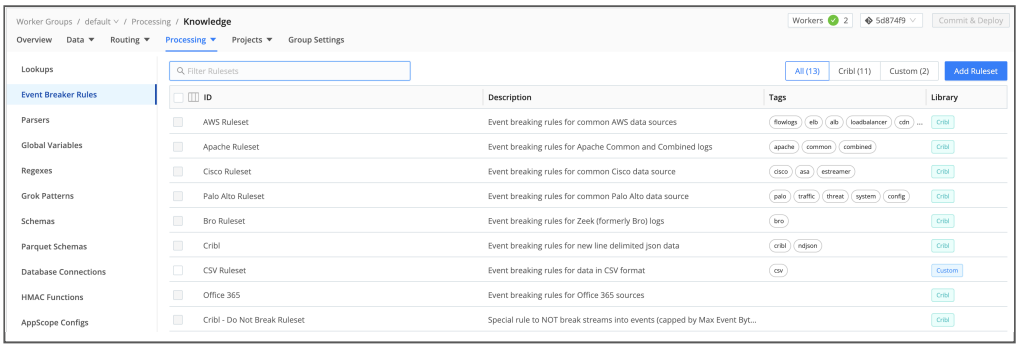
- Lookup Function.
- Ingest-time Lookups use case.
- Managing Large Lookups use case.
- Redis Function for faster lookups using a Redis integration (bypasses the Lookups Library).

16.2. Event Breakers

Event Breakers help break incoming streams of data into discrete events. To see how Event Breakers interact with the rest of Cribl Stream's data flow, see Event Processing Order.

Access Event Breakers

To access the Event Breakers management interface navigate to **Products** > **Cribl Stream** > **Worker Groups**. Select a Worker Group, then go to **Processing** > **Knowledge** > **Event Breaker Rules**. On the resulting **Event Breaker Rules** page, you can edit, add, delete, search, and tag Event Breaker rules and rulesets, as necessary.



Event Breaker Rulesets page

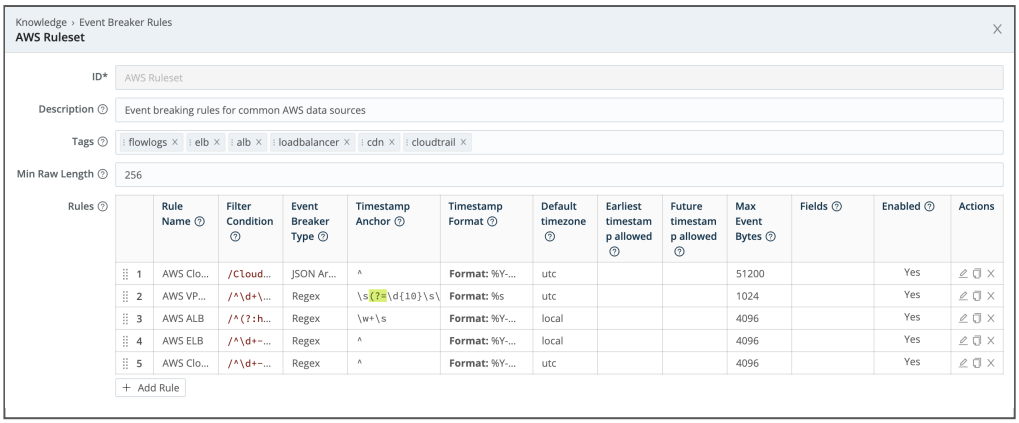
Limitations

Event Breakers are directly accessible only on Sources that require incoming events to be broken into a better-defined format. (Check individual Cribl Stream Sources' documentation for Event Breaker support.) Also, Event Breakers are currently not supported in Packs.

However, you can instead use the Event Breaker Function in Pipelines that process data from unsupported Sources, and in Pipelines within Packs.

Event Breaker Rulesets

Rulesets are **collections of Event Breaker rules** that are associated with Sources. Rules define configurations needed to break down a stream of data into events.



Rules within an example (AWS) ruleset that ships with Cribl Stream

Rules within a ruleset are ordered and evaluated top->down. One or more rulesets can be associated with a Source, and these rulesets are also evaluated top->down. For a stream from a given Source, the first matching rule goes into effect.

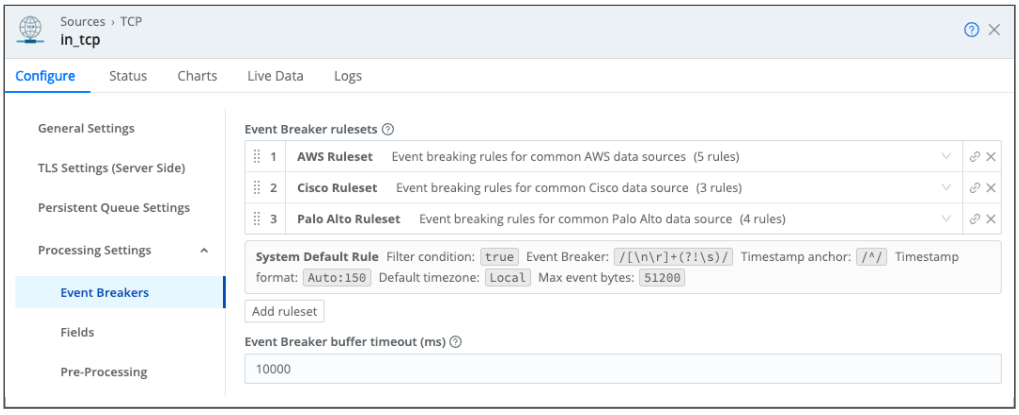
Rulesets and Rules - Ordered

```
Ruleset A
  Rule 1
  Rule 2
  ...
  Rule n

...

Ruleset B
  Rule Foo
  Rule Bar
  ...
  Rule FooBar
```

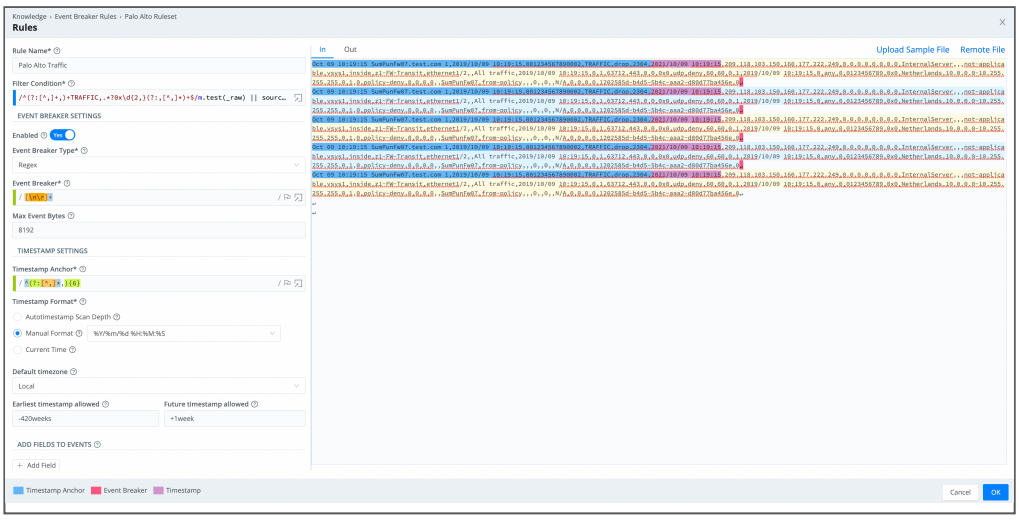
An example of multiple rulesets associated with a Source:



Three Event Breaker rulesets added to a Source

Rule Example

This rule breaks on newlines and uses Manual timestamping **after** the sixth comma, as indicated by this pattern: `^(?:[^,]*,){6}`.



An Event Breaker rule

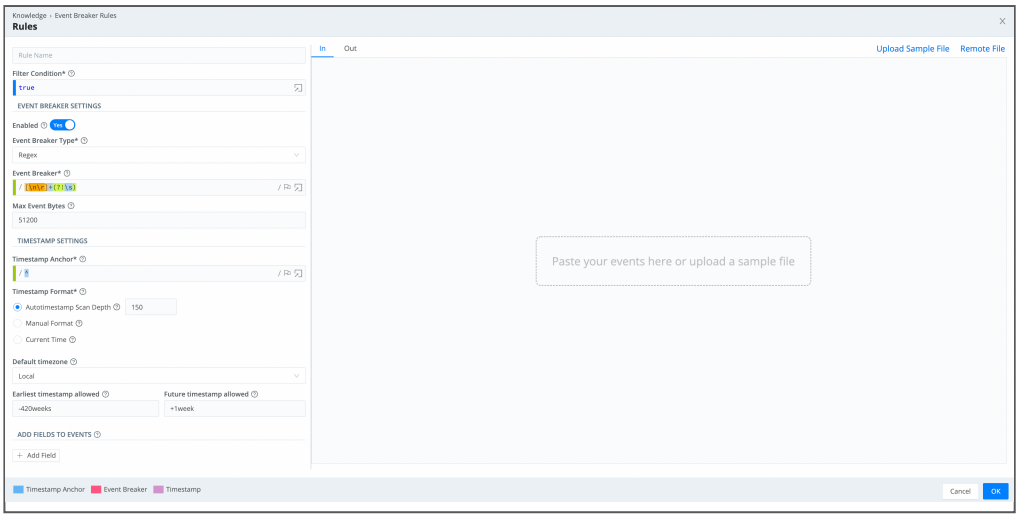
System Default Rule

The system default rule functionally sits at the bottom of the ruleset/rule hierarchy (but is built-in and not displayed on the Event Breakers page), and goes into effect if there are no matching rules:

- Filter Condition defaults to `true`
- Event Breaker to `[\n\r]+(?!\s)`
- Timestamp anchor to `^`
- Timestamp format to `Auto` and a scan depth of `150` bytes
- Max Event Bytes to `51200`
- Default Timezone to `Local`

How Do Event Breakers Work

On the **Event Breaker Rules** page (see screenshot above), select **Add Ruleset** to create a new Event Breaker ruleset. Select **Add Rule** within a ruleset to add a new Event Breaker.



Adding a new Event Breaker rule

Each Event Breaker includes the following components, which you configure from top to bottom in the above **Event Breaker Rules** modal:

Filter Condition

As a stream of data moves into the engine, a rule's filter expression is applied. If the expression evaluates to `true`, the rule configurations are engaged for the entire duration of that stream. Otherwise, the next rule down the line is evaluated.

The "stickiness" of the first `true` expression can lead to some unintended behavior. For example, if an S3 Source ingests an archive file that contains multiple files in different formats – where each file requires its own unique Event Breaker – events will not be broken correctly.

Event Breaker Type

After a breaker pattern has been selected, it will apply on the stream **continuously**. See below for specific information on different Event Breaker Types.

Timestamp Settings

After events are synthesized out of streams, Cribl Stream will attempt timestamping. First, a timestamp anchor will be located inside the event. Next, starting there, the engine will try to do one of the following:

- Scan up to a configurable depth into the event and autotimestamp, **or**
- Timestamp using a manually supplied `strptime` format, **or**
- Timestamp the event with the current time.

The closer an anchor is to the timestamp pattern, the better the performance and accuracy – especially if multiple timestamps exist within an event. For the manually supplied option, the anchor must lead the engine

right before the timestamp pattern begins.

Anchors preceding timestamps

This timestamping executes the same basic algorithm as the Auto Timestamp Function and the C.Time.timestampFinder() native method.

Cribl Stream truncates timestamps to three-digit (milliseconds) resolution, omitting trailing zeros.

In Cribl Stream 3.4.2 and above, where an Event Breaker has set an event's `_time` to the current time – rather than extracting the value from the event itself – it will mark this by adding the internal field `__timestampExtracted: false` to the event.

Add Fields to Events

After events have been timestamped, one or more fields can be added here as key-value pairs. In each field's **Value Expression**, you can fully evaluate the field value using JavaScript expressions.

Event Breakers **always** add the `cribl_breaker` field to output events. Its value is the name of the chosen ruleset. (Some examples below omit the `cribl_breaker` field for brevity, but in real life the field is always added.)

Max Event Bytes

If an event's final broken chunk reaches a matched rule's **Max event bytes** length, it will be broken again.

The highest **Max Event Bytes** value that you can set is about 128 MB (`134217728` bytes). Events exceeding that size will be split into separate events, but left unbroken. Cribl Stream will set these events' `__isBroken` internal field to `false`.

Event Breaker Types

Several types of Event Breaker can be applied to incoming data streams:

- Regex

- File Header
- JSON Array
- JSON New Line Delimited
- Timestamp
- CSV

Regex

The Regex breaker uses regular expressions to find breaking points in data streams.

After a breaker regex pattern has been selected, it will apply on the stream **continuously**. Breaking will occur at the beginning of the match, and the matched content will be consumed/thrown away. If necessary, you can use a positive lookahead regex to keep the content – e.g.: `(?=pattern)`

Capturing groups are **not allowed** to be used anywhere in the Event Breaker pattern, as they will further break the stream – which is often undesirable. Breaking will also occur if the final broken event's length reaches the rule's **Max event bytes**.

Example

Break after a newline or carriage return, but only if followed by a timestamp pattern:
Event Breaker: `[\n\r]+(?=\d+-\d+-\d+\s\d+:\d+:\d+)`

Sample Event - Multiline

```
--- input ---
2020-05-19 16:32:12 moen3628 ipsum[5213]: Use the mobile TCP feed, then you can prog
   Try to connect the FTP sensor, maybe it will connect the digital bus!
   Try to navigate the AGP panel, maybe it will quantify the mobile alarm!
2020-05-19 16:32:12 moen3628 ipsum[5213]: Use the mobile TCP feed, then you can prog
   Try to connect the FTP sensor, maybe it will connect the digital bus!
   Try to navigate the AGP panel, maybe it will quantify the mobile alarm!

--- output event 1 ---
{
  "_raw": "2020-05-19 16:32:12 moen3628 ipsum[5213]: Use the mobile TCP feed, then y
  "_time": 1589920332
}

--- output event 2 ---
{
  "_raw": "2020-05-19 16:32:12 moen3628 ipsum[5213]: Use the mobile TCP feed, then y
  "_time": 1589920332
}
```

File Header

You can use the File Header breaker to break files with headers, such as IIS or Bro logs. This type of breaker relies on a header section that lists field names. The header section is typically present at the top of the file, and can be single-line or greater.

After the file has been broken into events, fields will also be extracted, as follows:

- **Header Line**: Regex matching a file header line. For example, `^#`.
- **Field Delimiter**: Field delimiter regex. For example, `\s+`.
- **Field Regex**: Regex with one capturing group, capturing all the fields to be broken by field delimiter. For example, `^#[Ff]ields[:]?\s+(.*)`
- **Null Values**: Representation of a null value. Null fields are not added to events.
- **Clean Fields**: Whether to clean up field names by replacing non `[a-zA-Z0-9]` characters with `_`.

Example

Using the values above, let's see how this sample file breaks up:

Sample Event - File Header

```
--- input ---
#fields ts      uid     id.orig_h       id.orig_p       id.resp_h       id.resp_p
#types  time    string  addr    port    addr    port    enum
1331904608.080000       -     192.168.204.59  137     192.168.204.255 137     udp
1331904609.190000       -     192.168.202.83  48516   192.168.207.4   53      udp

--- output event 1 ---
{
  "_raw": "1331904608.080000       -     192.168.204.59  137     192.168.204.255 137
  "ts": "1331904608.080000",
  "id_orig_h": "192.168.204.59",
  "id_orig_p": "137",
  "id_resp_h": "192.168.204.255",
  "id_resp_p": "137",
  "proto": "udp",
  "_time": 1331904608.08
}

--- output event 2 ---
{
  "_raw": "1331904609.190000       -     192.168.202.83  48516   192.168.207.4   53
  "ts": "1331904609.190000",
  "id_orig_h": "192.168.202.83",
  "id_orig_p": "48516",
  "id_resp_h": "192.168.207.4",
  "id_resp_p": "53",
  "proto": "udp",
  "_time": 1331904609.19
}
```

JSON Array

You can use the JSON Array to extract events from an array in a JSON document (e.g., an Amazon CloudTrail file).

- **Array Field**: Optional path to array in a JSON event with records to extract. For example, `Records`.
- **Timestamp Field**: Optional path to timestamp field in extracted events. For example, `eventTime` or `level1.level2.eventTime`.

- **JSON Extract Fields**: Enable this toggle to auto-extract fields from JSON events. If disabled, only `_raw` and `time` will be defined on extracted events.
- **Timestamp Format**: If **JSON Extract Fields** is set to `No`, you **must** set this to **Autotimestamp** or **Current Time**. If **JSON Extract Fields** is set to `Yes`, you can select any option here.

Example

Using the values above, let's see how this sample file breaks up:

Sample Event - JSON Document (Array)

```
--- input ---
{"Records":[{"eventVersion":"1.05","eventTime":"2020-04-08T01:35:55Z","eventSource":"
{"eventVersion":"1.05","eventTime":"2020-04-08T01:35:56Z","eventSource":"ec2.amazonaw

--- output event 1 ---
{
  "_raw": "{\"eventVersion\":\"1.05\",\"eventTime\":\"2020-04-08T01:35:55Z\",\"events
  "_time": 1586309755,
  "cribl_breaker": "j-array"
}

--- output event 2 ---
{
  "_raw": "{\"eventVersion\":\"1.05\",\"eventTime\":\"2020-04-08T01:35:56Z\",\"events
  "_time": 1586309756,
  "cribl_breaker": "j-array"
}
```

JSON New Line Delimited

You can use the JSON New Line Delimited breaker to break and extract fields in newline-delimited JSON streams.

Example

Using default values, let's see how this sample stream breaks up:

Sample Event - Newline Delimited JSON Breaker

```
--- input ---
{"time":"2020-05-25T18:00:54.201Z","cid":"w1","channel":"clustercomm","level":"info"
{"time":"2020-05-25T18:00:54.246Z","cid":"w0","channel":"clustercomm","level":"info"

--- output event 1 ---
{
  "_raw": "{\"time\":\"2020-05-25T18:00:54.201Z\",\"cid\":\"w1\",\"channel\":\"cluste
  "time": "2020-05-25T18:00:54.201Z",
  "cid": "w1",
  "channel": "clustercomm",
  "level": "info",
  "message": "metric sender",
  "total": 720,
  "dropped": 0,
  "_time": 1590429654.201,
}

--- output event 2 ---
{
  "_raw": "{\"time\":\"2020-05-25T18:00:54.246Z\",\"cid\":\"w0\",\"channel\":\"cluste
  "time": "2020-05-25T18:00:54.246Z",
  "cid": "w0",
  "channel": "clustercomm",
  "level": "info",
  "message": "metric sender",
  "total": 720,
  "dropped": 0,
  "_time": 1590429654.246,
}
```

Timestamp

You can use the Timestamp breaker to break events at the beginning of any line in which Cribl Stream finds a timestamp. This type enables breaking on lines whose timestamp pattern is not known ahead of time.

Example

Using default values, let's see how this sample stream breaks up:

Sample Event - Timestamp Based Breaker

```
--- input ---
{"level":"debug","ts":"2021-02-02T10:38:46.365Z","caller":"sdk/sync.go:42","msg":"Ha
{"level":"debug","ts":"2021-02-02T10:38:56.365Z","caller":"sdk/sync.go:42","msg":"Ha

--- output event 1 ---
{
  "_raw": "{\"level\":\"debug\",\"ts\":\"2021-02-02T10:38:46.365Z\",\"caller\":\"sdk/
  "_time": 1612262326.365
}

--- output event 2 ---
{
  "_raw": "{\"level\":\"debug\",\"ts\":\"2021-02-02T10:38:56.365Z\",\"caller\":\"sdk/
  "_time": 1612262336.365
}
```

CSV

The CSV breaker extracts fields in CSV streams that include a header line. Selecting this type exposes these extra fields:

- **Delimiter**: Delimiter character to use to split values. Defaults to: `,`
- **Quote Char**: Character used to quote literal values. Defaults to: `"`
- **Escape Char**: Character used to escape the quote character in field values. Defaults to: `"`
  Example: Using default values, let's see how this sample stream breaks up:

Example

Using default values, let's see how this sample stream breaks up:

Sample Event - CSV Breaker

```
--- input ---
time,host,source,model,serial,bytes_in,bytes_out,cpu
1611768713,"myHost1","anet","cisco","ASN4204269",11430,43322,0.78
1611768714,"myHost2","anet","cisco","ASN420423",345062,143433,0.28

--- output event 1 ---
{
  "_raw": "\"1611768713\",\"myHost1\",\"anet\",\"cisco\",\"ASN4204269\",\"11430\",\"
  "time": "1611768713",
  "host": "myHost1",
  "source": "anet",
  "model": "cisco",
  "serial": "ASN4204269",
  "bytes_in": "11430",
  "bytes_out": "43322",
  "cpu": "0.78",
  "_time": 1611768713
}

--- output event 2 ---
{
  "_raw": "\"1611768714\",\"myHost2\",\"anet\",\"cisco\",\"ASN420423\",\"345062\",\"
  "time": "1611768714",
  "host": "myHost2",
  "source": "anet",
  "model": "cisco",
  "serial": "ASN420423",
  "bytes_in": "345062",
  "bytes_out": "143433",
  "cpu": "0.28",
  "_time": 1611768714
}
```

With **Type: CSV** selected, an Event Breaker will properly add quotes around all values, regardless of their initial state.

Cribl Versus Custom Rulesets

Event Breaker rulesets shipped by Cribl will be listed under the **Cribl** tag, while user-built rulesets will be listed under **Custom**. Over time, Cribl will ship more patterns, so this distinction allows for both sets to grow independently. In the case of an ID/Name conflict, the Custom pattern takes priority in listings and search.

Export and Import Rulesets

You can export and import Custom (or Cribl) rulesets as JSON files. This facilitates sharing rulesets among Worker Groups or Cribl Stream deployments.

To export a ruleset:

1. Select to open an existing ruleset, or create a new ruleset.
2. In the resulting modal, select **Advanced Mode** to open the JSON editor.
3. You can now modify the ruleset directly in JSON, if you choose.
4. Select **Export**, select a destination path, and name the file.

To import any ruleset that has been exported as a valid JSON file:

1. Create a new ruleset.
2. In the resulting modal, select **Advanced Mode** to open the JSON editor.
3. Select **Import**, and choose the file you want.
4. Select **OK** to get back to the **New Ruleset** modal.
5. Select **Save**.

Every ruleset must have a unique value in its top `id` key. Importing a JSON file with a duplicate `id` value will fail at the final **Save** step, with a message that the ruleset already exists. You can remedy this by giving the file a unique `id` value.

Edge: Build Breakers from Files

You can use Cribl Edge to apply and author Event Breakers while exploring files – even files that you have not saved as sample files. This option includes remote files that are viewable only from Edge. See Exploring Cribl Edge on Linux or Exploring Cribl Edge on Windows.

Troubleshooting

If you notice fragmented events, check whether Cribl Stream has added a `__timeoutFlush` internal field to them. This diagnostic field's presence indicates that the events were flushed because the Event Breaker buffer

timed out while processing them. These timeouts can be due to large incoming events, backpressure, or other causes.

Specify Minimum `_raw` Length

If you notice that the same Collector or Source is applying inconsistent Event Breakers to different datasets – e.g., intermittently falling back to the **System Default Rule** – you can address this by adjusting Breakers' **Min Raw Length** setting.

When determining which Event Breaker to use, Cribl Stream creates a substring from the incoming `_raw` field, at the length set by rules' **Max Event Bytes** parameters. If Cribl Stream does not get a match, it checks whether the substring of `_raw` has at least the threshold number of characters set by **Min Raw Length**. If so, Cribl Stream does not wait for more data.

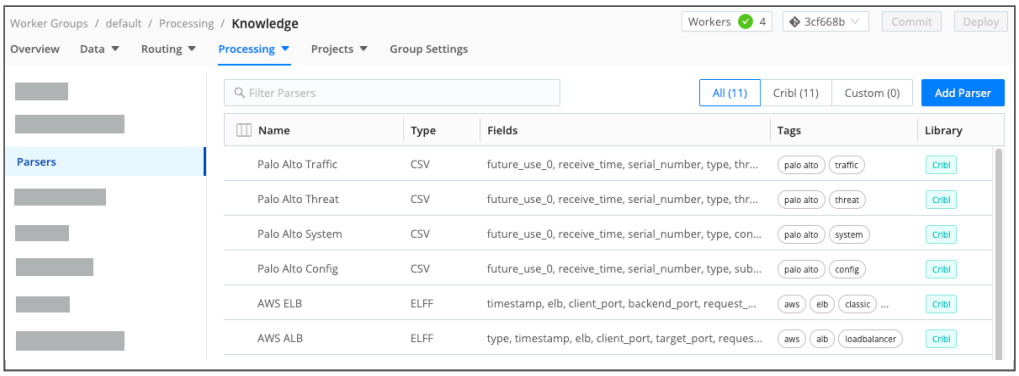
You can tune this **Min Raw Length** threshold to account for varying numbers of inapplicable characters at the beginning of events. The default is `256` characters, but you can set this as low as `50`, or as high as `100000` (100 KB).

16.3. Parsers Library

What Are Parsers

Parsers are definitions and configurations for the Parser Function. The purpose of the Parsers Library is to provide an interface for creating and editing Parsers. The library is searchable, and each parser can be tagged as necessary.

To find the library, select **Worker Groups** from the sidebar, and choose a Worker Group. Then, on the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Parsers**.



Parsers Library

Parsers can be used to **extract** or **reserialize** events. See Parser Function page for examples.

Supported Parser Types:

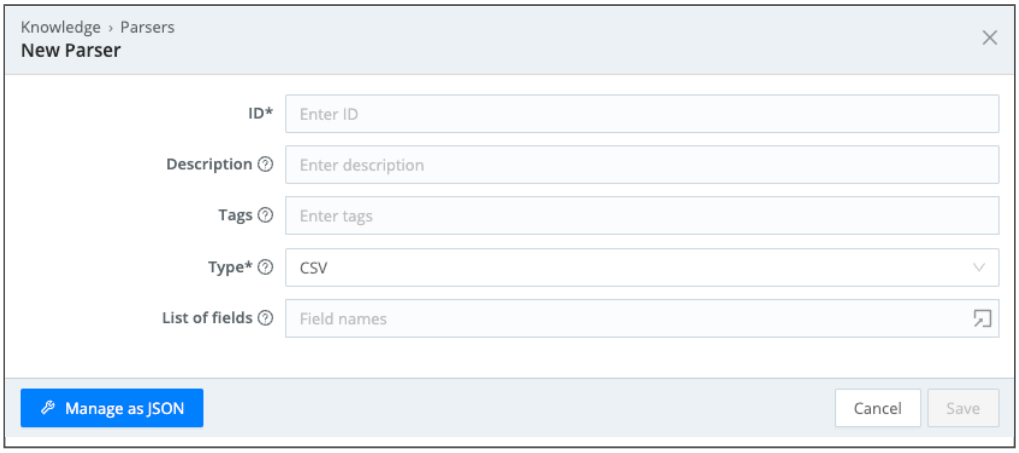
- CSV – Parse and reserialize comma-separated values.
- ELFF – Parse and reserialize events in Extended Log File Format.
- CLF – Parse and reserialize events in Common Log Format.

Creating a Parser

To create a parser, follow these steps:

1. In the sidebar, select **Worker Groups** (Cribl Stream) or **Fleets** (Cribl Edge) from the sidebar, and choose a Worker Group or Fleet.
2. On the **Worker Groups/Fleets** submenu, select **Processing** (Cribl Stream) or **More** (Cribl Edge), then **Knowledge**, then **Parsers**.
3. Select **Add Parser**.
4. Enter a unique **ID**.

5. Optionally, enter a **Description**.
6. Select a **Type** (see the supported types above).
7. Enter the **List of fields** expected to be extracted, in order. Select this field's Maximize icon (far right) if you'd like to open a modal where you can work with sample data and iterate on results.
8. Optionally, enter any desired **Tags**.



Adding a new parser

16.4. Global Variables Library

What Are Global Variables

Global Variables are reusable JavaScript expressions that can be accessed in Functions in any Pipeline.

To access the library, select **Worker Groups** from the sidebar, and choose a Worker Group. Then, on the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Global Variables**.

Typical use cases for Global Variables include:

- Storing a constant that you can reference from any Function in any Pipeline.
- Storing a relatively long value expression, or one that uses one or more arguments.

Global Variables can be of the following types:

- Number
- String
- Boolean
- Object
- Array
- Expression

Global Variables can be accessed via `C.vars.` – which can be called anywhere in Cribl Stream that JS expressions are supported. Typeahead is provided. More on Cribl Expressions here.

Examples

Scenario 1

Assign field `foo` the value in `theAnswer` Global Variable.

- Global Variable Name: `theAnswer`
- Global Variable Value: `42`
- **Sample Eval Function:** `foo = C.vars.theAnswer`

Scenario 2

Assign field `nowEpoch` the current time, in epoch format.

- Global Variable Name: `epoch`
- Global Variable Value: `Date.now()/1000`
- **Sample Eval Function:** `nowEpoch = C.vars.epoch()`

Scenario 3

Create a new field called `storage`, by converting the value of event field `size` to human-readable format.

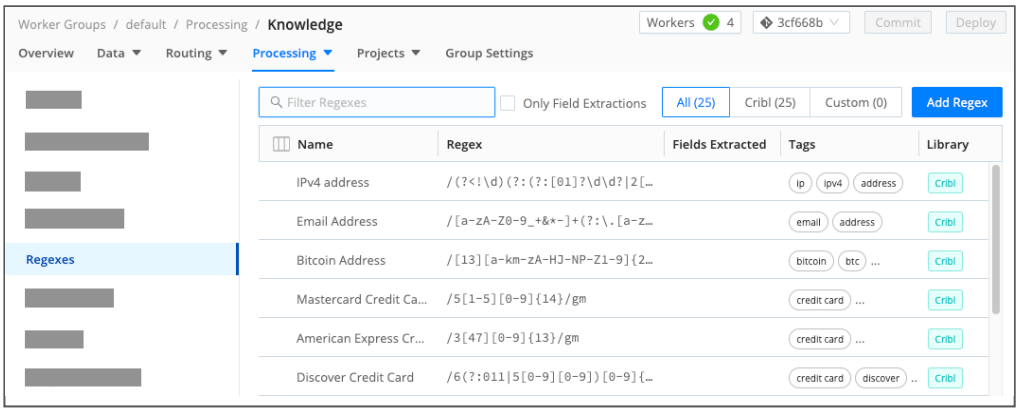
- Global Variable Name: `convertBytes`
- Global Variable Value: `` `${Math.round(bytes / Math.pow(1024, (Math.floor(Math.log(bytes) / Math.log(1024)))), 2)}${['Bytes', 'KiB', 'MiB', 'GiB', 'TiB', 'PiB', 'EiB', 'ZiB', 'YiB'][(Math.floor(Math.log(bytes) / Math.log(1024)))]}` ``
  Note the use of quotes or backticks around values. Use the opposite delimiter for the enclosing expression.
- Global Variable Argument: `bytes`
- **Sample Eval Function:** `storage = C.vars.convertBytes(size)`
  Note the use of `bytes` here as an argument.

16.5. Regex Library

What Is the Regex Library

Cribl Stream ships with a Regex Library that contains a set of pre-built common regular expression patterns. This library serves as an easily accessible repository of regular expressions. The Library is searchable, and you can assign tags to each pattern for further organization or categorization.

To access the library, select **Worker Groups** from the sidebar, and choose a Worker Group. Then, on the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Regexes**.

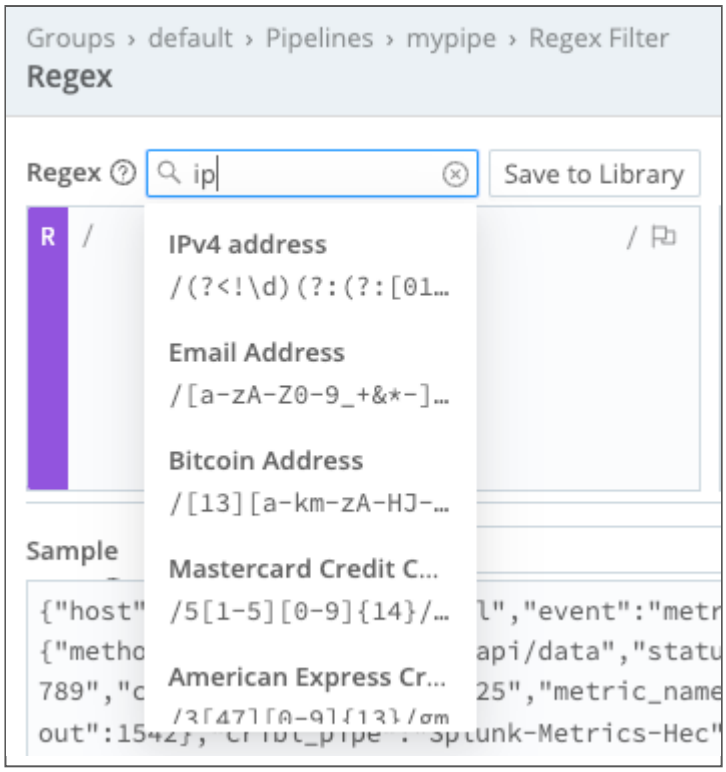


Regex Library

Using Library Patterns

To insert a pattern into a Function's regex field, first select the Advanced mode or Edit icon beside that field.

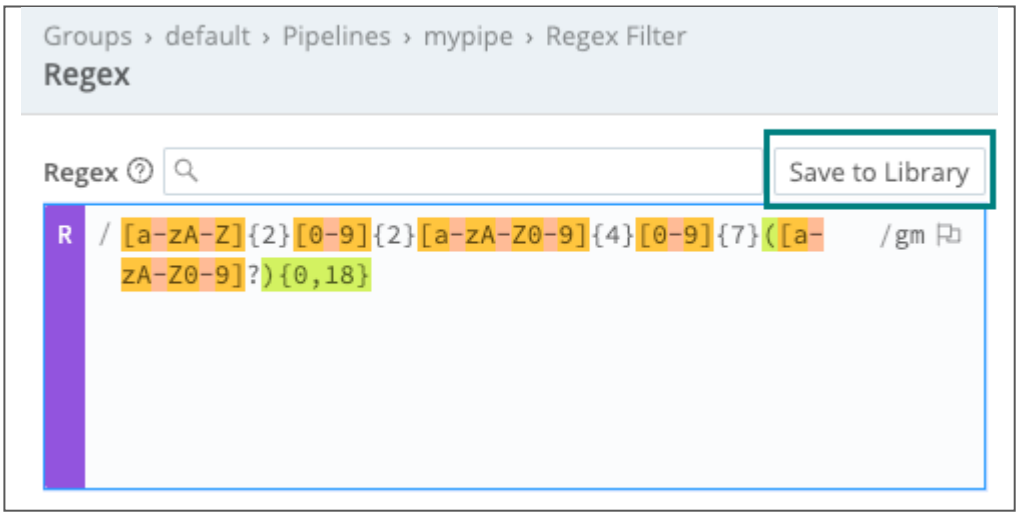
In the resulting Regex or Rules modal, Regex Library patterns will appear as typeahead options. Select a pattern to paste it in. You can then use the pattern as-is, or modify it as necessary.



Inserting a pattern from the Regex Library

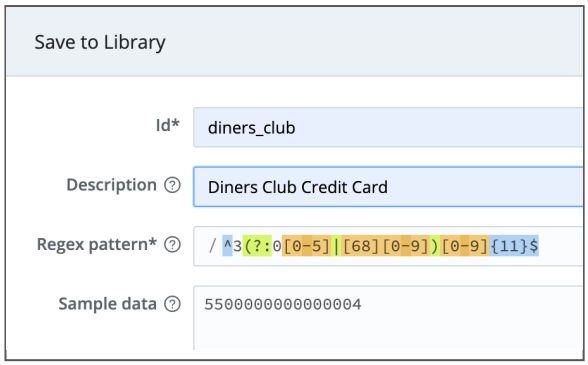
Adding Patterns to the Library

You can also add new, custom patterns to the Library. In the same modal, once you've built your pattern, select **Save to Library**.



Adding a custom pattern to the Regex Library from a Function's Regex modal

In the resulting modal, give your custom pattern a unique ID. Optionally, you can also provide a **Description** (name) and groom the **Sample data**. Then select **Save**.



Identifying the custom pattern

Your custom pattern will now reside in the Regex Library. It will be available to Functions using the same typeahead assist as Cribl's pre-built patterns.

Cribl vs. Custom and Priority

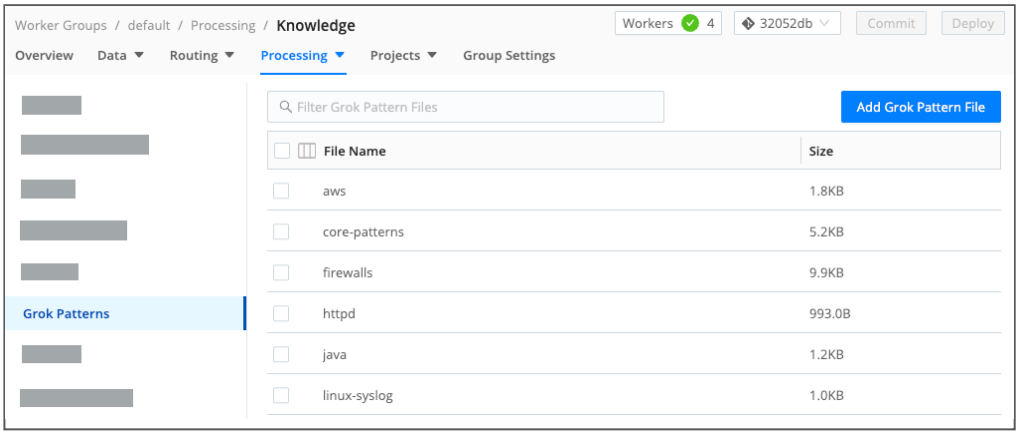
Within the Library, patterns shipped by Cribl will be listed under the **Cribl** tab, while those built by users will be found under **Custom**. Over time, Cribl Stream will ship more patterns, and this distinction allows for both sets to grow independently.

In the case of an ID/Name conflict, the Custom pattern takes priority in listings and search. For example, if a Cribl-provided pattern and a Custom one are both named `ipv4`, the one from Cribl will not be displayed or delivered as a search result.

16.6. Grok Patterns Library

What Is the Grok Patterns Library

Cribl Stream ships with a Grok Patterns Library that contains a set of pre-built common patterns, organized as files.



Grok Patterns Library

Managing Library Patterns

You can access the Grok Patterns Library by selecting **Worker Groups** from the sidebar and choosing a Worker Group. Then, on the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Grok Patterns**. The library contains several pattern files that Cribl provides for basic Grok scenarios, and is searchable.

To create a new pattern file, select **Add Grok Pattern File**. In the resulting modal, assign a unique **File name**, populate the file with patterns, then select **Save**.

Pattern files reside in: `$CRIBL_HOME/(default|local)/cribl/grok-patterns/`

Using Grok Patterns

In the current Cribl Stream version, you apply Grok patterns by inserting a Grok Function into a Pipeline, then manually typing or pasting patterns into the **Pattern** field(s).

16.7. Schemas Library

Cribl Stream supports two kinds of schemas:

- JSON schemas for validating JSON events, described on this page.
- Parquet schemas for writing data from a Cribl Stream Destination to Parquet files.

These schemas obviously serve different purposes. Beware of assuming that operations that work for one kind of schema can be used with the other. For example, the validation method for JSON schemas – `C.Schema('<schema_name>').validate(<object_field>)` – can't be used to validate Parquet schemas.

JSON Schemas

JSON schemas are based on the popular JSON Schema standard, and Cribl Stream supports schemas matching that standard's Drafts 0 through 7.

To access the schema library, select **Worker Groups** from the sidebar, and choose a Worker Group. Then, on the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Schemas**.

Its purpose is to provide an interface for creating, editing, and maintaining schemas.

You validate a schema using this built-in method:
`C.Schema('<schema_name>').validate(<object_field>)`.

You can call this method anywhere in Cribl Stream that supports JavaScript expressions. Typical use cases for schema validation:

- Making a decision before sending an event down to a destination.
- Making a decision before accepting an event (for example, drop an event if invalid).
- Making a decision to route an event based on the result of validation.

JSON Schema Example

To add this example JSON Schema, on the **Schemas** page, select **Add Schema**. Enter the following:

- ID: `schema1`.
- Description: (Enter your own description here.)
- Schema: Paste the following schema.

JSON Schema - Sample

```
{
  "$id": "https://example.com/person.schema.json",
  "$schema": "http://json-schema.org/draft-07/schema#",
  "title": "Person",
  "type": "object",
  "required": ["firstName", "lastName", "age"],
  "properties": {
    "firstName": {
      "type": "string",
      "description": "The person's first name."
    },
    "lastName": {
      "type": "string",
      "description": "The person's last name."
    },
    "age": {
      "description": "Age in years which must be equal to or greater than zero.",
      "type": "integer",
      "minimum": 0,
      "maximum": 42
    }
  }
}
```

Assume that events look like this:

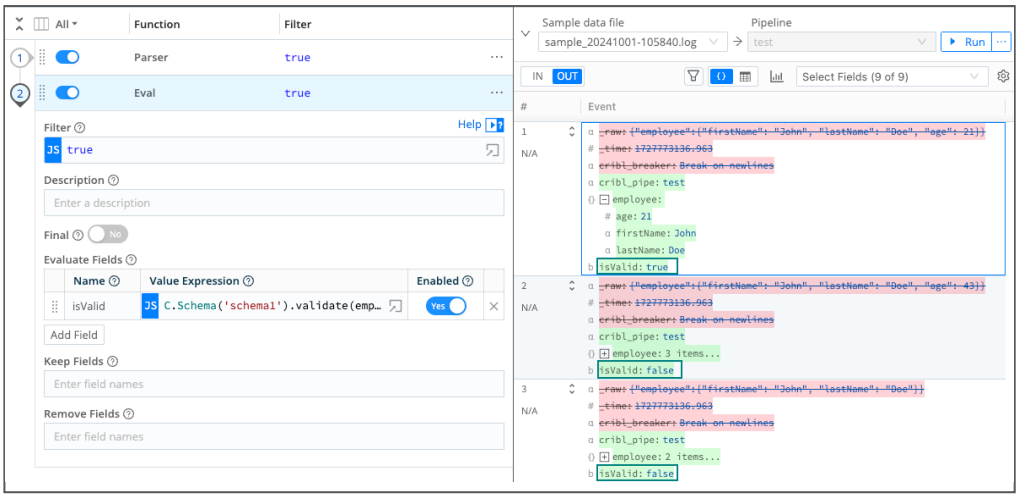
Events

```
{"employee":{"firstName": "John", "lastName": "Doe", "age": 21}}
{"employee":{"firstName": "John", "lastName": "Doe", "age": 43}}
{"employee":{"firstName": "John", "lastName": "Doe"}}
```

To validate whether the `employee` field is valid per `schema1`, we can use the following:
`C.Schema('schema1').validate(employee)`

Results:

- First event is **valid**.
- Second event is **not valid** because `age` is greater than the maximum of `42`.
- Third event is **not valid** because `age` is missing.



Schema validation results for the above events

16.8. Parquet Schemas

Cribl Stream supports two kinds of schemas:

- Parquet schemas for writing data from a Cribl Stream Destination to Parquet files, described on this page.
- JSON schemas for validating JSON events.

These schemas obviously serve different purposes. Beware of assuming that operations that work for one kind of schema can be used with the other. For example, the validation method for JSON schemas – `C.Schema('<schema_name>').validate(<object_field>)` – can't be used to validate Parquet schemas.

Configuring Parquet Schemas

Destinations whose **General Settings** > **Data format** drop-down includes a `Parquet` option can write out data as files in the Apache Parquet columnar storage format.

When logging is set to `debug`, you will see what schema is associated with the Parquet files that Cribl Stream writes out. On Linux, you can use the Cribl Stream CLI's `parquet` command to view a Parquet file, its metadata, or its schema.

If you turn on a Destination's **Parquet Settings** > **Automatic schema**, Cribl Stream will automatically generate a Parquet schema based on the events of each Parquet file it writes. The automatically-generated schema preserves the exact structure of the ingested events, with no data lost. In Cribl Stream v.4.4.2, every field in the generated schema will have a data type of `JSON`, `STRING`, `INT_64`, `UNSIGNED_INT_64`, or `DOUBLE`.

(The one exception is the Amazon Security Lake Destination, where automatic schema generation is not relevant because Amazon Security Lake exclusively uses the OCSF Parquet schemas already available in the drop-down.)

Pros and Cons of Automatically Generated Parquet schemas

When you decide whether or not to generate Parquet schemas automatically, consider these pros and cons.

Advantages:

- Configuration is minimal.
- There's no need to know how events you want to ingest are structured.
- There's no need to change Parquet schema when event structure changes.

Disadvantages:

- Writing Parquet files takes longer than with predefined schemas. Note that schema complexity increases linearly with the number of events used to generate the schema.
- Automatically-generated Parquet schemas cannot be as fine-tuned as predefined ones, to capture certain nuances. For example, encoding will always be `PLAIN`, compression will always be `SNAPPY`.
- Some aspects of event structure (such as maps and sets) cannot be captured in the schema.
- Some aspects of time-related fields cannot be captured in the schema.
- Because the system produces a new Parquet schema for each file written, there may be differences between successive schemas. This can limit your ability to concatenate a collection of Parquet files.

Configuring Parquet Schemas

If you are not using automatic schema generation, or if there's no pre-existing schema that suits your data, before configuring a Destination for Parquet output, you should add an existing Parquet schema, or create a new Parquet schema that suits the data you're working with.

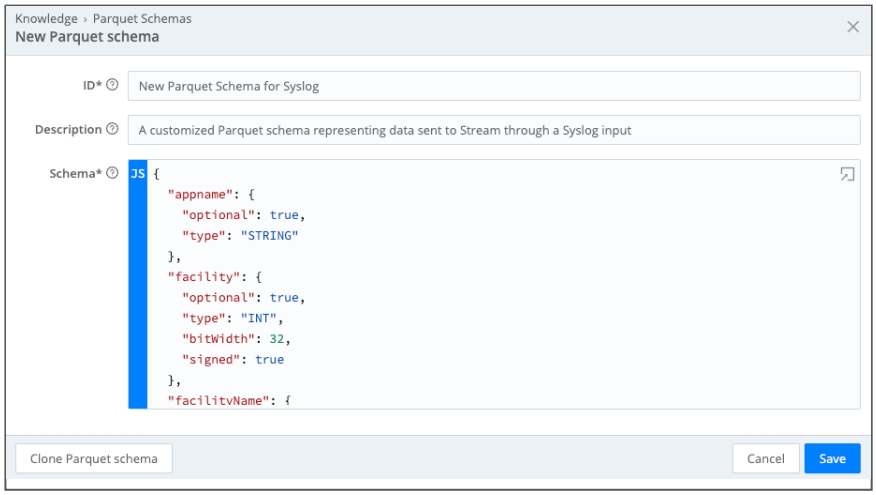
You do not need to start from scratch: Cribl provides sample Parquet schemas for you to clone and then customize as needed.

To access the Parquet schema library, select **Worker Groups** from the sidebar, and choose a Worker Group. Then, on the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Parquet Schemas**.

To add a Parquet schema, select **Add Parquet schema** to open the **New Parquet schema** modal.

You can also clone an existing Parquet schema to create a new schema:

1. Select the schema you want to start with, to open it in a modal.
2. Select **Clone Parquet Schema** to open the **New Parquet schema** modal.
3. Give the new schema a name and description.



Creating a Parquet schema

Now, when you configure your Destination, the schema you created will be available from the **Parquet Settings** > **Parquet schema** drop-down.

Creating/Modifying Parquet Schemas from Destinations

When the existing schemas on a Destination's **Parquet schema** drop-down don't meet your needs, follow this procedure to add or modify (clone) a new schema.

1. Navigate to the Parquet Schemaa Library at **Processing** > **Knowledge** > **Parquet Schemas**.
2. Add or modify the schema, as described above.

To modify an existing schema, Cribl strongly recommends that you first clone the schema, and give the clone its own distinct name. See Cloning Is Safer just below.

3. Return to the Destination, and select the new or modified schema from the **Parquet schema** drop-down.

Cloning Is Safer than Modifying

You can modify an existing schema, but Cribl strongly recommends that you first clone the schema, and give the clone its own distinct name. When you clone a schema, return to the Destination, and select the clone from the **Parquet schema** drop-down.

Modifying an existing schema in the Schema Library does **not** propagate your modifications to the Destination's copy of the schema. Cloning and renaming schemas is the safest approach, because it ensures that your Destination will use the newly modified version of the schema.

If you do not clone and rename the schema (that is, you leave the schema name unchanged), you still must re-select the schema in the Destination's **Parquet schema** drop-down to bring the modified version into the Destination.

Working with Parquet in Cribl Stream

Different Parquet readers and writers behave differently. Keep the following guidelines in mind when working with Parquet in Cribl Stream.

The Parquet Schema Editor

In the Parquet Schema editor, you express your Parquet schema in JSON. This does not look like the examples in the Parquet spec, which have their own syntax (like the repetition/name/type triple), but they are

functionally equivalent. See the examples below.

The editor provides autocompletion and validation to guide you. (However, Cribl Stream currently does not fully support autocompletion on deeply nested schemas.)

File Extensions

For now, Cribl Stream can read Parquet files only if they have the extension `.parquet`, `.parq`, or `.pqt`.

Field Content

When Cribl Stream writes to a Parquet file:

- If the data contains a field that **is not** present in the schema – i.e, an extra field – Cribl Stream writes out the parent rows, but omits the extra field.
- If the data contains a field that **is** present in the Parquet schema, but whose properties violate the schema, Cribl Stream treats this as a data mismatch. Cribl Stream drops the rows containing that field – it does not write those rows to the output Parquet file at all.
- If the data contains JSON, the JSON must be stringified. Otherwise, Cribl Stream treats this as a data mismatch, and does not write out the row. For example, this valid (but not stringified) JSON will trigger a data mismatch:
  `{ "name": "test"}`.
  The same JSON in stringified form will work fine:
  `"{\"name\": \"test\"}"`.

Data Types

Cribl Stream supports:

- All primitive types.
- All logical types.
- All converted types.

Converted types have been superseded by logical types, as described in the Apache Parquet docs. Cribl Stream can read Parquet files that use converted types, but will write out the same data using corresponding logical types.

Repetition Type

You have three alternatives when defining a field's Repetition type:

- Set `optional` to `true`.

- Set `repeated` to `true`.
- Set neither `optional` nor `repeated`. This **implicitly** sets the Repetition type to `required`, and it is the default.

Usage guidelines:

- Do not set both `optional` **and** `repeated` to `true`.
- Do not use the `required` key at all.
- Instead of omitting `optional`, you have the option to include it, but set it to `false`.
- Instead of omitting `repeated`, you have the option to include it, but set it to `false`.
- If any field's Repetition type is `repeated`, Cribl Stream represents this field as a single key whose value is an array – not as separate key-value pairs with identical keys.

Encodings

- Among the `*DICTIONARY` encodings, Cribl Stream supports only `DICTIONARY`. Trying to assign the unsupported encodings `PLAIN_DICTIONARY` or `RLE_DICTIONARY` will produce an error.
- `BYTE_STREAM_SPLIT` encoding can be used only with `DOUBLE` or `FLOAT` types, and otherwise produces errors.
- The `RLE` and all `DELTA*` encodings also produce errors.

Parquet Schema Expressed as JSON

These examples should give you a hint of how to express Parquet schema in JSON. For a full explanation of the Parquet syntax, see the Parquet spec.

List Example

In this example, the whole schema is named `the_list`, and its structure consists of a container named `list` whose zero or more elements are each named `element`. Note that in Parquet schema, to specify that a field is nested (that is, contains other fields), you just give it the type `group`.

Parquet Schema Example 1

```
message schema {
  REQUIRED group the_list (LIST) {
    REPEATED group list {
      REQUIRED BYTE_ARRAY element (STRING);
    }
  }
}
```

Expressed as JSON, the same schema is more spread-out, because to specify that a field is nested, you give it a sub-field named `fields`. (This is equivalent to declaring the nested field's type as `group`.)

Parquet Schema Example 1 Expressed as JSON

```
{
  "the_list": {
    "type": "LIST",
    "fields": {
      "list": {
        "repeated": true,
        "fields": {
          "element": {
            "type": "STRING"
          }
        }
      }
    }
  }
}
```

Map Example

In this example, the whole schema is named `the_map`, and its structure consists of a container named `key_value` whose zero or more pairs of elements each contain a `key` and a `value` element. Both the `key` and the `value` are strings in this case, but they could be other data types.

Parquet Schema Example 2

```
message schema {
  REQUIRED group the_map (MAP) {
    REPEATED group key_value {
      REQUIRED BYTE_ARRAY key (STRING);
      REQUIRED BYTE_ARRAY value (STRING);
    }
  }
}
```

Parquet Schema Example 2 Expressed as JSON

```
{
  "the_map": {
    "type": "MAP",
    "fields": {
      "key_value": {
        "repeated": true,
        "fields": {
          "key": {
            "type": "STRING"
          },
          "value": {
            "type": "STRING"
          }
        }
      }
    }
  }
}
```

Array of Arrays Example

In this example, the whole schema is named `array_of_arrays`, and its structure consists of a container named `list` whose zero or more elements – which are themselves lists – are each named `element`. Within each of those `element` lists are one or more additional `list/element` structures.

Parquet Schema Example 3

```
message schema {
  REQUIRED group array_of_arrays (LIST) {
    REPEATED group list {
      REQUIRED group element (LIST) {
        REPEATED group list {
          REQUIRED INT64 element;
        }
      }
    }
  }
}
```

Expressed as JSON, the same schema is cumbersome to read compared to Parquet, which was designed to express nested structures concisely.

Parquet Schema Example 3 Expressed as JSON

```
{
  "array_of_arrays": {
    "type": "LIST",
    "fields": {
      "list": {
        "repeated": true,
        "fields": {
          "element": {
            "type": "LIST",
            "fields": {
              "list": {
                "repeated": true,
                "fields": {
                  "element": {
                    "type": "INT64"
                  }
                }
              }
            }
          }
        }
      }
    }
  }
}
```

Limitations

Cribl Stream does not support writing Parquet files which employ any of the following:

- Parquet Modular Encryption.
- The Parquet Bloom Filter.
- Separation of metadata and/or column data into multiple files.

Cribl Stream does not support reading or writing Parquet files which employ the deprecated `INT96` data type.

16.9. Database Connections

Database Connections define the database management systems used by Database Collectors to retrieve events.

Accessing Database Connections

To access Database Connections, select **Worker Groups** from the sidebar, and choose a Worker Group. Then, on the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Database Connections**.

Select **Add Database Connection** to open a modal that provides the following controls.

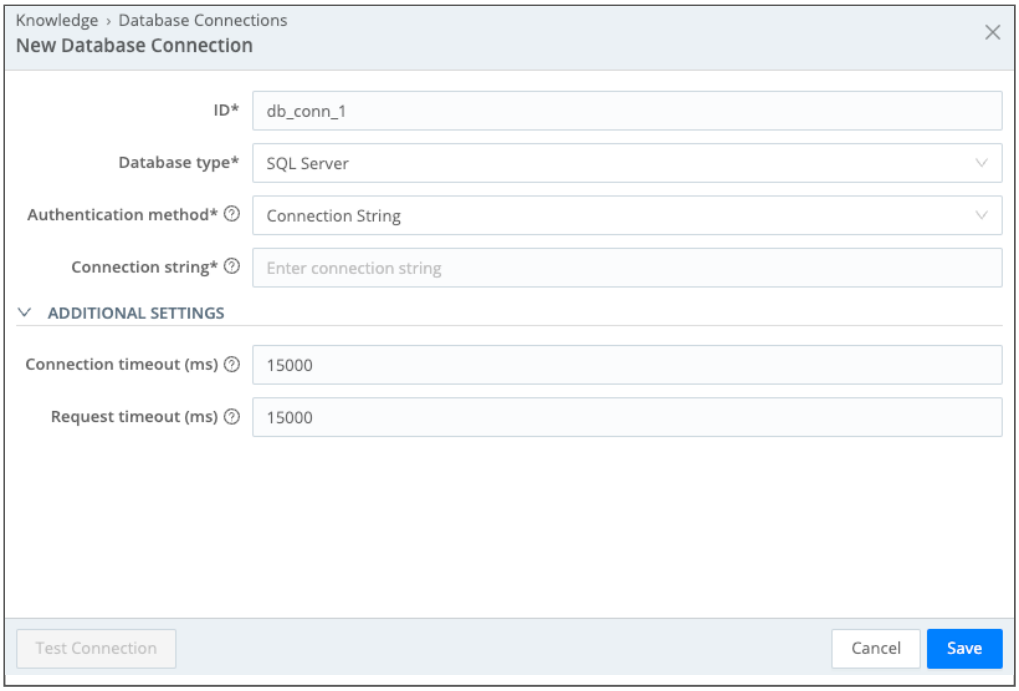
Initial Settings

ID: Enter a unique ID for this connection. (A descriptive ID will help all users recognize the connection by purpose.)

Database type: Select `MySQL`, `SQL Server`, `Postgres`, or `Oracle` from the drop-down.

- Oracle supports database version 12.1 and newer. Queries can retrieve up to 1 GB of large objects (CLOBS, LOBS, and NCLOBS) per field and use the `node-oracledb` library in Thin mode.

The **Database type** that you select exposes slightly different configuration fields and compatible values, listed below.



Authentication Settings

Set the **Authentication method** to one of the following options.

Connection String: Exposes a field where you directly enter your database connection string. The string's format varies according to your selected **Database type**.

- MySQL format: `mysql[s]://[[user][:password@]][host][:port][/db][?option=value]`
- SQL Server format: `Server=localhost; Database=test;User Id=SA; Password=Testing123![; Option=Value]`
    - To use a non-standard port, set your Server value as follows: `Server=localhost,1431`, where 1431 is the requested port.
- Postgres format: `postgres[ql]://[userspec@][hostspec][/dbname][?paramspec]`
- Oracle format: Easy Connect or Connection Description format:
    - Easy Connect: `<host_name>/<service_name>`
    - Connection Description: `(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=your_host_name)(PORT=1521))(CONNECT_DATA=(SERVICE_NAME=your_service_name)))`
    - Enter the **User** (username) and **Password** for your Oracle database account. This account must have the necessary permissions to perform the desired operations.

Cribl Stream requires Oracle database connections to use inline connection strings instead of external `tnsnames.ora` files. The inline connection string follows a specific format, using `FIELD=VALUE` pairs to specify details like the server, port, and service name. If you encounter connection errors, double-check the formatting and ensure all necessary fields are included. See Oracle's documentation for details.

Secret: Exposes a **Connection string secret** drop-down, where you select an existing stored text secret that provides your connection string in the appropriate format listed above. A **Create** button is available to define a new secret.

Config: When **Database type** is set to `SQL Server`, exposes a pane where you can enter a JSON connection configuration object. The object uses the Tedious driver and the node-mssql client.

Additional Settings

Connection timeout (ms): How long, in milliseconds, Cribl Stream should wait before assuming that a connection has failed. This defaults to `10000` (10 sec.) for MySQL databases, and to `15000` (15 sec.) for

SQL Server databases. For both, the minimum allowed value is `1000` (1 sec.), and the maximum is `60000` (1 minute).

Request timeout (ms): This setting appears only where **Database type** is set to `SQL Server`. Defines how long Cribl Stream should wait before assuming that a request has failed. If a query requires a longer timeout than the default `15000` (15 seconds), be sure that you know why – long-running queries can affect other parts of the system. Minimum is `1000` (1 second); maximum is `600000` (10 minutes).

Testing the Connection

To test a connection from the Leader Node, select **Test Connection** at the modal's lower left.

To test a connection from a Worker Node, ensure the Database Connection is committed and deployed, then teleport to the Worker and perform a **Test Connection**.

Examples

To adapt the following examples to your deployment, substitute your own credentials, domain names, etc, for those in the examples.

Connecting to a MySQL Database

- Database type: `MySQL`
- Connection String: `mysqls://userName:pa$$w0rd@server:3306/dbName`

Connecting to an Oracle Database

- Database type: `Oracle`
- Connection String:
  - Easy Connect: `my-oracle-server.example.com/XEPDB1`
  - OracleNet Connection (Named Pair): `(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=my-oracle-server.example.com)(PORT=1521))(CONNECT_DATA=(SERVICE_NAME=XEPDB1)))`

Using Active Directory to Connect to SQL Server on Azure

- Database type: `SQL Server`
- Connection String: `Server=tcp:server.database.windows.net,1433;User ID=userName@domain.onmicrosoft.com;Password=pa$$w0rd;Encrypt=True;TrustServerCertif Directory Password";Database="dbName"`

Using NTLM to Connect to SQL Server

Windows Challenge/Response, also known as Microsoft New Technology LAN Manager (NTLM), is an authentication protocol for systems running the Windows operating system.

- Database type: `SQL Server`
- Configuration Object:

```
{
  "authentication": {
    "type": "ntlm",
    "options": {
      "userName": "userName",
      "password": "pa$$w0rd",
      "domain": "domain"
    }
  },
  "options": {
    "connectTimeout": 15000,
    "trustServerCertificate": true
  },
  "connectionTimeout": 15000,
  "port": 1433,
  "server": "server",
  "database": "database"
}
```

16.10. HMAC Functions

HMAC (Hash-based Message Authentication Code) Functions are a crucial security feature used to ensure the integrity and authenticity of messages. In Cribl, HMAC Functions are used with REST Collectors, where they secure data collection by generating a unique signature for each request. This signature is then verified by the server to ensure that the request has not been tampered with and is from a trusted source.

Why Use HMAC Functions?

- **Security**: HMAC Functions provide a way to verify the integrity and authenticity of messages, ensuring that data has not been altered in transit.
- **Authentication**: They help authenticate the source of the message, ensuring that it comes from a trusted entity.
- **Compliance**: Using HMAC Functions can help meet security compliance requirements by adding an additional layer of security to your data collection processes.

Where to Use HMAC Functions

HMAC Functions are used in REST Collectors. They are configured to generate a signature for each request, which is then included in the request headers. The server receiving the request can then verify the signature to ensure the request's integrity and authenticity.

For a practical example of how to use HMAC functions, refer to the Cribl REST Collector Configuration for the Duo API in Cribl's Collector Templates repository.

Creating an HMAC Function

To create an HMAC Function:

1. In the sidebar, select **Worker Groups** and choose a Worker Group.
2. On the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **HMAC Functions**.
3. Select **Add HMAC Function**.
4. Enter a unique **ID**.
5. Optionally, enter a **Description** and assign **Tags** that you can use to filter and group HMAC Functions.
6. Define a list of **HMAC signature strings** to evaluate and concatenate to form the HMAC signature string. This specifies the components of the request to include in the HMAC signature. For example, you might include the HTTP method, URL, and certain headers to ensure that the signature is unique and secure.

Expressions returned as undefined or null are ignored and not added to the final signature string. Each string can access the following variables:

- `method`: Uppercase HTTP verb used for the request: GET, PUT, POST, DELETE, and so on.
- `urlObj`: A URL object containing details of the URL and query string passed with the request.
- `headers`: An alphabetically ordered list of headers (by name) and values to send with the request.
- `body`: The contents of the HTTP body (if present) passed with the request.

7. Specify the **Signature string delimiter** character to use when joining the HMAC signature strings for evaluation. For example, `':'`, `'-'`, and `'\n'`. The value must be a JavaScript expression (which can evaluate to a constant value), enclosed in quotes or backticks. Leave blank to join without spaces.
8. Specify the **Authorization header name** that will contain the HMAC signature. Defaults to `signature`. This ensures the server knows where to find the signature in the request headers.
9. Define an **Authorization header expression** that forms the HMAC signature. The expression should incorporate the following:
   - `signatureString`: This contains the concatenated result of the HMAC signature strings.
   - HMAC generation: Use the `C.Crypto.createHmac` function to calculate the HMAC signature based on the `signatureString`, a specified secret (either as a text secret or inline), the SHA256 algorithm, and hexadecimal encoding.

   For example: `${C.Crypto.createHmac(`${signatureString}`, C.Secret('myTextSecret', 'text').value, 'sha256', 'hex')}`
10. Select **Save**, then **Commit** and **Deploy** your changes.

16.11. AppScope Configs

You can obtain high-fidelity application data from any Linux command or application using AppScope, an open-source tool from Cribl. This includes data that's difficult or impossible to obtain any other way. (Note that AppScope is no longer being actively developed by Cribl.)

AppScope is included in your Cribl Stream installation. One or two AppScope Sources are enabled right out-of-the-box; they are configured to send data to Cribl Edge or Cribl Stream on the same host.

AppScope ships with a set of config files that offer a variety of options for what events and metrics you want AppScope to capture, and whether to enable payload capture. These are: `sample_config`, `default_metrics_events`, `verbose_metrics_events`, and `verbose_metrics_events_payloads`.

To understand precisely what one of these files does, select it to open its **AppScope Configs** modal and select **Manage as JSON**. For explanations and definitions, see the Config File and Schema Reference sections in the AppScope docs.

You can customize the config files, or edit them via **Manage as JSON**. When editing, you can revert to the original state by selecting **Restore Default**. The safer option is to select **Clone AppScope config**, then edit and save your new version with a new file name. The sample configs, and any variants you have created and saved, constitute a reusable set of AppScope configurations in the AppScope Config Library.

When you have assigned an AppScope config to a Rule in an AppScope Source, and you change it in the Knowledge UI, the changes will not take effect until you do the following:

- In the AppScope Source **AppScope Rules** settings, re-assign the config to the Rule. (That is, unselect the config file, then select it again.)
- Save and commit.

Creating AppScope Configs

To access Appscope Configs:

1. In the sidebar, select **Worker Groups**, and choose a Worker Group.
2. Then, on the **Worker Groups** submenu, select **Processing**, then **Knowledge**, then **Appscope Configs**.

Select **Add AppScope config** to open a modal to begin creating an AppScope config, using the options below.

Once you've created AppScope configs, you can edit, delete, search, and tag them as desired.

General Settings

ID: Enter a unique name to identify this AppScope Config.

Description: Optionally, enter a description that will remind you what the config is for when you see it listed in the library.

Tags: Optionally, enter any desired tags.

Transports

AppScope offers several options for routing data. See Data Routing in the AppScope docs.

Use AppScope Source's IP/port or UNIX domain socket?: The default `Yes` setting applies the transport options defined in the associated AppScope Source. Toggling this to `No` exposes the following fields in this section.

Cribl authentication token: Optionally, set a value to add to the `config-event` header (as a top-level `authToken` property) when AppScope establishes a connection.

Send metrics and events over the same connection?: Defaults to `Yes`, which locks some settings into preconfigured values. Toggle to `No` if you prefer to route metrics and events independently.

Connection type: From the drop-down, choose one of the connection types described below, then enter values in whatever fields the UI exposes.

- When **Send metrics and events over the same connection?** is toggled to `Yes`, you configure a single connection by choosing `TCP`, `Edge` (the default), or `Unix`.
- When routing metrics and events independently, you configure one connection for metrics and another for events; the drop-down offers two additional connection types: `UDP` and `File`.

Transports and Connection Types

At the heart of any AppScope config are the transports you define. In AppScope, a transport specifies something to send, how to send it, and where to send it. The things to send can be metrics, events, or logs.

Depending on the choices you make in the **Transport** settings, the UI will make some or all of the following types of connections available.

UDP: The destination is the network server whose hostname or IP address you specify in the **Host** field, along with a UDP **Port** to listen on.

TCP: The destination is the network server whose hostname or IP address you specify in the **Host** field, along with a TCP **Port** to listen on. The **Enable TLS** toggle defaults to `No`.

Unix: The destination is a Unix domain server listening on the Unix domain **Socket path** you specify.

File: The destination is the file whose directory location you specify in the **File path** field, along with a **Buffering** method.

Edge: The destination is Cribl Edge, listening on a preconfigured Unix domain socket.

TLS Settings (TCP Only)

When the **Connection type** is `TCP`, the UI exposes the **Enabled** toggle, which defaults to `No`.

If you toggle **Enabled** to `Yes`:

- Set **Validate server certs** to `true` if you want the connection to fail when the TLS server certificate cannot be validated. Defaults to `No`.
- Leave **CA certificate path** blank if you toggled the **Validate server certs** to `true` and are using the local OS-provided trusted CA certificates to validate the server's certificate. Otherwise, specify the server path containing CA certificates, which must be in PEM format.

Logs Settings

Configure where and how AppScope should send its own logs.

Connection type: From the drop-down, choose one of the connection types described above, then enter values in whatever fields the UI exposes.

Log level: Set logging verbosity. When **Send metrics and events over the same connection?** is toggled to `Yes`, **Log level** is locked at `warning`.

File path: Specify a directory in which to store logs. If not specified, defaults to `/tmp/scope.log`.

Buffering: Set this method to `Line` if there's a chance that multiple scoped processes will be writing to the same file. This prevents the log file from getting scrambled, with interleaved lines. However, in single-writer scenarios, selecting `Full` often improves performance.

Metrics Settings

The Schema Reference in the AppScope docs lists and fully describes every metric that AppScope can emit.

Process (`proc.*`) metrics periodically report information about resource usage at a point in time. All other metrics report on actions taken by a scoped process. For examples, see Metrics and Events in AppScope in the AppScope documentation.

Should AppScope emit metrics?: Defaults to `Yes`, which exposes the following options.

Format: AppScope can emit metrics in either of two formats: `NDJSON` (the default), or `StatsD`. If you choose `StatsD`, the UI exposes the following fields:

- **StatsD prefix**: Optionally, enter a prefix for AppScope to add to metrics.
- **StatsD max length**: Optionally, enter a maximum length, in bytes, for StatsD-formatted metrics. AppScope will truncate any metric which exceeds the maximum length. (Defaults to `512`.)

Verbosity: Set a value between `0` and `9`. (Defaults to `4`.) Verbosity controls both the cardinality of metrics that AppScope emits, and which kinds of metrics AppScope aggregates. For details, see Metrics and Events in AppScope in the AppScope documentation. But the general principle is:

- At low verbosity, metrics summarize multiple actions over a reporting period.
- At higher verbosity, metrics provide details about single actions in real time.

Reporting period: Set the metric summary interval in seconds. Defaults to `10`.

Watch list: Select categories of metrics to emit. Defaults to the following categories: `StatsD`, `File System`, `Network`, `HTTP`, `DNS`, `Process`.

Events Settings

The Schema Reference in the AppScope docs lists and fully describes every event that AppScope can emit.

Should AppsScope emit events?: Defaults to `Yes`, which exposes the following controls in this section.

Event-rate limiter (events per second): AppScope discards events generated in excess of the limiter setting, which defaults to `10000`. To disable the limiter, set it to `0`.

Enhance filesystem event data: When toggled to `Yes` (the default), AppScope enhances `fs.open` events by adding the `uid`, `gid`, and `mode` fields.

Watch list: Specify categories of events to emit, and configure their content and structure. Defaults to the following categories: `Console`, `File`, `Filesystem`, `Network`, `DNS`, and `HTTP`. For details, see Categories.

Events Categories

The **Watch list** is a table providing a row for each enabled category of events. The **Type** column contains the category names. The other columns (**Name**, **Field**, and **Value**) contain regular expressions.

At the right edge of the **Name**, **Field**, and **Value** fields is a Copy button, a Flag button to append Regex flags, and an Expand button to open a validation modal.

AppScope emits an event when its values match all the regexes in the corresponding category's row. For **HTTP**, request and response events must also match the headers listed in the **Header** column.

Allow binary is a toggle, available only for **Console** events. When toggled to `Yes` (the default), **Console** events will include binary data along with text data. If you prefer to redact binary data, toggle to `No`.

The **Type** column enumerates any or all of the following event category names. Toggle **Enabled** to `Yes` to include a category.

- **Console**: Includes writes to standard out and error. Use this to monitor console output, especially in containerized environments where logging to files isn't commonly done.
- **File**: Includes writes to files. Use this to monitor log files and/or any other files of interest.
- **Filesystem**: Includes filesystem operations like `open`, `close`, and `delete`.
- **Network**: Includes `open` and `close` events on network connections.
- **DNS**: Includes DNS request and response events.
- **HTTP**: Includes HTTP request and response events.
- **Granular**: Seldom used, and not emitted by default. Can be useful when tracking down a problem. When this type is enabled, AppScope sends more events than it otherwise would, giving you a more granular view of the activity of the scoped process.

Some usage examples:

- For `fs.*` events, AppScope normally emits `fs.open` and `fs.close` events. With **Granular** enabled, every time a read or write occurs, AppScope emits `fs.read` or `fs.write`, respectively.
- For `net.*` events, AppScope normally emits `net.open`, `net.close`, and `net.app`.With **Granular** enabled, every time a read or write is done on the socket, AppScope emits `net.rx` or `net.tx`, respectively.

Payloads

AppScope never sends encrypted payloads to disk, to Cribl Stream, or to Cribl Edge.

Capture all payloads: Enable capturing all payloads. Defaults to `No`. Enable this setting with caution: when scoping I/O-intensive programs, it can produce large amounts of data.

Protocol detection: Select **Add Protocol** to specify a protocol (for example, StatsD, HTTP, Redis) for AppScope to detect in network payloads, as well as what AppScope should do upon detecting that protocol. AppScope checks the first packet on a channel against the regular expression for each protocol until it finds a match. Then AppScope treats the matching protocol as the detected protocol for its channel, and ignores any others listed. See Sample Protocols for regexes that detect common protocols.

Name: Enter a short, descriptive name to define the protocol-detect event. AppScope inserts this value into the header for payloads sent to Cribl. Since AppScope sends this as JSON, you cannot include double quotes or backslashes.

Regex: Enter a regular expression to detect the desired protocol.

Generate protocol-detect-events: Toggle to `Yes` to generate protocol-detect events. Defaults to `No`.

Capture payload: Toggle to `Yes` to send payloads from matching streams to the configured destinations. Defaults to `No`.

Convert to hex: When toggled to `Yes` (the default), AppScope converts part of the payload to a hex-string before applying the regex. Otherwise, AppScope applies the regex to the binary payload.

Bytes to convert: The number of bytes to convert to hex before applying the regex. Defaults to `256`.

Payload directory: Specify the directory where AppScope should store payload files. Consider using a performant filesystem to reduce I/O performance impacts. Defaults to `tmp`. When **General Settings** > **Send metrics and events over the same connection?** is toggled to `Yes`, AppScope ignores this field and sends payloads to the default destination.

Advanced Settings

Send process-start message?: When toggled to `Yes` (the default), enables the process-start message. This message is the first one AppScope sends upon establishing a connection. It describes AppScope's configuration for that session, as well as the application being scoped.

Command directory: If you want to dynamically change AppScope configuration while scoping a running process, save a `scope.<pid>` file to a **command directory** of your choice, where `<pid>` is the PID of the scoped process, and the file contains lines of the form `<ENV_VAR>=<value>`. Once per reporting period, AppScope looks for a `scope.<pid>` file in the **command directory**, which defaults to `/tmp`. You can configure reporting period in the **Metrics** tab.

Metadata: If you want to add a field to events and metrics that AppScope emits, select **Add Metadata** and define it as a key-value pair. Key/value definitions cannot include environment variables.

Per-process configs: Optionally, define a config that, given a process that fits a particular pattern, will partly or completely override the config you have defined already.

Select **Add config** and configure the **Filters** relevant to the process(es) you want to match:

- **Process name**: Enter a string to match the basename of the scoped process.
- **Process argument**: Enter an expression to match the scoped process's full command line including options and arguments.
- **Hostname**: Enter a string to match the hostname of the machine where the scoped process is running.
- **Username**: Enter a string to match the username for the scoped process's UID.
- **Environment**: To match when an environment variable is set, enter its name alone (for example, `FOO`). To match when the variable is set with a particular value, enter both (for example, `FOO=bar`).
- **Ancestor**: Enter a string to match the basename of the scoped process's parent, parent's parent, and so on.

Then, in the **Config** column, select **Edit**. This takes you through the settings, beginning with **General Settings**, but this time you'll be specifying what in the previously-defined settings to override when a process matches your **Filters**.

Protocol Detection Examples for Payloads

Here are some example definitions for detecting protocols in payloads.

Redis

This regex detects the plain-text Redis serialization protocol (RESP).

Name: `Redis`

Regex: `"^[*]\\d+|^[+]\\w+|^[$]\\d+"`

Mongo

This regex detects the MongoDB wire protocol. Since it's binary, we convert to hex.

Name: `Mongo`

Regex: `^2401000000000000000000000d407`

Convert to hex: `Yes`

Convert length: `14`

HTTP

By default, AppScope uses an internally-defined protocol detector for HTTP similar to this example.

Name: `HTTP`

Regex: `"HTTP\\/1\\.[0-2]|PRI \\* HTTP\\/2\\.0\r\n\r\nSM\r\n\r\n"`

StatsD

By default, AppScope uses an internally-defined protocol detector for StatsD similar to this example.

Name: `STATSD`

Regex: `"^([^:]+):([\\d.]+)\\|(c|g|ms|s|h)"`

TLS

By default, AppScope uses an internally-defined protocol detector for TLS/SSL similar to this example.

Name: `TLS`

Regex: `"^(?:(?:16030[0-3].{4})|(?:8[0-9a-fA-F]{3}01))"`

Convert to hex: `Yes`

Convert length: `5`

17. Reference

17.1. API Docs

To complement our API Reference, below are some examples of using the Cribl Stream API to address common scenarios. If you want to automate an action in Cribl Stream for which you can't find documentation, ask us in Cribl Community's `#docs` channel.

Breaking Change – v.4.0+

In Cribl Stream 4.0 and later, `PATCH` requests to all APIs – except for `samples` and `system` endpoints – require the resource to already exist. (In previous versions, a `PATCH` request would create a resource that didn't exist.) To accommodate this change, make a `POST` request to create an item before any `PATCH` request to update it.

Use the Correct API URL

Every Cribl API URL includes a server URL and an endpoint path, which vary depending on the type of deployment.

The server URL follows these patterns:

- Cribl.Cloud deployment:
  `https://<workspaceID>.<organizationID>.cribl.cloud/<endpoint_path>`
- Cribl.Cloud example – default Workspace, "foo-bar-h45h" OrganizationID:
  `https://main.foo-bar-h45h.cribl.cloud/<endpoint_path>`
- On-prem deployment:
  `https://<cribl-stream-leader>:9000/<endpoint_path>`

The endpoint path always begins with `/api/v1/`, but the remainder varies. For example, the `/system/outputs` endpoint follows these patterns:

- Single-instance deployment: `/api/v1/system/outputs/{id}`
- Distributed deployment: `/api/v1/m/{workerGroup}/system/outputs/{id}`
- For licenses limited to a single Worker Group, the `{workerGroup}` value will always be `default`

When composing requests to the Cribl API, use the pattern that matches your deployment type. Adapt examples from this page in the same way.

In Cribl.Cloud and other distributed deployments, you must **Commit** and **Deploy** your changes after following the steps in the examples. With the API, you can automate commit/deploy commands, too.

Obtain API Bearer Tokens

Other than calls to `/auth/login` and `/health`, all API requests require a Bearer or access token. You obtain the token in different ways, depending on where your Cribl Stream instance is deployed, as outlined in this section. You can make the listed requests at the command line, programmatically, or using the UI.

On-Prem

To obtain a Bearer token, send a local authentication request and payload to the API as shown below. Adapt the example to include your Leader hostname (or IP address), username, and password.

If you're using SSO/OpenID Connect Authentication, you must toggle **Allow local auth** on, because you'll need to be a Local user when you authenticate via the API.

Request:

```
POST https://<cribl-stream-leader>:9000/api/v1/auth/login
```

Payload:

```
{
    "username": "<username>",
    "password": "<password>"
}
```

Example request using `curl`:

```
curl -X POST https://<cribl-stream-leader>:9000/api/v1/auth/login -H "Content-Type: a
```

You'll get a JSON object as the response, for example:

```
{
    "token": "<JWT_Token>",
    "forcePasswordChange": false
}
```

Use this Bearer token in all subsequent requests. Include it in the Authorization header, like this:

```
Bearer <JWT_token>
```

Cribl.Cloud

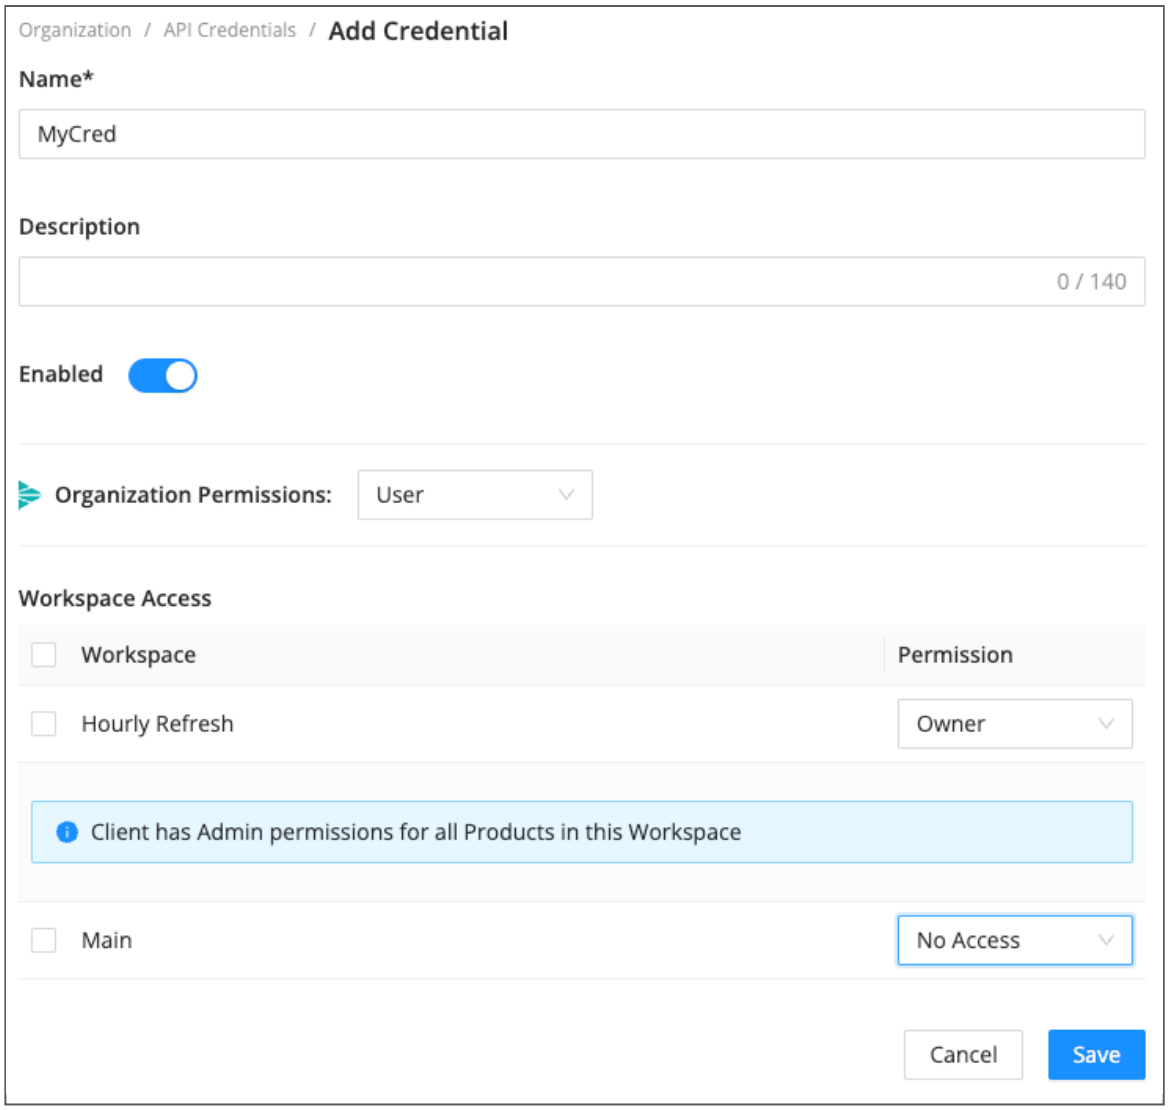
Cribl.Cloud Owners and Admins can generate API access tokens directly in their Organization's portal. This is a two-tier process:

- Generate a Credential to expose a Client ID/Client Secret pair.
- Use the Credential's Client ID and Client Secret to obtain an access token, valid for 24 hours, that can be used to run API calls against Cribl APIs.

Create an API Credential

Owners and Admins can create Credentials:

1. Make sure you are logged in as either an Owner or an Admin.
2. On the top bar, select **Products**, and then select **Cribl**.
3. In the sidebar, expand **Organization**, and then select **API Credentials**.
4. Select **Add Credential** (or **Add an API credential**, if this is the first Credential in the system).
5. Specify a **Name** and an optional **Description** of the Credential's purpose.
6. Under **Organization Permissions**, select the permission that the Credential's tokens will grant.
   The **Organization Permissions** selector is available on certain plan/license tiers. Without a proper license, all tokens will be granted the Admin Role. See Cribl.Cloud Roles for details on the available permissions.
7. If you chose the **User** permission, under **Workspace Access**, define access to specific Workspaces.
   An **Admin** Organization permission automatically grants admin access to all Workspaces.
8. If you selected the **Member** permission for any Workspace, additionally select product-level permissions for that Workspace. (The User permission is not available for API Credentials.)
   An **Admin** Workspace permission automatically grants admin access to all products.
9. Confirm with **Save**.



Creating a Cribl.Cloud API Credential

Use an API Credential

The new API Credential will appear on the **API Credentials** page within a few seconds. Each Credential exposes a **Client ID and Secret**, details of Workspace access and other information. After Credentials are created, Owners and Admins can use them to generate tokens, and then pass these tokens to Cribl APIs.

Getting an API Credential's Client ID and Secret

Obtain Tokens

Obtain a 24-hour access token using a displayed Credential's Client ID and Client Secret. Example curl request, with placeholders:

```
curl --request POST \
--url "https://login.cribl.cloud/oauth/token" \
--header "content-type: application/json" \
--data '{"grant_type":"client_credentials", "client_id": "<client_id>", "client_secr
```

Make API Calls

Using the token returned by the preceding example, you can make requests to Cribl APIs. Example curl request, with placeholder token value:

Single-instance Distributed

```
curl --location 'https://main-<organizationID>.cribl.cloud/api/v1/m/{workerGroup}
--header 'Authorization: Bearer <token-generated-above>'
```

Refresh Tokens

Admins are responsible for ensuring that their applications obtain a new token within each token's 24-hour expiration window. This can be done at any time before expiration.

Manage API Credentials

A Cribl.Cloud Organization's Owners and Admins can view, edit, and disable existing Credentials. Only Owners can delete Credentials.

Update Basic Configurations

You can use the API to programmatically update the configuration of any object type that the API supports (such as Sources and Destinations).

Example: Periodically rotate S3 keys on a preconfigured S3/MinIO destination.

1. Send a `GET` request to the `/outputs` endpoint to retrieve the definition for a Destination (in this case, `MinIO`). The response provides the definition in its payload, as a JSON object.

Example request:

Single-instance Distributed

```
curl -X GET "<url>/api/v1/m/{workerGroup}/system/inputs/<output id>" -H "accept:
```

Example response:

```
{
  "systemFields": [
    "cribl_pipe"
  ],
  "signatureVersion": "v4",
  "objectACL": "private",
  "partitionExpr": "`${host}/${sourcetype}`",
  "format": "json",
  "baseFileName": "CriblOut",
  "compress": "none",
  "maxFileSizeMB": 32,
  "maxFileOpenTimeSec": 300,
  "maxFileIdleTimeSec": 30,
  "maxOpenFiles": 100,
  "onBackpressure": "block",
  "id": "minio",
  "type": "minio",
  "endpoint": "http://minio:9090",
  "bucket": "test",
  "destPath": "keyprefix",
  "stagePath": "tmp",
  "awsApiKey": "minioadmin",
  "awsSecretKey": "minioadmin"
}
```

2. Edit the definition so that when you send it back in a `PATCH` request, it updates the desired Destination's S3 keys.
    - Edit the value of the `id` field to be the ID of the specific Destination whose keys you want to rotate, for example, `minio_042`.
    - Edit the values of the S3 key fields, for example, `"awsApiKey": "minioadmin_new_api_key"` and `"awsSecretKey": "minioadmin_new_secret_key"`.

3. Send the edited definition as the payload of a `PATCH` request to the `/outputs/{id}` endpoint. This patches (that is, updates) the specified MinIO Destination's configuration.

Upload a Lookup File

This section demonstrates how to upload a Lookup file via the API. The following examples assume that we're uploading the file to a Worker Group named `default`.

1. Send a `PUT` request to the `/system/lookups` endpoint to upload the file. Example:

Single-instance Distributed

```
curl -X PUT "<url>/api/v1/m/{workerGroup}/system/lookups?filename=example.csv" \
-H "Authorization: Bearer <token>" -H 'Content-Type: text/csv' \
--data-binary '@/path/to/your/example.csv'
```

You will receive a JSON object response similar to the following example:

```
{"filename":"example.csv.random.tmp","rows":100,"size":200}
```

2. Send a `POST` request referencing the Lookup file to the `/system/lookups` endpoint. Replace the file name with the response from the previous `PUT` request. This both creates the Lookup and moves the Lookup file to its final destination. Example:

Single-instance Distributed

```
curl -X POST "<url>/api/v1/m/{workerGroup}/system/lookups" \
-H "accept: application/json" -H "Authorization: Bearer <token>" \
-H "Content-Type: application/json" \
-d '{"id":"example.csv","fileInfo":{"filename":"example.csv.random.tmp"}}'
```

Example response:

```
{
  "items": [
    {
      "id": "example.csv",
      "size": 200
    }
  ],
  "count": 1
}
```

3. If replacing an existing lookup, send a `PATCH` request referencing the existing file name in the URL and the body. Example:

Single-instance | Distributed

```
curl -X PATCH "<url>/api/v1/m/{workerGroup}/system/lookups/example.csv" \
-H "accept: application/json" -H "Authorization: Bearer <token>" \
-H "Content-Type: application/json" \
-d '{"id":"example.csv","fileInfo":{"filename":"example.csv.random.tmp"}}'
```

Example response:

```
{
  "items": [
    {
      "id": "example.csv",
      "size": 200
    }
  ],
  "count": 1
}
```

Distributed Upload

In a distributed environment, for lookup files of manageable size: Cribl recommends uploading the Lookup file only to the Leader Node, and then making a selective commit and deploy with only those Lookup file changes. The Leader then notifies Worker Nodes that a new configuration is available, and Worker Nodes will pull the new configuration from the Leader Node.

Create HEC Tokens with Python

Cribl SE Jon Rust has written a Python script which demonstrates how to authenticate to the Cribl API, make a simple POST request, and add a new HEC token.

To use the script, you'll need:

- Python 3.
- The Python 3 Requests module (use brew or pip3 to install).
- A working, distributed Cribl Stream installation, with a configured Splunk HEC Source.
- An admin username and password.

The script and instructions for usage can be found in Jon Rust's GitHub repo.

Manage Packs via APIs

You can perform Pack operations by running Cribl API calls on the command line. This is required if you plan to automate Pack operations – for example, in a CI/CD pipeline. For more details, see Managing Packs via API .

17.2. HTTP Response Codes

The following table contains all HTTP response codes that Cribl Stream API can return.

Code	Meaning
200	OK
204	No Content
400	Bad Request
401	Unauthorized
403	Forbidden
404	Not Found
405	Method Not Allowed
415	Unsupported Media Type
500	Internal Server Error
502	Bad Gateway
503	Service Unavailable

17.3. Cribl Expression Syntax

As data travels through a Cribl Stream Pipeline, it is operated on by a series of Functions. Functions are fundamentally JavaScript code.

Functions that ship with Cribl Stream are configurable via a set of inputs. Some of these configuration options are literals, such as field names, and others can be JavaScript expressions.

Expressions are **valid units** of code that resolve to a value. Every syntactically valid expression resolves to some value, but conceptually, there are two types of expressions: those that **assign** value to a variable (a.k.a., with side effects), and those that **evaluate** to a value.

Assigning a value	Evaluating to a value

`x = 42`
`newFoo = foo.slice(30)`
	`(Math.random() * 42)`
	`3 + 4`
	`'foobar'`
	`'42'`

Filters and Value Expressions

Let's consider evaluation expressions before assignment expressions.

Filters

Filters are used in Routes to select a stream of the data flow, and in Functions to scope or narrow down the applicability of a Function. Filters are expressions that **must** evaluate to either `true` (or truthy) or `false` (or falsy). Keep this in mind when creating Routes or Functions. For example:

- `sourcetype=='access_combined' && host.startsWith('web')`
- `source.endsWith('.log') || sourcetype=='aws:cloudwatchlogs:vpcflow'`

This table shows examples of truthy and falsy values.

Truthy	Falsy

`true`
`42`
`-42`
`3.14`
`"foo"`
	`false`
	`null`
	`undefined`
	`0`
	`NaN`

Truthy	Falsy
`Infinity` `-Infinity`	`''` `""`

Value Expressions

Value expressions are typically used in Functions to assign a value – for example, to a new field. For example:

- `Math.floor(_time/3600)`
- `source.replace(/.{3}/, 'XXX')`

Best Practices for Creating Predictable Expressions

- In a value expression, ensure that the source variable is not `null`, `undefined`, or `empty`. For example, assume you want to have a field called `len`, to be assigned the length of a second field called `employeeID`. But you're not sure if `employeeID` exists. Instead of `employeeID.length`, you can use a safer shorthand, such as: `(employeeID || '').length`.
- If a field does not exist (undefined), and you're doing a comparison with its properties, then the boolean expression will **always** evaluate to false. For example, if `employeeID` is undefined, then both of these expressions will evaluate to false: `employeeID.length > 10` , and `employeeID.length < 10` .
- `==` means "equal to," while `===` means "equal value **and** equal type." For example, `5 == 5` and `5 == "5"` each evaluate to **true**, while `5 === "5"` evaluates to **false**.
- A ternary operator is a very powerful way to create conditional values. For example, if you wanted to assign either `minor` or `adult` to a field `groupAge`, based on the value of `age`, you could do: `(age >= 18) ? 'adult' : 'minor'`.

Fields with Non-Alphanumeric Characters

If there are fields whose names include non-alphanumeric characters – e.g., `@timestamp` or `user-agent` or `kubernetes.namespace_name` – you can access them using `__e['<field-name-here>']`. (Note the single quotes.) More details here.

In any other place where the field is referenced – e.g., in the Eval function's field names – you should use a single-quoted literal, of the form: `'<field-name-here>'`.

Wildcard Lists

Wildcard Lists are used throughout the product, especially in various Functions, such as Eval, Mask, Publish Metrics, Parser, etc.

Wildcard Lists, as their name implies, accept strings with asterisks (`*`) to represent one or more terms. They also accept strings that start with an exclamation mark (`!`) to **negate** one or more terms. This allows for implementing any combination of allowlists and blocklists.

Wildcard Lists are order-sensitive, evaluated from left to right. This is especially relevant when you use negated terms. For negations to take precedence over wildcards when evaluated, you must list negations before wildcards.

Some examples:

Wildcard List	Value	Meaning
List 1	`!foobar, foo*`	All terms that start with **foo**, except **foobar**.
List 2	`!foo*, *`	All terms, except for those that start with **foo**.
List 3	`*, !foo`	All terms (wildcard matches first, negation isn't evaluated).

You cannot use wildcards to target Cribl Stream internal fields that start with `__` (double underscore). You must specify these fields individually. For example, `__foobartab` cannot be removed by specifying `__foo*`.

17.4. Cribl Expressions

Native Cribl Stream methods can be found under `C.*`, and can be invoked from any Function that allows for expression evaluations. For example, to create a field that is the SHA1 of a another field's value, you can use the Eval Function with this **Evaluate Fields** pair:

Name	Value Expression
myNewField	`C.Mask.sha1(myOtherField)`

Where fields' names contain special characters, you can reference them using the `__e['<field-name-here>']` convention. For details, see Fields with Non-Alphanumeric Characters.

Cribl expressions offer methods and properties in the following classes:

- C.Crypto - data encryption and decryption
- C.Encode and C.Decode - encoding and decoding data
- C.Lookup - running lookups
- C.Mask - masking sensitive data
- C.Net - network methods
- C.Text - text manipulation
- C.Time - time and date manipulation
- C.Schema - schema validation
- C.Secret - secret management
- C.env - environment properties
- C.os - system methods
- C.vars - global variables
- C.version - Cribl Stream versions
- C.Misc - various other methods

17.4.1. C.Crypto – Data Encryption And Decryption

C.Crypto.decrypt()

```
Crypto.decrypt(value: string, escape: boolean = false, escapeSeq = '"'): string
```

Decrypts all occurrences of ciphers in the given value. Instances that cannot be decrypted (for any reason) are left intact.

Returns `value` with ciphers decrypted.

Parameter	Type	Description
`value`	string	String in which to look for ciphers.
`escape`	boolean	Set to `true` to escape double quotes in output after decryption (for example, for data encrypted in Splunk.) Defaults to `false`.
`escapeSeq`	string	String used to escape double quotes. The default `'"'` escapes CSV output.

Examples

To decrypt the contents of the `encrypted` field, use:

```
C.Crypto.decrypt(encrypted)
```

C.Crypto.encrypt()

```
Crypto.encrypt(value: Buffer | string, keyclass: number, keyId?: string, defaultVal?
```

Encrypts the given value with the `keyId`, or with a `keyId` picked up automatically based on `keyclass`.

Returns the encrypted value. If encryption does not succeed, returns `defaultVal` if specified; otherwise, `value`.

Parameter	Type	Description
`value`	string | Buffer	The value to encrypt.
`keyclass`	number	Key Class to pick a key from, if `keyId` isn't specified.
`keyId`	string	Encryption `keyId`, takes precedence over `keyclass`.
`defaultVal`	string	Value to return if encryption fails; if unspecified, the original value is returned.

Examples

To encrypt the `customer` field using key with `keyId` 2, use:

```
C.Crypto.encrypt(customer, -1, 2)
```

To encrypt the same field with a key selected from the Key Class 3, without specifying a `keyId`:

```
C.Crypto.encrypt(customer, 3)
```

C.Crypto.createHmac()

```
Crypto.createHmac(value: string | Buffer, secret: string, algorithm: string = 'sha25
```

Generates an HMAC that can be added to events, or can be used to validate events that contain an HMAC.

Returns the calculated HMAC digest on success; otherwise, `value`.

Parameter	Type	Description
`value`	string | Buffer	The data to encrypt. When the `outputFormat` is invalid or undefined, this parameter is returned as the digest, via a Buffer.
`secret`	string	The secret key used to generate the MAC.
`algorithm`	string	The hash algorithm used to generate the MAC. Defaults to `'sha256'`. Run `openssl list -digest-algorithms` to see the list of available algorithms.

Parameter	Type	Description
`outputFormat`	`'base64' | 'hex' | 'latin1'`	Output format for the MAC. Defaults to `'hex'`.

Examples

To generate HMAC from the `customer` field, provide the secret as the second argument:

```
C.Crypto.createHmac(customer, 'kETvYtLKZkgIzBvfRdVcZULBITANjOMd')
```

To additionally specify that you want to use the SHA512 hash algorithm and to output the HMAC in `latin1` format, run:

```
C.Crypto.createHmac(customer, 'kETvYtLKZkgIzBvfRdVcZULBITANjOMd', 'sha512', 'latin1'
```

17.4.2. C.Decode And C.Encode - Encoding And Decoding

C.Decode – Data Decoding Methods

C.Decode.base64()

```
Decode.base64(val: string, resultEnc: string = 'utf8'): string | Buffer | undefined
```

Performs base64 decoding of the given string.

Returns a string or Buffer, depending on the `resultEnc` value.

Parameter	Type	Description
`val`	string	Value to decode.
`resultEnc`	`'utf8' | 'utf8-valid' | 'buffer'`	Encoding to use to convert the binary data to a string. Use `'utf8-valid'` to validate that result is valid UTF8; use `'buffer'` if you need the binary data in a Buffer. Defaults to `'utf8'`.

Examples

To decode an `encoded` field and return the decoded value as a Buffer, use:

```
C.Decode.base64(encoded, 'buffer')
```

C.Decode.gzip()

```
Decode.gzip(value: Buffer | string, encoding?: BufferEncoding) : string
```

Gunzips the supplied value.

Parameter	Type	Description
`value`	any	Value to gunzip.

Parameter	Type	Description
`encoding`	string	Encoding of `value`, for example: `'base64'`, `'hex'`, `'utf-8'`, `'binary'`. Default is `'base64'`. If data is received as Buffer (from gzip with encoding: `'none'`), decoding is skipped.

Examples

To decode a `hostname` field which had been encoded using `hex`, run:

```
C.Decode.gzip(hostname, 'hex')
```

C.Decode.hex()

```
Decode.hex(val: string): number
```

Performs hex to number conversion. Returns `NaN` if value cannot be converted to a number.

Parameter	Type	Description
`val`	string	Hex string to parse to a number (for example, `0xcafe`).

C.Decode.uri()

```
Decode.uri(val: string): string
```

Performs URI-decoding of the given string.

Parameter	Type	Description
`val`	string	Value to decode.

C.Decode.inflate()

```
Decode.inflate(value: Buffer | string, encoding: BufferEncoding = 'base64', isRaw =
```

Inflates the supplied value.

Parameter	Type	Description
`value`	string | Buffer	The value to inflate. May be a Buffer or a string.
`encoding`	string	If a string `value` is provided, this specifies how it has been encoded. If no `encoding` is provided, `base64` is used. This parameter is ignored if `value` is already a Buffer.
`isRaw`	boolean	Indicates whether the data is in raw deflate format (without zlib headers). Default value is `false`.

Examples

To base64-decode and inflate the value contained in a `_raw` field, you can use:

```
C.Decode.inflate(_raw)
```

To additionally specify a different encoding to use, run:

```
C.Decode.inflate(_raw, 'hex')
```

C.Encode – Data Encoding Methods

`C.Encode.base64()`

```
Encode.base64(val: string | Buffer, trimTrailEq: boolean = false, encoding?: BufferEn
```

Returns a base64 representation of the given string or Buffer.

Parameter	Type	Description
`val`	any	Value to encode.
`trimTrailEq`	boolean	Whether to trim any trailing `=`.
`encoding`	string	Optional parameter that specifies the encoding of the value. Options include `base64`, `hex`, `utf-8`, and `binary`. The default is `utf-8`.

Examples

To base64-encode the `username` field, and remove the trailing `=`, use:

```
C.Encode.base64(username, true)
```

To base64-encode the `hexValue` field, where the value of the field is a hex string:

```
C.Encode.base64('4672616e6b7575757575', undefined, 'hex')
```

C.Encode.gzip()

```
Encode.gzip(value: Buffer | string, encoding?: string) : string | Buffer
```

Gzips, and optionally base64-encodes, the supplied value.

Parameter	Type	Description
`value`	string	Value to gzip.
`encoding`	string	Encoding of `value`, for example: `'base64'`, `'hex'`, `'utf-8'`, `'binary'`, `'none'`. Default is `'base64'`. If `'none'` is specified, data will be returned as a Buffer.

Examples

To encode the `hostname` field, for example using `hex` encoding, run:

```
C.Encode.gzip(hostname, 'hex')
```

C.Encode.hex()

```
Encode.hex(val: string | number): string
```

Rounds the number to an integer and returns its hex representation (lowercase). If a string is provided, it will be parsed into a number or `NaN`.

Parameter	Type	Description
`val`	string | number	Value to convert to hex.

C.Encode.uri()

```
Encode.uri(val: string): string
```

Returns the URI-encoded representation of the given string.

Parameter	Type	Description
`val`	string	Value to encode.

C.Encode.deflate()

```
Encode.deflate(value: Buffer | string, encoding: BufferEncoding | 'none' = 'base64',
```

Deflates and optionally base64-encodes the supplied value.

Parameter	Type	Description
`value`	string | Buffer	Value to deflate.
`encoding`	string	Encoding to apply to the deflated result, for example: `base64`, `hex`, `utf-8`, `binary`, `none`. Default is `base64`. If `none` is specified, data will be returned as a Buffer.
`toRaw`	boolean	Indicates whether to return the raw deflated data, without zlib headers. Default is `false`, which will prepend normal zlib header bytes to the returned value.

Examples

To deflate and hex-decode the value provided in an `inflated` field, run:

```
C.Encode.deflate(inflated, 'hex')
```

17.4.3. C.Lookup – Inline Lookup Methods

C.Lookup – Exact Lookup

```
Lookup: (file: string, primaryKey?: string, otherFields: string[]=[],ignoreCase: boo
```

Returns an instance of a lookup to use inline.

Examples

In this example, `host` is the name of the primary key field:

```
C.Lookup('lookup_name.csv', 'IP_field_name_in_lookup_file').match(host)
```

Here, the quoted `'event_field_or_string_to_match'` could be a string to match in the primary key field:

```
C.Lookup('name_of_lookup_file.csv', 'field_in_csv_to_match').match('event_field_or_s
```

This example checks whether `someValue` is present or not and returns the answer as a boolean.

```
C.Lookup('file', 'primaryKeyCol', additionalCols).match('someValue')
```

This expression returns a string – the `fieldToReturn` column from the matched lookup row:

```
C.Lookup('file', 'primaryKeyCol', additionalCols).match('someValue','fieldToReturn')
```

This expression returns an array – the specified `fieldToReturn1` and `fieldToReturn2` columns from the matched lookup row:

```
C.Lookup('file', 'primaryKeyCol').match('someValue', ['fieldToReturn1', 'fieldToRetu
```

To return an array with all columns from the matched lookup row, you can use:

```
C.Lookup('file', 'primaryKeyCol').match('someValue', [])
```

`C.Lookup` can load lookup files of up to 10 MB.

All inputs to Lookup methods' `match()` method must be strings. If your lookup file contains numeric fields, convert them to strings, e.g.: `.match(String(<fieldname>))`.

You can use the optional `otherFields[]` argument, shown in the above `C.Lookup()` signatures and examples, to limit which columns of the lookup table will be available in a subsequent `.match()` call. If omitted, or set to `undefined`, all columns will be available.

Cribl Stream 4.1 and later support returning all columns from a matched row. Use the empty-array convention shown in the above examples: `.match('someValue',[])`.

C.LookupCIDR – CIDR Lookup

```
LookupCIDR: (file: string, primaryKey?: string, otherFields: string[]=[]) => InlineL
```

Returns an instance of a CIDR lookup to use inline.

C.LookupIgnoreCase – Case-insensitive Lookup

```
LookupIgnoreCase: (file: string, primaryKey?: string, otherFields: string[]=[]) => I
```

Returns an instance of a lookup (ignoring case) to use inline. Works identically to `C.Lookup`, except ignores the case of lookup values. (Equivalent to calling `C.Lookup` with its fourth `ignoreCase?` parameter set to `true`).

C.LookupRegex – Regex Lookup

```
LookupRegex: (file: string, primaryKey?: string, otherFields: string[]=[]) => Inline
```

Returns an instance of a Regex lookup to use inline.

C.Lookup.match()

```
InlineLookup.match(value: string): boolean

InlineLookup.match(value: string, fieldToReturn?: string): any
InlineLookup.match(value: string, fieldToReturn: string[]): {[key: string]: any}
```

Parameter	Type	Description
`value`	string	the value to look up.
`fieldToReturn`	string | string []	name of the lookup file > field to return.

Examples

To find the last row where the value from column `foo` matches the string `abc`, you can use the following expression. If a matching row is found, the expression returns the row's value for column `bar`.

```
C.Lookup('lookup-exact.csv', 'foo').match('abc', 'bar')
```

To find the last row where the value from column `transport` matches the string `tcp`, you can use the following expression. If a matching row is found, the expression returns the row's value for column `port_number`.

```
C.Lookup('service_names_port_numbers.csv', 'transport').match('tcp', 'port_number')
```

You can find the last row where the CIDR range in `cidr` includes `192.168.1.1` with the following expression. If a matching row is found, the expression returns the row's value for column `bar`.

```
C.LookupCIDR('lookup-cidr.csv', 'cidr').match('192.168.1.1', 'bar')
```

The following expression finds the last row where the value from column `cidr` matches `hostIP`. If a matching row is found, it returns the row's value for column `location`.

```
C.LookupCIDR('lookup-cidr.csv', 'cidr').match(hostIP, 'location')
```

To find the last row where the regex in column `foo` matches the string `manchester`, use the following expression. If a matching row is found, the expression returns the row's value for column `bar`.

```
C.LookupRegex('lookup-regex.csv', 'foo').match('manchester', 'bar')
```

With `C.LookupRegex`, ensure that your lookup file contains no empty lines – not even at the bottom. Any empty rows will cause `C.LookupRegex().match()` to always return `true`.

17.4.4. C.Mask – Data Masking Methods

C.Mask.CC()

```
Mask.CC(value: string, unmasked: number = -4, maskChar: string='X'): string
```

Checks whether a value could be a valid credit card number, and masks a subset of the value. By default, all digits except the last 4 will be replaced with `X`.

Parameter	Type	Description
`value`	string	The string to mask, **if and only if** it could be a valid credit card number.
`unmasked`	number	Number of digits to leave unmasked: positive for left, negative for right, `0` for none.
`maskChar`	string	String to replace each digit with.

Examples

Let's assume your parsed data contains a `creditCard` field. You can mask this number by using a Mask Function. Apply it to the `cardNumber` field and create the following masking rule:

Match Regex	Replace Expression	Example result
`(.*)` (catches the whole field contents)	`${C.Mask.CC(g1)}`	`cardNumber: XXXXXXXXXX4860`

To control how the masking is performed, you can specify how many digit should be unmasked and what masking character to use:

Match Regex	Replace Expression	Example result
`(.*)` (catches the whole field contents)	`${C.Mask.CC(g1, 4, "Z")}`	`cardNumber: 6011ZZZZZZZZZZZZ`

C.Mask.crc32()

```
Mask.crc32(value: string): string
```

Generates a CRC32 hash of given value.

Parameter	Type	Description
`value`	string	The string to hash.

C.Mask.IMEI()

```
Mask.IMEI(value: string, unmasked: number = -4, maskChar: string='X'): string
```

Checks whether a value could be a valid IMEI number, and masks a subset of the value. By default, all digits except the last 4 will be replaced with `X`.

Parameter	Type	Description
`value`	string	The string to mask, **if and only if** it could be a valid IMEI number.
`unmasked`	number	Number of digits to leave unmasked: positive for left, negative for right, `0` for none.
`maskChar`	string	String to replace each digit with.

Examples

Let's assume your parsed data contains an `imei` field. You can mask this number by using a Mask Function. Apply it to the `imei` field and create the following masking rule:

Match Regex	Replace Expression	Example result
`(.*)` (catches the whole field contents)	`${C.Mask.IMEI(g1)}`	`imei: XXXXXXXXXXX7011`

To control how the masking is performed, you can specify how many digit should be unmasked and what masking character to use:

Match Regex	Replace Expression	Example result
`(.*)` (catches the whole field contents)	`${C.Mask.CC(g1, 4, "M")}`	`cardNumber: 5356MMMMMMMMMM`

C.Mask.isCC()

```
Mask.isCC(value: string): boolean
```

Checks whether the given value could be a valid credit card number, by computing the string's Luhn's checksum modulo 10 == `0`.

Parameter	Type	Description
`value`	string	String to check for being a valid credit card number.

Examples

The following example expression uses `isCC()` to check whether the `cardNumber` field actually contains a credit card number. If it does, the card number is replaced with the `REDACTED` string, otherwise, en empty string is returned.

```
C.Mask.isCC(cardNumber) ? C.Mask.REDACTED : ""
```

C.Mask.isIMEI()

```
Mask.isIMEI(value: string): boolean
```

Checks whether the given value could be a valid IMEI number, by computing the string's Luhn's checksum modulo 10 == `0`.

Parameter	Type	Description
`value`	string	String to check for being a valid IMEI number.

Examples

The following example expression uses `isCC()` to check whether the `imei` field actually contains ab IMEI number number. If it does, the IMEI number is replaced with the `REDACTED` string, otherwise, en empty string is returned.

```
C.Mask.isIMEI(imei) ? C.Mask.REDACTED : ""
```

C.Mask.luhn()

```
Mask.luhn(value: string, unmasked: number = -4, maskChar: string='X'): string
```

Checks that value Luhn's checksum mod 10 is `0`, and masks a subset of the value. By default, all digits except the last 4 will be replaced with `X`. If the value's Luhn's checksum mod 10 is not `0`, then the value is returned unmodified.

Parameter	Type	Description
`value`	string	The string to mask, **if and only if** the value's Luhn's checksum mod 10 is `0`.
`unmasked`	number	Number of digits to leave unmasked: positive for left, negative for right, `0` for none.
`maskChar`	string	String to replace each digit with.

C.Mask.luhnChecksum()

```
Mask.luhnChecksum(value: string, mod: number=10): number
```

Generates the Luhn checksum (used to validate certain credit card numbers, IMEIs, etc.). By default, the mod 10 of the checksum is returned. Pass mod = `0` to get the actual checksum.

Parameter	Type	Description
`value`	string	String whose digits you want to perform the Luhn checksum on.
`mod`	number	Return checksum modulo this number. If `0`, skip modulo. Default is `10`.

C.Mask.md5()

```
Mask.md5(value: string, len?: string | number, encoding?: BufferEncoding): string
```

Generates an MD5 hash of a given value.

`C.Mask.md5()` doesn't work when Cribl Stream is running in FIPS mode.

Parameter	Type	Description
`value`	string	The string to hash.
`len`	string | number	Length of hash to return: 0 for full hash, a +number for left or a -number for right substring. If a string is passed it's length will be used.
`encoding`	string	Optional parameter that specifies the encoding of the value. Options include `base64`, `hex`, `utf-8`, and `binary`. The default is `utf-8`.

Examples

To hash the contents of a `username` field with the MD5 algorithm, run:

```
C.Mask.md5(username)
```

To hash the contents of an `authToken` field, where the value of the field is a base64-encoded string, with the MD5 algorithm, run:

```
C.Mask.md5(authToken, undefined, 'base64')
```

C.Mask.random

```
Mask.random(len?: string | number): string
```

Generates a random alphanumeric string.

Parameter	Type	Description
`len`	string | number	Length of the result; or, if a string, use its length.

Examples

Assuming you have some identifying user information in a `username` field, you can replace it with a random string of the same length with:

```
C.Mask.random(username)
```

Input	Output
`McGoatFace`	`xY2KLHkyTg`

`C.Mask.repeat()`

```
Mask.repeat(len?: number | string, char: string = 'X'): string
```

Generates a repeating char/string pattern, e.g., `XXXX`.

Parameter	Type	Description
`len`	string | number	Length of the result; or, if a string, use its length.
`char`	string	Pattern to repeat `len` times.

Examples

The following example will repeat the `GOAT` string as many time as there are characters in the first parameter, `goat`, so four times:

```
C.Mask.repeat("goat", "GOAT")
```

`C.Mask.sha1()`, `C.Mask.sha256()`, `C.Mask.sha512()`

```
Mask.sha1(value: string, len?: string | number, encoding?: BufferEncoding): string
Mask.sha256(value: string, len?: string | number, encoding?: BufferEncoding): string
Mask.sha512(value: string, len?: string | number, encoding?: BufferEncoding): string
```

Generates an SHA1, SHA256, or SHA512 hash of given value.

Parameter	Type	Description
`value`	string	The string to hash.
`len`	string | number	Length of hash to return: `0` for full hash, a +number for left, or a -number for right substring. If a string is passed, its length will be used.
`encoding`	string	Optional parameter that specifies the encoding of the value. Options include `base64`, `hex`, `utf-8`, and `binary`. The default is `utf-8`.

Examples

To hash the contents of a `secret` field with the SHA256 algorithm, run:

```
C.Mask.sha256(secret)
```

To hash the contents of an `authToken` field, where the value of the field is a base64-encoded string, with the SHA256 algorithm, run:

```
C.Mask.sha256(authToken, undefined, 'base64')
```

C.Mask.REDACTED

```
Mask.REDACTED: string
```

The literal `'REDACTED'`.

17.4.5. C.Net – Network Methods

C.Net.cidrMatch()

```
Net.cidrMatch(cidrIpRange: string, ipAddress: string): boolean
```

Determines whether the supplied IPv4 or IPv6 `ipAddress` is inside the range of addresses identified by `cidrIpRange`.

Parameter	Type	Description
`cidrIpRange`	string	IP address range in CIDR format. E.g., `10.0.0.0/24`.
`ipAddress`	string	The IP address to test for inclusion in `cidrIpRange`.

Examples

(IPv4): `C.Net.cidrMatch('10.0.0.0/24', '10.0.0.100')` returns `true`.

(IPv6): `C.Net.cidrMatch('2001:db8::/32', '2001:db8:0:0:0:ffff:0:0')` returns `true`.

C.Net.communityIDv1()

```
Net.communityIDv1(sourceIP: string, destIP: string, sourcePort: number | undefined, 
```

Calculates the Community ID for a given network flow. A Community ID is a unique identifier that is reversible – it is the same for both sides of a connection. It is calculated based on source and destination IP addresses, ports, a protocol, and (optionally) a seed (explained below). When the protocol is ICMP, the Community ID will be reversible provided that the network flow uses types with a clear request/response relationship (for example, Echo and Echo Reply).

Usage

This method returns a Base64-encoded string.

Provide IP addresses – whether IPv4 or IPv6 – as strings.

When the protocol is ICMP (v4 or v6), `sourcePort` corresponds to message type and `destPort` corresponds to message code. For other Layer 3 protocols, `sourcePort` and `destPort` should be `undefined`.

You can specify `proto` either as a number (recommended, to avoid ambiguity) or a string.

- If a string, `proto` must be the desired protocol's keyword as specified in the IANA protocol registry.
- For network flows coming from the Cribl Stream NetFlow Source, use the protocol name as-is – the Source will provide it in correct form.

The optional `seed` parameter defaults to `0`. If you want to generate different Community IDs for different use cases within the same flow, change `seed` to a different value for each use case.

Parameter	Type	Description
sourceIP	string	Source IPv4 or IPv6 address
destIP	string	Destination IPv4 or IPv6 address
sourcePort	number or undefined	Source port. For ICMP, use the ICMP type. For other portless protocols, use `undefined`.
destPort	number or undefined	Destination port. For ICMP, use the ICMP code. For other portless protocols, use `undefined`.
proto	number or string	IP protocol number, such as `6`, `17`, or `1`. May also be the protocol name, such as `'tcp'`, `'udp'`, or `'icmp'`.
seed	number	Optional seed value; defaults to `0`

Examples

Bidirectional TCP flow using the protocol number.

```
// Protocol number 6 is TCP

C.Net.communityIDv1('1.2.3.4','5.6.7.8',1122,3344,6)
// '1:wCb3OG7yAFWelaUydu0D+125CLM='

C.Net.communityIDv1('5.6.7.8','1.2.3.4',3344,1122,6)
// '1:wCb3OG7yAFWelaUydu0D+125CLM='
```

Bidirectional UDP flow using the protocol name.

```
C.Net.communityIDv1('1.2.3.4','5.6.7.8',1122,3344,'udp')
// '1:0Mu9InQx6z4ZiCZM/7HXi2WMhOg='

C.Net.communityIDv1('5.6.7.8','1.2.3.4',3344,1122,'udp')
// '1:0Mu9InQx6z4ZiCZM/7HXi2WMhOg='
```

ICMP Echo/Echo Reply flow.

```
// Protocol number 1 is ICMP
// Echo is Type=8, Code=0
// Echo Reply is Type=0, Code=0

// Echo (equivalent of request)
C.Net.communityIDv1('1.2.3.4','5.6.7.8',8,0,1)
// '1:crodRHL2FEsHjbv3UkRrfbs4bZ0='

// Echo Reply (equivalent of response)
C.Net.communityIDv1('5.6.7.8','1.2.3.4',0,0,1)
// '1:crodRHL2FEsHjbv3UkRrfbs4bZ0='
```

C.Net.isIp()

```
Net.isIp(value: string): boolean
```

Determines whether the value supplied is an IP address (either IPv4 or IPv6).

Parameter	Type	Description
value	string	The IP address to test.

C.Net.isIpV4()

```
Net.isIpV4(value: string): boolean
```

Determines whether the value supplied is an IPv4 address.

Parameter	Type	Description
`value`	string	The IP address to test.

C.Net.isIpV6()

```
Net.isIpV6(value: string): boolean
```

Determines whether the value supplied is an IPv6 address.

Parameter	Type	Description
`value`	string	The IP address to test.

C.Net.isIPV4Cidr()

```
Net.isIPV4Cidr(value: string): boolean
```

Determines whether a value supplied is an IPv4 CIDR range.

Returns `true` if the value is a valid IPv4 CIDR range; otherwise, `false`.

Parameter	Type	Description
`value`	string	String value that may be an IPv4 CIDR range.

C.Net.isIPV6Cidr()

```
Net.isIPV6Cidr(value: string): boolean
```

Determine whether a value supplied is an IPv6 CIDR range.

Returns `true` if the value is a valid IPv6 CIDR range; otherwise, `false`.

Parameter	Type	Description
`value`	string	String value that may be an IPv6 CIDR range.

Parameter	Type	Description

C.Net.isIpV4AllInterfaces()

```
Net.isIpV4AllInterfaces(value): boolean
```

Determines whether the value supplied is the IPv4 all-interfaces address, typically used to bind to all IPv4 interfaces – i.e., '0.0.0.0'.

Parameter	Type	Description
`value`	any	The IP address to test.

C.Net.isIpV6AllInterfaces()

```
Net.isIpV6AllInterfaces(value): boolean
```

Determines whether the value supplied is an IPv6 all-interfaces address, typically used to bind to all IPv6 interfaces – one of: '::', '0:0:0:0:0:0:0:0', or '0000:0000:0000:0000:0000:0000:0000:0000'.

Parameter	Type	Description
`value`	any	the IP address to test.

C.Net.ipv6Normalize()

```
Net.ipv6Normalize(address: string): string
```

Normalizes an IPV6 address based on RFC draft-ietf-6man-text-addr-representation-04.

Parameter	Type	Description
`address`	string	The IPV6 address to normalize.

C.Net.isPrivate()

```
Net.isPrivate(address: string): boolean
```

Determines whether the supplied IPv4 address is in the range of private addresses per RFC1918.

Parameter	Type	Description
`address`	string	The IP address to test.

C.Net.parseAddressOrRangeString()

```
Net.parseAddressOrRangeString(source: string, mask?: string | number)
```

Parses a string representation of an IP or IP range.

Returns an `IPv4` or `IPv6` object. When the `source` argument is an IP range, this method returns the first IP in the range.

Parameter	Type	Description
`source`	string	The string to parse.
`mask`	string | number	Optional parameter containing the CIDR mask. Used only when `source` is a valid IP string.

C.Net.IPv4_CIDR_REGEX

```
Net.IPv4_CIDR_REGEX: RegExp
```

The regular expressions for matching IP CIDR.

17.4.6. C.Text – Text Methods

C.Text.entropy()

```
Text.entropy(bytes: Buffer | string): number
```

Computes the Shannon entropy of the given Buffer or string.

Returns the entropy value; or `-1` in case of an error.

Parameter	Type	Description
`bytes`	Buffer | string	value to undergo Shannon entropy computation.

C.Text.hashCode()

```
Text.hashCode(val: string | Buffer | number): number
```

Computes hashcode (djb2) of the given value.

Returns hashcode value.

Parameter	Type	Description
`val`	string | Buffer | number	value to be hashed.

C.Text.isASCII()

```
Text.isASCII(bytes: Buffer | string): boolean
```

Checks whether all bytes or chars are in the ASCII printable range.

Returns `true` if all chars/bytes are within ASCII printable range; otherwise, `false`.

Parameter	Type	Description
`bytes`	string | Buffer	value to check for character range.

C.Text.isUTF8()

```
Text.isUTF8(bytes: Buffer | string): boolean
```

Checks whether the given Buffer contains valid UTF8.

Returns `true` if bytes are UTF8; otherwise, `false`.

Parameter	Type	Description
`bytes`	Buffer | string	bytes to check.

C.Text.parseWinEvent()

```
Text.parseWinEvent(xml: string, nonValues: string[] = Text._WIN_EVENT_NON_VALUES): a
```

Parses an XML string representing a Windows event into a compact, prettified JSON object. Works like `C.Text.parseXml`, but with Windows events, produces more-compact output. For a usage example, see Reducing Windows XML Events.

Returns an object representing the parsed Windows Event; or `undefined` if the input could not be parsed.

Parameter	Type	Description
`xml`	string	an XML string; or an event field containing the XML.
`nonValues`	string[]	array of string values. Elements whose value equals any of the values in this array will be omitted from the returned object. Defaults to `['-']`, meaning that elements whose value equals `-` will be discarded.

C.Text.parseXml()

```
Text.parseXml(xml: string, keepAttr: boolean = true, keepMetadata: boolean = false, 
```

Parses an XML string and returns a JSON object. Can be used with Eval Function to parse XML fields contained in an event, or with ad hoc XML.

Returns an object representing the parsed XML; or `undefined` if the input could not be parsed. An input collection of elements will be parsed into an array of objects.

Parameter	Type	Description
`xml`	string	XML string, or an event field containing the XML.
`keepAttr`	boolean	whether or not to include attributes in the returned object. Defaults to `true`.
`keepMetadata`	boolean	whether or not to include metadata found in the XML. The `keepAttr` parameter must be set to `true` for this to work. Defaults to `false`. (Eligible metadata includes namespace definitions and prefixes, and XML declaration attributes such as encoding, version, etc.)
`nonValues`	string[]	array of string values. Elements whose value equals any of the values in this array will be omitted from the returned object. Defaults to `[]` (empty array), meaning discard no elements.

C.Text.relativeEntropy()

```
Text.relativeEntropy(bytes: Buffer | string, modelName: string = 'top_domains'): numl
```

Computes the relative entropy of the given Buffer or string.

Returns the relative entropy value, or `-1` in case of an error.

Parameter	Type	Description
`bytes`	Buffer | string	Value whose relative entropy to compute.
`modelName`	string	Optionally, override the default `$CRIBL_HOME/data/lookups/model_relative_entropy_top_domains.csv` model used to test the input. Create a custom lookup file with the same column and value structure as the default, and store it in the same path, as `model_relative_entropy_<custom-name>.csv`. To reference it, pass your `<custom-name>` substring as the `modelName` parameter.

When using `modelName` in a distributed deployment, the corresponding paths are `$CRIBL_HOME/groups/<worker-group-name>/data/lookups/`. Creating your custom lookup file via Cribl Stream's UI will automatically set the appropriate paths.

17.4.7. C.Time – Time Methods

C.Time.adjustTZ()

```
Time.adjustTZ(epochTime: number, tzTo: string, tzFrom: string = 'utc'): number | und
```

Adjusts a timestamp from one timezone to another.

Returns the adjusted timestamp, in UNIX epoch time (ms).

Parameter	Type	Description
`epochTime`	number	Timestamp to adjust, in UNIX epoch time.
`tzTo`	string	Timezone to adjust to (full name).
`tzFrom` (optional)	string	Timezone of the timestamp.

Cribl relies on this list of TZ Database Time Zones.

Note that these are timezone identifiers (full names), not abbreviations such as “CET”, “PST”, “EST”, and so on.

Examples

To adjust a timestamp found in the `_time` field to a selected timezone (here, Australia/Melbourne), use:

```
C.Time.adjustTZ(_time, "Australia/Melbourne")
```

The method returns the timestamp in milliseconds. If you want to further operate on it using methods such as `strftime()`, which takes as parameter UNIX epoch time in seconds, you can divide it by 1000:

```
C.Time.strftime(C.Time.adjustTZ(_time, "Australia/Melbourne") / 1000, "%d %B %Y %H %I
```

C.Time.clamp()

```
Time.clamp(date: T, earliest: T, latest: T, defaultDate?: T ): T  | undefined
```

Constrains a parsed timestamp to realistic earliest and latest boundaries.

Returns a JavaScript Date object or timestamp, depending on the format of the `date` parameter.

Parameter	Type	Description
`date`	Date | number	Timestamp to constrain, in UNIX epoch time (ms) or JavaScript Date format.
`earliest`	Date | number	Earliest allowable timestamp, in UNIX epoch time (ms) or JavaScript Date format.
`latest`	Date | number	Latest allowable timestamp, in UNIX epoch time (ms) or JavaScript Date format.
`defaultDate` (optional)	Date | number	Default date, in UNIX epoch time (ms) or JavaScript Date format. This date is used for values that fall outside the `earliest` or `latest` boundaries.

Examples

Suppose you have a date in a `"YYYY-MM-DD"` format in a `time` field. To make sure this date does not exceed the range of 1 Jan 2020 – 1 Jan 2025, you can use:

```
C.Time.clamp(time, "2020-01-01", "2025-01-01")
```

Input	Output
`"2016-02-11"`	`"2020-01-01"` (set to the earliest value)
`"2026-01-01"`	`"2025-01-01"` (set to the latest value)
`"2023-12-24"`	`"2023-12-24"` (unchanged, because it fits inside the defined range)

To make sure that all dates that fall outside the bounds are changed to a specific value, add the third parameter:

```
C.Time.clamp(time, "2020-01-01", "2025-01-01", "2022-02-22")
```

Input	Output
`"2016-02-11"`	`"2022-02-22"` (set to the default value)
`"2026-01-01"`	`"2022-02-22"` (set to the default value)
`"2023-12-24"`	`"2023-12-24"` (unchanged, because it fits inside the defined range)

C.Time.strftime()

```
Time.strftime(date: number | Date | string, format: string, utc: boolean = true): st
```

Formats a Date object or timestamp number as a time string, using d3js time format.

Returns representation of the given date in the specified format.

Parameter	Type	Description
`date`	number | Date | string	Date to format, in UNIX epoch time (in seconds) or JavaScript Date format.
`format`	string	New format for the date.
`utc` (optional)	boolean	Whether to output the time in UTC (`true`), rather than in local timezone.

Examples

To transform a `_time` field containing a UNIX timestamp to a string with time formatted, for example: `15 November 2023, 08:03`, you can use:

```
C.Time.strftime(_time, "%d %B %Y, %H:%M")
```

Some common formats (assuming UNIX timestamp of 1702460134) are:

Format	Output
`"%Y-%m-%d"` (ISO date)	`"2023-12-13"`
`"%d %B %Y %H:%M:%S"`	`"13 December 2023 09:35:34"`

Format	Output
`"%x %X"` (the locale's date and time format)	`"12/13/2023 9:35:34 AM"`

For detailed reference of the date and time tokens, see d3js reference or Auto Timestamp.

C.Time.strptime()

```
Time.strptime(str: string, format: string, utc: boolean = true, strict: boolean = fa
```

Extracts time from a string using d3js time format that defines the format of the incoming string.

Returns a parsed JavaScript Date object, or `null` if the specified `format` did not match.

Parameter	Type	Description
`str`	string	Timestamp to parse.
`format`	string	Format to parse.
`utc` (optional)	boolean	Whether to interpret times as UTC (`true`), rather than as local time.
`strict` (optional)	boolean	Whether to return `null` if there are any extra characters after timestamp.

Examples

To convert a string in the `"YYYY-MM-DD"` format, for example `"2023-12-12"`, to a Date object, use:

```
C.Time.strptime(F, "%Y %m %d")
```

Additionally, to interpret the time in UTC, and make sure null is returned if the timestamp contains any trailing characters, use:

```
C.Time.strptime(F, "%Y %m %d", true, true)
```

For detailed reference of the date and time tokens, see d3js reference or Auto Timestamp.

C.Time.timestampFinder()

```
Time.timestampFinder(utc?: boolean).find(str: string): IAutoTimeParser
```

Extracts time from the specified field, using the same algorithm as the Auto Timestamp Function and the Event Breaker Function.

Returns representation of the extracted time; truncates timestamps to three-digit (milliseconds) resolution, omitting trailing zeros.

Parameter	Type	Description
`utc`	boolean	Whether to output the time in UTC (`true`), rather than in local timezone.
`str`	string	The field in which to search for the time.

Examples

To find timestamps in the `_raw` field and output them in UTC, you can use:

```
C.Time.timestampFinder(true).find(_raw)
```

You can then format the string output with `strftime()`:

```
C.Time.strftime(C.Time.timestampFinder(true).find(_raw), "%d.%m.%Y, %H.%M")
```

C.Time.timePartition()

```
Time.timePartition(date: number | Date | string, level: 'd' | 'h'): string | undefin
```

Provides the part of the file path prefix that contains the date.

Returns a string in the format `YYYY/MM/DD` for `d` and `YYYY/MM/DD/HH` for `h`.

Parameter	Type	Description
`date`	number | Date | string	Datetime to extract the file path prefix for.
`level`	string	Granularity of the partitioning, `d` for daily, and `h` for hourly.

Examples

To get the file path prefix from the `_time` field:

```
C.Time.timePartition(_time)
```

This will return the prefix in the form of, for example: `2024/04/23`.

C.Time.s3TimePartition()

```
Time.s3TimePartition(date: number | Date | string, level: 'd' | 'h'): string | undef
```

Provides the full S3 file path prefix for a given datetime.

Returns the file path prefix as a string.

Parameter	Type	Description
`date`	number | Date | string	Datetime to extract the file path prefix for.
`level`	string	Granularity of the partitioning, `d` for daily, and `h` for hourly.

Examples

To get the S3 file path prefix from the `_time` field:

```
C.Time.s3TimePartition(_time)
```

This will return the prefix in the form of, for example: `hjhg-2024/aj-04/ai-23`.

17.4.8. Miscellaneous Expression Methods

C.Schema – Schema Methods

C.Schema

```
Schema: (id: string) => SchemaValidator
```

C.Schema.validate()

```
SchemaValidator.validate(data: any): boolean
```

Validates the given object against the schema.

Returns `true` when schema is valid; otherwise, `false`.

Parameter	Type	Description
`data`	any	Object to be validated.

Examples

To validate whether a `myField` conforms to `schema1`, you can use:

```
C.Schema('schema1').validate(myField)
```

See Schema Library for more details.

C.Secret – Secrets-Management Methods

C.Secret()

```
Secret: (id: string, type?: string): ISecret
Secret(id: string, type: 'keypair') => IPairSecret
Secret(id: string, type: 'text') => ITextSecret
Secret(id: string, type: 'credentials') => ICredentialsSecret
```

Returns a secret matching the specified ID.

Parameter	Type	Description
`id`	string	ID of the secret.
`type` (optional)	'text' | 'keypair' | 'credentials'	Type of the secret.

Examples

To return a text secret with ID `victorias` (or with undefined, if no such secret exists), use:

```
C.Secret('victorias', 'text')
```

You can also get attributes of secrets with the following expressions:

```
C.Secret('api_key', 'keypair').secretKey
C.Secret('secret_hash', 'text').value
C.Secret('user_pass', 'credentials').password
```

Common returned attributes for `ISecret` objects:

- `secretType` – one of `keypair`, `text`, or `credentials`.
- `description` (optional) – the secret description.
- `tags` (optional) – a comma separated list of tags.

Additional returned attributes for `IPairSecret` objects:

- `apiKey` – the API key value
- `secretKey` – the Secret key value

Additional returned attributes for `ITextSecret` objects:

- `value` – the text value

Additional returned attributes for `ICredentialsSecret` objects:

- `username` – the username value
- `password` – the password value

See Securing Cribl Stream > Secrets for more details.

C.env – Environment

`C.env`

```
env: {[key: string]: string;}
```

Returns an object containing Cribl Stream's environment variables. All internal variables, that is, those starting with `CRIBL_`, are accessible in this method.

Examples

To return the parent of Cribl's `bin` directory (generally `/opt/cribl`), use:

```
C.env.CRIBL_HOME
```

To return the hostname of the machine where Cribl Stream is running, use:

```
C.env.HOSTNAME
```

C.os – System Methods

`C.os.hostname()`

Returns hostname of the system running this Cribl Stream instance.

C.vars – Global Variables

See Global Variables Library for more details.

C.version – Cribl Stream Versions

C.version

Returns the Cribl Stream version currently running.

C.confVersion

Returns the commit hash of the Worker Node's current config version. (Evaluates only against live data sent through Worker Nodes. Values will be undefined in the Leader's Preview pane.)

C.Misc – Miscellaneous Utility Methods

C.Misc.zip()

```
Misc.zip(keys: string[], values: any[], dest?: any): any
```

Sets the given keys to the corresponding values on the given `dest` object. If `dest` is not provided, a new object will be constructed.

Returns object on which the fields were set.

Parameter	Type	Description
`keys`	string[]	Field names corresponding to keys.
`values`	any[]	Values corresponding to values.
`dest`	any	Object on which to set field values.

Examples

Let's take the following expression:

```
people = C.Misc.zip(titles, names)
```

If sample data contains: `titles=['ceo', 'svp', 'vp']`, `names=['foo', 'bar', 'baz']`, this expression create an object called `people`, with key names from elements in `titles`, and with corresponding values from elements in `names`.

Result: `"people": {"ceo": "foo", "svp": "bar", "vp": "baz"}`

C.Misc.uuidv4()

```
C.Misc.uuidv4(): string
```

Returns a version 4 (random) UUID in accordance with RFC-4122.

Examples

To create a UUIDv4, use:

```
C.Misc.uuidv4()
```

Result: a conforming UUIDv4, such as `58d8be36-4db0-4b1c-ac80-28bb03c45e0d`. It is highly improbable that two version 4 UUIDs will ever have the same value.

C.Misc.uuidv5()

```
C.Misc.uuidv5(name: string, namespace: string): string
```

Returns a version 5 (namespaced) UUID in accordance with RFC-4122 for the given `name` and `namespace`. If `namespace` is not a valid UUID, this function will fail.

Parameter	Type	Description
`name`	string	Any arbitrary name to use in UUID generation.
`namespace`	string	One of `DNS`, `URL`, `OID`, or `X500` to use a predefined namespace, or else a valid UUID.

Examples

To create a UUIDv5 with the predefined DNS namespace, use:

```
C.Misc.uuidv5('example', 'DNS')
```

Result: a UUID that is highly likely to be the same for the same name and namespace. In this case, the result would be `7cb48787-6d91-5b9f-bc60-f30298ea5736`.

C.Misc.validateUUID()

```
C.Misc.validateUUID(maybeUUID: string): boolean
```

Returns `true` if `maybeUUID` is a valid UUID of any version, and false otherwise.

Parameter	Type	Description
`maybeUUID`	string	A string to test for a valid UUID.

Examples

```
C.Misc.validateUUID(C.Misc.uuidv4())
```

Result: returns `true`

```
C.Misc.validateUUID('clearly not a UUID')
```

Result: returns `false`

C.Misc.getUUIDVersion()

```
C.Misc.getUUIDVersion(uuid: string): number
```

Returns a `number` of the UUID version given by `uuid` if it is a valid UUID, otherwise `undefined`.

Parameter	Type	Description
`uuid`	string	A UUID for which to determine the version.

Examples

```
C.Misc.getUUIDVersion(C.Misc.uuidv4())
```

Result: `4`

```
C.Misc.getUUIDVersion(C.Misc.uuidv5('example', 'X500'))
```

Result: `5`

17.5. CLI Reference

Command line interface basics

In addition to starting and stopping the Cribl Stream server, the Cribl Stream command line interface enables you to initiate many configuration and administrative tasks directly from your terminal.

Command Syntax

To execute CLI commands, the basic syntax is:

```
cd $CRIBL_HOME/bin
./cribl <command> <sub-command> <options> <arguments>
```

Not all commands have sub-commands.

To see help for any command, append the `--help` option, for example:

```
./cribl vars --help

./cribl vars get --help

./cribl vars get -i myArray --help
```

The `scope` command is an exception: it has no `--help` option, but it has its own CLI Reference in the AppScope documentation.

Avoiding Surprises

Immediate Execution

As indicated in the sample output below, some commands take effect immediately.

Commands that require further input will echo the sub-commands, options, and arguments they expect.

Persistent Volumes

If you start Cribl Stream with the `CRIBL_VOLUME_DIR` variable, all subsequent CLI commands should have this variable defined. Otherwise, those commands will apply the Cribl Stream default directories, yielding misleading results.

You can set `CRIBL_VOLUME_DIR` as an environment variable, or you can explicitly include it in each command, as in this example:

```
CRIBL_VOLUME_DIR=<writable-path-name> /opt/cribl/bin/cribl status
```

When set, `$CRIBL_VOLUME_DIR` overrides `$CRIBL_HOME`.

Avoid setting `$CRIBL_VOLUME_DIR` to an existing folder because it creates predefined folders in the specified directory. If that directory already contains folders with those names, they will be overwritten.

Commands Available

To see a list of available commands, enter `./cribl` alone (or the equivalent `./cribl help`). To execute a command, or to see its required parameters, enter `./cribl <command>`.

`help`

Displays a list of commands with a description (help) for each. Defaults to a selection of generally useful commands.

Usage

```
./cribl help [-a]
```

Options

```
  -a              - Display the list of all commands, except for `scope`.
```

Sample Response

```
Software version: 4.4.2
Usage: [sub-command] [options] [args]

Commands:
help               - Display help
mode-edge          - Configure instance in Edge mode
mode-managed-edge  - Configure instance in Managed-Edge mode
mode-master        - Configure instance in Leader mode
mode-single        - Configure instance in Single-Instance mode
mode-worker        - Configure instance in Worker mode
reload             - Reload instance
restart            - Restart instance
start              - Start instance
status             - Display status
stop               - Stop instance
version            - Print version

auth               - Authentication
boot-start         - Enable/Disable boot-start
diag               - Manage diagnostics bundles
encrypt            - Encrypt with cribl secret
git                - Manage Worker Groups config
keys               - Manage encryption keys
nc                 - Listen on a port for traffic and output stats and data
node               - Execute a JavaScript file
pack               - Manage Cribl Packs
parquet            - Manage Parquet files and schemas
pipe               - Feed stdin to a pipeline
vars               - Manage global variables
```

Starting in version 3.0, former “master” application components have been renamed “Leader.” As long as some legacy terminology remains within CLI commands/options, configuration keys/values, and environment variables, this document will reflect the options available.

limits

Controls the availablity of Cribl features.

Usage

```
./cribl limits <options> <args>
```

Options

```
  [-s <scripts>] - Enable custom scripts API
```

mode-master

Configures instance as a Leader.

Usage

```
./cribl mode-master <options> <args>
```

Options

```
  [-d <deploymentId>]     - Deployment ID for reporting telemetry on multiple deploymer
  [-H <host>]             - Hostname/IP (defaults to 0.0.0.0).
  [-p <port>]             - Port (defaults to 4200).
  [-n <certName>]         - Name of the saved certificate to use. Mutually exclusive wi
  [-k <privKeyPath>]      - Path on server to the private key to use. PEM format. Can i
  [-c <certPath>]         - Path on server to the certificate to use. PEM format. Can i
  [-u <authToken>]        - Authentication token to include as part of the connection h
  [-S <tls>]              - Sets, or disables, secure communication between Leader and
  [-i <ipWhitelistRegex>] - Regex matching IP addresses that are allowed to establish a
  [-r <resiliency>]       - Resiliency mode for the Leader. Accepts: ["none", "failover
  [-v <failoverVolume>]   - For resiliency=failover, the volume to use as shared storag
```

mode-single

Configures instance as a Single-instance deployment.

Usage

```
./cribl mode-single [--help]
```

Options

```
  [-d <deploymentId>] - Deployment ID for reporting telemetry on multiple deployments
```

mode-edge

Configures Cribl Edge as a Single-instance deployment.

Usage

```
./cribl mode-edge [--help]
```

Options

```
  [-d <deploymentId>] - Deployment ID for reporting telemetry on multiple deployments
  [-H <host>]         - Hostname/IP (defaults to 127.0.0.1).
  [-p <port>]         - Port (defaults to 9420).
  [-s <socket>]       - Location of the AppScope socket.
```

mode-worker

Configures Cribl Stream as a Worker instance.

Running this command resets all the related options. This means that even if you want to change only one option, you also need to provide values for all the other arguments.

Usage

```
./cribl mode-worker -H <host> -p <port> <options> <args>
```

The `-H <host> -p <port>` parameters are required.

Options

```
[-d <deploymentId>] - Deployment ID for reporting telemetry on multiple deployments
 -H <host>          - Leader's hostname or IP address.
 -p <port>          - Leader's cluster communications port (e.g.: 4200).
[-n <certName>]     - Name of the saved certificate to use. Mutually exclusive with
[-k <privKeyPath>]  - Path on server to the private key to use. PEM format. Can refe
[-c <certPath>]     - Path on server to the certificate to use. PEM format. Can refe
[-u <authToken>]    - Authentication token to include as part of the connection head
[-S <tls>]          - Sets, or disables, secure communication between Leader and Worl
[-e <envRegex>]     - Regex to select environment variables to report to Leader. E.g
[-t <tags>]         - Tag values to report to Leader.
[-g <group>]        - Worker Group to report to Leader.
```

When you generate bootstrap scripts via the UI to add or update Workers, these scripts automatically set the `-S` option according to the Leader TLS configuration.

mode-managed-edge

Configures Cribl Edge as an Edge Node.

Running this command resets all the related options. This means that even if you want to change only one option, you also need to provide values for all the other arguments.

Usage

```
./cribl mode-managed-edge -H <host> -p <port> <options> <args> && ./cribl restart
```

The `-H <host> -p <port>` parameters are required.

Options

```
[-d <deploymentId>] - Deployment ID for reporting telemetry on multiple deployments
 -H <host>          - Leader's hostname or IP address.
 -p <port>          - Leader's cluster communications port (e.g.: 4200).
[-n <certName>]     - Name of the saved certificate to use. Mutually exclusive with
[-k <privKeyPath>]  - Path on server to the private key to use. PEM format. Can refe
[-c <certPath>]     - Path on server to the certificate to use. PEM format. Can refe
[-u <authToken>]    - Authentication token to include as part of the connection head
[-S <tls>]          - Sets, or disables, secure communication between Leader and Worl
[-e <envRegex>]     - Regex to select environment variables to report to Leader. E.g
[-t <tags>]         - Tag values to report to Leader.
[-g <group>]        - Fleet to report to Leader.
```

When you generate bootstrap scripts via the UI to add or update Workers, these scripts automatically set the `-S` option according to the Leader TLS configuration.

pack

Manages Cribl Packs.

Usage

```
./cribl pack <sub-command> <options> <args>
```

Sub-commands and Options

```
export            - Export Cribl Packs, args:
   -m <mode>      - Mode to export. Accepts: merge_safe, merge, default_only.
  [-o <filename>] - Where to export the Pack on disk.
  [-n <name>]     - Name to override the installed Pack's name on export.
  [-g <group>]    - The Worker Group/Fleet to execute within.
install           - Install a Cribl Pack, args:
  [-d]            - Run install in debug.
  [-f]            - Force install.
  [-c]            - Disallow installation of Packs with custom functions.
  [-n <name>]     - Name of the Pack to install, defaults to source.
  [-g <group>]    - The Worker Group/Fleet to execute within
list              - List Cribl Packs, args:
  [-v]            - Display all Pack info
  [-g <group>]    - The Worker Group/Fleet to execute within
uninstall         - Uninstall a Cribl Pack, args:
  [-d]            - Run uninstall in debug
  [-g <group>]    - The Worker Group/Fleet to execute within
upgrade           - Upgrade a Cribl Pack, args:
  [-d]            - Run upgrade in debug
  [-s <source>]   - Provide the Pack source
  [-m <minor>]    - Only upgrade to minor version
  [-g <group>]    - The Worker Group/Fleet to execute within
```

Sample Response

```
id          version  spec  displayName    author       description
-------------------------------------------------------------------------------
HelloPacks  1.0.0    ----  Hello, Packs!  Cribl, Inc.  A sample pack with a simple e
```

`parquet`

For any Parquet file: view (`cat`) the file, its metadata (`details`), or its `schema`. This command is available only on Linux.

Usage

```
./cribl parquet <sub-command> -f <file>
```

Sub-commands and Options

```
cat             - Cat parquet events to console, args:
   -f <file>    - Path to parquet file
  [-m <max>]    - Maximum events to print
details         - Print all parquet details (schema and statistics), args:
   -f <file>    - Path to parquet file
schema          - Print parquet schema, args:
   -f <file>    - Path to parquet file
```

Examples

View a Parquet file:

```
./cribl parquet cat -f /some_parquet_file
```

```
{"__bytes":274,"Unnamed: 0":0,"name":"apples","quantity":10,"price":2.6,"date":"2018·
...
```

View a Parquet file's metadata, including encoding and compression:

```
./cribl parquet details -f /some_parquet_file
```

```
{
  "schema": {
    "Unnamed: 0": {
      "optional": true,
      "type": "INT64"
    },
    ...
  },
  "path": "../../../src/sluice/js/util/__tests__/data/parquet/single/small_fruits.pa
  "num_rows": 40000,
  "num_cols": 11,
  "num_real_cols": 11,
  "num_row_groups": 1,
  "created_by": "parquet-cpp-arrow version 11.0.0",
  "schema_root_name": "schema",
  "metadata": {
    "pandas": "{\"index_columns\": [{\"kind\": \"range\", \"name\": null, \"start\":
    ...
  },
  "version": "PARQUET_2_6",
  "metadataSize": 6072,
  ...
    }
  ]
}
```

View a Parquet file's schema (not including encoding or compression), expressed as JSON like in the Parquet Schema editor:

```
./cribl parquet schema -f /some_parquet_file
```

```
{
  "Unnamed: 0": {
    "optional": true,
    "type": "INT64"
  },
  "name": {
    "optional": true,
    "type": "STRING"
  },
  "quantity": {
    "optional": true,
    "type": "DOUBLE"
  },
  "price": {
    "optional": true,
    "type": "DOUBLE"
...
  }
}
```

reload

Reloads Cribl Stream. Executes immediately.

Usage

```
./cribl reload [--help]
```

Sample Response

```
Reload request submitted to Cribl
```

restart

Restarts Cribl Stream. Executes immediately.

Executing this command cancels any running collection jobs.

Usage

```
./cribl restart [--help]
```

Sample Response

```
Stopping Cribl, process 17
..............
Cribl is not running
Starting...
....
Cribl started
```

`start`

Starts Cribl Stream. Executes immediately. Upon first run, echoes the Cribl Stream default login credentials.

Usage

```
./cribl start <options> <args>
```

Options

```
[-d <dir>]  - Configuration directory
[-r <role>] - Process role
```

Sample Response

```
Starting...
...
Cribl started
```

`status`

Displays status of Cribl Stream, including the API Server address, instance's mode (Leader or Worker), process ID, and GUID (fictitious example below). Executes immediately.

Usage

```
./cribl status [--help]
```

Sample Response

```
Address: http://172.17.0.3:9000
Mode: master
Status: Up
Software Version: 3.1.0-f765e418
Config Version: 347079c
Master: 0.0.0.0:4200
PID: 4100
GUID: e706052a-ace9-4511-a7c7-b58a414a07d3
```

`stop`

Stops Cribl Stream. Executes immediately.

Executing this command cancels any running collection jobs.

Usage

```
./cribl stop [--help]
```

Sample Response

```
Stopping Cribl, process 3951
.............
Cribl is not running
```

version

Displays Cribl Stream version. Executes immediately.

Usage

```
./cribl version [--help]
```

Sample Response

```
Software Version: 4.7.3-6f48361f
```

auth

Log into or out of Cribl Stream.

Usage

```
./cribl auth <sub-command> <options> <args>
```

Sub-commands and Options

```
login             - Log in, args:
  [-H <host>]     - Host URL (e.g. http://localhost:9000)
  [-u <username>] - Username
  [-p <password>] - Password
  [-f <file>]     - File with credentials
logout            - Log out
```

Arguments of the `login` subcommand correspond to the following environment variables:

Argument	Variable
<username>	CRIBL_USERNAME
<password>	CRIBL_PASSWORD
<host>	CRIBL_HOST

Login Examples

Launch interactive login:

```
$CRIBL_HOME/bin/cribl auth login
```

Append credentials as command arguments:

```
$CRIBL_HOME/bin/cribl auth login -h <url> -u <username> -p <password>
```

All `-h` and `host` arguments are optional, provided that the `cribl.yml` file's `api:` section lists the API host and port.

Provide credentials in environment variables:

```
CRIBL_HOST=<url> CRIBL_USERNAME=<username> CRIBL_PASSWORD=<password>
$CRIBL_HOME/bin/cribl auth login
```

Provide credentials in a file:

```
$CRIBL_HOME/bin/cribl auth login -f <path/to/file>
```

Corresponding file contents:

```
host=<url>
username=<username>
password=<password>
```

boot-start

Enables or disables Cribl Stream boot-start.

Usage

```
./cribl boot-start <sub-command> <options> <args>
```

Sub-commands and Options

```
  disable             - Disable boot-start, args:
    [-m <manager>]    - Init manager (systemd|initd)
    [-c <configDir>]  - Config directory for the init manager
  enable              - Enable boot-start, args:
    [-m <manager>]    - Init manager (systemd|initd)
    [-u <user>]       - User to run the instance as
    [-c <configDir>]  - Config directory for the init manager
```

Sample Response

```
  Enabling Cribl to be managed by initd...
  boot-start enable command needs root privileges...
  Enabled Cribl to be managed by initd as user=root.
```

`cloud-workspace`

Updates an on-premises Cribl Stream Leader with a new config in the `instance.yml` file called `cloudWorkspace`. With this config, the local Cribl Stream Leader will connect to the Cribl.Cloud Leader and send it usage metrics.

Usage

```
./cribl cloud-workspace -H <host> -p <port> # etc: flags
```

Options

```
[-d <deploymentId>]     - Deployment ID used to report telemetry on multiple deploym
[-H <host>]             - Hostname/IP (defaults to 0.0.0.0).
[-p <port>]             - Port (defaults to 4200).
[-n <certName>]         - Name of the saved certificate to use. Mutually exclusive w
[-k <privKeyPath>]      - Path on server to the private key to use. PEM format. Can
[-c <certPath>]         - Path on server to the certificate to use. PEM format. Can
[-u <authToken>]        - Authentication token to include as part of the connection
[-S <tls>]              - Sets, or disables, secure communication between Leader and
[-i <ipWhitelistRegex>] - Regex matching IP addresses that are allowed to establish
[-r <resiliency>]       - Resiliency mode on the Leader. Accepts: ["none", "failover
[-v <failoverVolume>]   - For resiliency=failover, the volume to use as shared storag
```

decrypt

Decrypts data with a secret key. See the related encrypt command.

Usage

```
decrypt -v <encrypted value> -s <path to secret key>
```

Sub-commands and Options

```
 -v <value>             - Value to decrypt.
[-s <criblSecretPath>] - cribl.secret decrypt key path. If you do not specify a crib
```

diag

Manages diagnostic bundles.

Usage

```
./cribl diag <sub-command> <options> <args>
```

Sub-commands and Options

```
create                  - Creates diagnostic bundle for this instance, args:
  [-d]                  - Run create in debug mode
  [-j]                  - Do not append '.txt' to js files
  [-t <maxIncludeJobs>] - Latest number of jobs to include in bundle
  [-M]                  - Exclude metrics from bundle
  [-g]                  - Exclude git from bundle
  [-i]                  - Include install logs
list                    - List existing diagnostic bundles
send                    - Send diagnostics bundle to Cribl Support, args:
   -c <caseNumber>      - Cribl Support Case Number
  [-p <path>]           - Diagnostic bundle path (if empty then new bundle will be c
heapsnapshot            - Generate heap snapshot of a Cribl process, args:
   -p <pid>             - The pid of the process to dump the heap snapshot
```

diag create

```
Created a Cribl diagnostic bundle at /opt/cribl/diag/<product>-zedborcdb72f-20210820
```

diag heapsnapshot -p 12345

The response format is `Heap-<epoch-timestamp>-<pid>.heapsnapshot`:

```
Heap-1672574400000-12345.heapsnapshot
```

encrypt

Encrypts data with a secret key. See the related decrypt command.

Usage

```
encrypt -v my_token -s <path to secret key>
```

Sub-commands and Options

```
 -v <value>             - Value to encrypt.
[-s <criblSecretPath>] - cribl.secret encrypt key path. If you do not specify a crib
```

Sample Response

```
LzmJ3uqA6WXtXjaLPwuM++WX84o3fPxBaubA6Q0look=
```

git

Manages Worker Group/Fleets'/Fleets' configuration.

Usage

```
./cribl git <sub-command> <options> <args>
```

Sub-commands and Options

```
commit           - Commit, args:
  [-g <group>]   - Group ID.
  [-m <message>] - Commit message.
commit-deploy    - Commit and Deploy, args:
   -g <group>    - Group ID.
  [-m <message>] - Commit message.
deploy           - Deploy, args:
   -g <group>    - Group ID.
  [-v <version>] - Deploy version.
list-groups      - List Worker Groups/Fleets.
```

Sample Response

```
Successfully committed version 7c04de1
```

groups

Deprecated. See git.

keys

Manages encryption keys. You must append the `-g <group>` argument to specify a Worker Group/Fleet. As a fallback, append the argument `-g default`, for example: `./cribl keys list -g default`

Usage

```
./cribl keys <sub-command> <options> <args> -g <group>
```

Sub-commands and Options

```
  add                - Add encryption keys, args:
    [-a <algorithm>] - Encryption algorithm. Supported values: aes-256-cbc (default), a
    [-c <keyclass>]  - Key class to set for the key.
    [-k <kms>]       - KMS to use. Must be configured; see cribl.yml.
    [-e <expires>]   - Expiration time, in epoch time.
    [-i]             - Use an initialization vector. (IV size configurable for algorith
    [-s <ivSize>]    - (For algo 'aes-256-gcm' only) Initialization vector size (bytes
    [-g <group>]     - Worker Group ID.
  list               - List encryption keys, args:
    [-g <group>]     - Worker Group ID.
```

Sample Response

```
  Adding key succeeded. Key count=1
```

nc

Listens on a port for traffic, and outputs stats and data. (Netcat-like utility.)

Usage

```
./cribl nc -p <port> <options> <args>
```

Options

```
 -p <port>           - Port to listen on.
[-f <family>]        - If this is "6" then nc will listen on ::1, otherwise it listen
[-s <statsInterval>] - Stats output interval (ms), use 0 to disable.
[-u]                 - Listen on UDP port instead.
[-o]                 - Output received data to stdout.
[-t <throttle>]      - throttle rate in (unit)/sec, where units can be KB,MB,GB, and
```

Sample Response

```
2021-08-20T22:44:30.457Z - starting server on 0.0.0.0:9999
2021-08-20T22:44:30.462Z - server listening 0.0.0.0:9999
2021-08-20T22:44:31.461Z - messages: 0, socks: 0, thruput: 0MBps
2021-08-20T22:44:32.466Z - messages: 0, socks: 0, thruput: 0MBps
...
2021-08-20T22:44:39.212Z - got connection: 127.0.0.1:37190
2021-08-20T22:44:39.213Z - got connection: 127.0.0.1:37192
```

node

Run with no options, displays a command prompt, as shown here:

```
>
```

To execute a JavaScript file, you can enter path/file name at the prompt.

With the `-v` option, prints the version of NodeJS that is running.

With `-e`, evaluates a string. Write to console to see the output, for example:

```
./cribl node -e 'console.log(Date.now())'
1629740667695
```

Usage

```
./cribl node <options> <args>
```

Options

```
[-e <eval>] - String to eval
[-v]        - Prints NodeJS version
```

Sample Response

```
v14.15.1
```

pipe

Feeds stdin to a Pipeline.

Usage

```
./cribl pipe -p <pipelineName> <options> <args>
```

Examples:

```
cat sample.log |  ./cribl pipe -p <pipelineName>
cat sample.log |  ./cribl pipe -p <pipelineName> 2>/dev/null
```

Options

```
 -p <pipeline>    - Pipeline to feed data thru
[-d]              - Include dropped events
[-c <cpuProfile>] - Perform CPU profiling
[-t]              - Perform pipeline tracing
[-a <pack>]       - Optional Cribl Pack context. Mutually exclusive with -b.
[-b <project>]    - Optional Cribl Project context
[-i]              - Runs the pipe command without sandboxing javascript expressions
```

Sample Response

```
...

...
```

`scope`

Greps your apps by the syscalls. Executes immediately.

See the AppScope CLI Reference for usage and examples.

`vars`

Manages Cribl Stream Global Variables.

Usage

```
./cribl vars <sub-command> <options> <args>
```

Sub-commands and Options

```
Sub-commands:
add                   - Add global variable, args:
   -i <id>            - Global variable ID
   -t <type>          - Type
   -v <value>         - Value
  [-a <args>]         - Arguments
  [-d <description>] - Description
  [-c <tags>]         - Custom Tags (comma separated list)
  [-g <group>]        - Group ID
get                   - List global variables, args:
  [-i <id>]           - Global variable ID
  [-g <group>]        - Group ID
remove                - Remove global variable, args:
   -i <id>            - Global variable ID
  [-g <group>]        - Group ID
update                - Update global variable, args:
   -i <id>            - Global variable ID
  [-t <type>]         - Type
  [-v <value>]        - Value
  [-a <args>]         - Arguments
  [-d <description>] - Description
  [-c <tags>]         - Custom Tags (comma separated list)
  [-g <group>]        - Group ID
```

Sample Response

```
[
  {
    "type": "number",
    "lib": "cribl",
    "description": "Sample number variable ",
    "value": "42",
    "tags": "cribl,sample",
    "id": "theAnswer"
  }
]
```

17.6. Environment Variables

You can use the following environment variables to configure your Cribl Stream installation.

Name	Purpose
`CRIBL_TMP_DIR`	Defines the root of a temporary directory. See Usage Notes below.
`CRIBL_VOLUME_DIR`	Sets a directory that persists modified data between different containers or ephemeral instances. When set, this environment variable overrides `CRIBL_HOME`. It also creates predefined subdirectories in the specified directory. If that directory already contains subdirectories with those names, they will be overwritten.
`CRIBL_BOOTSTRAP`	Quickstart a Cribl instance by configuring this variable.
`CRIBL_BOOTSTRAP_HOST`	Host name for connecting to the Leader Node when setting up a new Worker Node.
`CRIBL_API_HOST`	Overrides the **Host** setting.
`CRIBL_API_PORT`	Overrides the **Port** setting.
`CRIBL_EDGE`	(Cribl Edge only) When set to any value, runs this command at container start: `cribl mode-edge -H 0.0.0.0`. This launches the instance as an Edge Node, listening on a host at `0.0.0.0`.
`CRIBL_EDGE_FS_ROOT`	(Cribl Edge running in a container only) Location of the host OS filesystem when mounting in a container. Defaults to `/hostfs`.
`CRIBL_K8S_POD`	(Cribl Edge on Kubernetes only) Sets the name of the Kubernetes Pod in which Cribl Edge is deployed.
`CRIBL_K8S_TLS_REJECT_UNAUTHORIZED`	(Cribl Edge on Kubernetes only) Set to `0` to disable certificates validation when connecting to the Kubernetes APIs. When you disable this environment variable, all Kubernetes features (including Metadata, Metrics, Logs, and AppScope metadata) will tolerate invalid TLS certificates (such as, expired, self-signed, and so forth) when connecting to the Kubernetes APIs.
`CRIBL_SERVICEACCOUNT_PATH`	(Cribl Edge on Kubernetes only) Path to the `ServiceAccount` to use to query the Kubernetes API. Defaults to `/var/run/secrets/kubernetes.io/serviceaccount`.

Name	Purpose
`CRIBL_NOEXEC`	When set to `1`, prevents the Exec Source from processing any data, effectively putting it into a "disabled" state. To re-enable, remove or unset the `CRIBL_NOEXEC` variable.

Distributed Deployment Variables

You can use the following environment variables to configure your distributed Cribl Stream instance.

Name	Purpose
`CRIBL_DIST_MASTER_URL`	URL of the Leader Node. Example: `CRIBL_DIST_MASTER_URL=tls://<authToken>@leader:4200` See Usage Notes below.
`CRIBL_DIST_MODE`	`worker` or `master`. Defaults to `worker`, if (and only if) `CRIBL_DIST_MASTER_URL` is present.
`CRIBL_DIST_WORKER_PROXY`	Communicate to the Leader Node via a SOCKS proxy. See Usage Notes below.

Usage Notes

This section explains how to use certain complex environment variables.

`CRIBL_DIST_MASTER_URL`

Use this format:

```
<tls|tcp>://<authToken>@host:port?group=defaultGroup&tag=tag1&tag=tag2&tls.
<tls_settings>
```

The auth token can include only alphanumeric characters or the underscore (`_`). Do not include `<`, `>`, `"`, `` ` ``, `\r`, `\n`, `\t`, `{`, `}`, `|`, `\`, `^`, or `'`.

Here are the components:

- `group` – The preferred Worker Group assignment.
- `resiliency` – The preferred Leader failover mode.

- `volume` – The location of the NFS directory to support Leader failover.
- `tag` – A list of tags that you can use to map (Stream, Edge) the Worker to a Worker Group.
- `disableSNIRouting` – Whether Server Name Indicator (SNI) routing is enabled on the Worker Node. Boolean; defaults to `false`.

  Do not edit this advanced setting without supervision by Cribl Support. Changing this setting can affect the scalability of your system because it determines how Cribl Stream routes connections between Leader Nodes and Worker Nodes. See the Known Issue that resulted in this setting for more details.

- `tls.privKeyPath` – Private Key Path.
- `tls.passphrase` – Key Passphrase.
- `tls.caPath` – CA Certificate Path.
- `tls.certPath` – Certificate Path.
- `tls.rejectUnauthorized` – Validate Client Certs. Boolean; defaults to `false`.
- `tls.requestCert` – Authenticate Client (mutual auth). Boolean; defaults to `false`.
- `tls.commonNameRegex` – Regex matching peer certificate > subject > common names allowed to connect. Used only if `tls.requestCert` is set to `true`.

To generate a random authentication token, leave `<authToken>` unchanged. You can define it to add your own token instead, but make sure it's secure enough.

CRIBL_TMP_DIR

Sources use this variable to construct temporary directories in which to stage downloaded Parquet data. If `CRIBL_TMP_DIR` is not set (the default), Cribl applications create subdirectories within your operating system's default temporary directory:

- For Cribl Stream: `<OS_default_temporary_directory>/stream/`.
- For Cribl Edge: `<OS_default_temporary_directory>/edge/`.

For example, on Linux, Stream's default staging directory would be `/tmp/stream/`.

If you explicitly set this `CRIBL_TMP_DIR` environment variable, its value replaces this OS-specific default parent directory.

CRIBL_DIST_WORKER_PROXY

`CRIBL_DIST_WORKER_PROXY` lets you configure a SOCKS proxy for communication between the Leader Node and Worker Nodes.

The default protocol is SOCKS5, which uses the format: `socks5://<username>:<password>@<host>:<port>`. Only `<host>:<port>` are required.

You can alternatively specify SOCKS4 as the protocol with the format: `socks4://<proxyhost>:<port>`. To authenticate on a SOCKS4 proxy with username and password, use this format: `socks4://<username>:<password>@<proxyhost>:<port>`. The `<proxyhost>` can be a hostname, IPv4, or IPv6.

To configure a SOCKS proxy via the UI, see Configure SOCKS Proxy. To configure an HTTP(S) proxy to use for your Sources and Destinations, refer to System Proxy Configuration.

CRIBL_BOOTSTRAP_HOST

`CRIBL_BOOTSTRAP_HOST` overrides the Add/Bootstrap New Worker script generator's default hostname.

For example, if you set `CRIBL_BOOTSTRAP=myhost`, then `myhost` will appear in the script modal's **Leader hostname/IP** field, instead of the URL used in the browser.

CRIBL_BOOTSTRAP

`CRIBL_BOOTSTRAP` enables specifying a URL, an absolute disk file path, or a YAML string, in order to bootstrap a configuration to the `$CRIBL_HOME/local` directory. Cribl Stream applies this configuration only upon its first startup.

For any method, Cribl Stream expects each targeted config file to be YAML-formatted. Each file's top-level keys should be the paths to config files inside the `$CRIBL_HOME/local/...` subdirectory.

Below is an example of a bootstrap file. Its output, when Cribl Stream starts, would be to create three files inside the `$CRIBL_HOME/local/cribl` path: `inputs.yml`, `outputs.yml`, and `pipelines/route.yml`.

```
cribl/inputs.yml:
  inputs:
    <id>:
      <config>
cribl/outputs.yml:
  outputs:
    <id>:
      <config>
cribl/pipelines/route.yml:
  id: default
  groups: {}
  comments: []
  routes:
    ...
```

For details about each file's syntax, see Config Files and its child topics.

Adding Fallback Leaders

You can configure fallback Leader Nodes to support high availability and failover. Use the following environment variables.

Name	Purpose
`CRIBL_DIST_MASTER_RESILIENCY=failover`	Sets the Leader's `Resiliency` to `Failover` m
`CRIBL_DIST_MASTER_FAILOVER_VOLUME=/tmp/shared`	Sets the location of the NFS directory to support failover.
`CRIBL_DIST_MASTER_FAILOVER_MISSED_HB_LIMIT`	Determines how many Lease refresh periods ela the standby Nodes attempt to promote themsel primary. Cribl recommends setting this to `3`.
`CRIBL_DIST_MASTER_FAILOVER_PERIOD`	Determines how often the primary Leader refre on the Lease file. Cribl recommends setting this
`CRIBL_INSTANCE_HOME`	In `Failover` mode, this variable points to the L `root` directory, as opposed to the shared volun to access `$CRIBL_INSTANCE_HOME/local/_system/in` (`C:\ProgramData\Cribl\local\_system.yr` Edge on Windows).

GitOps Variables

Cribl Stream provides the following environment variables to facilitate using GitOps in Cribl Stream.

You can use these variables to override the defaults in the UI if you are not using systemd to manage the `cribl` service.

Bootstrap Variables

Name	Purpose
`CRIBL_GIT_REMOTE`	Location of the remote repo to track. Can contain username and password for HTTPS auth.
`GIT_SSH` / `GIT_SSH_COMMAND`	See Git's documentation.
`CRIBL_GIT_BRANCH`	Git ref (branch, tag, commit) to track/check out.
`CRIBL_GIT_AUTH`	One of: `none`, `basic`, or `ssh`.
`CRIBL_GIT_USER`	Used for `basic` auth.
`CRIBL_GIT_PASSWORD`	Used for `basic` auth.
`CRIBL_GIT_OPS`	Controls which GitOps workflow to use. One of: `push` to enable the GitOps push workflow, or `none` to disable GitOps.
`CRIBL_INTERACTIVE`	Controls whether git commands called by Cribl CLI at startup are interactive.
`CRIBL_GIT_SSH_KEY`	Content of the SSH key used to access git remote.
`CRIBL_GIT_STRICT_HOST_KEY_CHECKING`	Controls whether to check the host key strictly.

Additional Environment Variables

Cribl Stream uses the following variables for multiple purposes.

Name	Purpose
`CRIBL_SPOOL_DIR`	Specifies the base path where events from various Sources and Destinations are spooled. Defaults to `$CRIBL_HOME/state/spool` or

Name	Purpose
	`$CRIBL_VOLUME_DIR/state/spool`.

CRIBL_HOME

`CRIBL_HOME` is a special internal environment variable that indicates the location of the Cribl binary (`bin` directory). You do not set it manually, but it is referred to in multiple places and commands.

17.7. Config Files

Understanding Configuration Paths and Files

Even though all Cribl Stream Routes, Pipelines, and Functions can be managed from the UI, it's important to understand how the configuration works under the hood. Here is how configuration paths and files are laid out on the filesystem.

Path Placeholder	Expanded Path
`$CRIBL_HOME`	Standalone Install: `/path/to/install/cribl/` – referred to below as `$CRIBL_HOME` Cribl App for Splunk Install: `$SPLUNK_HOME/etc/apps/cribl/`

All paths below are relative to `$CRIBL_HOME` in a Single-instance deployment, or to `$CRIBL_HOME/groups/<group-name>/` in a Distributed deployment.

Category	Relative Path
Default Configurations Out-of-the-box defaults (rewritable) and libraries (expandable)	`default/cribl`
Local Configurations User-created integrations and resources	`local/cribl`
System Configuration	`(default|local)/cribl/cribl.yml` See cribl.yml
API Configuration	`(default|local)/cribl/cribl.yml` > `[api]` section See cribl.yml
Source Configuration	`(default|local)/cribl/inputs.yml` See inputs.yml
Destination Configuration	`(default|local)/cribl/outputs.yml` See outputs.yml
License Configuration	`(default|local)/cribl/licenses.yml`

Category	Relative Path
Regexes Configuration	`(default|local)/cribl/regexes.yml`
Breakers Configuration	`(default|local)/cribl/breakers.yml`
Limits Configuration	`(default|local)/cribl/limits.yml`
Service Processes Configuration	`(default|local)/cribl/service.yml` See service.yml
Pipelines Configuration	`(default|local)/cribl/pipelines/<pipeline_name>` Each Pipeline's config resides within its subdirectory.
Packs Configuration	`default/<pack_name>` Each Pack's code and config reside within its subdirectory.
Routes Configuration	`(default|local)/cribl/pipelines/routes.yml`
Functions	`(default|local)/cribl/functions/<function_name>` Each Function's code resides within its subdirectory.
Functions Configuration	`(default|local)/cribl/functions/<function_name>/...` Each Function's config resides within its subdirectory.
Roles Configuration	`(default|local)/cribl/roles.yml` RBAC Role definitions. See roles.yml.
Policies Configuration	`(default|local)/cribl/policies.yml` RBAC Policy definitions. See policies.yml.
Permissions Configuration	`(default|local)/cribl/perms.yml` User permissions. See perms.yml.
Secrets Configuration	`(default|local)/cribl/secrets.yml` Cribl Stream secrets. See secrets.yml.

Configurations and Restart

You can **Restart** and **Reload** via the UI. In the sidebar, select **Settings**, then **Global**. Under **System** > **Controls** select **Reload** or **Restart**.

In a distributed environment, Worker Nodes poll the Leader for configuration changes. Many of these changes require a quick reload to read the new configuration, while others require a restart of the Cribl processes on the Worker Node.

Upon restarts, be aware of the following:

- Syslog data still being received over UDP might be dropped.
- Worker Nodes will temporarily disappear from the Leader's **Workers** or **Edge Nodes** page.
- Aggregation and suppression operations will start over.
- Worker Nodes' local copies of Monitoring metrics will be dropped.
- Cribl Stream will drop any events still in RAM that were bound for persistent queues. (However, PQ data already written to disk will persist through the restart.)

Changes that require reloads include configuration changes to:

- Functions
- Pipelines
- Packs
- Routes
- Lookups
- Parquet schemas
- Global variables
- Group Settings > Limits
- Group Settings > Logging > Levels

Changes that require restarts include configuration changes to:

- Distributed mode (Leader versus Managed Worker Node or Single instance)
- Worker Group assignment
- Event Breakers
- QuickConnect configs
- Sources
- Destinations
- Group Settings > General Settings > TLS
- Group Settings > General Settings > Advanced
- Group Settings > Worker Processes > Process count and Memory

Some general guidelines to keep in mind:

- Configuration changes generated by most UI interactions – for instance, changing the order of Functions in a Pipeline, or changing the order of Routes – **do not require restarts**.

- Some configuration changes in the **Settings** UI **do require restarts**. These will prompt you for confirmation before restarting.
- All direct edits of configuration files in `bin|(local|default)/cribl/...` **will require restarts**.
- Worker Nodes might temporarily disappear from the Leader's **Workers** or **Edge Nodes** tab while restarting.
- A `git commit` command on the Leader Node's host (using a freestanding `git` client not embedded in Cribl's CLI or UI) **will require either a reload or restart**.
- When using the Cribl App for Splunk, changes to Splunk configuration files might or might not require restarts. Please check current Splunk docs.

Configuration Layering and Precedence

As on most *nix systems, Cribl configurations in `local` take precedence over those in `default`. There is no layering of configuration files.

Editing Configuration Files Manually

When config files **must** be edited manually, save all changes in `local`.

17.7.1. Cribl.Yml

`cribl.yml` contains settings for configuring API and other system properties.

$CRIBL_HOME/default/cribl/cribl.yml

```
api: # [object]
  host: # [string] Address to bind to. Defaults to 0.0.0.0.
  port: # [number] Port to listen to. Defaults to 9000.
  retryCount: # [number] Number of times to retry binding to API port. Defaults to 1
  retrySleepSecs: # [number] Period, in seconds, between consecutive port binding re
  baseUrl: # [string] URL base path from which to serve all assets (useful when behi
  disabled: # [boolean] Flag to enable/disable local UI access. Defaults to false.
  workerRemoteAccess: # [boolean] Enable teleporting to Worker Nodes'. Defaults to fa
  revokeOnRoleChange: # [boolean] Log users out when their roles change. Defaults to
  authTokenTTL: # [number] How long (in seconds) authentication tokens remain valid.
  idleSessionTTL: # [number] How long (in seconds) Cribl Stream will observe no user
  headers: # [object] Custom HTTP headers to be sent with every response.
  loginRateLimit: # [string] Rate limit, expressed as maximum number of requests per
  ssoRateLimit: # [string] Rate limit for SSO and SLO callback endpoints. Expressed a
  apiCache: # [object] Toggle to 'No' to disable caching of browser's frequent API re
  ssl: # [object] SSL Settings
    disabled: # [boolean] SSL is enabled by default.
    privKeyPath: # [string] Path to private key.
    certPath: # [string] Path to certificate.

auth: # [object] Authentication Settings
  type: # [string] Type - Select one of the supported authentication providers.

  # -------------- if type is ldap ---------------

  secure: # [boolean] Secure - Enable to use a secure ldap connection (ldaps://), dis
  ldapServers: # [array of strings] LDAP servers - List of LDAP servers, each entry s
  bindDN: # [string] Bind DN - Distinguished name of entity to authenticate with LDAP
  bindCredentials: # [string] Password - Distinguished Name password used to authenti
  searchBase: # [string] User search base - Starting point to search LDAP for users,
  usernameField: # [string] Username field - LDAP user search field, e.g. cn or uid
  searchFilter: # [string] User search filter - LDAP search filter to apply when find
  groupSearchBase: # [string] Group search base - Starting point to search LDAP for g
  groupMemberField: # [string] Group member field - LDAP group search field, e.g. mem
  groupSearchFilter: # [string] Group search filter - LDAP search filter to apply whe
  groupField: # [string] Group name field - LDAP group field, e.g. cn
  connectTimeout: # [number] Connection timeout (ms)
  rejectUnauthorized: # [boolean] Reject unauthorized - Valid for secure LDAP connect
  fallback: # [boolean] Fallback on fatal error - Attempt local authentication if LDA
  groups: # [object]
    default: # [string] Default role - Default role assigned to groups not explicitly
    mapping: # [object] Mapping - Group(s)-to-role(s) mappings
```

```
# ------------------------------------------------------

# -------------- if type is saas ---------------

issuer: # [string] Issuer - Issuer from which to accept and validate JWT tokens.
tenantId: # [string] Organization ID - The organization ID within which this instar
loginUrl: # [string] Login URL - The URL to redirect unauthenticated users to.

# ------------------------------------------------------

# -------------- if type is splunk ---------------

host: # [string] Host - Hostname or address of Splunk instance that provides authe
port: # [number] Port - Port of Splunk instance that provides authentication. Defa
ssl: # [boolean] SSL - Whether SSL is enabled on Splunk instance that provides autl
fallback: # [boolean] Fallback on fatal error - Attempt local authentication if Sp
groups: # [object]
  default: # [string] Default role - Default role assigned to groups not explicitl
  mapping: # [object] Mapping - Group(s)-to-role(s) mappings

# ------------------------------------------------------

# -------------- if type is openid ---------------

name: # [string] Provider name - The name of the identity provider service. Manual
audience: # [string] Audience - The Audience from provider configuration. This wil
client_id: # [string] Client ID - The client_id from provider configuration.
client_secret: # [string] Client secret - The client_secret provider configuration
scope: # [string] Scope - Space-separated list of authentication scopes. Default:
auth_url: # [string] Authentication URL - The full path to the provider's authenti
token_url: # [string] Token URL - The full path to the provider's access token URL
userinfo_url: # [string] User Info URL - The full path to the provider's user info
logout_url: # [string] Logout URL - The full path to the provider's logout URL. Le
userIdExpr: # [string] User identifier - Expression used to derive userId from the
rejectUnauthorized: # [boolean] Validate certs - Validate certificates; set to fal
filter_type: # [string] Filter type - Optional method for limiting access per user
groupField: # [string] Group name field - Field on the id_token that contains the
fallback: # [boolean] Allow local auth - Allows locally configured users to log in
groups: # [object]
```

    useEnvVars: true
  # If there is a custom gitignore rule that excludes cribl.secret from bundle
  bundler:
    bundleGitIgnoredPatterns: '**/cribl.secret'
```

17.7.2. Breakers.Yml

Cribl's default Event Breaker Library is stored in `$CRIBL_HOME/default/cribl/breakers.yml`.

$CRIBL_HOME/default/cribl/breakers.yml

```
breaker_id: # [object]
  lib: # [string] Library
  description: # [string] Description - Brief description of this ruleset. Optional.
  tags: # [string] Tags - One or more tags related to this ruleset. Optional.
  rules: # [array] Rules - List of rules. Evaluated in order, top down.
    - name: # [string] Rule Name - Rule Name.
      condition: # [string] Filter Condition - Filter expression (JS) that matches da
      type: # [string] Event Breaker Type - Event Breaker Type
      timestampAnchorRegex: # [string] Timestamp Anchor - Regex to match before atter
      timestamp: # [object] Timestamp Format - Auto, manual format (strptime) or curi
        type: # [string] Timestamp Type
        length: # [number] Length
        format: # [string] Format
      timestampTimezone: # [string] Default timezone - Timezone to assign to timestar
      timestampEarliest: # [string] Earliest timestamp allowed - The earliest timesta
      timestampLatest: # [string] Future timestamp allowed - The latest timestamp val
      maxEventBytes: # [number] Max Event Bytes - The maximum number of bytes that ar
      fields: # [array] Fields - Key value pairs to be added to each event.
      - name: # [string] Name - Field Name.
        value: # [string] Value Expression - JavaScript expression to compute fields
      disabled: # [boolean] Disabled - Allows breaker rule to be enabled or disabled
```

17.7.3. Certificates.Yml

`certificates.yml` maintains a list of configured certificates and their parameters.

$CRIBL_HOME/local/cribl/certificates.yml

```
certificate_id: # [object]
  description: # [string] Description - Brief description of this certificate. Optio
  cert: # [string] Certificate - Drag/drop or upload host certificate, in PEM/Base64
  privKey: # [string] Private key - Certificate private key.
  passphrase: # [string] Passphrase - Passphrase. Optional.
  ca: # [string] CA certificate - Optionally, drag/drop or upload all CA certificate
  inUse: # [array of strings] Referenced - List of configurations referencing this c
```

17.7.4. Groups.Yml

`groups.yml` maintains a list of groups and their configuration versions.

$CRIBL_HOME/local/cribl/groups.yml

```
group_id: # [object]
  configVersion: # [string] Config Version - Configuration version that is active fo
  onPrem: # [boolean] On prem - Whether the group accepts on-prem or cloud worker no
  isFleet: # [boolean] Is Fleet - Fleet groups only manage edge nodes.
  workerRemoteAccess: # [boolean] UI access - Enable authenticated viewing of Worker
```

17.7.5. Inputs.Yml

`inputs.yml` contains settings for configuring inputs into Cribl.

$CRIBL_HOME/default/cribl/inputs.yml

```
inputs: # [object]
  collection_input: # [object]
    type: # [string] Input Type
    breakerRulesets: # [array of strings] Event Breaker rulesets - A list of event b
    staleChannelFlushMs: # [number] Event Breaker buffer timeout - The amount of tim
    sendToRoutes: # [boolean]  - Select whether to send data to Routes, or directly

    # -------------- if sendToRoutes is false ---------------

    connections: # [array] Quick Connections - Direct connections to Destinations, o
      - pipeline: # [string] Pipeline/Pack - Select Pipeline or Pack. Optional.
        output: # [string] Destination - Select a Destination.

    # --------------------------------------------------------

    preprocess: # [object]
      disabled: # [boolean] Disabled - Enable Custom Command
      command: # [string] Command - Command to feed the data through (via stdin) and
      args: # [array of strings] Arguments - Arguments
    throttleRatePerSec: # [string] Throttling - Rate (in bytes per second) to thrott
    metadata: # [array] Fields - Fields to add to events from this input.
      - name: # [string] Name - Field name
        value: # [string] Value - JavaScript expression to compute field's value, en
    disabled: # [boolean] Disabled - Enable/disable this input
    pipeline: # [string] Pipeline - Pipeline to process data from this Source before
    environment: # [string] Environment - Optionally, enable this config only on a s
    pqEnabled: # [boolean] Enable Persistent Queue

    # -------------- if pqEnabled is true ---------------

    pq: # [object]
      mode: # [string] Mode - With Smart mode, PQ will write events to the filesyste
      maxBufferSize: # [number] Max buffer size - The maximum amount of events to ho
      commitFrequency: # [number] Commit frequency - The number of events to send do
      maxFileSize: # [string] Max file size - The maximum size to store in each queu
      maxSize: # [string] Max queue size - The maximum amount of disk space the queu
      path: # [string] Queue file path - The location for the persistent queue files
      compress: # [string] Compression - Codec to use to compress the persisted data

    # --------------------------------------------------------

    streamtags: # [array of strings] Tags - Add tags for filtering and grouping in S
```

```
kafka_input: # [object]
  type: # [string] Input Type
  brokers: # [array of strings] Brokers - List of Kafka brokers to use, eg. localh
  topics: # [array of strings] [required] Topic - Topic to subscribe to. Warning:
  groupId: # [string] Group ID - Specifies the consumer group this instance belong
  fromBeginning: # [boolean] From beginning - Whether to start reading from earlie
  kafkaSchemaRegistry: # [object] Kafka Schema Registry Authentication
    disabled: # [boolean] Disabled - Enable Schema Registry

    # -------------- if disabled is false ---------------

    schemaRegistryURL: # [string] Schema Registry URL - URL for access to the Conf
    tls: # [object] TLS settings (client side)

  brokers: # [array of strings] Brokers - List of Event Hubs Kafka brokers to conn
  topics: # [array of strings] [required] Event Hub name - The name of the Event Hu
  groupId: # [string] Group ID - Specifies the consumer group this instance belongs
  fromBeginning: # [boolean] From beginning - Whether to start reading from earlies
  connectionTimeout: # [number] Connection timeout (ms) - Maximum time to wait for
  requestTimeout: # [number] Request timeout (ms) - Maximum time to wait for a succ
  sasl: # [object] Authentication - Authentication parameters to use when connecti
    disabled: # [boolean] Disabled - Enable authentication.

    # -------------- if disabled is false ---------------

    mechanism: # [string] SASL mechanism - SASL authentication mechanism to use. Pl
    username: # [string] Username - The username for authentication. For Event Hubs
    authType: # [string] Authentication method - Enter password directly, or selec

    # ---------------------------------------------------------

  tls: # [object] TLS settings (client side)
    disabled: # [boolean] Disabled

    # -------------- if disabled is false ---------------

    rejectUnauthorized: # [boolean] Validate server certs - For Event Hubs, this sh

    # ---------------------------------------------------------

  sessionTimeout: # [number] Session timeout (ms) -
    Timeout (a.k.a session.timeout.ms in Kafka domain) used to detect client failu
    If the client sends the broker no heartbeats before this timeout expires, the
    Value must be lower than rebalanceTimeout.
    See details [here](https://github.com/Azure/azure-event-hubs-for-kafka/blob/mas
  rebalanceTimeout: # [number] Rebalance timeout (ms) -
    Maximum allowed time (a.k.a rebalance.timeout.ms in Kafka domain) for each work
    If the timeout is exceeded, the coordinator broker will remove the worker from
    See details [here](https://github.com/Azure/azure-event-hubs-for-kafka/blob/mas
  heartbeatInterval: # [number] Heartbeat interval (ms) -
    Expected time (a.k.a heartbeat.interval.ms in Kafka domain) between heartbeats
    Value must be lower than sessionTimeout, and typically should not exceed 1/3 of
    See details [here](https://github.com/Azure/azure-event-hubs-for-kafka/blob/mas
  minimizeDuplicates: # [boolean] Minimize duplicates - Enable feature to minimize
  metadata: # [array] Fields - Fields to add to events from this input.
```

```

17.7.6. Instance.Yml

Instance configuration is located under `$CRIBL_HOME/local/_system/instance.yml` (`C:\ProgramData\Cribl\local\_system.yml` for Cribl Edge on Windows).

$CRIBL_HOME/local/_system/instance.yml or C:\ProgramData\Cribl\local_system.yml for Cribl Edge on Windows

```
distributed:
  mode: # [string] One of: master | worker | single | edge | managed-edge.
  master: # [object]
    disableSNIRouting: # [boolean] Whether SNI routing is enabled. See (Environment V
    host: # [string] Instance host address.
    port: # [number] Instance post number.
    tls: # [object]
      disabled: # [boolean]
      certificateName: # [string] TLS certificate name.
      rejectUnauthorized: # [boolean] False if ignoring untrusted certificates.
      requestCert: # [boolean] Whether certificates are required and validated.
      privKeyPath: # [string] Path to private key file. Can reference $ENV_VARS.
      certPath: # [string] Path to certificate file. Can reference $ENV_VARS.
      caPath: # [string] Path to CA certificate file. Can reference $ENV_VARS.
      commonNameRegex: # [any] Allowed common names in peer certificates' subject (re
      # Available values: 'TLSv1.3' | 'TLSv1.2' | 'TLSv1.1' | 'TLSv1'
      minVersion: # [string] Minimum TLS version.
      maxVersion: # [string] Maximum TLS version.
      servername: # [string] Server name.
    resiliency: # [string] Preferred failover mode, one of: none | failover.
    ipWhitelistRegex: # [string] IP addresses allowed to send data (regex).
    maxActiveCxn: # [number] Max number of active connections allowed per Worker Proc
    authToken: # [string] Token used for communication between Leader and managed nod
    compression: # [string] Codec used to compress persisted data. One of: none | gzi
    connectionTimeout: # [number] Maximum time to wait for a connection to complete s
    writeTimeout: # [number] Time (ms) to wait for a write to complete before assumin
    configBundles: # [object]
      remoteUrl: # [string] Bucket to use for remote bundle storage, in s3://${bucket
  group: # [string] Group the managed node belongs to.
  envRegex: # [string] Regex used to filter env variable names that can be sent by ma
  tags: # [array of strings] Tags associated with managed node, can be used by Leade
```

17.7.7. Jobs.Yml

`jobs.yml` maintains parameters for configured Collectors, corresponding to those listed on the **Collectors** page. Each collection job is listed according to the pattern shown below.

$CRIBL_HOME/local/cribl/jobs.yml

```
collection_job: # [object]
  workerAffinity: # [boolean] Worker affinity - If enabled tasks are created and run
  collector: # [object]
    type: # [string] Collector type - The type of collector to run.

    # -------------- if type is azure_blob ---------------

    conf: # [object] [required]

```

17.7.8. Job-Limits.Yml

`job-limits.yml` maintains parameters for Collection jobs and system tasks. In the UI, you can configure these per Worker Group at **Group Settings** > **General Settings** > **Limits** > **Jobs**.

Where we do not specify or validate a minimum or maximum value, Cribl provides a prudent default. Adjust this initial value to match your architecture and needs.

$CRIBL_HOME/default/cribl/job-limits.yml

```
concurrentJobLimit: # [number; default: 10, minimum: 1] Concurrent job limit - The t
concurrentSystemJobLimit: # [number; default: 10, minimum: 1] Concurrent system job
concurrentScheduledJobLimit: # [number, default: -2] Concurrent scheduled job limit
concurrentTaskLimit: # [number; default: 2, minimum: 1] Concurrent task limit - The
concurrentSystemTaskLimit: # [number; default: 1, minimum: 1] Concurrent system task
maxTaskPerc: # [number; default: 0.5, minimum: 0, maximum: 1] Max task usage percent
taskPollTimeoutMs: # [number; default: 60000, minimum: 10000] Task poll timeout - Th
jobArtifactsReaperPeriod: # [string; default: 30 min.] Artifact reaper period - Time
finishedJobArtifactsLimit: # [number; default: 100 items, minimum: 0] Finished job a
finishedTaskArtifactsLimit: # [number; default: 500 items, minimum: 0] Finished task
taskManifestFlushPeriodMs: # [number; default: 100, minimum: 100, maximum: 10000] Ma
taskManifestMaxBufferSize: # [number; default: 1000, minimum: 100, maximum: 10000] M
taskManifestReadBufferSize: # [string; default: 4 KB] Manifest reader buffer size -
schedulingPolicy: # [string; default: LeastInFlight] Job dispatching - The method by
jobTimeout: # [string; default: 0] Job timeout - Maximum time a job is allowed to ru
taskHeartbeatPeriod: # [number; default: 60, minimum: 60] Task heartbeat period - Th
```

17.7.9. Leader.Yml

`leader.yml` contains configuration for a secondary Leader and is located under `$CRIBL_HOME/local/cribl` in the volume of that Leader.

This configuration file is created when you have configured a Leader for failover and the new Leader becomes active in case of failover.

$CRIBL_HOME/local/cribl/leader.yml

```
distributed:
  mode: # [string] One of: master | worker | single | edge | managed-edge.
  master: # [object]
    disableSNIRouting: # [boolean] Whether SNI routing is enabled. See (Environment V
    host: # [string] Instance host address.
    port: # [number] Instance post number.
    tls: # [object]
      disabled: # [boolean]
      certificateName: # [string] TLS certificate name.
      rejectUnauthorized: # [boolean] False if ignoring untrusted certificates.
      requestCert: # [boolean] Whether certificates are required and validated.
      privKeyPath: # [string] Path to private key file. Can reference $ENV_VARS.
      certPath: # [string] Path to certificate file. Can reference $ENV_VARS.
      caPath: # [string] Path to CA certificate file. Can reference $ENV_VARS.
      commonNameRegex: # [any] Allowed common names in peer certificates' subject (re
      # Available values: 'TLSv1.3' | 'TLSv1.2' | 'TLSv1.1' | 'TLSv1'
      minVersion: # [string] Minimum TLS version.
      maxVersion: # [string] Maximum TLS version.
      servername: # [string] Server name.
    ipWhitelistRegex: # [string] IP addresses allowed to send data (regex).
    maxActiveCxn: # [number] Max number of active connections allowed per Worker Proc
    authToken: # [string] Token used for communication between Leader and managed nod
    compression: # [string] Codec used to compress persisted data. One of: none | gzi
    connectionTimeout: # [number] Maximum time to wait for a connection to complete s
    writeTimeout: # [number] Time (ms) to wait for a write to complete before assumin
    configBundles: # [object]
      remoteUrl: # [string] Bucket to use for remote bundle storage, in s3://${bucket
  group: # [string] Group the managed node belongs to.
  envRegex: # [string] Regex used to filter env variable names that can be sent by ma
  tags: # [array of strings] Tags associated with managed node, can be used by Leade
```

17.7.10. Licenses.Yml

`licenses.yml` maintains a list of Cribl Stream licenses.

$CRIBL_HOME/default/cribl/licenses.yml

```
licenses: # [array of string] - list of licenses
```

17.7.11. LIMITS.YML

`limits.yml` maintains parameters for the system. In a distributed deployment, these parameters are configured on both the Leader and the Workers.

In the UI, you can configure them:

- On the Leader at **Settings** > **Global** > **General Settings > Limits**.
- On a single instance at **Settings** > **General Settings > Limits**.
- On Worker Groups at `<Group/Fleet-name>` > **Group Settings** > **General Settings > Limits**.

Where we do not specify or validate a minimum or maximum value, Cribl provides a prudent default. Adjust this initial value to match your architecture and needs.

$CRIBL_HOME/default/cribl/limits.yml

```
samples: # [object] Samples
  maxSize: # [string; maximum: 3 MB; default: 256 KB] Max sample size - Maximum file
maxMetrics: # [number; default: 1000000] Total allowed number of metric series, conf
minFreeSpace: # [string; default: 5 GB] Min free disk space - The minimum amount of
maxPQSize: # [string; default: 1 TB] Maximum persistent queue size per Worker Proces
metricsGCPeriod: # [string; default: 60s] Metrics GC period - The interval on which
metricsMaxCardinality: # [number; default: 1000] Metrics cardinality limit - The sys
metricsMaxDiskSpace: # [string; default: 64GB] Metrics max disk space - Maximum allo
metricsWorkerIdBlacklist: # [array of strings] Metrics worker tracking - List of met
metricsNeverDropList: # [array of strings] Metrics never-drop list - List of metric
metricsFieldsBlacklist: # [array of strings] Disable field metrics - List of event f
metricsDirectory: # [string] Metrics directory - Directory in which to store metrics
cpuProfileTTL: # [string; default: 30m] CPU profile TTL - The time-to-live for colle
eventsMetadataSources: # [array of strings] Event metadata sources - List of event m
edgeMetricsMode: # [string] Metrics to send from Edge Nodes - Choose a set of metric
kvStoreEnableWAL: # [boolean; default: false] Use Write-Ahead Log (WAL) mode — When
kvStoreWALMaxBytes: # [number; default: 5242880] Maximum size of the WAL file in byt
kvStoreServicePeriod: # [number; enabled default: 60000; disabled default: 10000] In
bundleDownloadTimeoutSeconds: # [number; default: 0] Maximum time a Cribl Stream Wor

# -------------- if edgeMetricsMode is custom ---------------

edgeMetricsCustomExpression: # [string] Metrics expression - JavaScript expression t

# -----------------------------------------------------

enableMetricsPersistence: # [boolean; default: true] Persist metrics - Set this to f
```

17.7.12. Logger.Yml

`logger.yml` maintains logging levels and redactions, per channel. In the UI, you can configure these at **Settings** > **Global** > **System** > **Logging**.

$CRIBL_HOME/default/cribl/logger.yml

```
redactFields: # [array of strings] - list of fields to redact
redactLabel: # [string] - redact label
channels: # [object] Logger channels as logger ID/log level pairs. Log levels: error
  DEFAULT: info
  input:DistMaster: debug
  output:DistWorker: debug
```

17.7.13. Mappings.Yml

Mapping ruleset configurations are stored in `$CRIBL_HOME/default/cribl/mappings.yml`.

$CRIBL_HOME/default/cribl/mappings.yml

```
mapping_ruleset_id: # [object]
  conf: # [object]
    functions: # [array] Functions - List of functions to pass data through
  active: # [boolean]
```

17.7.14. Messages.Yml

`messages.yml` stores messages displayed in the UI's `Messages` fly-out.

$CRIBL_HOME/local/cribl/logger.yml

```
message_id: # [object]
  severity: # [string] Severity
  title: # [string] Title
  text: # [string] Text
  time: # [number] Occurrence Time
  group: # [string] Group
  metadata: # [array]
```

17.7.15. Outputs.Yml

`outputs.yml` contains configuration settings for Cribl Stream Destinations.

$CRIBL_HOME/default/cribl/outputs.yml

```
outputs: # [object]
  default_output: # [object]
    type: # [string] Output Type
    defaultId: # [string,null] Default Output ID - ID of the default output. This wi
    pipeline: # [string] Pipeline - Pipeline to process data before sending out to t
    systemFields: # [array of strings] System fields - Set of fields to automatical
    environment: # [string] Environment - Optionally, enable this config only on a s
    streamtags: # [array of strings] Tags - Add tags for filtering and grouping in S
  webhook_output: # [object]
    type: # [string] Output Type
    url: # [string] URL - URL to send events to.
    method: # [string] Method - The method to use when sending events. Defaults to P
    format: # [string] Format - Specifies how to format events before sending out. D

    # -------------- if format is custom ---------------

    customSourceExpression: # [string] Source expression - Expression to evaluate as
    customDropWhenNull: # [boolean] Drop when null - Whether or not to drop events w
    customEventDelimiter: # [string] Event delimiter - Delimiter string to insert be
    customContentType: # [string] Content type - Content type to use for request. De

    # --------------------------------------------------------

    concurrency: # [number] Request concurrency - Maximum number of ongoing requests
    maxPayloadSizeKB: # [number] Max body size (KB) - Maximum size, in KB, of the re
    maxPayloadEvents: # [number] Max events per request - Max number of events to in
    compress: # [boolean] Compress - Whether to compress the payload body before sen
    rejectUnauthorized: # [boolean] Validate server certs - Reject certs that are no
    timeoutSec: # [number] Request timeout - Amount of time, in seconds, to wait for
    flushPeriodSec: # [number] Flush period (sec) - Maximum time between requests. S
    extraHttpHeaders: # [array] Extra HTTP headers - Extra HTTP headers.
      - name: # [string] Name - Field name
        value: # [string] Value - Field value
    useRoundRobinDns: # [boolean] Round-robin DNS - Enable to use round-robin DNS lo
    failedRequestLoggingMode: # [string] Failed request logging mode - Determines wh

```

17.7.16. Parsers.Yml

`parsers.yml` stores configuration data for the Knowledge > Parsers Library.

$CRIBL_HOME/default/cribl/parsers.yml

```
parser_id: # [object]
  lib: # [string] Library
  description: # [string] Description - Brief description of this parser. Optional.
  tags: # [string] Tags - One or more tags related to this parser. Optional.
  type: # [string] Type - Parser/Formatter type to use.
  fields: # [array of strings] List of Fields - Fields expected to be extracted, in
```

17.7.17. Perms.Yml

`perms.yml` stores Permissions configured for Cribl Stream users.

```
perms:
  - gid:    # [string]
    id:     # [string] Not used if type is 'groups'.
    type:   # [string] Resource type, one of: 'groups' | 'datasets' | 'dataset-provi
    policy: # [string] Policy name.
```

17.7.18. Policies.Yml

`policies.yml` contains RBAC Policy definitions. Default example:

$CRIBL_HOME/default/cribl/policies.yml

```
GroupFull:
  args:
    - groupName
  template:
    - PATCH /master/groups/${groupName}/deploy
    - GroupEdit ${groupName}
GroupEdit:
  args:
    - groupName
  template:
    - '* /m/${groupName}'
    - '* /m/${groupName}/*'
    - GroupRead ${groupName}
GroupCollect:
  args:
    - groupName
  template:
    - POST /m/${groupName}/lib/jobs
    - PATCH /m/${groupName}/lib/jobs/*
    - POST /m/${groupName}/jobs
    - PATCH /m/${groupName}/jobs/*
    - GroupRead ${groupName}
GroupRead:
  args:

- GET /version/status/*
- GET /mappings
- GET /mappings/*
- GET /system/messages
- GET /system/message/*
- GET /ui/*
- POST /system/metrics/query
- GET /clui
- POST /system/capture

17.7.19. Regexes.Yml

`regexes.yml` maintains a list of regexes. Cribl's Regex Library ships under `default`. Each regex is listed according to the following pattern:

$CRIBL_HOME/default/cribl/regexes.yml

```
regex_id: # [object]
  lib: # [string] Library
  description: # [string] Description - Brief description of this regex. Optional.
  regex: # [string] Regex pattern - Regex pattern. Required.
  sampleData: # [string] Sample data - Sample data for this regex. Optional.
  tags: # [string] Tags - One or more tags related to this regex. Optional.
```

17.7.20. Roles.Yml

`roles.yml` contains RBAC Role definitions. Default example:

$CRIBL_HOME/default/cribl/roles.yml

```
admin:
  description: 'Members with admin role have permission to do anything and everythin
  policy:
    - '* *'

17.7.21. Samples.Yml

`samples.yml` contains metadata about about stored sample data files (size, number of events, date created, name, etc.). Each sample is listed according to the following pattern:

$CRIBL_HOME/local/cribl/samples.yml

```
sample_id: # [object]
  sampleName: # [string] File Name - Filename to save the sample as. Required.
  pipelineId: # [string] Associate with Pipeline - Select a pipeline to associate wi
  description: # [string] Description - Brief description of this sample file. Optio
  ttl: # [number] Expiration (hours) - Time to live for the sample, the TTL is reset
  tags: # [string] Tags - One or more tags related to this sample file. Optional.
```

The corresponding sample files reside in `$CRIBL_HOME/data/samples`.

17.7.22. Schemas.Yml

`schemas.yml` stores configuration data for the Knowledge > Schema Library.

$CRIBL_HOME/default/cribl/schemas.yml

```
schema_id: # [object]
  description: # [string] Description - Brief description of this schema. Optional.
  schema: # [string] Schema - JSON schema matching standards of draft version 2019-09
```

17.7.23. Scripts.Yml

`scripts.yml` stores configuration data for scripts configured at **Settings** > **Global** > **Scripts**:

$CRIBL_HOME/local/cribl/scripts.yml

```
script_id: # [object]
  command: # [string] Command - Command to execute for this script
  description: # [string] Description - Brief description of this script. Optional.
  args: # [array of strings] Arguments - Arguments to pass when executing this script
  env: # [object] Env Variables - Extra environment variables to set when executing s
```

17.7.24. Secrets.Yml

`secrets.yml` stores secrets for Cribl Stream.

The secrets are decrypted and encrypted using a `cribl.secret` file. `cribl.secret` is unique per Worker Group and resides in the `$CRIBL_HOME/groups/<group-name>/local/cribl/auth` directory on Leader nodes, or in `$CRIBL_HOME/local/cribl/auth` for Workers or single-instance deployments.

Cribl automatically decrypts plaintext secrets from secrets.yml on startup and stores them in memory, keeping your data secure.

```
<secret-id>:
  secretType: # [string] One of: keypair | text | credentials
  secrets:
    # -------------- if secretType is keypair ---------------
    apiKey: "<encrypted-value>"
    secretKey: "<encrypted-value>"

    # -------------- if secretType is text ------------------
    value: "<encrypted-value>"

    # -------------- if secretType is credentials -----------
    username: "<encrypted-value>"
    password: "<encrypted-value>"
```

17.7.25. Service.Yml

`service.yml` maintains configuration for Cribl Stream service processes.

In the UI, you can configure them on the Leader at **Settings** > **Global** > **System** > **Service Processes** > **Services**.

Be careful about reducing the predefined limits. Extremely low values can prevent some Cribl Stream components from functioning.

$CRIBL_HOME/default/cribl/service.yml

```
connections: # [Object] - Heap memory limit for the connection listener processes.
  procs: # [number; default: 1, minimum: 1]
  memoryLimit: # [string; default: 2GB]
metrics: # [Object] - Heap memory limit for the metrics process
  procs: # [number; default: 1] – Single process; values other than 1 will be treate
  memoryLimit: # [string; default: 2GB]
notifications: # [Object] - Heap memory limit for the notifications process
  procs: # [number; default: 1] – Single process; values other than 1 will be treate
  memoryLimit: # [string; default: 2GB]
```

17.7.26. VARS.YML

`vars.yml` stores configuration data for the Knowledge > Global Variables Library.

$CRIBL_HOME/default/cribl/vars.yml

```
variable_id: # [object]
  lib: # [string] Library
  description: # [string] Description - Brief description of this variable. Optional
  type: # [string] Type - Type of variable.
  value: # [string] Value - Value of variable
  tags: # [string] Tags - One or more tags related to this variable. Optional.
```

18. Better Practices / Usage Examples

18.1. Tips And Tricks

In designing, supporting, and troubleshooting, complex Cribl Stream deployments and workflows, we've found the following general principles helpful.

Every use case is different. Don't hesitate to contact Cribl Support for help with solving your specific needs.

Architecture and Deployment

Separate Data by Worker Groups, Routes, or Both?

Separate your data volume by Worker Groups, or by Routes, or both. Common business reasons for sorting by Groups include data isolation by business group, ensuring data privacy, and achieving cost savings through geo-isolation. Another consideration is: Which type of separation will be the easiest to understand and manage as your organization grows?

Connecting Cribl Stream Groups/Instances with Same Leader:

Cribl HTTP or Cribl TCP

Where Workers share the same Leader, the obvious choices for sending data between those Workers are the Cribl HTTP Source and Destination pair, or the Cribl TCP Source and Destination pair. Either option prevents double-counting of this internal data flow against your on-prem license or Cribl.Cloud plan.

Connecting Stream Groups/Instances with Different Leaders:

TCP JSON

When sending between Cribl Stream Worker Groups and/or instances connected to **different** Leaders, use the TCP JSON Source and Destination pair. While Cribl Stream supports multiple Sources/Destinations for sending and receiving, TCP JSON is ideal because it supports TLS, has solid compression, and is overall well-formatted to maintain data's structure between sender and receiver.

Input Side: Event Breakers and Timestamping

Validate timestamping and event breaking before turning on a Source.

If a Source supports Event Breakers (e.g., AWS Sources), it is much more efficient to perform JSON unroll in a Breaker, versus in a Pipeline Function.

Routes

Avoid Route Creep

Design data paths to move through as few Routes as possible. This usually means we want to reduce volume of events as early as possible. If most of the events being processed are sent to a Destination by the first Route, this will spare all the other Routes and Pipelines wasted processing cycles and testing against whether filter criteria are met.

Prevent Function Creep

As a mirror principle, clone events as late as possible in the Routes. This will minimize the number of Functions acting on data, to the extent possible.

Leave No Data Behind

Create a catchall Route at the end of the list to explicitly route events that fail to match any Route filters.

Pipelines and Functions Logic

Don’t Overload Pipelines

Do not use the same Pipeline for both pre-processing and post-processing. This makes isolation and troubleshooting extremely difficult.

Extract or Parse by Desired Yield

If you need to extract one or just a few fields, use the Regex Extract Function. If you need to extract all or most of an event’s fields, use the Parser Function.

Use Function Groups for Legibility

Function groups might be helpful in organizing your Pipeline. These groups are abstractions, purely for visual context, and do not affect the movement of data through Functions. Data will move down the listed Functions, ignoring any grouping assignments.

Use Comments to Preserve Legibility

Comment, comment, comment. There is a lot of contextual information which might become lost over time as users continue to advance and add Routes and Pipelines to Cribl Stream. A good principle is to keep the design decisions as simple and easy to understand as possible, and to document the assumptions around each Route and Pipeline in comments as clearly as possible.

Create Expressions Around Fields with Non-Alphanumeric Characters

If there are fields with non-alphanumeric characters – e.g., `@timestamp` or `user-agent` or `kubernetes.namespace_name` – you can access them using `__e['<field-name-here>']`. (Note the single quotes.) For more details, see MDN's Property Accessors documentation. In any other place where such fields are referenced – e.g., in an Eval Function's Field names – you should use a single-quoted literal, of the form: `'<field-name-here>'`.

Specify Fields' Precedence Order in Expressions

In any Source that supports adding **Fields (Metadata)**, your **Value** expression can specify that fields in events should override these fields' values. E.g., the following expression's L->R/OR logic specifies that if an inbound event includes an `index` field, use that field's value; otherwise, fall back to the `myIndex` constant defined here: `` `${__e['index'] || 'myIndex'}` ``.

Break Up `_raw`

Consider avoiding the use of `_raw` as a temporary location for data. Instead, split out explicitly separate fields/variables.

Optimize PQ Using File Size

Consider using a smaller maximum file size in Persistent Queues settings, for better buffering.

Output Side

Although this might be obvious: Ship metrics out to a dedicated alerting/metrics engine (ELK, Grafana, Splunk, etc.)

Troubleshooting

Troubleshoot streams processing systems from right to left. Start at the Destination, and check for block status from the Destination back to the Source.

Don’t run health checks on data ports too frequently, as this can lead to false-positives errors.

18.2. Lookup Applications

18.2.1. Ingest-Time Lookups

Enriching Data in Motion

To enrich events with new fields from external sources (such as `.csv` files), we use Cribl Stream's out-of-the-box Lookup Function. Ingestion-time lookups are not only great for normalizing field names and values, but also ideal for use cases where:

- Fast access via the looked-up value is required. For example, when you don't have a `datacenter` field in your events, but you do have a `host-to-datacenter` map, and you need to search by `datacenter`.
- Looked-up information must be temporally correct. For example, assume that you have a highly dynamic infrastructure, and you need to resolve a resource name (e.g., a container name) to its address. You can't afford to defer this to search time/runtime, as the resource and its records might no longer exist.

To use large binary databases (like GeoIP `.mmdb` files) for Cribl Stream lookups, see Managing Large Lookups. To achieve faster lookups, use Cribl Stream's Redis Function.

Working with Lookups – Example 1

Let's assume we have the following lookup file. Given the field `conn_state` in an event, we would like to add a corresponding ingestion-time field called `action`.

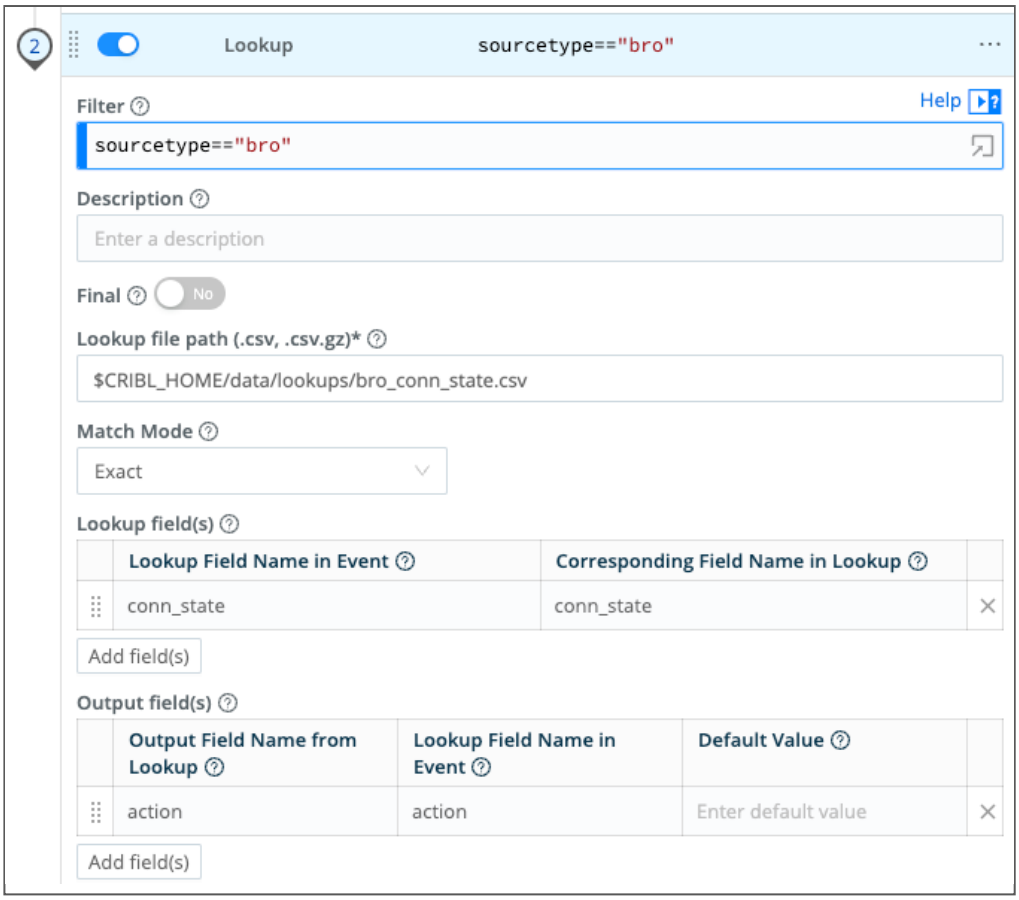
bro_conn_state.csv

```
action,"conn_state","conn_state_meaning"
dropped,S0,"Connection attempt seen, no reply."
allowed,S1,"Connection established, not terminated."
allowed,SF,"Normal establishment and termination."
blocked,REJ,"Connection attempt rejected."
allowed,S2,"Connection established and close attempt by originator seen (but no repl
allowed,S3,"Connection established and close attempt by responder seen (but no reply
allowed,RSTO,"Connection established, originator aborted (sent a RST)."
allowed,RSTR,"Established, responder aborted."
dropped,RSTOS0,"Originator sent a SYN followed by a RST, we never saw a SYN-ACK from
dropped,RSTRH,"Responder sent a SYN ACK followed by a RST, we never saw a SYN from tl
dropped,SH,"Originator sent a SYN followed by a FIN, we never saw a SYN ACK from the
dropped,SHR,"Responder sent a SYN ACK followed by a FIN, we never saw a SYN from the
allowed,OTH,"No SYN seen, just midstream traffic (a 'partial connection' that was no
```

First, make sure you have a Route and Pipeline configured to match desired events.

Next, let's add a **Lookup** function to the Pipeline, with these settings:

- **Lookup file path**: `$CRIBL_HOME/data/lookups/bro_conn_state.csv` (note that Environment variables are allowed in the path).
- **Lookup Field Name in Event** set to `conn_state`.
- **Corresponding Field Name in Lookup** set to `conn_state`.
- **Output Field Name from Lookup** set to `action`.
- **Lookup Field Name in Event** set to `action`.



Lookup Function to add `action` field

To confirm success, verify that this search returns expected results: `sourcetype="bro" action::allowed`. Change the `action` value as necessary.

Working with Lookups – Example 2

Let's assume we have the following lookup file, and given **both** the fields `impact` and `priority` in an event, we would like to add a corresponding ingestion-time field called `severity`.

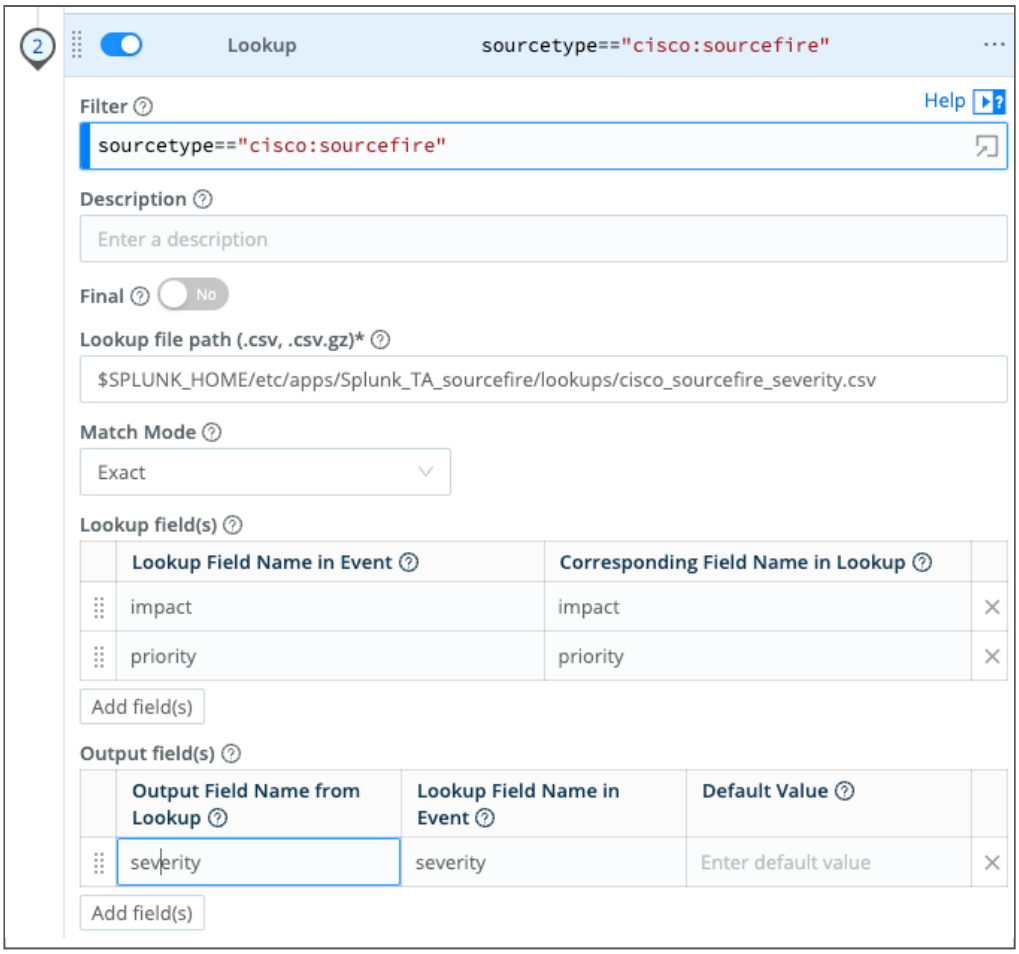
cisco_sourcefire_severity.csv

```
impact,priority,severity
1,high,critical
2,high,critical
3,high,high
4,high,high
0,high,high
"*",high,high
.....
"*",medium,medium
1,low,medium
2,low,medium
3,low,low
4,low,low
0,low,low
"*",low,low
1,none,low
2,none,low
3,none,informational
4,none,informational
0,none,informational
"*",none,informational
```

First, make sure you have a Route and Pipeline configured to match desired events.

Next, let's add a **Lookup** function to the Pipeline, with these settings:

- **Lookup file path**: `$SPLUNK_HOME/etc/apps/Splunk_TA_sourcefire/lookups/cisco_sourcefire_severity.csv` (note that Environment variables are allowed in the path).
- **Lookup Field Name(s) in Event** set to `impact` and `priority`.
- **Corresponding Field Name(s) in Lookup** set to `impact` and `priority`.
- **Output Field Name from Lookup** set to `severity`.
- **Lookup Field Name in Event** set to `severity`.



Lookup Function to add `severity` field

To confirm success, verify that this search returns expected results: `sourcetype="cisco:sourcefire" severity::medium`. Change the `severity` value as necessary.

18.2.2. Managing Large Lookups

This page offers a general approach to managing large lookup files. While Cribl Stream's Git integration normally helps manage configuration changes, large lookups are exceptions. In many cases, you might want to exclude these files from Git, to reduce excessive deploy traffic. This approach can also prevent Git Push commands from encountering large file errors.

Good scenarios for this approach are:

- Large binary files – like databases – which don't benefit from Git's typical efficient storage of only the deltas between versions. (With binary files, Git must replace the whole file for each new version.)
- Files updated frequently and/or files updated independent of Cribl Stream.
- Files replicated on many Worker Nodes.

The steps below assume access to a command line and (more importantly) to your OS' filesystem. Where you lack such access – for example, in a Cribl.Cloud deployment – load lookup files of all sizes via Cribl Stream's UI, as outlined in Lookups Library.

About the MaxMind GeoLite Example

We'll illustrate this with an example that often combines all three conditions: setting up the free, popular MaxMind GeoLite2 City database to support Cribl Stream's GeoIP lookup Function. This example anticipates a Cribl Stream production distributed deployment, where the GeoLite database is updated nightly across multiple Workers.

This example includes complete instructions for this particular setup. However, you can generalize the example to other MaxMind databases, and to other large lookup files – including large `.csv`'s that similarly receive frequent updates.

Reducing Deploy Traffic

The general approach for handling large lookups is:

- Do not place these files in the standard `$CRIBL_HOME/data/lookups`.
- Instead, place them in a `$CRIBL_HOME` subdirectory that's excluded from Git version control, through inclusion in the `$CRIBL_HOME/.gitignore` file. Deploying the files to the Leader Node and all desired Workers will require a manual procedure and will be required for the initial deployment as well as subsequent updates.

The example below uses `$CRIBL_HOME/state` subdirectory, which is already listed in the default `.gitignore` file that ships with Cribl Stream.

If you prefer, you can use a different path, which might be a path outside `$CRIBL_HOME`. If you choose this alternative, be sure to add that path to `.gitignore`.

However, Cribl recommends using a `$CRIBL_HOME` subdirectory like `$CRIBL_HOME/state`, because this inherits appropriate permissions and simplifies backup/restore operations.

Let's move on to the MaxMind GeoLite specifics.

Download and Extract the Database

To enable the GeoIP Function using the MaxMind GeoLite 2 City database, your first steps are:

1. Create a free MaxMind account, at the page linked above.
2. Log in to your MaxMind account portal and select **Download Databases**.
3. On the Download page, look for the database you want. (In this example, you'd locate the **GeoLite2 City** section.) Note the **Format: GeoIP2 Binary**, and select **Download GZIP**.

GeoLite2 City database: Download binary GZIP

4. Extract the archive to your local system.
5. Change to the directory created when you extracted the archive. This directory's name will correspond to the date you downloaded the file, so in the above `2020-10-06` example, you would use:
   `$ cd GeoLite2-City_20201006`

Copy the Database File to the Leader and Worker Nodes (Recommended)

In distributed deployments, Cribl recommends copying the MaxMind database separately to the Leader and all Worker Nodes. For example, placing it in the `$CRIBL_HOME/state` path minimizes the Git commit/deploy overhead for nightly updates to the binary database file.

Once in the database's directory, execute commands of this form:

```
$ scp *.mmdb <user>@<leader-node>:
$ scp *.mmdb <user>@<worker-node>:
```

Copy the file to each Worker in the Worker Group where you intend to use Cribl Stream's GeoIP Function.

The above commands copy the `.mmdb` database file into your user's home directory on each Node. Next, we'll move it to `$CRIBL_HOME/state` on each Node. Execute these commands on both the Leader and Worker Nodes:

```
$ sudo mv ~/*.mmdb <$CRIBL_HOME>/state/
$ sudo chown -R cribl:cribl <$CRIBL_HOME>/state/
```

Now that the database is in place, your Pipelines can use the GeoIP Function to enrich data. In the Function's **GeoIP file (.mmdb)** field, insert the complete `$CRIBL_HOME/state/<filename>.mmdb` file path.

Copy the Database File Only to the Leader (Alternative)

In smaller deployments, you might choose to copy this MaxMind database only to the Leader Node, and to let Workers receive updates via Git commit/deploy. In this case, the final commands above might look like this:

Shell

```
$ sudo cp ~/*.mmdb /opt/cribl/groups/<group-name>/data/lookups/
$ cd /opt/cribl/groups/<group-name>/data/lookups/
$ sudo chown cribl:cribl *.mmdb
```

Automatic Updates to the MaxMind Database

Use the GeoIP Update program MaxMind provides to automatically update your databases. See MaxMind's Automatic Updates for GeoIP2 and GeoIP Legacy Databases documentation for details.

You'll need two modifications specific to Cribl Stream:

- GeoIP Update must be set up on the Leader, and on each Worker in any Group that uses GeoIP lookups.

- You need to configure GeoIP Update to point to the directory where the MaxMind database file resides. The program uses a configuration file named `GeoIP.conf` and you utilize the `DatabaseDirectory` parameter to define the location for storing the database file. See MaxMind's GeoIP.conf documentation for details.
  For example, the default setting in `GeoIP.conf` writes output to `/usr/local/share/GeoIP`. You must change this setting to the path where your databases actually reside. If you're using the recommended architecture above, you'd set: `DatabaseDirectory <$CRIBL_HOME>/state/`.

A Cribl Worker restart is necessary for the new data to be loaded. Even though the update happens automatically, the cached version loaded at the Worker's startup persists until the Worker is restarted. To ensure that updated MaxMind databases are used for processing, schedule regular Worker restarts to coincide with the automatic updates. This applies to all Cribl Stream deployments, both on-prem and Cribl.Cloud.

Memory Considerations

Storage aside, large lookup files can also require additional RAM on each Worker Node that processes the lookups. For details, see Memory Sizing for Large Lookups.

18.2.3. Lookups As Filters For Masks

You can make your data architecture more maintainable by using Lookups to route and transform events within Cribl Stream. This use case demonstrates an unusual solution, but one that served one Cribl customer's particular goals (which might overlap with yours):

- Ingest many (hundreds of) different `sourcetype/index` field combinations.
- Send all this data through a common Pipeline.
- Stack four Mask Functions in the Pipeline.
- Evaluate and process each `sourcetype/index` field combination **only** within its applicable Mask Functions – either two or three Masks per combination.

This last restriction reduces latency, by preventing Mask Functions from evaluating non-applicable events, simply to ignore them.

Just to reiterate, this use case outlined here responded to this customer's requirements – one Pipeline combining multiple Mask Functions, for many `sourcetype/index` combinations. More typically, you'd use multiple Pipelines to process different `sourcetype/index` combinations.

To enable this approach, the example below centralizes masking logic for multiple conditions in a Lookup table and corresponding Lookup Functions. The Lookup's output filters events to the applicable Mask Functions. Specifically, we'll show how to instruct Cribl Stream to:

- Check for a particular `index/sourcetype` combination in each event, and
- Based on that combination, determine which Masks to apply to that event.

Design the Lookup

To use a lookup as a filter, you'd start by creating a comma-separated lookup table in this format, and adding it to Cribl Stream:

index_tracker.csv

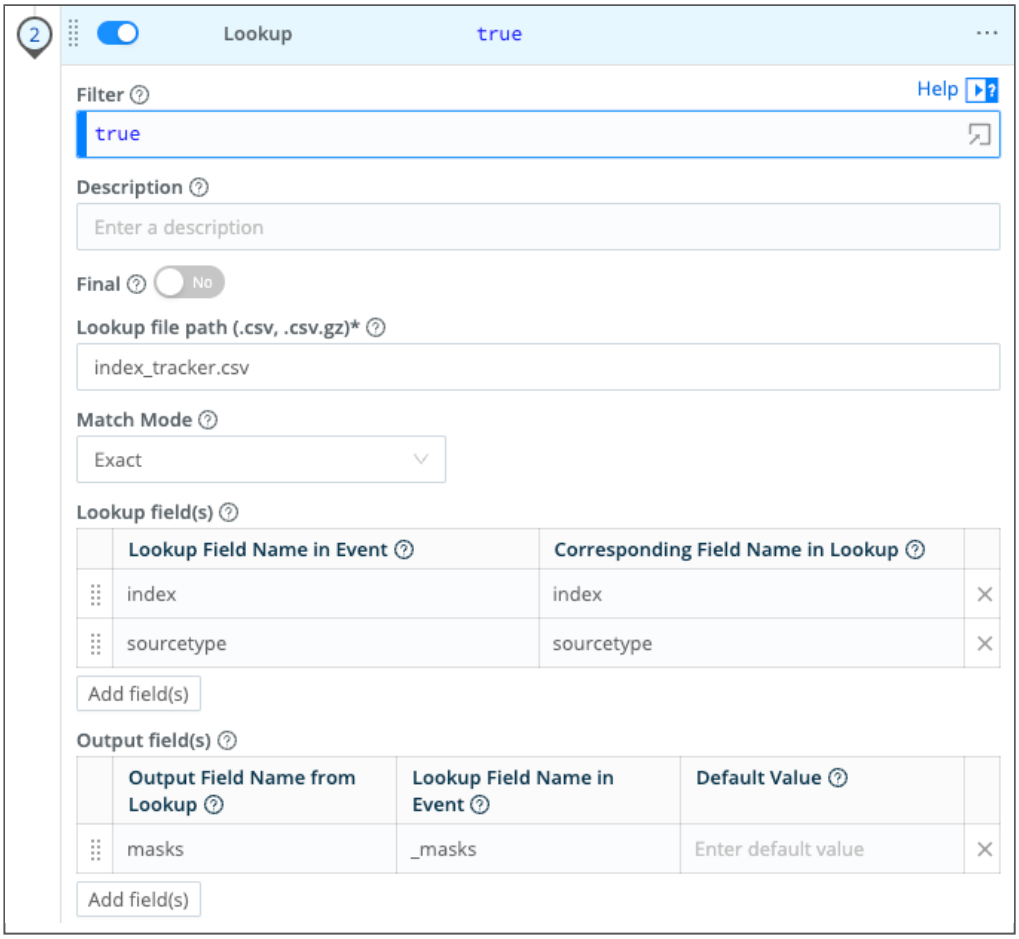
```
index,sourcetype,masks
apache_common, sourcetypec, ssn|credit_card|auth_token
syslog,sourcetypeb,ssn|auth_token
weblog,sourcetypea,auth_token|bearer_token
```

Below the header, each row specifies an index, a sourcetype, and (in the third column) a pipe-delimited list of applicable masks.

To make this example work, the table must have only **one** row for each index/sourcetype combination. (This unusual restriction is particular to this scenario.) So, as you build out the lookup table, you cannot add new masks for **existing** index/sourcetype combinations by appending new rows. Instead, you must modify the third column of the existing rows.

Configure the Pipeline

Create a Cribl Stream Pipeline with a Lookup Function configured like this, pointing to your lookup table:



Lookup Function's configuration

This Function keys against both the `index` and `sourcetype` fields. When it finds a matching combination, it adds a new key-value pair to your event for future filtering.

The key of that key-value pair (namely, `__masks`) starts with a double underscore, to make it a Cribl Stream internal field. This convention ensures that the key-value pair will **not** get passed along to the Destination.

However, you might prefer to export the key-value pair. For example, you might want a Splunk Destination to index the list of masks applied to a given event, alongside that event. (This approach applies to many forensic

use cases.) If so, remove the double underscore from the above Function's **Lookup Field Name in Event** value, and from the subsequent Filter expressions for each Mask Function.

Each Mask Function has a JavasScript Filter that breaks the pipe-delimited string into an array, and determines whether the tag for that type of mask (e.g., `bearer_auth`) is in the `__masks` key-value pair. If so, it applies the mask processing. If not, the event moves on to the Pipeline's next Mask Function.

Here are the four Mask Functions below the Lookup Function:

Mask Functions

In this particular example, the pipe-delimited mask tags in the lookup table's third column match the Mask Functions' names, as well as matching their **Filter** conditions. This is just for simplicity – the Functions could have any names, as long as the **Filter** expressions match the tags.

18.2.4. Lookups And Regex Magic

Regular expressions are not just for field extractions – they can also be used inside lookup tables, and in Functions, to replace and manipulate values within fields. Let's walk through a Pipeline that demonstrates four different ways to leverage regular expressions in Cribl Stream.

Why Lookup Tables Matter

When organizations use host naming standards, it is easy to understand things like regions, availability zones (AZs), IP addresses, and more. For example, consider an Amazon host called:

```
ec2-35-162-133-145.us-west1-a.compute.amazonaws.com
```

This is an EC2 host with a (dashed) IP address `35-162-133-145`, in the `us-west1` region, in Availability Zone `a`. You can also see the domain: `compute.amazonaws.com`.

While we can understand the enriched host names, we don't know which indexes to route the data to, nor which sourcetypes to assign to the events, without looking up this information from another source. Doing so is often a huge challenge for organizations. To solve this challenge, let's combine Regex Extract, Lookup, and Eval Functions with some sample events to demonstrate the power of Cribl Stream.

Sample Events

The events below have timestamps broken out, but no indexes, sourcetypes, or other details have been assigned yet:

1	2021-02-05 20:18:31.286 -06:00	_raw: Feb 06 2021 02:18:31.286 GMT: ec2-35-162-133-145.us-west1-a.compute.amazonaws.com: cloud-init[2929]: url_helper.py[DEBUG]: [0/1] open 'http://145.133.162.42/latest/api/token' with {'url': 'http://1... The Regex Extract Function

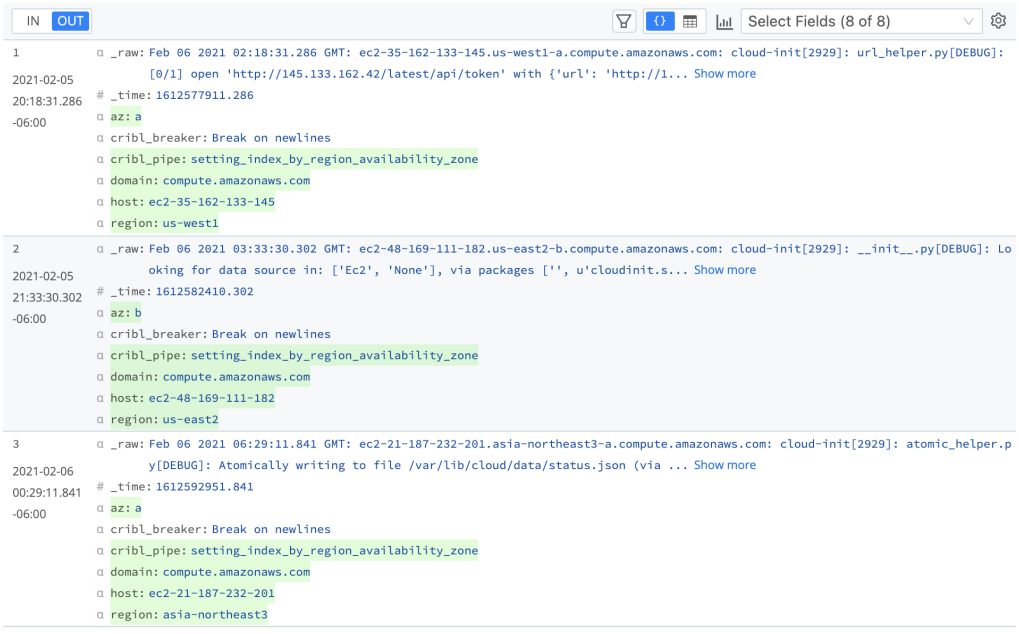
Before we can assign an index or sourcetype, we need to extract the `host`, `region`, `az`, and `domain` fields from the events. We can use a Regex Extract Function with this regular expression to extract all four fields:

```
GMT:\s+(?<host>[^.]+)\.(?<region>\w+-\w+\d+)-(?<az>[^.]+)\.(?<domain>[^:]+):
```

Here's that Regex Extract in a Cribl Stream Pipeline:

Results of the Regex Extract Function

On the **OUT** tab of Cribl Stream's Preview pane, the extracted fields of `az`, `domain`, `host`, and `region` now appear below the `_raw` event. You can use these extracted fields for searching in your preferred search solution.



Lookups

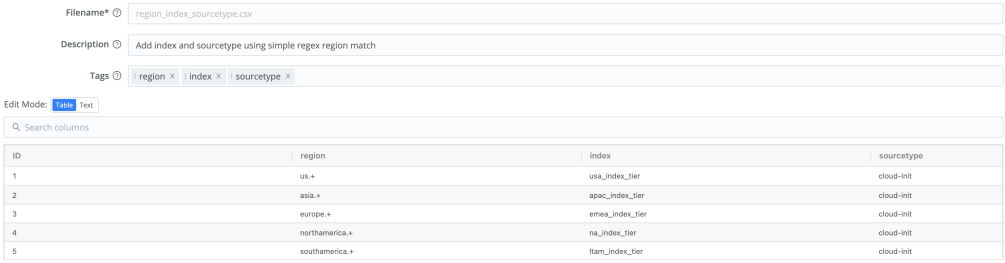
We still need to determine the index and sourcetype. Cribl Stream's Lookup Function enriches events with external fields. We'll use it with the newly extracted `region` field to assign an `index` and `sourcetype` to these events.

Lookup File

First, we need to create a lookup table for the Function to reference. For this, we'll use regex again.

In the table below, five simple regular expressions map the extracted `region` field to the appropriate `index` and `sourcetype`. For example, the region `us-west1-a` starts with `us`, so it matches the first regular expression: `us.+`

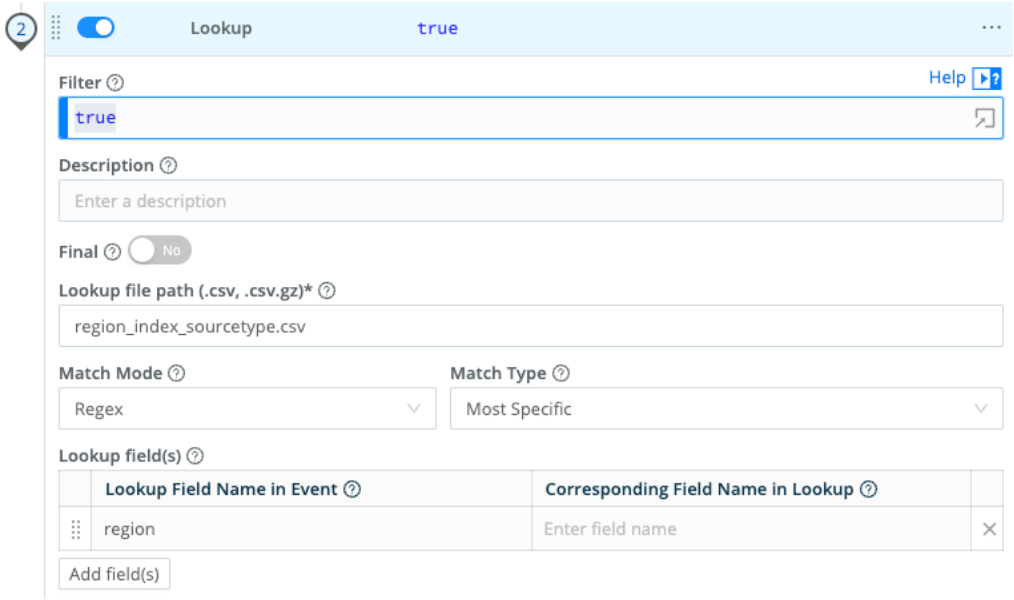
We use this lookup table's first row to assign an index of `usa_index_tier`, and a sourcetype of `cloud-init`, to each matching event. The region patterns in the table's four remaining rows work the same way.



ID	region	index	sourcetype
1	us.+	usa_index_tier	cloud-init
2	asia.+	apac_index_tier	cloud-init
3	europe.+	emea_index_tier	cloud-init
4	northamerica.+	na_index_tier	cloud-init
5	southamerica.+	ltam_index_tier	cloud-init

Lookup Function

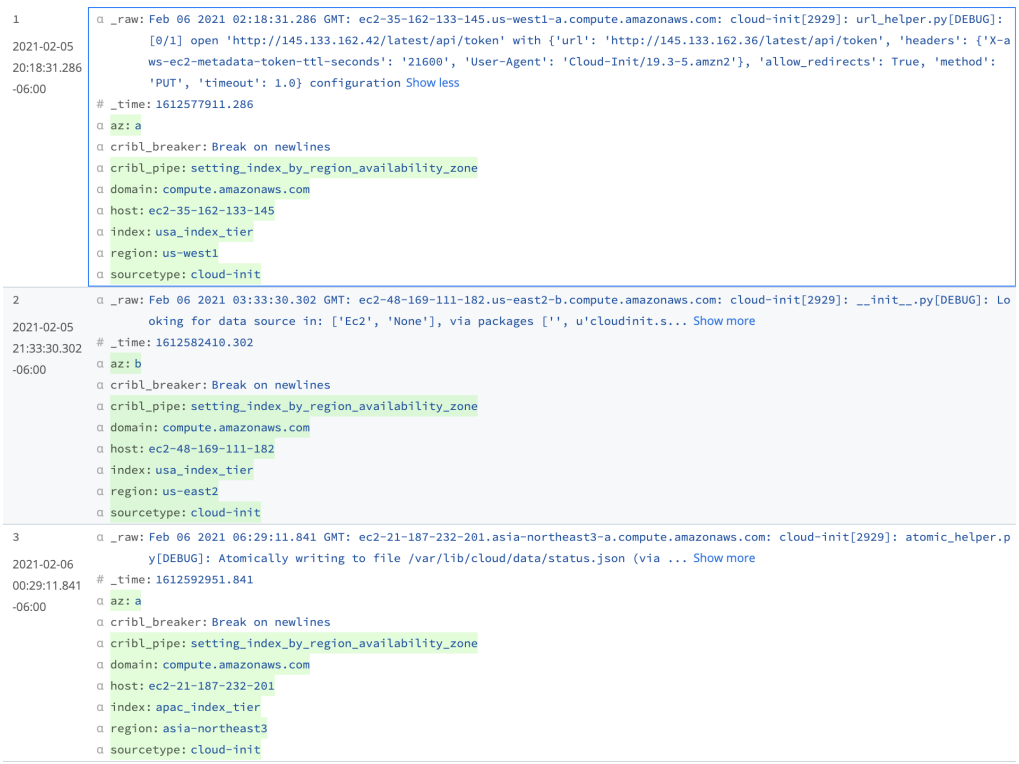
With the lookup table saved as `region_index_sourcetype.csv`, the Lookup Function below matches the events' extracted `region` field against the regular expressions, and returns the matching `index` and `sourcetype`.



There's actually more here than meets the eye. Note that we've specified no **Output Fields**. From the Lookup Function's documentation, we know this means that the Function will default to outputting **all** fields in the lookup table. So we get the contents of both remaining columns in the table we saw above: `index` and `sourcetype`.

Results of the Lookup Function

With the Lookup Function added to our Pipeline, the Preview pane's **OUT** tab shows that the `index` and `sourcetype` are now added to each event.

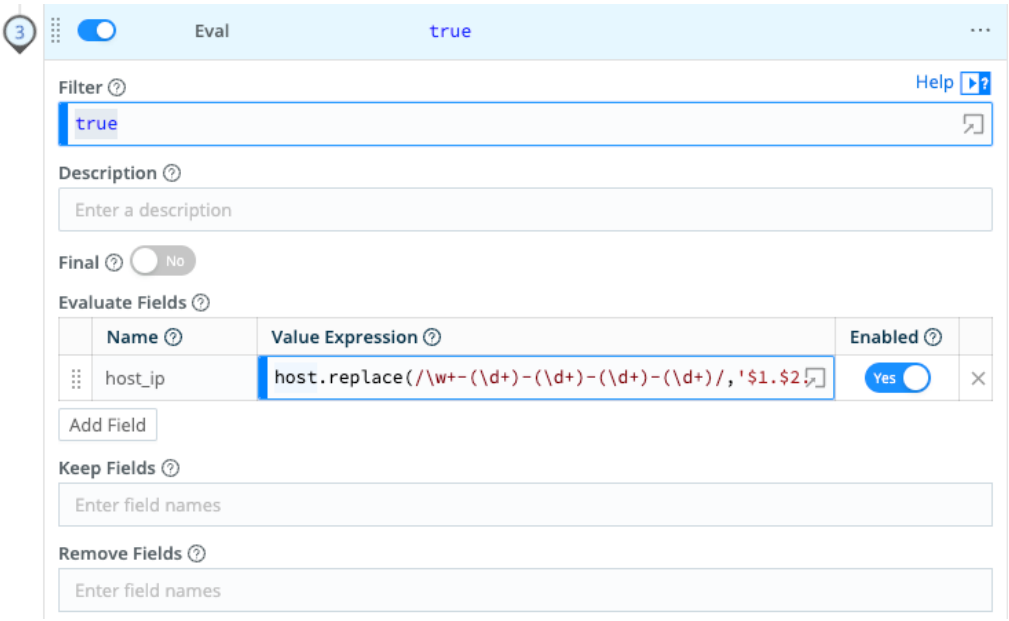


Getting Host IP Address from Host Name

Since the IP address is present in the `host` field, we can create the `host_ip` field using an Eval Function with this replace method:

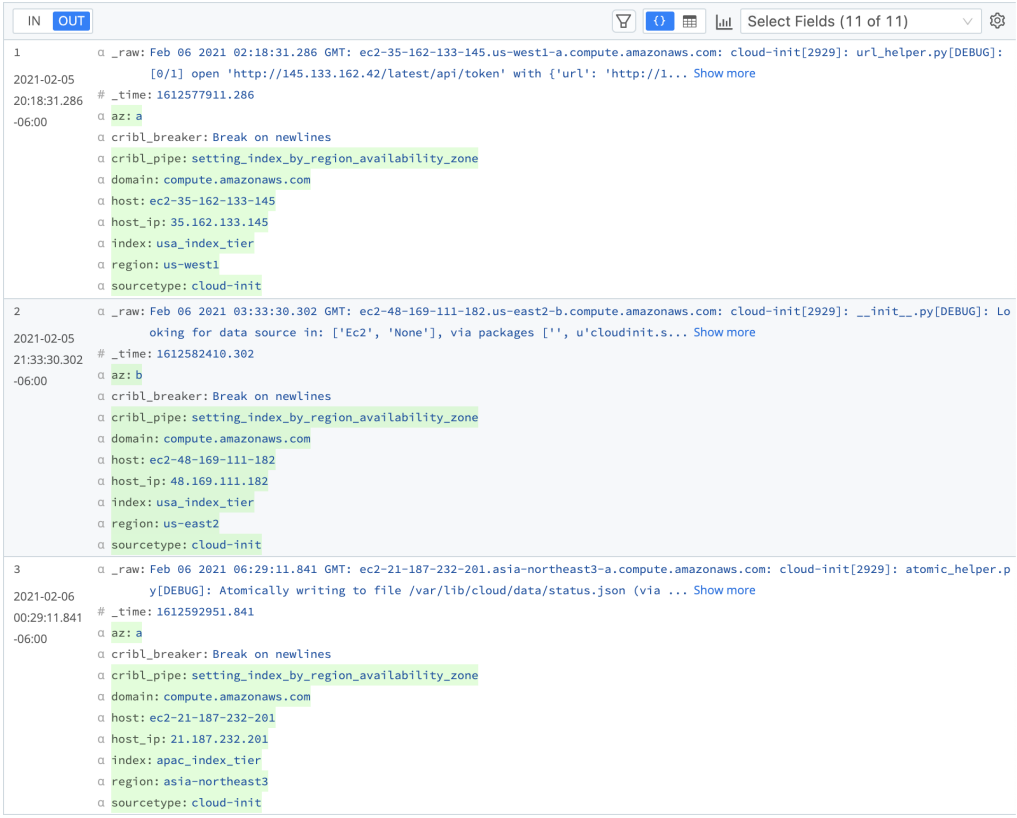
```
host.replace(/\w+-(\d+)-(\d+)-(\d+)-(\d+)/,'$1.$2.$3.$4')
```

This regular expression uses capture groups and pulls the four IP octets present in the hostname to build the `host_ip`. These four capture groups are noted as `$1.$2.$3.$4`, respectively. This method is very fast, and removes the need to perform a DNS lookup from the `host` field to get the host's IP address. Magic!



Results of the Eval Function and Replace Method

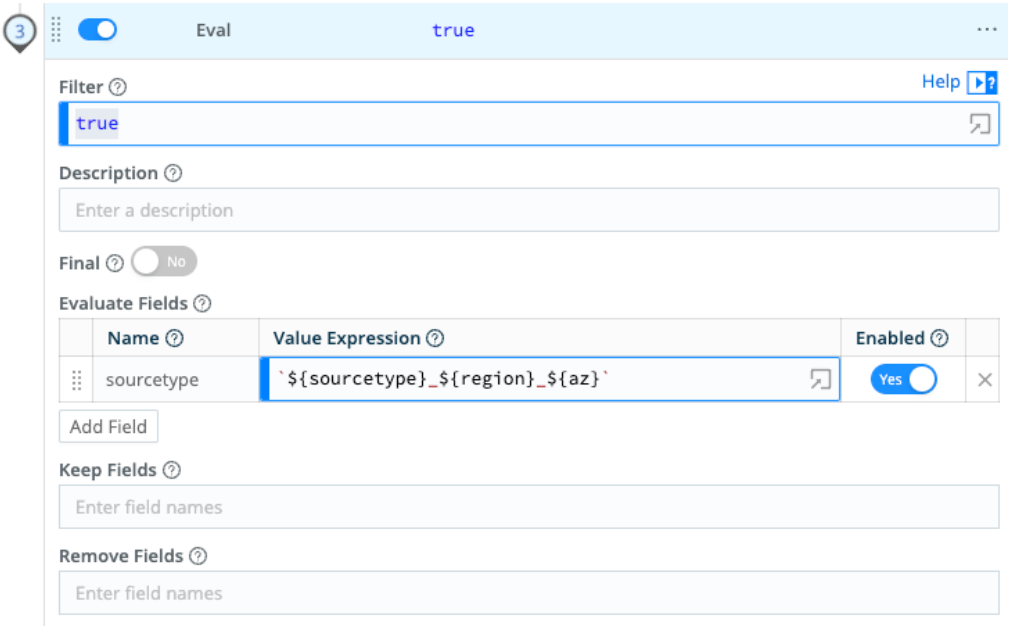
The `host_ip` field is now added to the events, displayed below `host`:



Customizing the Sourcetype

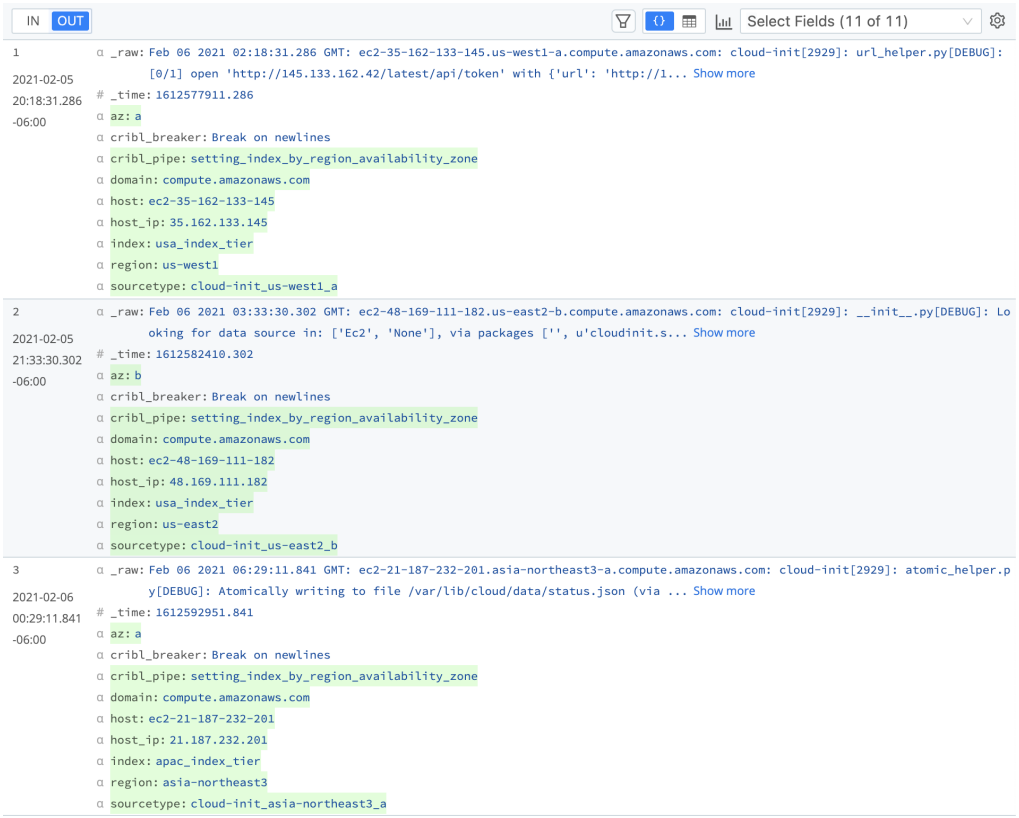
Finally, let's put some sense into the `sourcetype` field, using another Eval Function. By combining the values of the `${sourcetype}_${region}_${az}`, the sourcetype becomes `cloud-init_us-west1_a` – so now you can understand much more about the sourcetype at a glance.

Examine this Eval Function's value expression, taking careful note of the backticks (` `) and braces ({ }) that surround the field names, and the underscore (_) that separates them.



Results of the Eval Function to Combine Values

Take a look at the updated sourcetypes, and enjoy exploring Cribl Stream with your new knowledge!



Try This at Home

Below you'll find the lookup table, Pipeline, and sample events demonstrated in this use case. Create the lookup file first, and then import the Pipeline. (The order matters, because the Pipeline import depends on the lookup table's presence.)

Lookup Table

To create the lookup table in Cribl Stream's UI, select **Knowledge** > **Lookups**, then click **New Lookup File** and select **Create with Text Editor**.

Copy and paste in the header and rows listed below, then save the result as: `region_index_sourcetype.csv`.

region_index_sourcetype.csv

```
region,index,sourcetype
us.+,usa_index_tier,cloud-init
asia.+,apac_index_tier,cloud-init
europe.+,emea_index_tier,cloud-init
northamerica.+,na_index_tier,cloud-init
southamerica.+,ltam_index_tier,cloud-init
```

Pipeline

Below is an export of the whole Cribl Stream Pipeline presented here. Import this JSON to get a Pipeline named: `setting_index_by_region_availability_zone.json`.

Magic Pipeline

```
{
  "id": "setting_index_by_region_availability_zone",
  "conf": {
    "output": "default",
    "groups": {},

```

18.2.5. Updating Lookups In Multiple Packs

Lookups provide a flexible way to enrich events en route to their Destinations. You can use Lookups in multiple Packs to share complex configurations and workflows across multiple Worker Groups, or across organizations.

Here, we will be walking you through a particularly challenging setup: What happens if you have a very large Lookup that requires frequent updates? To make it more interesting, what happens if the same Lookup is being used in multiple Packs? In the first part, we will discuss how to update a Lookup file in multiple Packs and the second, we will address the best way to set up a large Lookup file that needs frequent updates.

Updating Lookups in Multiple Packs

Manually updating multiple Packs with an ever-evolving Lookup table is a non-starter, so let's examine a better alternative.

Create the Lookup File in the Worker Group

The first step is to create a Lookup file in the Worker Group. For ease of sharing and use, make sure the Lookup file is not located in the Pack.

Our example Lookup file is `host_destination_test.csv`.

Validate that the Lookup File Is on the Worker Node

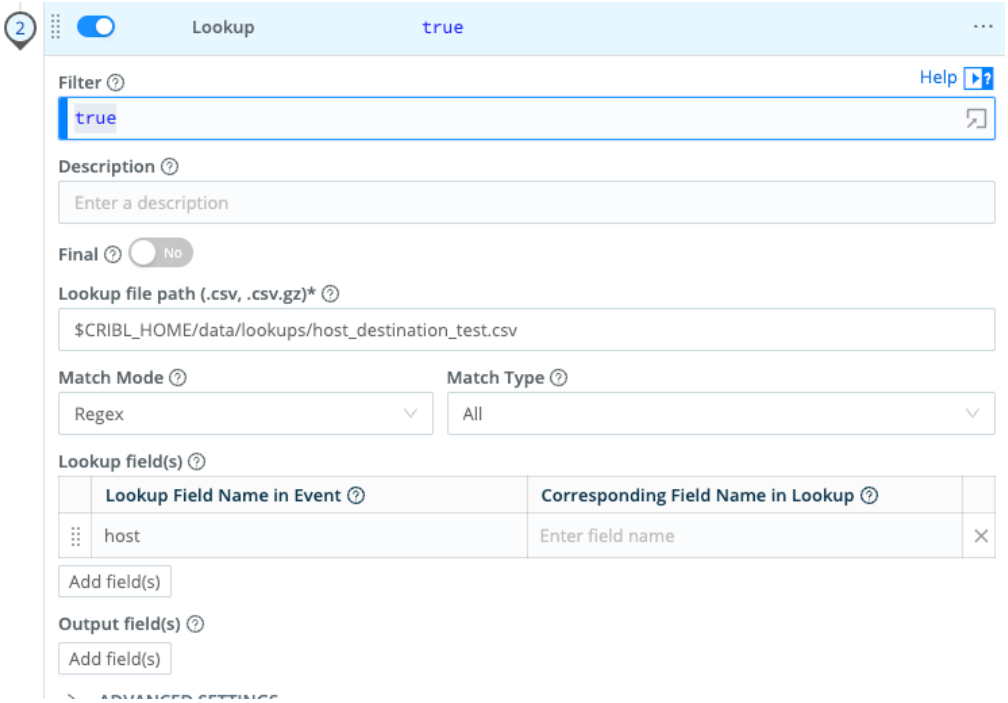
After you **Commit** and **Deploy** to propagate the Lookup table to the Workers, validate that you can view the Lookup.

In our example, the path is: `$CRIBL_HOME/data/lookups/host_destination_test.csv`.

Point the Pack(s) to the Lookup File

In your Pack(s), add a Lookup Function and point it to the Worker Node Lookup file location. In our example, the path is: `$CRIBL_HOME/data/lookups/host_destination_test.csv`.

Do not use point the Pack to the Leader Lookup File location, such as: `$CRIBL_HOME/groups/<your group>/data/lookups/host_destination_test.csv`. Also, do not point it directly to the Pack Lookup file, such as `host_destination_test.csv`.



Lookup Function's configuration

Setting up a Lookup File with Dynamic Updates

In this part, we will walk through the best way to set up a large Lookup file that requires frequent updates.

We will use the Cribl Lookups APIs to:

Update a Lookup file → Load it to the Leader Node's `$CRIBL_HOME/groups/<Group-Name>/data/lookups` subdirectory → Commit and Deploy → The changes in the Lookup file will propagate to the Worker Nodes that belong to this Worker Group.

The advantage of this approach, compared to updating the Lookup files on the Worker Nodes direcly, is that you do not need to know all the `IP` address and `hostnames` of the Worker Nodes. It's also more efficient to update in one location.

The sequence of the API calls are as follows:

- `PUT` the Lookup into the Leader Node's `$CRIBL_HOME/groups/<Group-Name>/data/lookups` subdirectory.
- `PATCH` the Lookup (with updates) into Leader Node's `$CRIBL_HOME/groups/<Group-Name>/data/lookups` subdirectory.
- `POST` to commit and push the new Lookup table to the Worker Nodes in the Worker Group.
- `PATCH` to deploy the changes.

Store the Lookup Table on the Leader Node

To set up a Lookup table that can be updated dynamically, upload it and store it on the Leader Node. In our example, we stored the file in: `/opt/host_destinations.csv`.

PUT the Lookup into the Worker Group

In this step, we use the Cribl Lookup API to `PUT` the Lookup into the Worker Group. Run the following in your terminal:

```
curl -X PUT "http://192.168.56.254:9000/api/v1/m/default/system/lookups?filename=hos
-H "Authorization: Bearer <your token>" -H 'Content-Type: text/csv'
--data-binary '@/opt/host_destination.csv'
```

Response:

```
filename":"host_destination.csv.kmtVCQs.tmp","rows":11,"size":245
```

PATCH the Lookup

Using the Cribl Lookup API, we use the temporary file `host_destination.csv.kmtVCQs.tmp` from the prior step as the input to our `PATCH` command:

```
curl -X PATCH "http://192.168.56.254:9000/api/v1/m/default/system/lookups/host_desti
-H "accept: application/json" -H "Authorization: Bearer <your token>"
-H "Content-Type: application/json"
-d '{"id":"host_destination.csv","fileInfo":{"filename":"host_destination.csv.kmtVCQ
```

Response:

```
{"items":[{"id":"host_destination.csv","size":245}],"count":1}
```

Commit the Lookup to the Worker Group

In our example, we are using the `default` Worker Group. We are also using the API selectively to commit only the Lookup table to the `default` Worker Group. For details, see Selectively Commit Changes.

```
curl -X POST "http://192.168.56.254:9000/api/v1/version/commit"
-H "accept: application/json" -H "Authorization: Bearer <your token>"
-H "Content-Type: application/json"
-d '{"message":"automation@cribl:commit","group":"default","files":["groups/default/(
```

Response:

```
{"items":
[{"branch":"master","commit":"8377ec8bbd21f460d9554f671dc79d217d991afd","root":false,"su
{"changes":2,"insertions":2,"deletions":0},"files":{"modified":
["groups/default/data/lookups/host_destination.csv","groups/default/data/lookups/host_de
```

Save the commit number in the response payload for the next step:
`8377ec8bbd21f460d9554f671dc79d217d991afd`

Deploy the Lookup to the Worker Nodes

In this final step, we use `PATCH` to deploy the commit to the Worker Nodes. Note the value of the commit from the previous step.

```
curl -X PATCH "http://192.168.56.254:9000/api/v1/master/groups/default/deploy"
-H "accept: application/json" -H "Authorization: Bearer <your token>"
-H "Content-Type: application/json"
-d '{"version":"8377ec8bbd21f460d9554f671dc79d217d991afd"}'
```

Response:

```
{"items":[{"description":"Default Worker
Group","tags":"default","configVersion":"8377ec8bbd21f460d9554f671dc79d217d991afd","work
```

18.2.6. Updating Lookups With A REST API

This page documents a technique for uploading, committing, and deploying Lookup files with a REST API. In this use case, an external team modifies the Lookup file nightly. Our procedure describes a method for deploying the modified file to the Worker Groups.

As an alternate method, you can also use the Cribl API to upload a Lookup file.

1. Create the Lookup table.

Create a Lookup table and store it on the Leader Node. In this example, the path and filename are `/opt/host_destinations.csv`.

2. Send the PUT command to upload the modified Lookup file.

Note the location of the external updated CSV file: `@/opt/host_destination.csv`. Then send the following command:

```
curl -X PUT "http://192.168.56.254:9000/api/v1/m/default/system/lookups?filename=hos
-H "Authorization: Bearer <token> -H 'Content-Type: text/csv'
--data-binary '@/opt/host_destination.csv'
```

You'll receive a JSON object response like this:

```
{"filename":"host_destination.csv.kmtVCQs.tmp","rows":11,"size":245}
```

Bearer Tokens

See bearer token for information on incorporating your bearer token into the cURL command.

3. Send the PATCH command to update the Lookup file on the Worker Group.

We use the temporary file (`host_destination.csv.kmtVCQs.tmp`) from the `PUT` command as input to the `PATCH` command.

```
curl -X PATCH "http://192.168.56.254:9000/api/v1/m/default/system/lookups/host_desti
-H "accept: application/json" -H "Authorization: Bearer <token> -H "Content-Type: ap
-d '{"id":"host_destination.csv","fileInfo":{"filename":"host_destination.csv.kmtVCQ
```

You'll receive a JSON object response like this:

{"items":[{"id":"host_destination.csv","size":245}],"count":1}

4. Send the POST command to commit the modified Lookup file.

In the following example, we use `default` as the Worker Group name.

Note the second value from the commit: `8377ec8bbd21f460d9554f671dc79d217d991afd`. We'll need it for the `deploy` command.

Note that the following command only commits the Lookup table in the `default` Worker Group. See our Version Control documentation for more information on selectively committing changes.

```
curl -X POST "http://192.168.56.254:9000/api/v1/version/commit"
-H "accept: application/json" -H "Authorization: Bearer <token> -H "Content-Type: ap
-d '{"message":"automation@cribl:commit","group":"default","files":["groups/default/
```

Response:

```
{"items":
[{"branch":"master","commit":"8377ec8bbd21f460d9554f671dc79d217d991afd","root":false,"su
{"changes":2,"insertions":2,"deletions":0},"files":{"modified":
["groups/default/data/lookups/host_destination.csv","groups/default/data/lookups/host_de
```

5. Send the PATCH command to deploy the modified Lookup file.

Once again, we use `default` as the Worker Group name.

Note the second value from the commit in the deploy version: `8377ec8bbd21f460d9554f671dc79d217d991afd`.

```
curl -X PATCH "http://192.168.56.254:9000/api/v1/master/groups/default/deploy"
-H "accept: application/json" -H "Authorization: Bearer <token> -H "Content-Type: ap
-d '{"version":"8377ec8bbd21f460d9554f671dc79d217d991afd"}'
```

Response:

```
{"items":[{"description":"Default Worker
Group","tags":"default","configVersion":"8377ec8bbd21f460d9554f671dc79d217d991afd","work
```

18.3. Sampling Applications

18.3.1. Sampling

Sampling at Ingest-Time

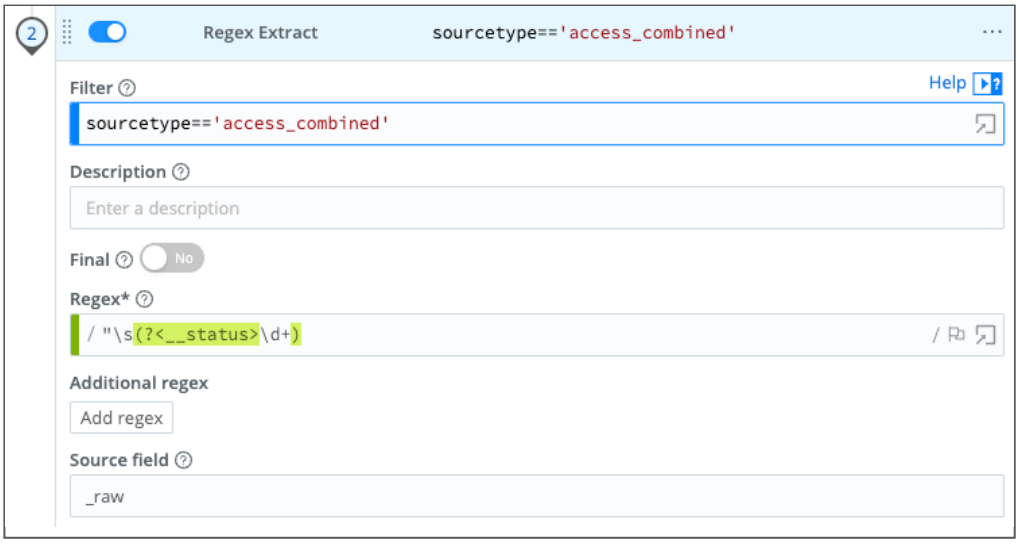
Let's say that you wanted to analyze and troubleshoot with **highly verbose/voluminous** data – for example, CDN logs, ELB Access Logs, or VPC Flows – but you were concerned about storage requirements and search performance. With Sampling, you can bring in enough samples that your analysis remains statistically significant, and also do all the necessary troubleshooting.

See the example below, or see more details in Access Logs and Firewall Logs.

Sampling Example

Let's use the out-of-the-box **Sampling** function to sample all events from `sourcetype=='access_combined'` where `status` is `'200'`. We'll sample these at 5:1 (and all other events at 1:1). This should lower the volume of all verbose successes (`200`s), but still bring in **all** potentially erroneous events (`400`s, `500`s, etc.) that can be used for troubleshooting.

- First, make sure you have a Route and Pipeline configured to match desired events.
- Next, let's add a **Regex Extract** Function to extract the status field from `_raw`, and let's call the resulting field `__status`. Remember, fields that start with `__` are special fields in Cribl Stream, and can be used anywhere in a Pipeline.



Extracting the `__status` field

Next, let's add a **Sampling** function, and scope it to all events where `sourcetype=='access_combined'`. Let's apply a filter condition of `__status == 200`, and a Sample Rate of `5`.

Sampling success responses

To confirm that sampling works, compare the event count of all `200`s before and after.

Each time an event goes through the **Sampling** function, an index-time `sampled::<rate>` field is added to it. You can use this field in your statistical functions, as necessary.

18.3.2. Sample Logs

Collecting samples of the event data you plan to work with in Cribl Stream can make your Cribl Stream onboarding experience even quicker and more efficient than if you don't.

When you set out to collect sample data, first decide whether to collect before or after the sending agent processes it.

- If you can, collect the data **after** the agent processes it. Then you can set up Cribl Stream Pipelines more accurately the first time. The best option is live capture with Cribl Stream. Next best is gathering files.
- If the only practical option is to collect data **before** it reaches the agent, that works, too. (This will usually be a matter of gathering files.) Since setting up Pipelines is an iterative process, you can still arrive at an optimal setup even if it takes a bit longer.

Regardless of what sending agent you're using, either the Capturing Data with Cribl Stream or the Gathering Original Files section will apply.

Beyond that, there are two supplemental sections: one about how to export data from Elasticsearch, and the other about exporting from Splunk. Of course, these are only two possibilities in a long list of sending agents. If you are using a sending agent that's not covered here, please join us on Cribl's Community Slack at https://cribl-community.slack.com/ and share your questions about collecting sample logs.

Describing Sample Data

For every group of sample files, create a `README` file which includes:

- Sourcetype (e.g., the type of log you're collecting samples from).
- Originating app or appliance.
- Delivery mechanism (e.g., syslog, Filebeat, Splunk UF, or something else).
- Whether the was data collected before or after processing by the agent.
- A brief description of the data.

Capturing Data with Cribl Stream

Though not always the easiest, this is the best option, because samples are captured exactly as they will look when handed off to Cribl Stream in production. You'll set Cribl Stream up as a passthrough which gets samples "right off the wire" and dumps them to DevNull.

Configuring Sources

In Cribl.Cloud:

Check the landing page to see whether the pre-defined Sources (Elastic, syslog, and Splunk, among others) are sufficient for your needs. If you need others, configure them using ports in the range 20000-20010.

Or, if your deployment is on-prem or in a private cloud:

Download and install Cribl Stream.

```
$ mkdir /opt; cd /opt
$ curl -Lso - $(curl https://cdn.cribl.io/dl/latest-x64) | tar zxvf -
$ cribl/bin/cribl start
```

Open `localhost:9000` in a browser.

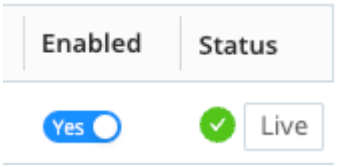
Configure the Source you need. For simplicity, use port 1024 or higher. (If you must use lower ports you'll need to follow a different installation procedure.)

Directing Data to Cribl Stream

Point your sending agent at the Cribl Stream Source you created above. How you do this depends on what sending agent you use. See this Cribl blog for a how-to that focuses on Cribl.Cloud but also applies to on-prem deployments.

Live-capturing Data

Once data has begun flowing, click the **Live** button for your chosen Source.



The **Live** button initiates capture

Grab 100 to 500 events, at a minimum. Try to capture as much variety as possible, even if that requires multiple captures.

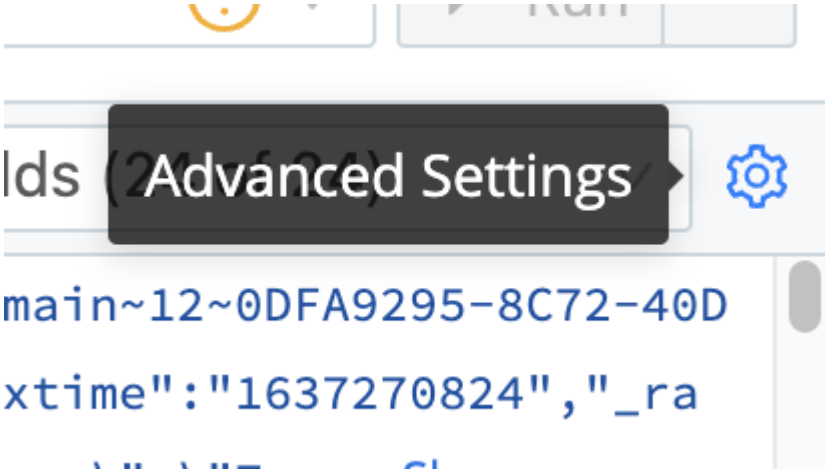
When finished, click **Save as Sample File**. Note the file name (and rename if you like). Close the sample window.

In the **Routing** > **Data Routes** tab, select the Route you are using.

Your sample file(s) should appear in the **Sample Data** pane on the right. If the **Sample Data** pane does not appear, type] (right square bracket) key to unhide it.

For each file you want to download:

- Click the file name.
- Click the (gear icon) for **Advanced Settings**:



The **Advanced Settings** icon

- In the resulting pop-up, select **Save** > **NDJSON**.
- Once the file finishes downloading:
  - Move the file into the directory you've created for that set of sample files - which should also include a `README` as described above.
- When all files have been moved into the directory, compress the directory as a `.tgz` archive.

Gathering Original Sample Files

If live-capturing data with Cribl Stream is impractical for you, gather sample files that the sending agent has not yet processed, using the following general workflow:

- Create a directory in which to store samples.
- Copy a sample file into the new directory.
- Repeat until all desired sample files have been copied.
- Add a `README` file to the directory, as described above.
- Redact sensitive content in the data, if required.
- Archive the directory (e.g., with a command like `tar -czf samples.tgz samples`) for portability; send it to your Cribl representative, if you are working with one.

Exporting Data from a Platform

If your data is in Elastic or Splunk, and you can neither capture live nor obtain original samples, use one of the following export procedures. Then complete the workflow above, using the exported files instead of original sample files.

If Splunk uses props and/or transforms to modify the `_raw` data of your logs, you **must** obtain your sample data from the source, because the exported data will **not** include events in their original form.

Exporting Data from Elastic

1. Elastic often transforms the data it stores. To the extent possible, note any particulars about the shape and content of the original data before it reached Elastic. Take special care to record the effects of any Logstash pipeline configs on the sample data. Record all this information in the `README` you create. This will make it easier to create the most effective filters in Cribl Stream.
2. Install the Logstash plugins logstash-input-elasticsearch and logstash-output-csv:

```
$ cd /opt/logstash
$ bin/logstash-plugin install logstash-input-csv
$ bin/logstash-plugin install logstash-output-csv
```

3. Compose a query to retrieve the data you want. Be sure to include the `message` field, whose value should be the original event.
4. Substitute your query for the placeholder in the following config snippet, and save the snippet as `output-csv.conf`:

```
input {
 elasticsearch {
    hosts => "elastic-host:9200"
    index => "target-index"
    query => '
  {"query": {
    # your ES query here
        }
      }
    }
}}'
  }
}
output {
  csv {
    fields => ["message", "field1", "field2"]
path => "/home/user/ES-sourcetype-export.csv"
  }
}
```

5. Run your export operation:

```
/opt/logstash/bin/logstash -f output-csv.conf
```

Exporting Data from Splunk

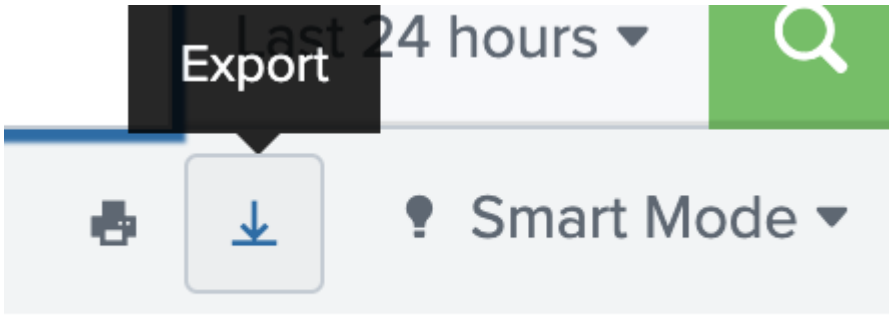
You can export logs from Splunk using the GUI or command line.

In the Splunk GUI:

1. Run a search that returns the appropriate sample of target logs. Adjust the number of samples by appending `| head <number_of_samples_desired>` to your search. For example, to grab 100 samples of Cisco ASA firewall data:

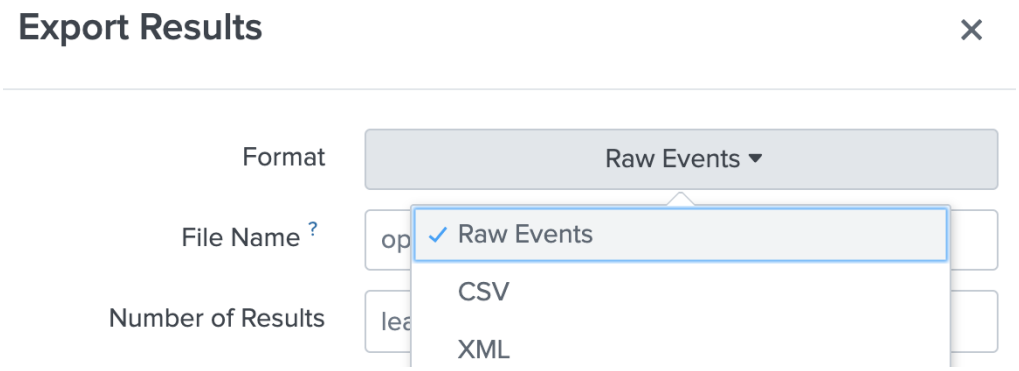
```
index=firewall sourcetype=cisco:asa | head 100
```

2. Adjust the search as needed to exclude or include the events you want to send.
3. When your search is collecting the desired samples, export the search results:



Exporting search results

4. Then select **Raw Events**, name the file after the source or sourcetype, and save.



Exporting raw events

Or, in the Splunk CLI:

You can obtain the same results as described in the previous section using commands like the following.

```
% $SPLUNK_HOME/bin/splunk search "index=firewall sourcetype=cisco:asa | head 100" -ou
```

18.3.3. Access Logs: Apache, ELB, CDN, S3, Etc.

Recipe for Sampling Access Logs

Access logs are extremely common. They're often emitted by web servers or similar/related technologies (proxies, loadbalancers, etc.), and tend to be highly voluminous. Typical examples include Apache access logs, and CDN logs such as those from Amazon Cloudfront, Amazon S3 Server Access Logs, AWS ELB Access Logs, etc.

For large installations, bringing everything into an analytics tool is often so cost-prohibitive (in terms of storage, resources, and/or license) that most users don't even bother. However, some of the logs contain relevant information when looked at individually (such as errors). The much larger majority contains relevant information when looked at in the aggregate (e.g., successes to determine traffic patterns).

It would be great if we could find a middle ground. With the Sampling Function, you can! Specifically, you can:

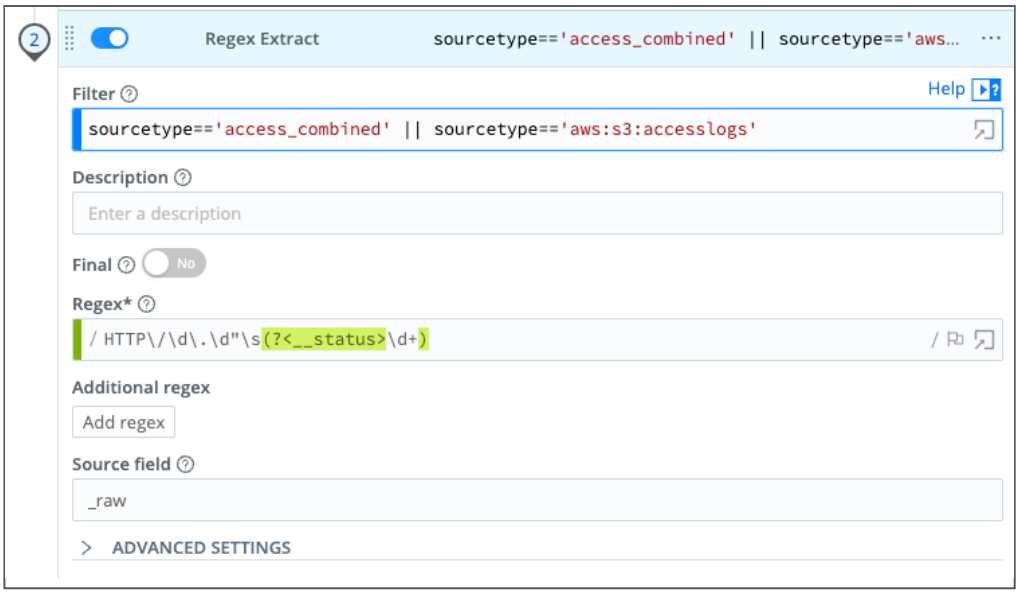
- Ingest enough sample events from the majority category that your aggregate analysis remains statistically significant.
- Ingest **all** events from the minority categories, and perform troubleshooting and introspection with full-fidelity data.

Using `status` as the Sampling Condition

Most of the access logs (including the ones mentioned above) have very similar formats. One quick way to sample is to look at the value of the `status` field. `2XX`s indicate success and tend to be, by far, the most common ones – with `200` being the top. **Therefore, `200` is the perfect candidate for sampling**. All other statuses occur much less frequently, indicate conditions that often need to be looked at, and can be brought in with full fidelity.

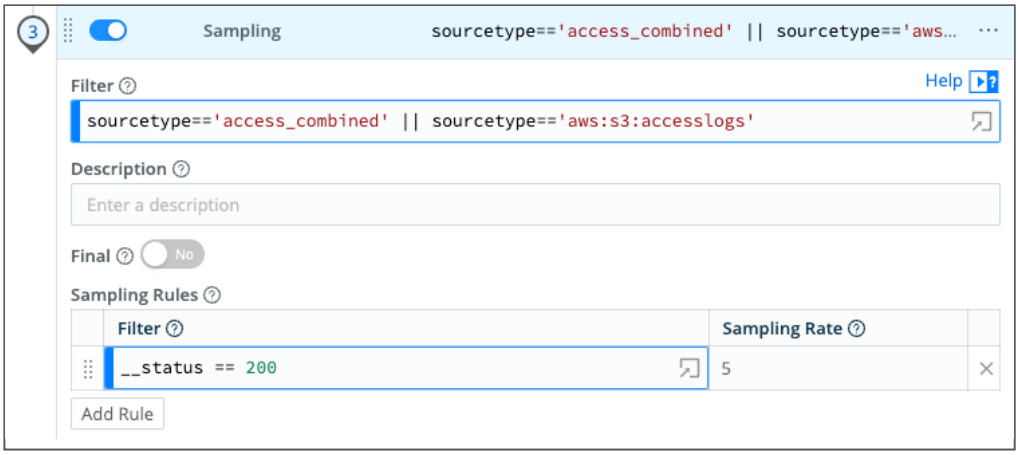
Sample Status 200 at 5:1

1. Add a **Regex Extract** Function that looks at these sourcetypes: `sourcetype=='access_combined' || sourcetype=='aws:s3:accesslogs'`
2. Configure that Function to extract a field called `__status` with this regex: `/HTTP\/\d\.\d"\s(?<__status>\d+)/`



Defining the Regex Extract Function

3. Add a Sampling Function to sample `5:1` when `__status==200`.
4. Save.



Sampling success reponses

Note About Sampling

Each time an event goes through the **Sampling** Function, an index-time `sampled::<rate>` field is added to it. Use this field in your statistical Functions, as necessary.

Other Sourcetypes

Examples of other sourcetypes that will benefit from sampling, but might need a different `__status` extraction regex:

Sourcetype	Filter Expression
Amazon Cloudfront Access Logs	`sourcetype=='aws:cloudfront:accesslogs'`
Amazon ELB Access Logs	`sourcetype=='aws:elb:accesslogs'`

18.3.4. Firewall Logs: VPC Flow Logs, Cisco ASA, Etc.

Recipe for Sampling Firewall Logs

Firewall logs are another source of important operational (and security) data. Typical examples include Amazon VPC Flow Logs, Cisco ASA Logs, and other technologies such as Juniper, Checkpoint, or pfSense.

As with Access Logs, bringing in **everything** for operational analysis might be cost-prohibitive. But sampling with Cribl Stream can help you:

- Ingest enough sample events from the majority category that your aggregate analysis remains statistically significant. E.g., sample all `ACCEPT`s at `5:1`.
- Ingest **all** events from the minority categories, and perform troubleshooting and introspection with full-fidelity data. E.g., bring in all `REJECT`s.

Sampling VPC Flow Logs

AWS' VPC Flow Logs feature enables you to capture information about the IP traffic going to and from network interfaces in your VPC. Flow Log data can be published to Amazon CloudWatch Logs and Amazon S3.

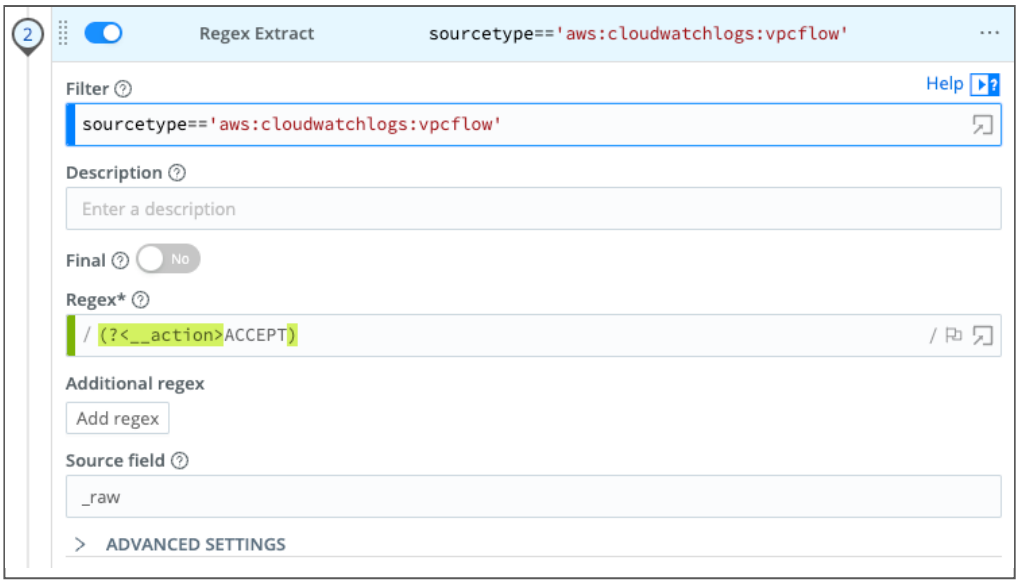
Typical VPC Flow Logs look like this:

Flow Log Records for Accepted and Rejected Traffic

```
2 123456789010 eni-abc123de 172.31.16.139 172.31.16.21 20641 22 6 20 4249 1418530010
2 123456789010 eni-abc123de 172.31.9.69 172.31.9.12 49761 3389 6 20 4249 1418530010 1
```

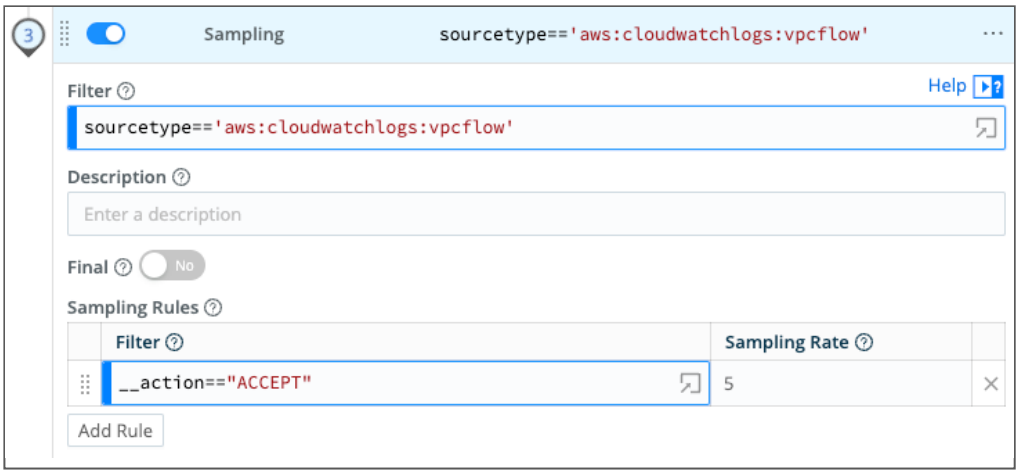
Let's use a **very simple** Filter condition and only look for `ACCEPT` events:

1. Add a **Regex Extract** Function that looks at: `sourcetype=='aws:cloudwatchlogs:vpcflow'`
2. Configure that Function to extract a field called `__action` with this regex: `/(?<__action>ACCEPT)/`



Extracting the `__action` field

3. Add a **Sampling** Function to sample `5:1` when `__action=="ACCEPT"`.
4. Save.



Sampling ACCEPT events

Note About Sampling

Each time an event goes through the Sampling Function, an index-time field is added to it: `sampled: <rate>`. It's advisable that you use that in your statistical functions, as necessary.

Other Sourcetypes

Other sourcetypes that will benefit from sampling, but might need a different `__action` extraction regex:

Sourcetype	Filter Expression
Cisco ASA Logs	`sourcetype=='cisco:asa'`
Related sourcetypes to consider sampling:	`sourcetype=='cisco:fwsm'` `sourcetype=='cisco:pix'`

18.4. Transformation Applications

18.4.1. Code Function Examples

The Code Function is a powerful way to transform events without needing to write a custom function. Using JavaScript methods such as `map`, `reduce`, `forEach`, `some`, and `every` is possible.

Cribl still recommends that you use Cribl Stream's basic, built-in Functions, like Eval, as much as possible. But these use cases demonstrate some basic ways to use the new Code Function to solve questions asked in the Cribl's Slack Community.

Basic Examples

Example Event Data

The first several examples below use the following JSON object as a sample event. You can copy and paste this event into Cribl Stream's **Sample Data** pane. Add the `Do Not Break` Ruleset to your Source, select the `noBreak1MB` Event Breaker, and under your Source's **Advanced Settings**, enable `Parse JSON Event`.

```
{
  "cpus": [
    {"number": 1, "name": "CPU1", "value": 2.3},
    {"number": 2, "name": "CPU2", "value": 3.1},
    {"number": 3, "name": "CPU3", "value": 5.1},
    {"number": 4, "name": "CPU4", "value": 1.3}
  ],
  "arch": "Intel x64"
}
```

Accessing Fields in an Event

To access a field inside an event, you can use the `__e` special variable. The `__e` prefix allows for access to the `(context)` event inside a JavaScript expression. For example, if you want to access the extracted field `field-name`, use the following syntax:

```
__e['field-name']
```

In other words, think of your code executing in a context like this:

```
function(__e: Event) {
 // your code here
}
```

Eval a Field

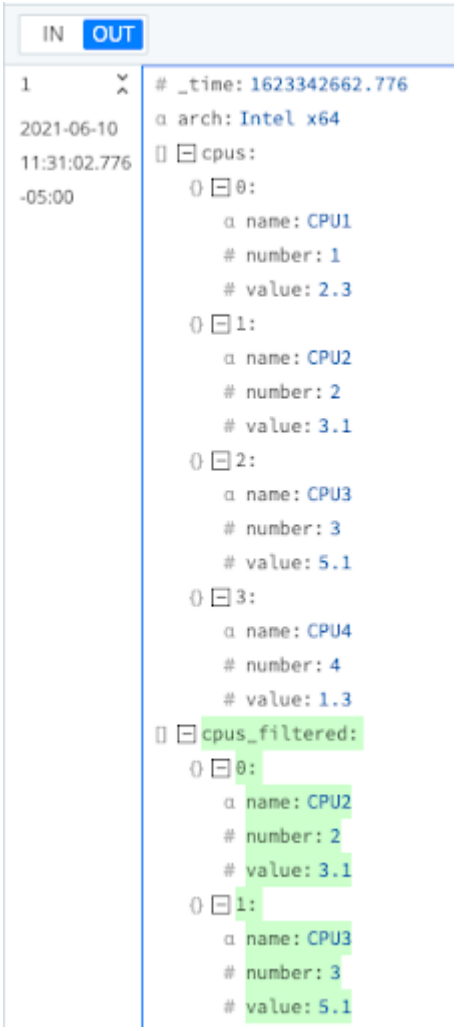
To create a new field, it is as simple as assigning the field to a value. For example, if you want to create a field `test` with the value `Hello, Goats!`, use the following syntax:

```
__e['test'] = 'Hello, Goats!'
```

JSON Filter

To filter the `cpus` array inside the event, you can use the `filter` function to keep only certain values, based on a logic condition. In the example below, only entries where the value is greater than or equal to `3` are kept, and placed into a new field called `cpus_filtered`.

```
__e['cpus_filtered'] = __e['cpus'].filter(entry => entry.value >= 3)
```

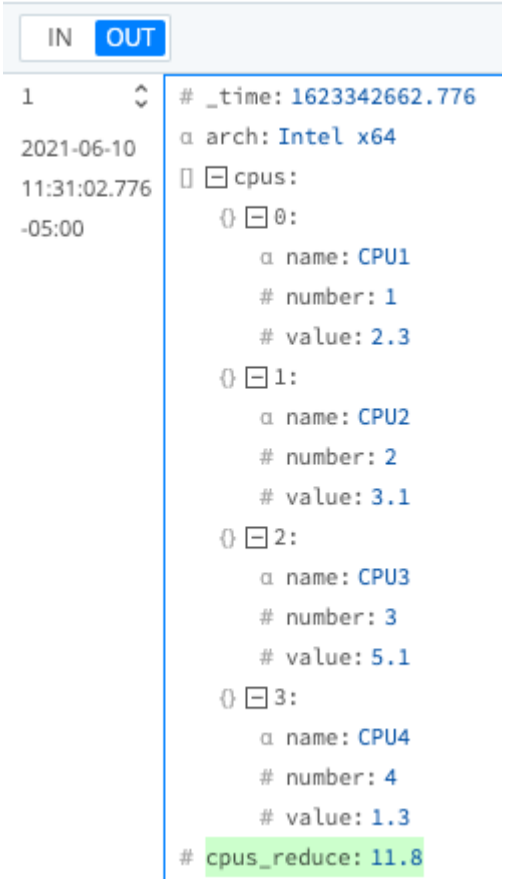


Code Function example: JSON Filter

Reduce

The `reduce` method allows you to summarize data across an array, with a returned accumulator value. In the example below, a new field, `cpus_reduce`, will be created with a value of `11.8`.

```
__e['cpus_reduce'] = __e['cpus'].reduce((accumulator, entry) => accumulator + entry.
```



Code Function example: Reduce

Some/Every

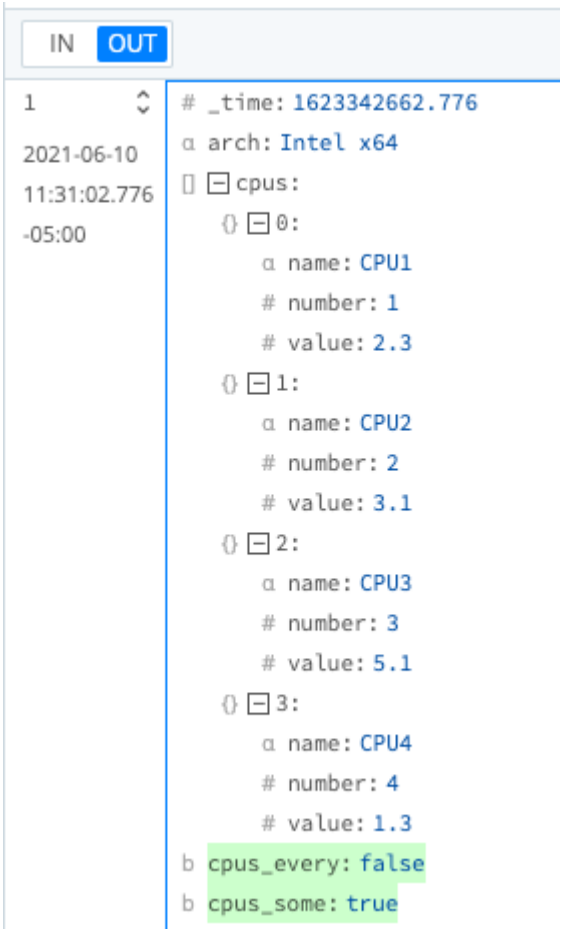
The `some` and `every` methods return a boolean result (`true`/`false`).

The `some` method checks that there is at least one logic validation that returns `true`. In the example below, `cpus_some` would be set to `true` because there is at least one object with a value greater than or equal to `3`.

```
__e['cpus_some'] = __e['cpus'].some(entry => entry.value >= 3)
```

The `every` method checks that every entry in the array returns `true`. If so, the result is `true`; otherwise, this returns `false`. In the example below, the value for `cpus_every` would be `false`, because not all values in the event are greater than or equal to `10`.

```
__e['cpus_every'] = __e['cpus'].every(entry => entry.value >= 10)
```



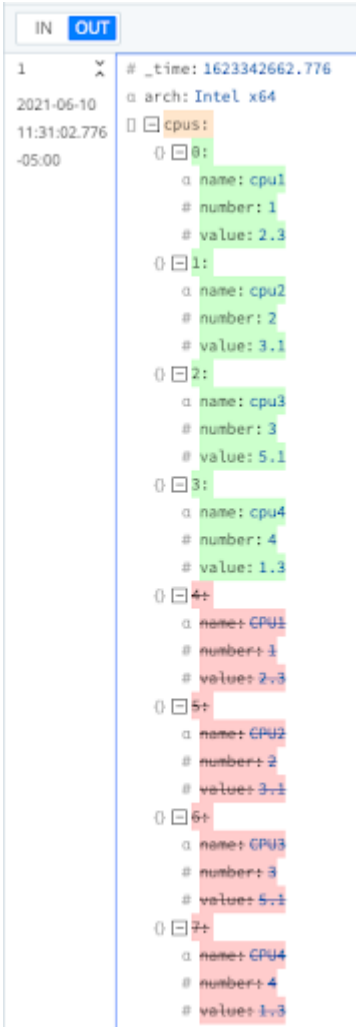
Code Function example: Some/Every

Advanced Examples

Transform a Specific Field

In this example, each `cpus` member will have its `name` field transformed to lowercase. Object.assign is used to keep the original object, while assigning the `name` field to the desired value.

```
__e['cpus'] = __e['cpus'].map(entry => Object.assign(entry, {'name': entry.name.toLo
```

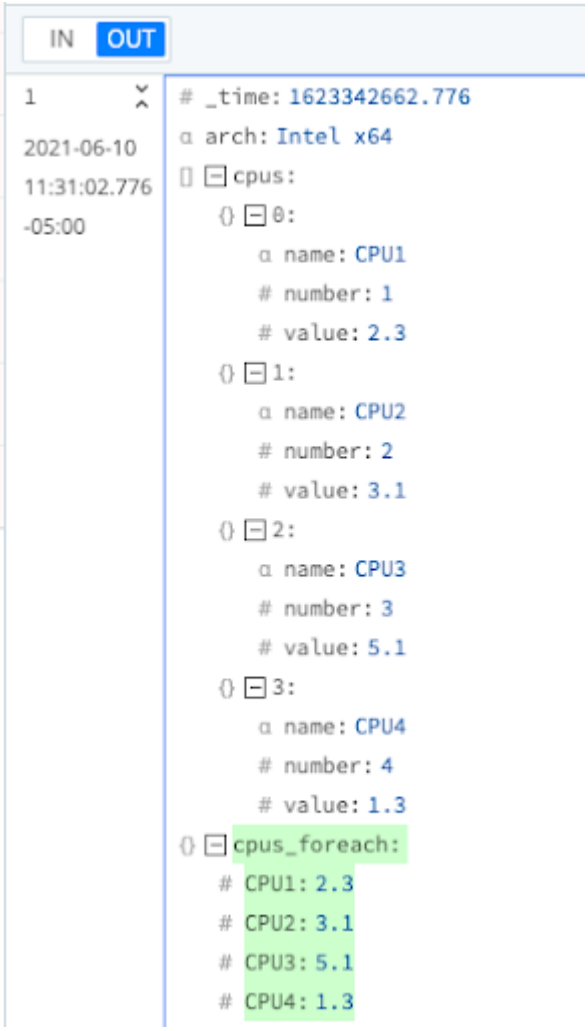


Code Function example: Transform a Field

forEach

The `forEach` method loops over each element of an array. However, unlike the `map` method, it does not return the value, and it requires a separate temporary variable for result collection.

```
let test = {};
__e['cpus'].forEach((entry, index) => test[entry.name] = entry.value);
__e['cpus_foreach'] = test;
```



Code Function example: forEach

You could also accomplish the same result by replacing the middle line above with the `map` method below:

```
__e['cpus'].map(item => test[item.name] = item.value);
```

Building a New Array

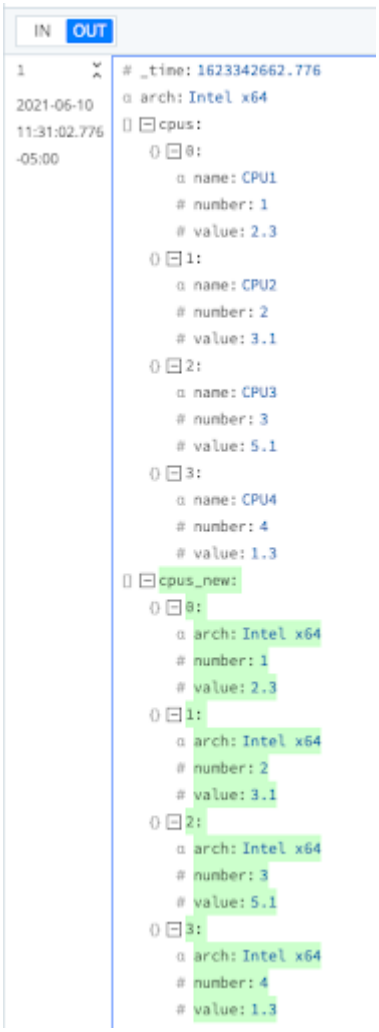
In this example, we create a new array to include some of the original values from each object in the `cpus` array, but we also dynamically inject a new field containing the `arch` field (CPU architecture) from the original event's top level.

```
__e['cpus_new'] = __e['cpus'].map(entry => {
    const container = {};

   for (const [key, value] of Object.entries(entry)) {
        container[key] = value;
    }

   container['arch'] = __e['arch'];

   delete container.name;
    return container;
})
```



Code Function example: Build a new array

Managing and Troubleshooting Code Execution

Cribl Stream provides the following options for tuning the logic you build with the Code Function.

Logging

Users can access the log messages generated by their Function from the **Preview Log**.

Log messages from a Code Function

Debugging

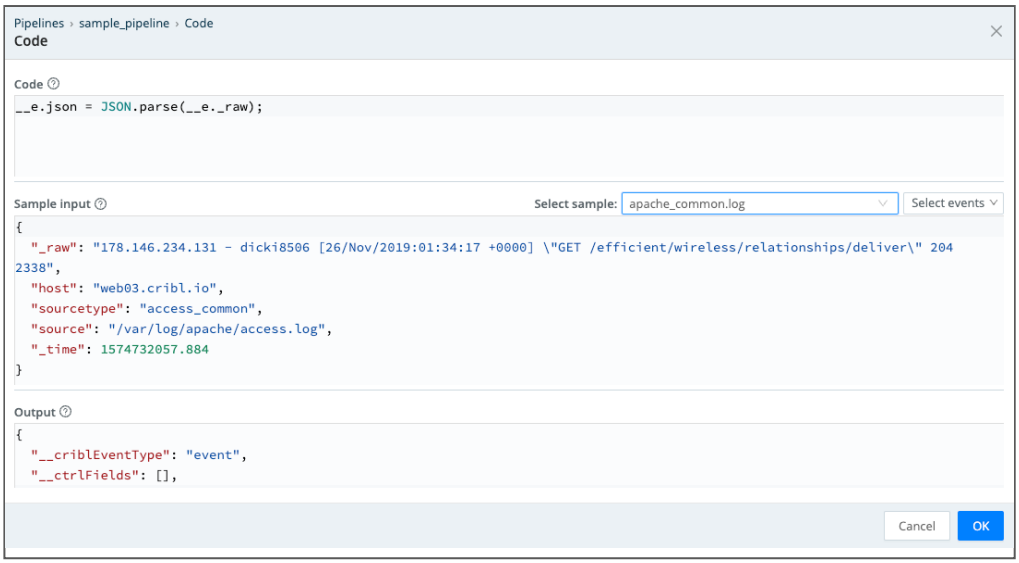
The Code Function's execution context defines a helper function called `debug` that can be used for debugging purposes.

Messages logged by this `debug` helper function are shown in the Preview Log by default.

You can also route these messages to regular logs, although this requires setting the Function's log level (`func:code`) to `debug`.

Previewing

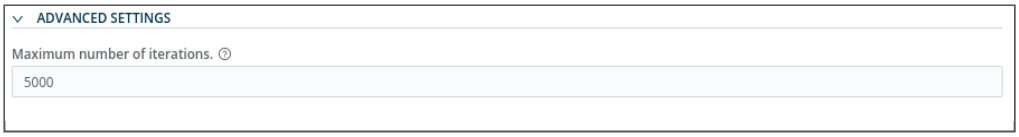
By using the expanded editor, users can run the expression against a sample event, and can preview the transformation:



Previewing a Code Function's transformation of an event

Infinite-Loop Protection

The Code Function keeps watching user-defined functions to detect infinite loops that would cause processing to hang. To limit the number of iterations allowed per instance of your Code Function, adjust the **Advanced Settings > Maximum number of iterations** option. This defaults to `5,000`; the maximum number allowed is `10,000`. Once the limit is reached, the Code Function will stop processing whatever is after the statement that exhausted the allowed maximum.



Infinite-Loop protection in a Code Function

Loops

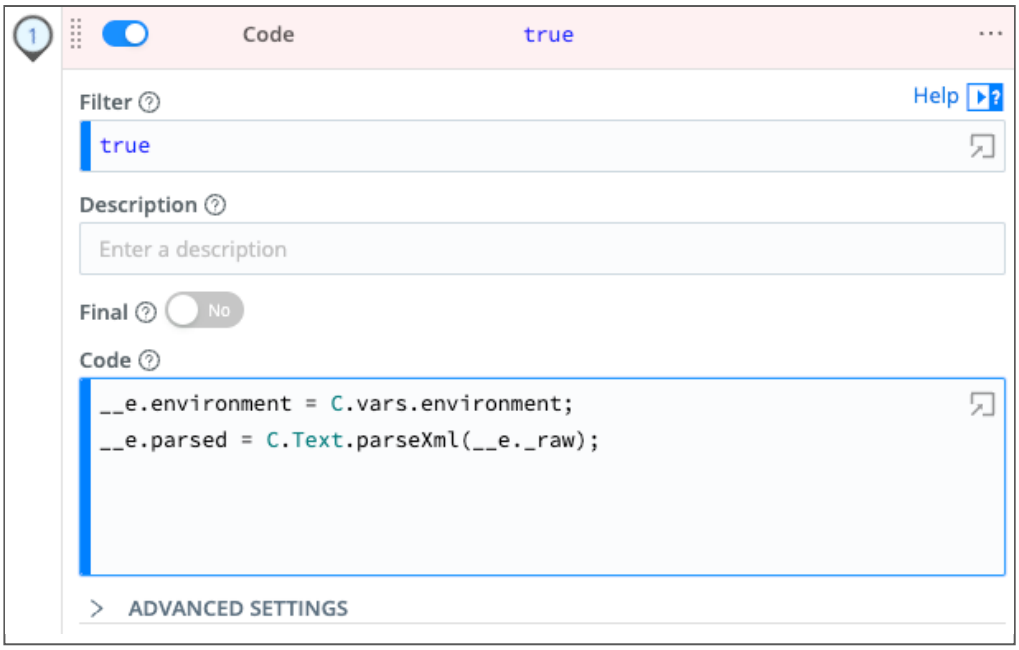
All JavaScript loops and statements are allowed: `for`, `for-of`, `while`, `do-while`, `switch`, etc.

Functions

Users can define their own functions to better organize their code. Both traditional and arrow functions are allowed.

Access to `C.*` Global Object

From the Code's Function body, you can access Cribl Stream's global `C.*` object and its methods/expressions.



The global `C.*` object of a Code Function

18.4.2. Ingest-Time Fields

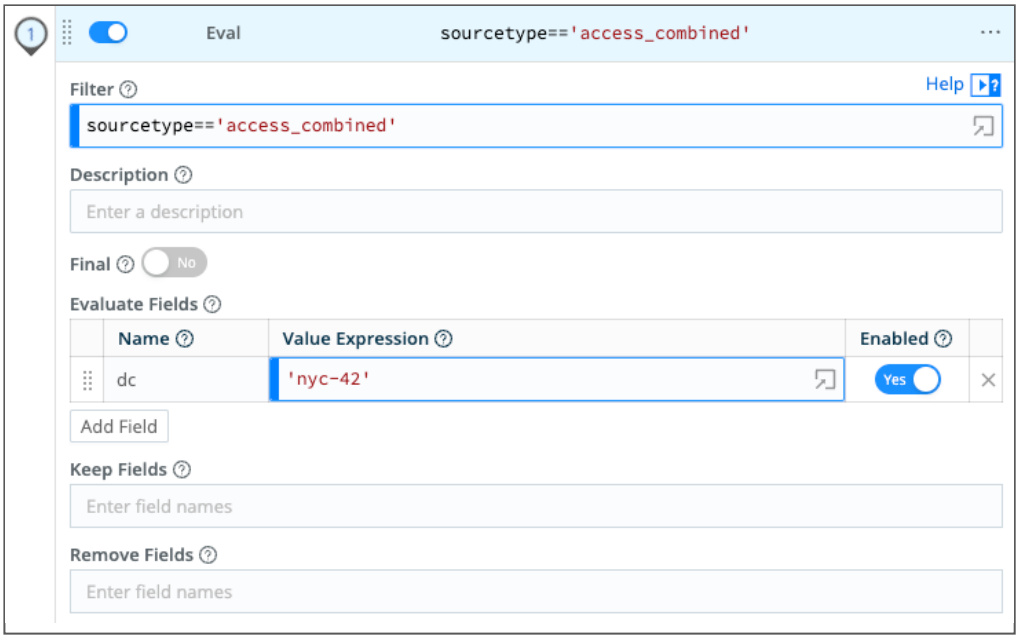
Adding Fields to Data in Motion

To add new fields to any event, we use the out-of-the-box **Eval** Function. We can either apply a Filter to select the events, or we can use the default `true` Filter expression to apply the Function to all incoming events.

Adding Fields Example

Let's see how we add `dc::nyc-42` to all events with `sourcetype=='access_combined'`:

- First make sure you have a Route and Pipeline configured to match desired events.
- Next, let's add an **Eval** function to it with `sourcetype=='access_combined'` as Filter.
- Next, let's click on **Add Field**, add our `dc` field, and click **Save**.



Adding the `dc` field

To confirm, verify that this search returns results: `sourcetype="access_combined" dc::nyc-42`

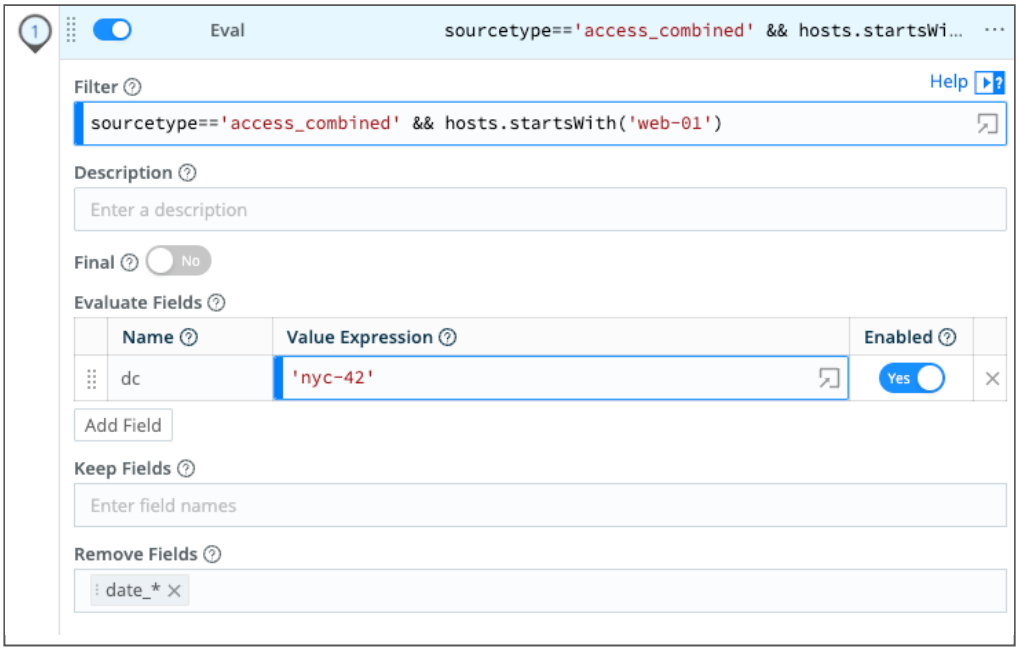
- You can add more conditions to the filter, if you'd like. For example, to limit the field to only events from hosts that start with `web-01`, we can change the filter input to `sourcetype=='access_combined' && hosts.startsWith('web-01')`.

This is a **very** powerful method to change incoming events in real time. In addition to providing the right context at the right time, users can further benefit substantially by using `tstats` for **faster** analytics.

Removing Fields

You can remove fields by listing and/or wildcarding field names. Let's see how we can remove all fields that start with `date_`.:

- First, make sure you have a Route and Pipeline configured to match desired events.
- Next, let's add an **Eval** function to it (as above).
- Next, in **Remove Fields**, add `date_*` and hit Save.



Goodbye `date_` field

To confirm, verify that this search: `sourcetype="access_combined" date_minute=*` will soon stop returning results. Enjoy a more efficient Splunk!

18.4.3. Masking And Obfuscation

Masking and Anonymization of Data in Motion

To mask patterns in real time, we use the out-of-the-box Mask Function . This is similar to `sed`, but with much more powerful functionality.

Masking Capabilities

The Mask Function accepts multiple replacement rules, and accepts multiple fields to apply them to.

Match Regex is a JS regex pattern that describes the content to be replaced. It can optionally contain matching groups. By default, it will stop after the first match, but using `/g` will make the Function replace all matches.

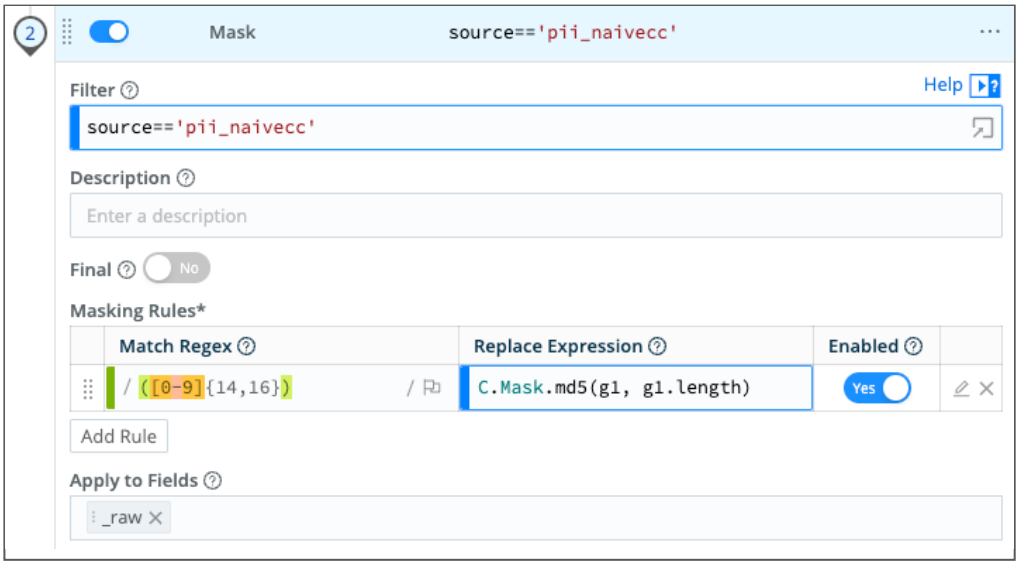
Replace Expression is a JS expression or literal to replace matched content.

Matching groups can be referenced in the **Replace Expression** as `g1`, `g2`... `gN`, and the entire match as `g0`.

There are several masking methods that are available under `C.Mask.`:

`C.Mask.random`: Generates a random alphanumeric string `C.Mask.repeat`: Generates a repeating char/string pattern, e.g., `XXXX` `C.Mask.REDACTED`: The literal 'REDACTED' `C.Mask.md5`: Generates a MD5 hash of given value `C.Mask.sha1`: Generates a SHA1 hash of given value `C.Mask.sha256`: Generates a SHA256 hash of given value

Almost all methods have an optional `len` parameter which can be used to control the length of the replacement. `len` can be either a number or string. If it's a string, its length will be used. For example:



Masking Examples

Let's look at the various ways that we can mask a string like this one: `cardNumber=214992458870391`. The **Regex Match** we'll use is: `/(cardNumber=)(\d+)/g`. In this example:

- `g0 = cardNumber=214992458870391`
- `g1 = cardNumber=`
- `g2 = 214992458870391`

Random Masking with default character length (4):

- **Replace Expression**: `` `${g1}${C.Mask.random()}` ``
- **Result**: `cardNumber=HRhc`

Random Masking with defined character length:

- **Replace Expression**: `` `${g1}${C.Mask.random(7)}` ``
- **Result**: `cardNumber=neNSm8r`

Random Masking with length preserving replacement:

- **Replace Expression**: `` `${g1}${C.Mask.random(g2)}` ``
- **Result**: `cardNumber=DroJ73qmyaro51u3`

Repeat Masking with default character length (4):

- **Replace Expression**: `` `${g1}${C.Mask.repeat()}` ``
- **Result**: **Result**: `cardNumber=XXXX`

Repeat Masking with defined character choice and length:

- **Replace Expression**: `` `${g1}${C.Mask.repeat(6, 'Y')}` ``
- **Result**: `cardNumber=YYYYYY`

Repeat Masking with length preserving replacement:

- **Replace Expression**: `` `${g1}${C.Mask.repeat(g2)}` ``
- **Result**: `cardNumber=XXXXXXXXXXXXXXX`

Literal REDACTED masking:

- **Replace Expression**: `` `${g1}${C.Mask.REDACTED}` ``
- **Result**: `cardNumber=REDACTED`

Hash Masking (applies to: md5, sha1 and sha256):

- **Replace Expression**: `` `${g1}${C.Mask.md5(g2)}` ``
- **Result**: `cardNumber=f5952ec7e6da54579e6d76feb7b0d01f`

Hash Masking with left N-length* substring (applies to: md5, sha1 and sha256):

- **Replace Expression**: `` `${g1}${C.Mask.md5(g2, 12)}` ``
- **Result**: `cardNumber=d65a3ddb2749` *Replacement length will **not** exceed that of the hash algorithm output; MD5: 32 chars, SHA1: 40 chars, SHA256: 64 chars.

Hash Masking with right N-length* substring (applies to: md5, sha1 and sha256):

- **Replace Expression**: `` `${g1}${C.Mask.md5(g2, -12)}` ``
- **Result**: `cardNumber= 933bfcebf992` *Replacement length will **not** exceed that of the hash algorithm output; MD5: 32 chars, SHA1: 40 chars, SHA256: 64 chars.

Hash Masking with length* preserving replacement (applies to: md5, sha1 and sha256):

- **Replace Expression**: `` `${g1}${C.Mask.md5(g2, g2)}` ``
- **Result**: `cardNumber= d65a3ddb27493f5` *Replacement length will **not** exceed that of the hash algorithm output; MD5: 32 chars, SHA1: 40 chars, SHA256: 64 chars.

18.4.4. Encryption Of Data In Motion

This page covers creating, modifying, and synchronizing symmetric keys.

Cribl Stream enables you to encrypt fields or patterns within events in real time, by using a `C.Crypto.encrypt()` expression in a Mask Function. The Mask Function accepts multiple replacement rules, and multiple fields to apply them to.

In that Function's configuration, a **Match Regex** defines the pattern of content to be replaced. The **Replace Expression** is a JavaScript expression or literal to replace matched content. You can use the `C.Crypto.encrypt()` method here to generate an encrypted string from a passed value.

Encryption Keys

You can configure symmetric keys through the CLI or UI. Users are free to define as many keys as required. Each key is characterized by the following:

- `keyId`: ID of the key.
- `algorithm`: Algorithm used with the key
- `keyclass`: Cribl Key Class (below) that the key belongs to.
- `kms`: Key management system for the key. Defaults to `local`.
- `created`: Time (epoch) when key was generated.
- `expires`: Time (epoch) after which the key is invalid. Useful for key rotation.
- `useIV`: Flag that indicates whether or not an initialization vector was used.

Key Classes

Key Classes in Cribl Stream are collections of keys that can be used to implement multiple levels of access control. Users (or groups of users) with access to data with encrypted patterns can be associated with key classes, for even more granular, pattern-level compartmentalized access.

Example

Users `U0, U1` have been given access to keyclass `0` which contains key IDs `0` and `1`. These keys are used to encrypt certain patterns in `datasetA`. Even though users `U0, U1, U2` have access to read this dataset, only `U0` and `U1` can decrypt its encrypted patterns.

Key Class	Dataset
`keyclass: 0` Keys: `keyId: 0, keyId: 1` Users: `U0, U1`	`datasetA` Users: `U0, U1, U2`

User `U1` has been given access to an **additional** keyclass, `1`, which contains key IDs `11` and `22`. These keys are used to encrypt certain **other** patterns in `datasetA`. Even though users `U0, U1, U2` have access to read this dataset – same as above – only `U1` can decrypt the additional encrypted patterns.

Key Class	Dataset
`keyclass: 1` Keys: `keyId: 11, keyId: 22` Users: `U1`	`datasetA` Users: `U0, U1, U2`

Configure Keys with the CLI

When using the `local` key management system, encryption keys in Cribl Stream are encrypted with `$CRIBL_HOME/local/cribl/auth/cribl.secret` and stored in `$CRIBL_HOME/local/cribl/auth/keys.json`. Cribl monitors the `keys.json` file for changes every 60 seconds.

When installed as a Splunk app, `$CRIBL_HOME` is `$SPLUNK_HOME/etc/apps/cribl`.

List Keys

Keys are added and listed using the `keys` command:

```
$CRIBL_HOME/bin/cribl keys list -g <workerGroupID>
```

Sample Command Output

```
keyId  description  algorithm    keyclass  kms    created         expires     useIV
-------------------------------------------------------------------------------
1      cbc          aes-256-cbc  0         local  1544906269.316  0           false
2      gcm          aes-256-gcm  1         local  1544906272.452  0           false
3      cbc          aes-256-cbc  2         local  1544906275.948  1545906275  true
4      gcm          aes-256-gcm  3         local  1544906278.026  0           true
```

Add Keys

Displaying `--help`:

```
$CRIBL_HOME/bin/cribl keys add --help
```

Sample Command Output

```
Add encryption keys
Usage: [options] [args]

Options:
[-a <algorithm>] - Encryption algorithm. Supported values: aes-256-cbc (default), aes
[-c <keyclass>]  - Key class to set for the key.
[-k <kms>]       - KMS to use. Must be configured; see cribl.yml.
[-e <expires>]   - Expiration time, in epoch time.
[-i]             - Use an initialization vector.
 -g <group>      - Worker Group's ID.
```

Adding a key to keyclass `1`, with no expiration date, on the `default` Worker Group:

```
$CRIBL_HOME/bin/cribl keys add -c 1 -i -g default
```

Sample Command Output

```
Adding key: success. Key count=1
```

(You would use the same syntax to reference a non-`default` Worker Group by its name.) ? Listing keys to verify key generation:

```
$CRIBL_HOME/bin/cribl keys list -g default
```

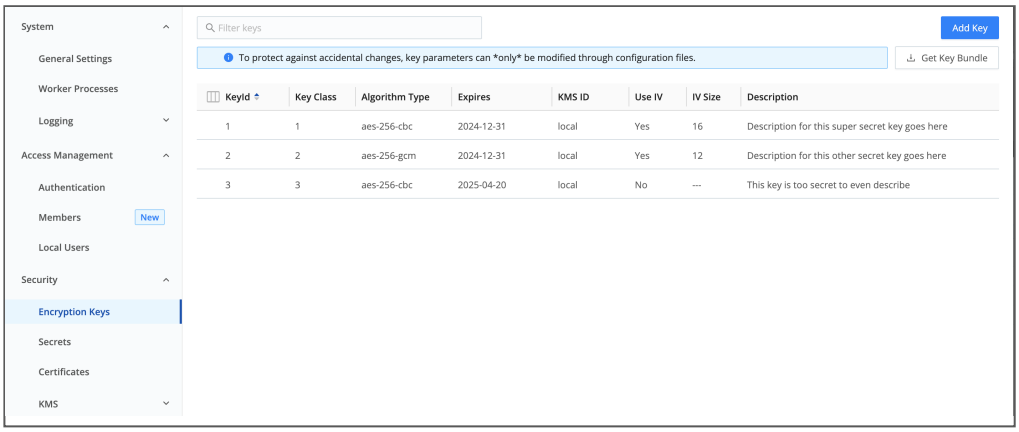
Sample Command Output

```
keyId  algorithm    keyclass  kms    created         expires     useIV
-------------------------------------------------------------------------
1      aes-256-cbc  1         local  1545243364.342  0           true
```

Configure Keys with the UI

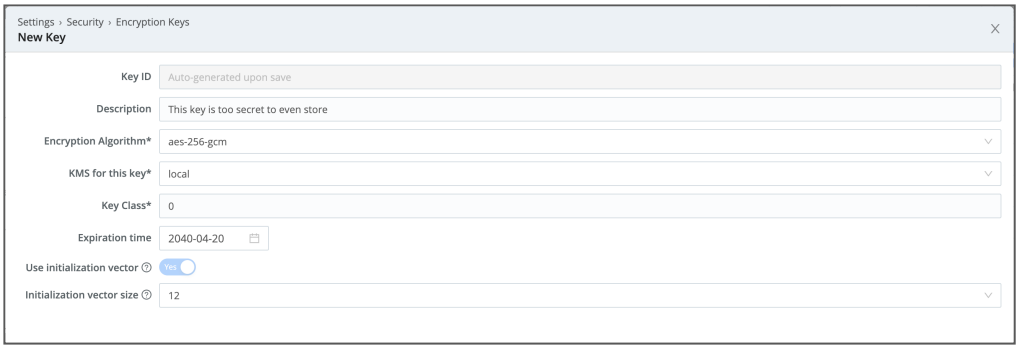
In a Single-instance deployment, you can access the key management interface through **Settings** > **Security** > **Encryption Keys**. In a Distributed deployment, for each Group, select **Worker Groups** > `<group-name>` > **Group Settings** > **Security** > **Encryption Keys**.

The **Encryption Keys** page lists existing keys, with sortable columns.



List or add keys through Cribl Stream

Select **Add Key** to display the creation modal shown below.



New Key configuration modal

Modify Keys

To protect against accidental changes, a key's parameters – once saved – can be edited only through configuration files.

When you update keys by editing the `keys.json` file, you must add them back to the directories above (respectively, on a single instance or on a distributed deployment's Leader Node).

Sync `auth/(cribl.secret|keys.json)`

To successfully decrypt data, the `decrypt` command will need access to the same keys that were used to encrypt, **in the Cribl instance where encryption happened**.

- In a single-instance deployment, the `cribl.secret` and `keys.json` files reside in: `$CRIBL_HOME/local/cribl/auth/`.
- In a distributed deployment, the `cribl.secret` and `keys.json` files reside on the Leader Node in: `$CRIBL_HOME/groups/<group-name>/local/cribl/auth/`.
- When using the UI, you can download these files by selecting **Get Key Bundle**.

Sync/copy these files over to their counterparts on the Search Head/decrypting side, residing in: `$SPLUNK_HOME/etc/apps/cribl/local/cribl/auth/`.

18.4.5. Reducing Windows XML Events

Here, we demonstrate how to use just a few Cribl Stream Functions to parse WindowsXML events and reduce their volume by 34–70%, dramatically reducing your downstream infrastructure requirements.

Using Eval and C.Text.parseWinEvent

Cribl Stream's internal C.Text.parseWinEvent method parses Windows XML strings and returns a prettified JSON object. You can use this function within an Eval Function to parse an event or an ad hoc XML string. It works like C.Text.parseXml, but with Windows events, it produces more-compact output.

As you can see from its signature, `C.Text.parseWinEvent` accepts an optional `nonValues` parameter that can further reduce an event's size by discarding characters that you specify as redundant.

(method) `C.Text.parseWinEvent(xml: string, nonValues?: string[]): any`

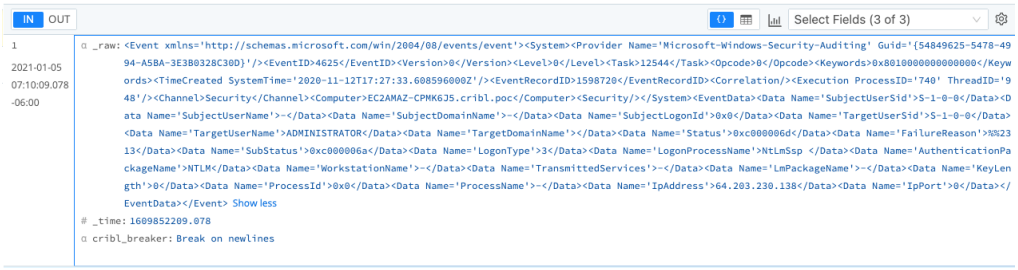
@param – `xml` – an XML string; or an event field containing the XML.

@param – `nonValues` – array of string values. Elements whose value equals any of the values in this array will be omitted from the returned object. Defaults to `['-']`, meaning that elements whose value equals `-` will be discarded.

@returns – an object representing the parsed Windows Event; or `undefined` if the input could not be parsed.

XML: Threat or Menace?

When working with XML, an anonymous Reddit user's quote sums up the challenge: "Some languages can be read by humans, but not by machines, while others can be read by machines but not by humans. XML solves this problem by being readable to neither." An example of a Windows XML event only reinforces this quote:



This Windows XML `_raw` event is 1.36KB in size:

	_raw Length	Full Event Length	Number of Fields	Number of Events
IN	1.36KB	1.43KB	3	1
OUT	1.36KB	1.47KB	4	1
DIFF	0.00%	↑ 2.73%	↑ 33.33%	0.00%

Eval to the Rescue

In our initial Eval Function below, the **Value Expression** uses `C.Text.parseWinEvent` to simply parse the `_raw` Windows XML event and turn it into a prettified JSON object:

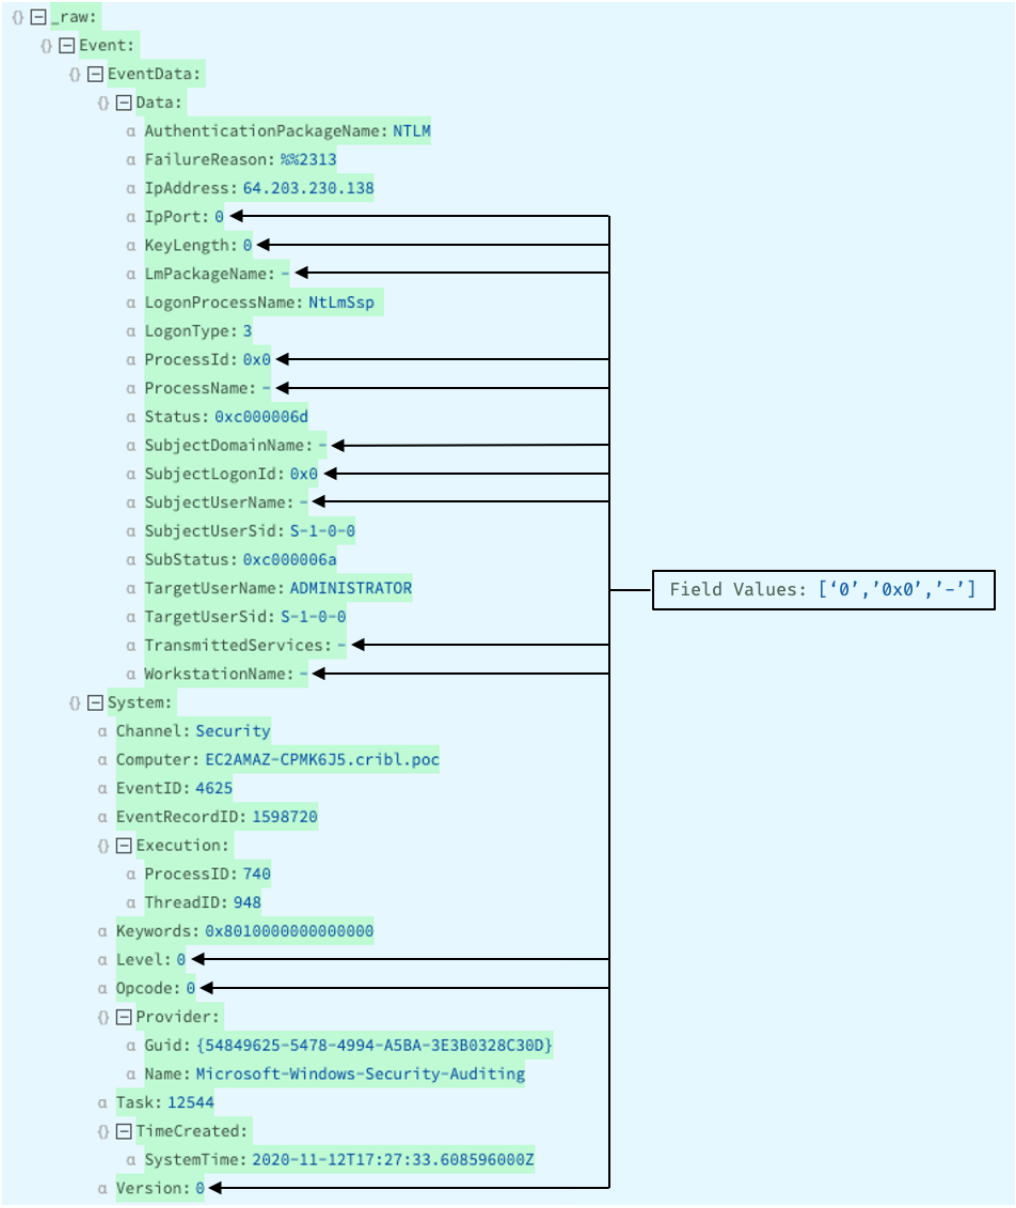
The resulting JSON event is now down to 921.00B in size, a 34.07% reduction of the event:

	_raw Length	Full Event Length	Number of Fields	Number of Events
IN	1.36KB	1.43KB	3	1
OUT	921.00B	1.00KB	4	1
DIFF	↓ -34.07%	↓ -29.76%	↑ 33.33%	0.00%

The `C.Text.parseWinEvent(_raw,[])` call yields verbose output that includes XML attributes. If you want flatter output, you can substitute `C.Text.parseXml(_raw, false)`.

Removing Unnecessary Fields with a Better Eval

But we can do better. The fields containing essentially null values (`'0'`,`'0x0'`, or `'-'`) bloat events, demanding extra infrastructure and storage:



Let's amplify the reduction by removing all of the fields whose values are in the set: `['0','0x0','-']`. This improved version of our Eval Function parses the Windows XML event, and discards `['0','0x0','-']` values. (Its preceding row also tidies up events by removing tabs and curly braces, and replacing newlines and returns with commas.) The result is an even **smaller** prettified JSON object.

If you compare this Preview-pane screenshot to the Preview screenshot above, you can confirm that the fields with values matching `['0','0x0','-']` are removed:

The event is now down to 678.00B in size, translating to a 51.47% reduction from the original event:

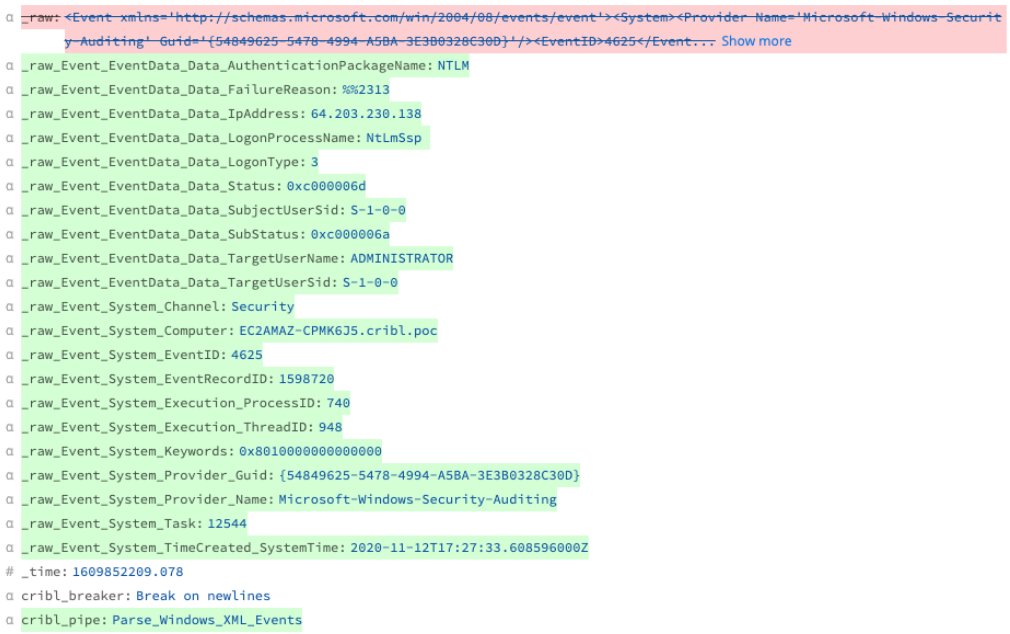
	_raw Length ⓘ	Full Event Length ⓘ	Number of Fields ⓘ	Number of Events ⓘ
IN	1.36KB	1.43KB	3	1
OUT	678.00B	785.00B	4	1
DIFF	↓ -51.47%	↓ -46.42%	↑ 33.33%	0.00%

Flatten Function

Cribl Stream's Flatten Function is designed to flatten fields out of a nested structure. Let's flatten the JSON object within `_raw`, to see if we can further reduce the event's size before we send it to our preferred

destinations.

Using Flatten, we've successfully created top-level fields from the nested JSON structure:



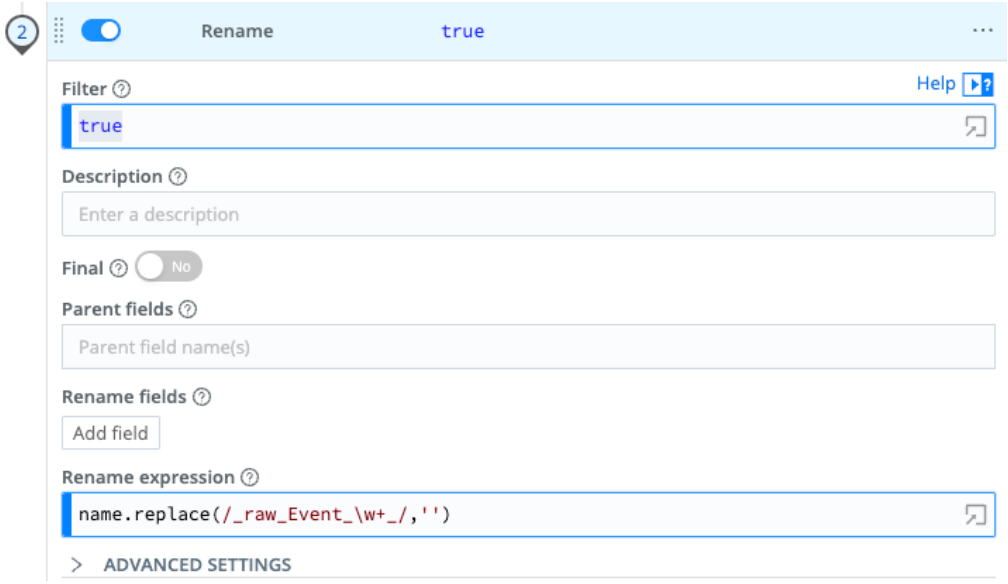
Don't worry about the `_raw` field's deletion (red strikeout). This is the Flatten Function's default behavior. We'll restore `_raw` after we clean and reduce the event even more.

The flattened field names are extracted from `_raw` and delimited with `_`. These field names are quite long. We can optimize them using the Rename Function.

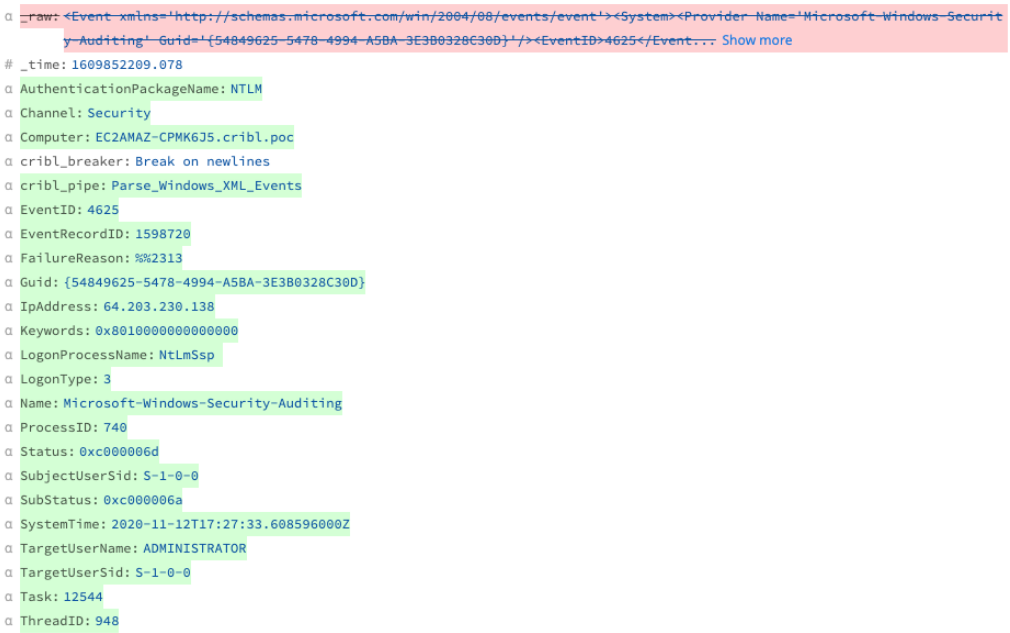
Rename Function

Rename is designed to change fields' names, or to reformat their names (e.g., to normalize names to camelcase). You can use Rename to change specified fields (much like Eval), or to accomplish bulk renaming based on a JavaScript expression (much like the Parser Function). But Rename offers a streamlined way to alter only field names, without other effects.

Let's use Rename to remove any unnecessary prefixes from the field names, to further shrink our events. In the **Rename Expression**, we build a JavaScript expression to match the field names' prefixes (up to the underscore):



The resulting field names are now much more compact, and easier to work with and manage:



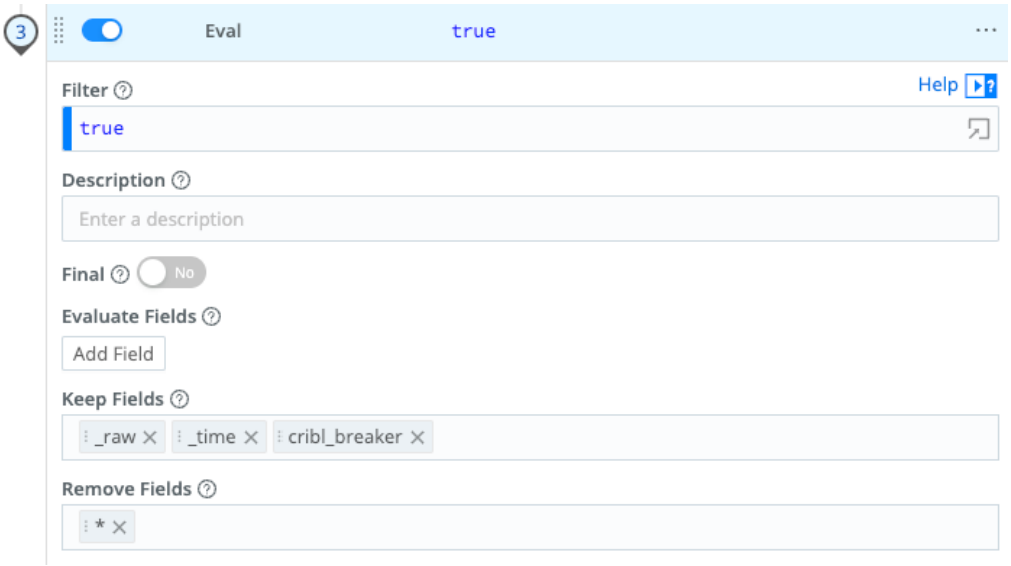
Serialize Function

We started with bloated Windows XML data, and we've parsed and prettified it into JSON. Next, we'll extract key-value pairs. We'll use the Serialize Function, which serializes an event's content into a predefined format.

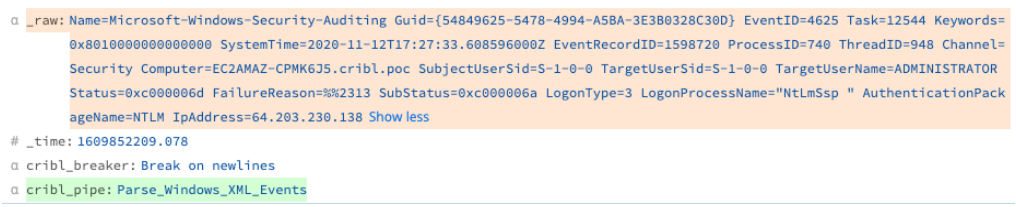
We set Serialize to change the **Type** to key-value pairs. (The Function's other supported target Types include JSON Object and CSV.) Serialize takes the extracted fields and puts them back into `_raw`.

In the Preview pane, the `_raw` field is now back, serialized into compact, tidy key-value pairs:

The last step is to remove any of the extracted fields you don't need before sending events to your destinations. We'll again call on the Eval Function, which adds or removes fields in events. (For a Splunk destination, these are index-time fields.) This final Eval Function looks like this:



To sum up, we've successfully transformed the original Windows XML event into key-value pairs:



And we've dramatically reduced the event's size, while retaining all of the necessary fields. The event is now down to 513.00B in size, translating to a 63.28% reduction from the original Windows XML:

	_raw Length	Full Event Length	Number of Fields	Number of Events
IN	1.36KB	1.43KB	3	1
OUT	513.00B	621.00B	4	1
DIFF	↓ -63.28%	↓ -57.61%	↑ 33.33%	0.00%

Try This at Home

Below is an export of the whole Cribl Stream Pipeline presented here. Import this JSON to experiment with it and modify it to match your own needs:

Win XML Pipeline

```
{
  "id": "Windows_Security_Events",
  "conf": {
    "output": "default",
    "groups": {},
    "asyncFuncTimeout": 1000,
    "functions": [
      {
        "filter": "true",
        "conf": {
          "comment": "This Cribl Stream Pipeline reduces Microsoft Windows XML events
        },
        "id": "comment"
      },
      {
        "filter": "true",
        "conf": {
          "add": [
            {
              "name": "_raw",

18.4.6. Regex Filtering

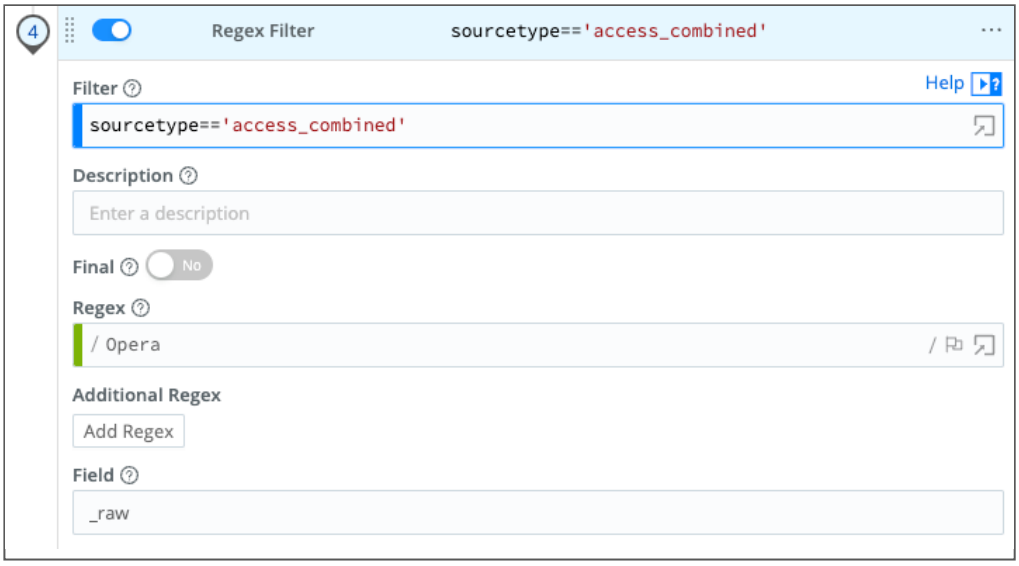
To filter events in real time (data in motion), we use the out-of-the-box **Regex Filter** Function. This is similar to nullqueueing with TRANSFORMS in Splunk, but the matching condition is way more flexible.

Regex Filtering Example

Let's see how we can filter out any `sourcetype=='access_combined'` events whose `_raw` field contains the pattern `Opera`:

First, make sure you have a Route and Pipeline configured to match desired events.

Next, let's add a **Regex Filter** Function to it:



Defining the Regex Filter Function

Next, verify that this search does **not** return any results: `sourcetype="access_combined" Opera`

You can add more conditions to the Filter input field. For example, to further limit the filtering to only events from hosts with domain `dnto.ca`, change the filter input to `sourcetype=='access_combined' && host.endsWith('dnto.ca')`.

This is a very flexible method for filtering incoming events in real time, on virtually any arbitrary conditions.

19. Troubleshooting

19.1. Known Issues

Learn about issues affecting Cribl Stream and/or Cribl Edge. Find out if they're already fixed, or discover temporary workarounds.

In the tables below, "Reported in" refers to the product version in which the given issue was first recorded. In some cases, you might encounter that issue in an older version as well.

See also Known Issues resolved in older product versions:

- Resolved in 4.9
- Resolved in 4.8
- Resolved in 4.7
- Resolved in 4.6
- Resolved in 4.5
- Resolved in 4.4
- Resolved in 4.3

- Resolved in 4.1
- Resolved in 4.0

Unresolved

Scheduled jobs in Single-instance mode do not resume when orphaned

Reported in	Resolved in	Ticket
4.9.0	TBD	CRIBL-29124

Problem: In Single-instance mode of Cribl Stream, orphaned scheduled jobs do not resume, resulting in stalled execution. This issue does not affect deployments in Distributed mode.

Workaround: None identified.

Erroneous FIPS mode detection in Cribl Edge on Windows

Reported in	Resolved in	Ticket
4.8.2	TBD	CRIBL-28927

Problem: Cribl Edge on Windows machines might encounter issues booting up when the `OPENSSL_MODULES` and `OPENSSL_CONF` environment variables are set.

Workaround: Use the Windows Registry to set the following environment variables to empty strings in the environment where the Cribl Edge service runs. For example:

```
CRIBL_VOLUME_DIR=C:\ProgramData\Cribl\
OPENSSL_CONF=
OPENSSL_MODULES=
```

Note: Upgrading Cribl Edge or running MSI repair will revert the workaround implemented in the registry. You will need to reapply the changes after the upgrade or repair.

Cribl server fails to start with AWS KMS and AssumeRole enabled

Reported in	Resolved in	Ticket
4.3.0	TBD	CRIBL-28922

Problem: When using AWS KMS with AssumeRole enabled, the Cribl server fails to start due to an error when accessing the `getCredentialsAsync` function. The error is logged as `boot failed, checking for rollback` in the `cribl.log` file.

Workaround: None identified.

Encrypted secrets are broken when using encoding other than `latin1`

Reported in	Resolved in	Ticket
2.1.0	TBD	CRIBL-28901

Problem: Secrets that contain characters in encodings other than `latin1` will return an incorrect value when decoded.

Workaround: Make sure your secrets use `latin1` encoding.

When you teleport into a Windows Edge Node and navigate to Health, the CPU Load Average panel displays no results.

Reported in	Resolved in	Ticket
4.6.1	TBD	CRIBL-25879

Problem: In Windows deployments of Cribl Edge, the **CPU Load Average** panel is blank when you teleport into a Node and view the **Health** page.

Workaround: None identified.

Dashboard UI charts missing metrics after application update

Reported in	Resolved in	Ticket
4.7.1	TBD	CRIBL-25601

Problem: After upgrading the application, dashboard charts may fail to display metrics recorded prior to the upgrade. This concerns the following charts:

- **Events In and Out**
- **Bytes In and Out**
- **Free Memory**
- **CPU Load Average**

This issue is intermittent and only affects visualization in the dashboard charts. Underlying data is flowing correctly.

Workaround: None identified.

Stopping a container does not initiate clean shutdown

Reported in	Resolved in	Ticket
4.6.1	TBD	CRIBL-25241

Problem: Stopping a container does not issue a graceful shutdown signal SIGTERM to the Cribl process. Containers apply their own timeouts for shutdown, and these override any application-level shutdown timeouts.

Workaround: None identified.

Empty directories that contained Parquet files are not deleted

Reported in	Resolved in	Ticket
4.3.1	TBD	CRIBL-23495

Problem: When certain Sources and Collectors ingest or collect Parquet files, they create directories for storing those files. After they send and delete the files, they should also delete the directories, but fail to do that, potentially consuming large numbers of inodes on the storage volume. Sources affected: Azure Blob Storage, Amazon S3. Collectors affected: Amazon S3, Filesystem/NFS, Google Cloud Storage.

Workaround: Configure a cron job to delete the empty directories.

After restarting the File Monitor Source, Event Breakers aren't processing CSV files correctly when the File Monitor Source is configured to collect CSV logs

Reported in	Resolved in	Ticket
4.4.4	TBD	CRIBL-22360

Problem: When the File Monitor Source is configured to collect CSV file logs and use CSV Event Breakers, subsequent event breaking is not working when the Source resets. The Event Breaker expects the first line of column headers, but they resume reading from a later point in the file where those headers aren't present.

Workaround: Use the default line breaker and a pre-processing Pipeline to drop lines that start with `#`. Optionally, use an `Eval` function to split `_raw` values on the column-separator character into separate fields and rename them as needed.

With Leader HA/Failover, creating diag bundles via CLI produces incorrect results

Reported in	Resolved in	Ticket
4.4.0	TBD	CRIBL-21258, CRIBL-21557

Problem: For deployments configured for Leader high availability/failover, creating diagnostic bundles via the UI works normally but creating them via the CLI does not. In Cribl Stream 4.4.0 and newer, the operation fails with a `not a git repository` error. In 4.4.0 and older, the diag bundle created contains obsolete data. In both cases the underlying cause is that the process that creates the diag bundle cannot access the `CRIBL_CONF_DIR` environment variable.

Workaround: Use the UI to create the diag bundle. Or, if you use the CLI, preface the `diag` command with the needed environment variable, like this: `CRIBL_CONF_DIR=/<path_to_failover_volume> cribl diag create`. If you have an `instance.yml` config file, you can find the path to the failover volume in the `distributed` section.

Fix: Error message improvements were made as part of CRIBL-21258. Fix for CRIBL-21557 is TBD.

Migrated Local Users appear in the Members UI with "No Access"

Reported in	Resolved in	Ticket
4.2.0	TBD	CRIBL-18973

Problem: Local Users are incorrectly shown in the **Settings** > **Members** UI with `No Access`. However, their Roles still function as originally configured, and still display correctly at **Settings** > **Global Settings** > **Access Management** > **Local Users**.

Workaround: Rely on the **Local Users** UI.

Fleet Upgrade Errors

Reported in	Resolved in	Ticket
4.1.3	TBD	CRIBL-18374

Problem: A Fleet's upgrade from a Leader can result in errors when the Edge Nodes use different `host/port/tls` settings than Worker Nodes.

Workaround: The Edge Nodes and Workers must connect to the leader using the `host/port/tls` connection details. If this is not possible, upgrade Edge Nodes separately using the boostrap script.

Datadog Agent Source fails to receive metrics

Reported in	Resolved in	Ticket
3.5.2	TBD	CRIBL-18281

Problem: When a Datadog Agent using Datadog API v2 sends metrics, Datadog Agent Source fails to receive them, because the Source uses Datadog API v1. Datadog Agent logs will show `API Key invalid, dropping transaction` errors. Debug logging will likely produce `Dropping request because of unallowed path message` errors with `statusCode: 403`, which Datadog Agent interprets as "invalid API key."

Workaround: In the `datadog.yaml` file, ensure that `use_v2_api.series` is set to `false`. Cribl Stream's Datadog Agent Source will then receive metrics normally, since both the Source and the Datadog Agent will be using Datadog API v1, which Datadog still supports.

Cannot clear Messages drawer while in GitOps Push mode

Reported in	Resolved in	Ticket
3.5.0	TBD	CRIBL-15239

Problem: When in GitOps `Push` mode, you cannot clear messages from the **Messages** drawer. Cribl Stream returns a `Forbidden` error.

Workaround: None identified.

Amazon Kinesis Data Streams Source resumes reading at earliest event when Leader Node is down

Reported in	Resolved in	Ticket
4.0.0	TBD	CRIBL-15059

Problem: After the Worker on which it is running restarts, the Kinesis Streams Source should resume reading a shard from the point where it left off. That point is a sequence number obtained from the Leader Node – but if the Leader Node is down, sequence numbers (state) will not be available. In this situation, the Worker should wait for the Leader Node to come back up, obtain the state, and then resume reading from the correct point in the shard.

However, due to this issue, the Worker does not wait for the Leader to come back up if the Leader stays down for over one minute. Instead, the Worker starts where **Optional Settings > Shard iterator start** says it should.

- If **Shard iterator start** is set to its default of `Earliest record`, the Worker will resume reading from the beginning of the shard, potentially collecting events it already collected earlier, producing duplicate events.
- If **Shard iterator start** is set to `Latest record`, the Worker will resume reading from the end of the shard, potentially missing events if the last event it collected before the restart is not the last event in the shard.

Workaround: None identified.

Recently added Worker Nodes fail to appear on the Monitoring page

Reported in	Resolved in	Ticket
3.5.0	TBD	CRIBL-14627

Problem: When Worker Nodes are added, there may be a delay before the Worker count is updated on the Monitoring page.

Workaround: Refresh your web browser.

Default commit message missing for non-admin users

Reported in	Resolved in	Ticket
4.0.0	TBD	CRIBL-14239

Problem: For users who have Roles as high as `owner_all`, but not `admin`, the Commit modal fails to display any **Default commit message** saved in **Git Settings**.

Workaround: Enter (or paste) a message per commit.

Diag bundles might fail to download from teleported Worker Nodes

Reported in	Resolved in	Ticket
4.1.0	TBD	CRIBL-13999

Problem: When you're remotely accessing a Worker Node's UI, diag bundles might fail to download from **Global Settings** > **Diagnostics**.

Workaround: Refresh the page and **Export** the bundle again. Alternatively, log directly into the Worker Node's UI before creating the diag.

Kubernetes Logs Source doesn't collect logs from exited or short-lived containers

Reported in	Resolved in	Ticket
4.0.0	TBD	CRIBL-13404

Problem: The Kubernetes Logs Source collects logs only from running containers, which can lead to missed logs from short-lived containers or those that exit before they start running.

Workaround: None identified.

Pipelines with Clone and other Functions can show inconsistent total processing times

Reported in	Resolved in	Ticket
4.0.0	TBD	CRIBL-13125

Problem: For Pipelines containing both a Clone Function and an async Functions (like Redis), the Pipeline Diagnostics modal's **Pipeline Profile** > **Process Time** graph will sum up the duration of all Functions' processing times. This sum can exceed the Pipeline's total duration displayed in the **Summary**.

Workaround: None identified.

Splunk HEC shows higher outbound data volume than other Splunk Destinations

Reported in	Resolved in	Ticket
3.5.1	TBD	CRIBL-11922

Problem: Events sent to the Splunk HEC Destination will show higher outbound data volume than the same events sent to the Splunk Single Instance or Splunk Load Balanced Destinations, which use the S2S binary protocol.

Workaround: None identified.

Persistent queue with compression requires oversize max queue limit

Reported in	Resolved in	Ticket
3.5.0	TBD	CRIBL-10965

Problem: If you configure persistent queueing to both enable **Compression** and set a **Max queue size** limit, set that limit optimistically and monitor the results. Due to an error in computing the compression factor, Cribl Stream will not fully use **Max queue size** values below or equal to the volume's available disk space. This can lead to a mostly empty disk, lost data (either blocked or dropped), and/or excessive backpressure.

Workaround: With **Compression** enabled, set the **Max queue size** to a value **higher** than the volume's total available physical disk space (disregarding compression). Alternatively, leave **Max queue size** empty, to impose no limit. Monitor overall throughput and the queue size (if PQ engages), to verify that Cribl Stream is maximizing the queue.

GitOps + License expiration = Catch-22

Reported in	Resolved in	Ticket
3.3.1	TBD	CRIBL-8600

Problem: If your Enterprise license expires while you have enabled the GitOps Push workflow, you will encounter the following block: Cribl Stream is in read-only mode, triggering a `Forbidden` error when you try

to update your license key. But you also cannot reset the workflow from `Push` to `None`, because the expired license disables GitOps features.

Workaround: Contact Cribl Support for help updating your license.

Syslog Source's previewed data doesn't proceed through Routes

Reported in	Resolved in	Ticket
3.2.1	TBD	CRIBL-8210

Problem: The Syslog Source's **General Settings** > **Input ID** field's default filter expression is `__inputId.startsWith('syslog:in_syslog:')`. The same filter appears in the **Preview Full** tab's **Entry Point** drop-down, except without the final colon. This means that data sent using **Preview Full**'s version of the filter will not go through Routes that use the **Input ID** version.

Workaround: When sending data from **Preview Full** to a Route, if both use the `syslog:in_syslog` filter, edit the Route's filter to remove the final colon. This will make the filter identical in both places, routing data correctly.

Upgrading a Pack overwrites Lookup and sample-data customizations

Reported in	Resolved in	Ticket
3.0.0	TBD	CRIBL-7998

Problem: Upgrading a Pack overwrites any customizations you've made to the Pack's original/default Lookup tables and sample-data files.

Workaround: Duplicate the Pack's default Lookup tables and sample-data files, and customize your duplicate copies. Upgrading the Pack will not overwrite your local copies.

Re-enabling a Function group mistakenly re-enables all its Functions

Reported in	Resolved in	Ticket
2.1.0	TBD	CRIBL-7053

Problem: When you change a Function group from disabled to enabled, all of its Functions are enabled, regardless of their individual enabled/disabled states when the group was disabled.

Workaround: Avoid disabling and re-enabling Functions as a group (e.g., for testing or stepwise debugging purposes).

Duplicate Workers/Worker GUIDs

Reported in	Resolved in	Ticket
3.0.1	TBD	CRIBL-5611

Problem: Multiple Workers have identical GUIDs. This creates problems in Monitoring, upgrading and versioning, etc., because all Workers show up as one.

Cause: This is caused by configuring one Worker and then copying its `cribl/` directory to other Workers, to quickly bootstrap a deployment.

Workaround: Don't do this! Instead, use the Bootstrap Workers from Leader endpoint.

Can't Enable KMS on Worker Group after installing license

Reported in	Resolved in	Ticket
3.0.0	TBD	CRIBL-5274

Problem: Enabling HashiCorp Vault or AWS KMS on a Worker Group, after installing a LogStream license on the same Group, fails with a spurious `External KMS is prohibited by the current license` error message.

Workaround: On the Leader, navigate to **Settings** > **Worker Processes**. Restart the affected Worker Group's `CONFIG_HELPER` process. Then return to that Worker Group's **Security** > **KMS** Settings, re-enter the same KMS configuration, and save.

Resolved in 4.9

The following issues were resolved in version 4.9 and its maintenance releases.

Windows Event Logs Source (Cribl Edge): imprecise seek position

Reported in	Resolved in	Ticket
4.9.0	4.9.3	CRIBL-29208

Problem: Within the Windows Event Logs Source, a Windows-native module incorrectly interprets the seek position argument as a 32-bit integer, leading to problems seeking to the correct position in the event log. This can lead to duplicate events, longer-than-expected collection times, and other issues.

Workaround: In the Source configuration modal, on the **Advanced Settings** tab, enable **Use Windows Tools**. While this workaround can resolve the seek position problem, it might degrade performance, especially for high-volume logs.

Significant increase in malformed HEC event errors

Reported in	Resolved in	Ticket
4.9.1	4.9.2	CRIBL-29063

Problem: A change to HEC parsing in 4.9.1 might cause an increase in `Dropping malformed HEC event, enable debug to see details` error logs, even when the incoming HEC payloads are known to be valid. Specifically, this can happen in JSON with multi-escaped quote characters (for example, `"type\\\\\\\":\\\\\\\"someType\\\\\\\"`). When this error occurs, Cribl Stream will not ingest the payload and will instead return a `400` error response.

Workaround: None identified. Users are advised to upgrade directly to 4.9.2 or later to avoid this issue.

Worker Nodes or Edge Nodes send false down alerts after turning off load balancing

Reported in	Resolved in	Ticket
4.9.1	4.9.3	CRIBL-28886

Problem: This issue affects Worker Nodes or Edge Nodes with load balancing enabled in a distributed environment. When you disable load balancing, commit and deploy the configuration changes, and restart the

Nodes, Cribl may send a false alert indicating the Nodes are down. Despite the alert, the Nodes remain healthy and operational.

Workaround: None identified.

Unable to upgrade or install Edge to 4.9.0 on Windows machines running .NET version older than 4.7.2

Reported in	Resolved in	Ticket
4.9.0	4.9.1	CRIBL-28774

Problem: Users are not able to install or upgrade to Edge 4.9.0 on Windows machines that are running .NET framework versions older than 4.7.2.

Workaround: Upgrade instances of .NET on your Windows machine to 4.7.2 or newer, then rerun the Cribl Edge installation or upgrade.

REST Collectors query unexpected pages with dual pagination

Reported in	Resolved in	Ticket
4.9.0	4.9.1	CRIBL-28716

Problem: A REST Collector configured to use pagination for both the discovery and collection steps could collect the wrong page. The field used to track the current page for the discover step interferes with the page tracking for the collect step. This causes the collection step to query unexpected pages, leading to inconsistent results.

Workaround: None identified.

Cannot use some words when accessing properties in Pipelines

Reported in	Resolved in	Ticket
4.9.0	4.9.1	CRIBL-28551

Problem: When Pipelines refer to property names containing certain words, an error message occurs: `Failed to build property accessor (...) err=Unallowed ref to '<keyword>'`. The words causing issues are: `AsyncFunction`, `AsyncGenerator`, `AsyncGeneratorFunction`, `Function`, `GeneratorFunction`, `Promise`, `Proxy`, `Reflect`, `Symbol`, `WebAssembly`, `console`, `eval`, `global`, `globalThis`, `process`, `setInterval`, `setTimeout`, `uneval`, `window`.

Workaround: When using any of the above words as property names, surround them by quotation marks, for example: `process.part.part` -> `'process.part.part'`.

Cribl Copilot for Pipelines does not work if accessed from Stream Projects

Reported in	Resolved in	Ticket
4.8.2	4.9.1	AI-802

Problem: After upgrading to Cribl 4.8.2, the "Add function with Copilot" feature does not work when accessed from **Projects** > **Data Projects** > **Pipelines**.

Workaround: Access the "Add function with Copilot" feature in Cribl Stream by going to **Processing** > **Pipelines** > select a Pipeline > **Add Function**.

Google Cloud Pub/Sub Source not populating `attributes` field in events

Reported in	Resolved in	Ticket
4.8.2	4.9.1	CRIBL-28408

Problem: The attributes from a PubSub message do not translate to the Cribl event because the `message.attributes` property from the `PubSub.Message` type is treated as an array instead of an object, resulting in a missing `__attributes` field.

Workaround: None identified.

REST Collector configuration no longer supports the ability to add placeholder values

Reported in	Resolved in	Ticket
4.9.0	4.9.1	CRIBL-28383

Problem: When you configure a REST Collector as a JSON file, you can normally define a placeholder value for various fields. Then, when you switch to the user interface, it prompts you to fill in the placeholders with the actual values. This feature is missing in Cribl Stream 4.9.0.

Workaround: None identified.

Users can't upgrade Cribl in-product when the `CRIBL_VOLUME_DIR` environment variable is set

Reported in	Resolved in	Ticket
4.8.2	4.9.0	CRIBL-28216

Problem: On Cribl Leaders, Cribl Edge, or Cribl Stream Linux instances that have the `CRIBL_VOLUME_DIR` environment variable set, you can't upgrade from 4.8.2 to 4.9.0 using the UI. This affects only upgrades from version 4.8.2.

These scenarios are **not** impacted by this issue:

- Upgrading from versions 4.8.1 and older to 4.9.0.
- Installations where `CRIBL_VOLUME_DIR` is not set.
- Windows installations.
- Containers or RPM installs.

Workaround: Upgrade these instances manually. See Upgrading Cribl Edge on Linux (CLI) for instructions.

The Cloud persistent queue (PQ) health checker sends false alerts for staging environment with only one Worker Node

Reported in	Resolved in	Ticket
4.9.0	4.9.1	CRIBL-28207

Problem: When a staging environment has only one Worker Node, the Cloud PQ health checker creates a critical alert with the message "cloud worker pq config errors".

Workaround: None identified.

`RangeError: offset is out of bounds` and nested field serialization issues in Splunk Load Balanced Destination with S2Sv4

Reported in	Resolved in	Ticket
4.0.0	4.9.0	CRIBL-28080

Problem: The Splunk Load Balanced Destination using S2Sv4 encounters issues when processing certain events:

1. When events contain a field with an array value with many items, parsing could fail with the error message `RangeError: offset is out of bounds.`
2. When events contain a field with a non-stringified object value greater then 1 KB, and **Nested field serialization** is set to `JSON`, the value could be truncated after stringification. The event is still sent but may miss some of the stringified object value.

Workaround:

1. Smaller-sized arrays may help.
2. Serialize nested fields as JSON before they reach the Splunk Destination with the Eval function.

Deploying configurations to Edge Subfleets sometimes fail with TLS enabled

Reported in	Resolved in	Ticket
4.8.2	4.9.0	CRIBL-27793

Problem: In a Cribl-managed instance of Edge, attempting to deploy configuration changes to a Subfleet sometimes fails if the Subfleet, or its parent Fleet, has TLS enabled and contains a certificate with a passphrase.

Workaround: There are two workaround options, in the Fleet or Subfleet settings:

- Use a certificate without a passphrase.
- Disable TLS in **API Server Settings**.

HMAC authentication fails due to empty signature strings

Reported in	Resolved in	Ticket
4.8.0	4.9.0	CRIBL-27682

Problem: HMAC authentication could fail when an API requires empty strings in the signature string builders. Cribl currently filters out any `falsy` values, including empty strings, which can prevent the correct generation of the HMAC value and lead to authentication failures.

Workaround: Varies. See a workaround example in our templates repository.

Persistent queue settings are missing in hybrid Worker Groups

Reported in	Resolved in	Ticket
4.8.1	4.9.0	CRIBL-27644

Problem: On Cribl.Cloud, persistent queue settings are unavailable in the UI for Sources and Destination running in hybrid (customer-managed) Worker Groups.

Workaround: You can configure persistent queues on hybrid Worker Groups by using the **Manage as JSON** option in Sources or Destinations.

A Google Cloud Pub/Sub Source authentication tooltip gives incorrect Google authentication information

Reported in	Resolved in	Ticket
4.8.2	4.9.1	CRIBL-27506

Problem: When you are configuring the Google Cloud Pub/Sub Source, the Authentication screen has a field named **Authentication method** with an incorrect tooltip. Starting in 4.8.2, you should no longer use the environmental variables `PUBSUB_PROJECT` and `PUBSUB_CREDENTIALS` to authenticate with Google, as stated in the tooltip.

Workaround: In 4.8.2 or later, use the `GOOGLE_APPLICATION_CREDENTIALS` environment variable to provide the location of a credential JSON file or the JSON file contents. When this option is set, Cribl Stream will first check whether the `GOOGLE_APPLICATION_CREDENTIALS` environment variable exists and properly set with valid credentials. If this environmental variable is missing or incorrect, Cribl Stream checks for credentials in two additional fallback locations, as described in the official Google Cloud documentation: How Application Default Credentials works.

C.Time Functions can crash Worker Nodes with old timestamps

Reported in	Resolved in	Ticket
4.7.3	4.9.0	CRIBL-26719

Problem: The `C.Time.s3TimePartition()` and `C.Time.timePartition()` Functions, commonly used for S3 and Cribl Lake Destinations, are susceptible to crashing Worker Processes when encountering events with timestamps prior to January 1st, 1970 (Unix epoch). These events, represented by negative (or `0`) values in the `_time` field, cause Worker Nodes to consume 100% CPU and become unresponsive.

Workaround: To prevent Worker Nodes crashes, insert a Pipeline before any Function or Destination using these methods. Configure the Pipeline to modify the `_time` field of affected events to a positive value (`>0`) (e.g., using the `Date.now()` function).

Unable to Load CPU Profiles in Cribl.Cloud

Reported in	Resolved in	Ticket
4.7.3	4.9.0	CRIBL-26311

Problem: Cribl.Cloud is currently experiencing an issue where users cannot view or download CPU profiles directly through the UI. CPU profiling is useful in troubleshooting performance issues.

Workaround:

1. **Open DevTools**: While on the Worker Process details page, right-click anywhere and select **Inspect**.
2. **Navigate to the Network Tab**: Locate the **Network** tab within DevTools.
3. **Filter Network Requests**: In the filter bar at the top of the Network tab, type `download`. This will filter the requests to only show those related to CPU profile downloads.
4. **Identify API Call**: Look for the latest network request with a path containing `download` (e.g., `/api/v1/workers/<worker_id>/profile/download`). This is the backend API call that fetches the

CPU profile data.

5. **Access Profile Data**: Right-click on the identified API call and select **Open in Sources panel**.
6. **Save Profile**: Copy this data and save it to a file with a `.cpuprofile` extension.

For profile visualization, consider using an open-source tool like Speedscope after saving the profile data. A more permanent solution involving UI updates is planned for a future release.

REST Collector state not updated on job cancellation

Reported in	Resolved in	Ticket
4.7.2	4.9.0	CRIBL-26485

Problem: Canceling a REST Collector job from the Job Inspector before it completes prevents state updates for events collected prior to cancellation. As a result, no state is saved for uncompleted tasks within the collection run.

Workaround: None identified.

When Source PQ is enabled, disk space fills to near capacity and Cribl Stream issues an error

Reported in	Resolved in	Ticket
4.7.2	4.9.0	CRIBL-26478

Problem: With Source-side persistent queues (PQs) enabled, the system is not releasing files correctly, causing the disk space to fill and potential Worker Node failures. In addition, the system frequently logs the following error: `Cannot read properties of undefined (reading 'on')`.

Workaround: You may be able to mitigate this issue by adjusting your Source-side PQ settings. Significantly decreasing the **Max buffer size** and increasing the **Max file size** may resolve the issue.

Chain Functions in Cribl Stream Projects can lead to infinite loops

Reported in	Resolved in	Ticket
4.7.3	4.9.0	CRIBL-25524

Problem: Currently, users can create infinite loops within a project by referencing a Pipeline within itself using a Chain Function.

Workaround: Until a permanent fix is implemented, users should avoid creating circular dependencies within Pipelines within a single project. Do not reference a Pipeline within itself using a Chain Function.

Upgrading to 4.7.0 with Google Cloud Security Operations Destination (formerly Google Chronicle)

Reported in	Resolved in	Ticket
4.7.0	4.9.0	CRIBL-25371

Problem: When upgrading to Cribl Stream 4.7.0, if an existing **Google Chronicle Destination** (now Google Cloud Security Operations) is configured on a particular Worker Group, all Destinations in that Worker Group will fail to load and process data until a commit and deploy is performed on the Worker Group.

If you use the **Google Chronicle Destination**:

Recommended: Proceed with the upgrade, but be prepared to immediately perform a commit and deploy on affected Worker Groups after upgrading Worker Nodes and Leaders. Worker Nodes will only resume data processing after a successful commit and deploy.

Workaround: None identified.

Licensing page displays a permission access warning when a Cloud Connection is enabled

Reported in	Resolved in	Ticket
4.7.0	4.9.0	CRIBL-25147

Problem: When you have an on-premises Cloud Connection to Cribl.Cloud and navigate to the Licensing page, a warning displays that the user does not have permission to access the resource. You won't be able to access the license page with a connected environment (as your Cribl.Cloud account now handles credits for the connected environment) but it is not a permissions issue.

Workaround: To view billing information for your connected environments, log into your Cribl.Cloud account and go to **Organization**, then **Billing & Usage**.

OTLP Metrics Function does not process metrics unless all metric names are quoted literals

Reported in	Resolved in	Ticket
4.6.1	4.9.0	CRIBL-24877

Problem: When the Publish Metrics Function is followed by the OTLP Metrics Function in a Pipeline, the OTLP Metrics Function may fail to produce any results. This failure is possible when the metric name expression for any of the published metrics uses an unquoted string literal and/or evaluates to a numeric value.

Workaround: If you must use a metric name expression in Publish Metrics, wrap the results of the expression in single or double quotes to ensure that it returns a string.

Optionally, leave the metric name expression blank and use the Rename Function to rename the metric names before sending them to the OTLP Metrics Function.

A File Monitor memory leak causes high memory usage only on Windows Edge Nodes

Reported in	Resolved in	Ticket
4.4.4	4.9.1	CRIBL-22970

Problem: When Cribl Edge is deployed on a Windows Node and the File Monitor Source is configured on that Node, a memory leak will cause high memory usage on the Windows Edge Node.

Workaround: None identified.

Kafka and Confluent mTLS requirement limits Schema Registry authentication

Reported in	Resolved in	Ticket
1.2.0	4.9.0	CRIBL-21047

Problem: The Kafka and Confluent Cloud Source and Destination only support mutual TLS (mTLS) authentication for the Kafka Schema Registry. This prevents you from configuring separate authentication

mechanisms for the Schema Registry and Kafka brokers, which is necessary when the Schema Registry and brokers are managed by different departments with distinct authentication requirements.

Workaround: None identified.

Healthy Destinations spuriously report `Blocked Status`

Reported in	Resolved in	Ticket
4.2.1	4.9.0	CRIBL-19322

Problem: Healthy TCP-based, Kafka-based, Splunk, and Metrics Destinations can spuriously report `Blocked Status` in the **Charts** tab, sometimes also logging the blocked status inaccurately.

Workaround: None identified.

Resolved in 4.8

The following issues were resolved in version 4.8 and its maintenance releases.

Removing Member from Team removes access after a lag

Reported in	Resolved in	Ticket
4.8.2	4.8.2+	CRIBL-27680

Problem: As the Owner or Admin of a Cribl.Cloud Organization, if you remove a Member from a Team, that user will retain any Team-associated Permissions on products and product resources for up to 30 minutes. (This lag does not affect Team changes on on-prem Organizations.)

Workaround: The intended access changes will take effect within 30 minutes.

In Cribl Edge, TLS certificate paths in Sources and Destinations are incorrect

Reported in	Resolved in	Ticket
4.8.0	4.8.2	CRIBL-26971

Problem: After Cribl Edge upgrades to 4.8.0 or later, TLS certificate paths for Cribl Edge Sources and Destinations are not updated. This may affect data flow in Fleets and Subfleets containing TLS-configured Sources or Destinations.

Workaround: Update the TLS certificate path.

1. In the parent Fleet, navigate to the Source or Destination that uses a TLS certificate.
2. In the **Certificate path** field, change `default` to `local`.
   For example:
   - Old path: `groups/default_fleet/default/edge/auth/certs/asd.crt`
   - New path: `groups/default_fleet/local/edge/auth/certs/asd.crt`
3. Save the Source or Destination.
4. Select **Commit and Deploy with Subfleets** so the Subfleets receive the change.

Splunk Destinations incorrectly detect that a downstream Splunk instance is shutting down

Reported in	Resolved in	Ticket
4.8.0	4.8.1	CRIBL-26969

Problem: Splunk Single Instance and Splunk Load Balanced Destinations might incorrectly detect that a downstream instance of Splunk is shutting down at frequent intervals. This only affects Destinations with **Max S2S version** set to `v3` and the **Minimize in-flight data loss** toggle enabled.

Workaround: Change the **Max S2S version** setting for the Destination to `v4`. Or, disable the **Minimize in-flight data loss** toggle.

Incoming data from Collectors sometimes incorrectly displays UTF-8 characters

Reported in	Resolved in	Ticket
4.8.0	4.8.2	CRIBL-26967

Problem: Cribl Stream sometimes displays incoming data containing multi-byte UTF-8 characters incorrectly when Collectors such as AWS S3 ingest events.

Workaround: None identified.

Wiz Source does not correctly paginate

Reported in	Resolved in	Ticket
4.7.2	4.8.2	CRIBL-26965

Problem: The Wiz Source in Cribl Stream does not correctly handle pagination. The default queries for each data type in the Wiz Source incorrectly pass the `endCursor` parameter, resulting in the same page of data being returned repeatedly.

Workaround: Modify each default query by changing `endCursor: endCursor` to `after: endCursor`.

Some elements are missing from JSON-formatted events collected by the Windows Event Logs Source

Reported in	Resolved in	Ticket
4.8.0	4.8.2	CRIBL-26960

Problem: JSON-formatted events collected by the Windows Event Logs Source don't contain the elements `UserData`, `DebugData`, `BinaryEventData`, and `ProcessingErrorData`.

Workarounds:

You can either:

- Set **Use Windows Tools** to `Yes` in the Windows Event Logs Source Advanced Settings.

Or:

- Set the **Event format** to **XML**. Create a Pipeline that contains the `C.Text.parseWinEvent(_raw)` expression, which will analyze the incoming XML event data and generate JSON-formatted output.

Missing in-product documentation for ServiceNow Cloud Observability Destination

Reported in	Resolved in	Ticket
4.8.0	4.8.2	CRIBL-26958, SAAS-10932

Problem: The ServiceNow Cloud Observability Destination documentation is not available in-product. Attempting to access the documentation within the product interface returns the error "Unable to load docs. Please check Cribl's online documentation instead."

Workaround: Refer to the online documentation for configuration instructions.

Windows Event Log events are mishandled when they're missing provider metadata

Reported in	Resolved in	Ticket
4.8.0	4.8.2	CRIBL-26944

Problem: Events without a valid provider are missing the `_raw` property. This happens in the Windows Event Logs Source when **Use Windows Tools** is set to `No` in Advanced Settings, and Render event message strings is enabled.

Workaround: Set **Use Windows Tools** to `Yes` or disable **Render event message strings**.

`_raw` field expansion is incomplete

Reported in	Resolved in	Ticket
4.7.2	4.8.0	CRIBL-26377

Problem: When capturing live data, the `_raw` field unexpectedly expands only to the first level. It should fully expand to reveal its entire nested JSON structure when tapped.

Workaround: None identified.

Splunk TCP Source and Destination: Incorrect Max S2S Version displayed in UI

Reported in	Resolved in	Ticket
4.6.1	4.8.2	CRIBL-26333

Problem: If a Splunk TCP Source or Destination was created before the **Max S2S Version** setting existed, the UI incorrectly displays `v4` as the **Max S2S Version**, instead of the actual default `v3`. This discrepancy can lead to version mismatch errors when forwarders upgraded to Splunk 9.1.4 attempt to send data.

Workaround: Manually change the **Max S2S Version** dropdown to `v3` and then back to `v4` in the UI, and save the configuration. This ensures the correct version is set in the config.

Unable to Send Data via S2S to Splunk Cloud and Splunk Enterprise

Reported in	Resolved in	Ticket
4.5.0	4.8.0	CRIBL-25842

Problem: Attempting to send data to recent versions of Splunk Cloud or Splunk Enterprise via Cribl Stream's Splunk Single Instance or Splunk Load Balanced Destinations integrations may encounter issues after upgrading Splunk.

Workaround: Use the Splunk HEC Destination to send traffic to Splunk. HEC is the recommended protocol for sending data to Splunk due to its better load balancing, compression, and overall performance.

Jobs stuck in "pending" status

Reported in	Resolved in	Ticket
4.7.2	4.8.0	CRIBL-24336, CRIBL-26359

Problem: Jobs can get stuck in **Pending** state when you commit and deploy configuration while the job is running. This prevents the job from running again, and if multiple jobs freeze, the job queue can fill up. Note that Worker upgrade jobs may fail when upgrading from versions earlier than 4.8.

Workaround: Restart the affected Worker and the Leader. To restart the Worker:

1. Log into Cribl Stream as an Admin.
2. Go to the **Workers** page.
3. Select the affected Worker's GUID. You will teleport to this Worker's UI.
4. On the colored top bar, select **Restart Stream**.

To restart the Cribl.Cloud Leader:

1. Get an API token for your Leader Node.
2. Use the following curl command to restart the Leader:
   ```
   curl "https://<workspace-org>.cribl.cloud/api/v1/system/settings/restart" -H "Authorization: Bearer $token" -H "Content-Type: application/json" --data-raw "{}"
   ```

where `workspace-org` comes from your Cribl.Cloud URL, and `$token` is the API token.

Incorrect Source URL in REST Collector events

Reported in	Resolved in	Ticket
2.4.4	4.8.2	CRIBL-24280

Problem: The REST Collector incorrectly displays the **Discovery URL** as the `source` field in collected events, instead of the actual **Collect URL**. This issue occurs when using OAuth2/token API for authentication.

Workaround: Manually adjust the `source` field in downstream processing or use a custom script to update the field after data collection.

Stream Projects: Post-processing Pipelines defined in Destination do not work

Reported in	Resolved in	Ticket
4.5.0	4.8.0	CRIBL-23197

Problem: When using Cribl Stream Projects, a post-processing Pipeline defined only in the Destination, not in the Project itself, will be ignored.

Workaround: Copy the post-processing Pipeline inside the Project:

1. In Cribl Stream's **Processing** > **Pipelines** table, click the Pipeline you're using for post-processing.
2. Select the Pipeline's gear ( ) button, and then the "Manage as JSON" button at the top right of the Pipeline settings.
3. Select **Export** and save the Pipeline in JSON format in a convenient location.
4. Go back to the **Project** screen and select **Pipeline** at the top.
5. Select **Add Pipeline**, and then **Import from File**.
6. Choose your exported configuration and confirm.

Post-processing should now function correctly in your Project.

Already-existing Webhook Destinations show unexpected UI behavior upon upgrade to 4.4.4

Reported in	Resolved in	Ticket
4.4.4	4.8.2	CRIBL-22184

Problem: If you have a Webhook Destination in a Cribl Stream deployment, and then upgrade that deployment to version 4.4.4, the UI will show an error; the new **Load balancing** toggle will be turned on with associated settings displayed; and the UI will not allow you to save changes.

Workaround: First, toggle **Load balancing** off. This will return the UI to normal behavior. Then, if you want to use the Destination without load balancing, configure as usual and save. Or, if you prefer, update the **Webhook URLs** to include one or more valid endpoints you want to send to, and save the Destination with **Load balancing** enabled.

Resolved in 4.7

The following issues were resolved in version 4.7 and its maintenance releases.

Splunk HEC Destination drops events when `_raw` is an empty string

Reported in	Resolved in	Ticket
1.6.0	4.7.2	CRIBL-25928

Problem: When sending events to a Splunk HEC Destination, if the `_raw` field is an empty string, Cribl Stream sends an empty string as `_raw` instead of trying to send the full serialized event. This results in an error from Splunk and the event is dropped.

Workarounds:

- Do not set `_raw` to an empty string in any Pipelines feeding a Splunk HEC Destination.
- If you do not know or cannot change the `_raw` contents prior to the Destination, add an Eval Function to a post-processing Pipeline with the expression: `_raw = _raw?.length ? _raw : undefined;`.

Splunk HEC Destination drops events with null `_time` values

Reported in	Resolved in	Ticket
1.1.0	4.7.2	CRIBL-25927

Problem: Events sent to a Splunk HEC Destination with a null `_time` field are dropped by Splunk, halting further processing of the entire payload (potential data loss).

Workaround: Assign the `_time` field to the current time in a post-processing Pipeline by adding an Eval Function before the Splunk HEC Destination with the expression: `_time === null ? Date.now() / 1000 : _time`.

Group and Fleet Naming Conflict

Reported in	Resolved in	Ticket
3.3.0	4.7.2	CRIBL-25888

Problem: Groups and Fleets in Cribl Stream can have similar names, potentially causing issues when differentiated only by a hyphen (-) and underscore (_). For example: When configuring a Worker Group (e.g., CRIBL_GOAT) through the user interface (UI), the configuration helper might mistakenly retrieve settings from the similarly named Group or Fleet (CRIBL-GOAT). This crossover can cause significant configuration errors and operational disruptions.

Workaround: To avoid this issue, we recommend adopting a naming convention with distinct names for each Group/Fleet.

REST Collector job state issues with pagination

Reported in	Resolved in	Ticket
4.6.0	4.7.2	CRIBL-25763

Problem: The REST Collector's job state is incorrectly updated between tasks when using pagination. This can lead to inconsistent state tracking and potential data gaps or overlaps in the collected data. You may notice that the state from one paginated task affects subsequent tasks within the same job, causing unexpected behavior.

Workaround: Do not use pagination in your collection jobs alongside state tracking. Instead, schedule individual collection jobs for each page to ensure state isolation.

Unlinked jemalloc library may cause memory spikes

Reported in	Resolved in	Ticket
4.7.0	4.7.2	CRIBL-25702

Problem: jemalloc library being unlinked from the Cribl binary can potentially lead to memory spikes, affecting the stability and performance of the application on large-scale deployments. This issue only affects on-prem deployments using x84_64 architecture.

Workaround: In `/etc/systemd/system/cribl.service`, manually link jemalloc by adding `Environment=LD_PRELOAD=/opt/cribl/bin/libjemalloc.so`:

```
# existing lines
Environment=CRIBL_SERVICE=1
Environment=CRIBL_SERVICE_NAME=cribl
# link the jemalloc library
Environment=LD_PRELOAD=/opt/cribl/bin/libjemalloc.so
```

Syslog Sources with octet-count framing malfunction on unframed TCP messages

Reported in	Resolved in	Ticket
4.0.0	4.7.2	CRIBL-25572

Problem: Syslog Sources configured with octet-count framing (pre 4.7.0), or with `octetCounting: true` (via **Manage as JSON** since 4.7.0), can malfunction if they receive unframed messages over TCP. This will cause the Source to return many warning messages like `Invalid octet count: undefined. Trying to skip to next frame` and the Worker may run out of memory.

Workaround: Do not send non-octet-counted messages to a Syslog Source that is configured for octet-count framing.

Project Editor unable to edit Pipelines

Reported in	Resolved in	Ticket
4.7.1	4.7.2	CRIBL-25559

Problem: A user assigned the `Editor` permission within a Cribl Stream project is unable to edit pipelines in that project. When attempting to edit a **Pipeline**, the user encounters a permissions error.

Workaround: None identified.

Collector and Source state lost during Leader failover

Reported in	Resolved in	Ticket
4.6.0	4.7.2	CRIBL-25539

Problem: When a Leader Node fails over, the state for REST Collectors, Database Collectors, Wiz Sources, Kinesis Sources, and Windows Event Forwarder (WEF) Sources is not preserved.

Workaround: None identified.

Prometheus summary metrics in OTLP Format cause Kafka Destination errors

Reported in	Resolved in	Ticket
4.7.0	4.7.2	CRIBL-25435

Problem: Using a Prometheus Source for summary metrics, the `quantile_values` are formatted as an object. However, for OTLP (OpenTelemetry Protocol) serialization, `quantile_values` must be in array format. This discrepancy causes errors when attempting to write summary metrics to Kafka Destinations, resulting in failed metric transmissions.

Workaround: None identified.

SQL Server Collector Database Connection fails with Config authentication

Reported in	Resolved in	Ticket
4.7.0	4.7.2	CRIBL-25418

Problem: When upgrading to Cribl Stream 4.7.0, SQL Server Collectors configured to use the `Config` authentication method will fail to load, causing the Database Collector to stop working. The only valid authentication method for SQL Server Collectors will be the `Connection String`. Additionally, the section to manage Database Connections (under Knowledge) will not load existing connections.

Workaround: Manually edit each `database-connections.yml` configuration file where SQL Server Database Connections use the `configObj` authentication type. Change the authentication method to

`connectionString`.

1. To convert a config object to a connection string, refer to the relevant fields in this table: SQLConnection.ConnectionString. For each line in the config object, take the key, find the corresponding label in the table, and create a key-value pair in the connection string. For example, if the config object is `{ userid: 'test', server: 'tcp:servername portnumber' }`, the connection string should be: `userID=test;server=tcp:servername portnumber`.
2. Edit the `database-connections.yml` file, change `authType` from `configObject` to `connectionString`, and add the connection string to the file. The config object can remain, but a valid connection string must be added to get the Database Collectors working again in Cribl Stream.
3. To store the connection string encrypted you need to save the configuration in the UI. Make a minor change to the Database Connection, like, add and then remove a character in the description, and then save the configuration. Commit and deploy the changes as necessary.

Extra Auth fields are visible when configuring a Splunk Load Balanced Destination

Reported in	Resolved in	Ticket
4.7.0	4.7.2	CRIBL-25411

Problem: When configuring a Splunk Load Balanced Destination, you will see an extra **Authentication method** and **Auth token** field in **General Settings** (the fields are visible just above **OPTIONAL SETTINGS** and are outside of the **Authentication tokens** group). These fields are not needed, ignore them.

Workaround: Disregard the extra fields and use the fields in the **Authentication tokens** group instead.

Syslog source UDP events incorrectly parsed when not starting with < character

Reported in	Resolved in	Ticket
4.7.0	4.7.1	CRIBL-25400

Problem: When sending events via UDP to a Syslog Source where the events are not valid syslog and do not start with a < character, events may be broken incorrectly, leading to warnings, errors, and incorrectly parsed events.

Workarounds:

- Use the **Manage as JSON** option on the Source config and add this line: `inferFraming: false`.
- Use the Raw UDP Source instead for UDP datagrams that are not valid syslog.

Some Sources and Destinations don't appear on the Health page for a Fleet

Reported in	Resolved in	Ticket
4.7.0	4.7.2	CRIBL-25372

Issue: Some Sources and Destinations will not appear on the **Health** page for a Fleet. This appears to affect predominantly Windows Sources.

Workaround: Navigate to the specific Source or Destination and select **Chart** to view Fleet health metrics.

When upgrading from the Leader, some Windows Edge Nodes can fail to upgrade

Reported in	Resolved in	Ticket
4.6.0	4.7.2	CRIBL-25339

Problem: When upgrading from the Leader, some Windows Edge Nodes fail to upgrade. This occurs intermittently and is not predictable. This issue may also cause the Windows Edge Node to lose its connection to Leader and stop sending data.

Workaround: If you encounter this issue, you can manually uninstall and reinstall Cribl Edge on any failed Windows Nodes. However, Cribl Edge Nodes on version 4.6.0 continue to be compatible with Leader versions between versions 4.6.0 and 4.7.0 so you do not need to upgrade Edge Nodes at this time. Specifically, we recommend that you do not set a `Target Version` on Fleets that contain Windows Edge Nodes until we resolve this issue.

REST Collectors fail to capture response headers with pagination

Reported in	Resolved in	Ticket
4.6.1	4.7.2	CRIBL-25018

Problem: When you use REST Collectors with pagination enabled and turn on the **Capture response headers** toggle (introduced in the 4.6.1 release and off by default), the response headers are not captured as expected. When you toggle on **Show internal fields** in the result and expand the `__collectible` object, the `resHeaders` field is missing. This issue prevents you from accessing response header information during paginated data collection.

Workaround: None identified.

Unable to upgrade Leader and Workers from the UI when using CDN

Reported in	Resolved in	Ticket
4.6.0	4.7.0	CRIBL-24999

Problem: You're unable to upgrade the Leader and Worker Nodes from the UI. The upgrade process fails to check compatibility for the CDN, causing the upgrade to be blocked. The UI may incorrectly indicate that the currently installed version is the latest, even when newer versions are available in the CDN.

Workaround: Point the upgrade process to the download **Path** instead of the CDN.

Incorrect `bucket_counts` format in OTLP Metrics via Kafka Destination

Reported in	Resolved in	Ticket
4.5.0	4.7.0	CRIBL-24860

Problem: When sending Prometheus histogram metrics to an OTLP-compatible Destination via Kafka, the `bucket_counts` field is incorrectly formatted as an object instead of an array. This causes errors during Protobuf encoding, specifically the error: `.opentelemetry.proto.metrics.v1.HistogramDataPoint.bucket_counts: array expected`. This results in failed metric transmissions and potential data loss.

Workaround: None identified.

Full Preview doesn't work with Packs used as pre-processing Pipeline

Reported in	Resolved in	Ticket
4.5.1	4.7.2	CRIBL-24516

Problem: Pipeline's **Full Preview** tab presents incorrect information when using a pre-processing Pipeline coming from a Pack. This occurs only when previewing from the Leader – **Full Preview** from a Worker Node displays data correctly.

Workaround: Teleport to a Worker Node and run **Full Preview** from the Worker Node level.

Throttling causes some Destination senders to reconnect at each DNS resolution interval

Reported in	Resolved in	Ticket
4.5.1	4.7.0	CRIBL-24505

Problem: When you've configured **Throttling** on a Destination, a design conflict with the DNS resolution process leads to the reconnection of all senders in each DNS resolution cycle (every 10 minutes by default). This could cause the Destination to temporarily block and/or engage PQ, depending on the configuration, until senders reconnect. This affects the Cribl TCP, Syslog, and TCP JSON Destinations when load balancing is enabled.

Workaround: Don't use **Throttling** at the Destination.

Inactive Destinations in GitOps environments block data flow

Reported in	Resolved in	Ticket
4.4.4	4.7.2	CRIBL-22623

Problem: In GitOps environments, inactive Destinations are causing data flow to be blocked because the default backpressure behavior is to block. When a Destination is inactive, it triggers backpressure, preventing data from being processed and sent to other active Destinations.

Workaround: Change the backpressure behavior from `Block` to `Drop` or `Buffer` for the affected Destinations.

Configuration updates not shared between primary and standby Leaders

Reported in	Resolved in	Ticket
3.5.0	4.7.0	CRIBL-12814, CRIBL-14556

Problem: With high availability/failover enabled, updates to the active Leader's configuration are not automatically synced to the standby Leader. Workers might not be able to connect to the standby Leader when it takes over.

Workaround: Use the filesystem to explicitly sync the updated `instance.yml` file across the two Leaders' hosts. In 4.0.3 through 4.6.1, as an intermediate fix, enabling HA will prevent further UI-based changes to **Distributed Settings**. This will enforce config changes via edits to portable `instance.yml` files.

GitOps Push mode doesn't support ad hoc Collection jobs

Reported in	Resolved in	Ticket
3.5.3	4.7.2	CRIBL-12868

Problem: If you've enabled the GitOps Push workflow, you will be unable to run ad hoc Collection jobs.

Workaround: There are two options. 1. Temporarily disable the Push workflow in your environment. 2. Create a scheduled Collection job (with a relaxed cron schedule) on your dev branch, and push it to production through your Push workflow.

Resolved in 4.6

The following issues were resolved in version 4.6 and its maintenance releases.

Some licensing limits are being applied incorrectly

Reported in	Resolved in	Ticket
4.6.0	4.6.1	CRIBL-24687

Problem: After the Leader restarts, Cribl Stream may not apply your license correctly. Because of this error, you may have insufficient user privileges for certain features and limits. For example, Cribl Stream may not

correctly apply certain licensing limits, such as the total data volume allowed. Under certain conditions, this issue can block data ingestion. Note that this issue is timing-dependent so it can affect different areas of the product after a Leader restart.

Workaround: Two workarounds are available:

- Reapply the license in the user interface without restarting the Leader.
- Wait approximately one hour for the license manager to perform a periodic license check. This will reapply the license and may resolve the issue.

In environments that use a proxy or a TLS-breaking security appliance, the Worker / Edge Node to Leader communication is disrupted

Reported in	Resolved in	Ticket
4.6.0	4.6.1	CRIBL-24451

Problem: In version 4.6.0, we added SNI routing to Cribl Edge and Cribl Stream. This caused a communication issue between the Leader Node and Worker / Edge Nodes in proxied deployments of Cribl Stream and Edge. Edge and Worker Nodes reference the Leader Node using the TLS server name, `stream` or `edge`, which web proxies will block.

Workaround: There are several workaround options:

- Disable SNI routing for firewalls / web proxies. See our instructions here: Disable SNI Routing.
- Downgrade the Stream Worker / Edge Node to `4.5.1`.
- Bypass Worker / Edge node traffic to the Crib.Cloud Leader or local Leader around the proxy or security appliance.
- (Applies to certain security appliances only) Verify whether connections to the hostname `stream` or `edge` are being blocked on the security appliance, and add an exception or bypass.
    - Alternatively, modify the `/etc/hosts` file on Worker / Edge Nodes (`C:\Windows\system32\drivers\etc\hosts` for Windows Edge Nodes) to override the hostname(s) `stream` / `edge` to `127.0.0.1`. This prevents false-positive threat evaluations on the security appliance from blocking Worker / Edge to Leader traffic, and potentially block inputs/outputs on Worker / Edge Nodes.

Cribl Stream displays a permissions-related error in some areas of the user interface

Reported in	Resolved in	Ticket
4.6.0	4.6.1	CRIBL-24310

Problem: This issue is another form of CRIBL-24687, documented above.

Workaround: See CRIBL-24687.

Limits settings for Redis are not available in Cribl.Cloud

Reported in	Resolved in	Ticket
4.6.0	4.6.1	CRIBL-24269

Problem: The **Limits** settings at Worker Group level that on-prem deployments use are not available in Cribl.Cloud. Because the Redis settings (including **Reuse Redis connections**) are within that **Limits** UI, Worker Nodes in Cribl.Cloud do not have access to those settings.

Workaround: None identified.

UI can omit details when viewing Email Notifications via Manage > Notifications menu

Reported in	Resolved in	Ticket
4.6.0	4.6.1	CRIBL-24169

Problem: When an Organization Admin views an Email Notification via the **Manage** > **Notifications** menu, the notification's condition and/or other details may appear empty even though they exist. This also affects Product Admins for on-prem deployments.

Workaround: The Organization or Product Admin should view the notification this way instead: In a Worker Group, open the **Notifications** tab for the Source that was configured to send the notification. The notification and all its details will appear as usual.

Data Lake Amazon S3 Destination partitioning scheme is incorrect

Reported in	Resolved in	Ticket
4.5.1	4.6.1	CRIBL-23878

Problem: When you create a new Data Lake Amazon S3 Destination, its partitioning scheme will be incorrect.

Workaround: Deleting the incorrect partitioning scheme will cause the Destination to replace it with the correct one. To do this:

1. Open the Destination's configuration modal and click **Manage as JSON**.
2. Find the row beginning with the key `"partitionExpr"` – its value will be the incorrect partitioning expression `C.Time.strftime(_time ? _time : Date.now()/1000, '%Y/%m/%d')`.
3. Delete that entire row.
4. Click **OK** and save the changes.
5. To verify, reopen the configuration modal and click **Manage as JSON**. Check the `"partitionExpr"` row – its value will now be the correct partitioning expression `C.Time.s3TimePartition(_time ? _time : Date.now()/1000, 'h')`.

Splunk Single Instance and Splunk Load Balanced Destinations sending high-cardinality events over S2S v4 can leak memory

Reported in	Resolved in	Ticket
4.0.0	4.6.1	CRIBL-23793

Problem: The memory leak can happen when **Advanced Settings > Max S2S version** is set to `v4` and the combinations of `source`, `sourcetype`, and `host` on events flowing out of the Destination exceed 300 per Worker Process.

Workaround: Set **Advanced Settings > Max connections** to a non-zero value. This reduces the number of senders active at any one time, while distributing load more evenly as Cribl Stream rotates randomly through downstream IPs once per load balancing period.

Leader incorrectly indicates version mismatch for Worker Nodes

Reported in	Resolved in	Ticket
4.5.0	4.6.1	CRIBL-23657

Problem: After upgrading an instance of Cribl Stream with `CRIBL_VOLUME_DIR` set, if the Leader has connected Worker Nodes running different versions, the warning icon is incorrectly located next to Worker Nodes running the same version as the Leader, instead of those running the Leader's prior version.

Workaround: Manually restart Cribl Stream after upgrading with `CRIBL_VOLUME_DIR` set.

Permissions error appears when you try to edit a Pipeline

Reported in	Resolved in	Ticket
4.5.1	4.6.0	CRIBL-23627

Problem: Cribl Stream Project Members with the Editor permission cannot view or edit Pipelines within the Stream Project.

Workaround: None identified.

An error can occur when you click Save to create a new Worker Group or Fleet

Reported in	Resolved in	Ticket
4.5.1	4.6.0	CRIBL-23496

Problem: In Edge and Stream, an error can occur when you click **Save** to create a new Worker Group or Fleet. This error appears as a warning: `The Config Helper service is not available because a configuration file doesn't exist or the settings are invalid. Please fix it and restart Cribl server.`

Workaround: Refresh the page.

Amazon S3 Source and Destination, Amazon SQS Destination, and CrowdStrike Source crash in FIPS mode

Reported in	Resolved in	Ticket
4.5.1	4.6.0	CRIBL-23436

Problem: When Cribl Stream in FIPS mode attempts to read or write files, the Amazon S3 Source and Destination, Amazon SQS Destination, and CrowdStrike Source crash with a `digital envelope routines::unsupported` error. This happens because the underlying Amazon AWS SDK v2 is configured to use the MD5 algorithm, which is not allowed in FIPS mode. Cribl Stream 4.6.0 fixes this problem by configuring the AWS SDK to skip the checksum computation that used MD5.

Workaround: None identified.

Extracted traces from the OpenTelemetry Source not sent to OpenTelemetry Destinations

Reported in	Resolved in	Ticket
3.2.0	4.6.1	CRIBL-23394

Problem: When the OpenTelemetry Source is configured to **Extract spans**, the resulting span event cannot be passed to OpenTelemetry Destinations, like Honeycomb.

Workaround: Disabling **Extract spans** allows batched spans to be ingested without problems.

Diagnostic bundles cannot be created when git is enabled

Reported in	Resolved in	Ticket
4.4.0	4.6.0	CRIBL-23374

Problem: Attempting to create a diagnostic bundle fails when git is enabled, resulting in an error.

Workaround: In the **Create & Export Diag Bundle** window, disable **Include git**.

Diag doesn't collect logs when the `log` directory is a link

Reported in	Resolved in	Ticket
4.5.0	4.6.0	CRIBL-23312

Problem: When the `log` directory is a symbolic link, diag doesn't collect log information (without throwing any errors).

Workaround: Avoid using symbolic links for the `log` directory, or use a direct mount.

Users cannot log into unsecured LDAP servers

Reported in	Resolved in	Ticket
4.5.0	4.6.0	CRIBL-23237

Problem:

With **Access Management** > **Authentication** > **Type** set to `LDAP` and **Secure** toggled to `No`, you should be able to configure and run an unsecured (`ldap://`) LDAP server. See LDAP Authentication. However, this bug causes the **Secure** toggle to have no effect when set to `No`, meaning that your LDAP server must be configured with secure (`ldaps://`) connections or you will not be able to log in.

Workaround: There are two possible workarounds:

1. Run your LDAP server with secure LDAP authentication.
2. If you wish to run your LDAP server **without** secure LDAP authentication, downgrade or upgrade to run a Cribl Stream version **other than** 4.5.0 or 4.5.1.

Azure Data Explorer (ADX) Destination does not retry HTTP requests that come back with `520` response codes

Reported in	Resolved in	Ticket
4.4.4	4.6.1	CRIBL-23189

Problem: Cribl Stream should, but does not, retry HTTP requests that return an `520 Internal server error` response code.

Workaround: None identified.

Windows upgrades of Cribl Edge do not respect original installation directory

Reported in	Resolved in	Ticket
4.4.4	4.6.1	CRIBL-23032

Problem: When upgrading a Windows installation of Cribl Edge that was originally installed in a custom Windows directory (`E:\` for example), the upgrader moves Cribl Edge back to the `C:\` directory.

Workaround: None identified.

Product Documentation: Reference Architecture image download link is broken

Reported in	Resolved in	Ticket
4.1.0	4.6.1	CRIBL-22502

Problem: The editable diagram that appears in the All-in-One Reference Architecture section of the documentation is broken for all non-current release versions. Clicking the link for the `SVG` or `draw.io` file download results in a 403 error.

Workaround: Use the links in the most recent version of the documentation.

Splunk TCP Source logs include an unclear message about an unsupported payload

Reported in	Resolved in	Ticket
4.0.0	4.6.0	CRIBL-21845

Problem: Because the Splunk TCP Source does not support ingesting compressed data via the Splunk S2S protocol, it cannot parse such payloads, and a correct error message in this situation would say "Could not parse payload. Turn compression off in upstream sender and try again." Instead, the Source logs the unclear message "Failed to parse S2S payload".

Workaround: None identified.

Resolved in 4.5

The following issues were resolved in version 4.5 and its maintenance releases.

High-volume UDP data dropped in Cribl.Cloud

Reported in	Resolved in	Ticket
4.1.3	4.5.0	SAAS-4399

Problem: Ingesting high rates of UDP events per second can cause Cribl.Cloud to drop some of the data. This limitation of the UDP protocol affects UDP-supporting Sources: Raw UDP, Metrics, SNMP Trap, and Syslog in UDP mode.

Workaround: To minimize the risk of data loss, deploy a hybrid Stream Worker Group, with Worker Nodes as close to the UDP senders as possible.

Cribl also recommends tuning the OS UDP buffer size.

S3 Collector Path extractors setting has no effect

Reported in	Resolved in	Ticket
4.4.4	4.5.1	CRIBL-23338

Problem: In the S3 Collector, the **Collector Settings** > **Path extractors** setting has no effect because of a defect in the `index.js` file.

Workaround: Contact Cribl Support for assistance replacing the `index.js` file with a corrected one.

Running a reverse proxy with a custom baseUrl breaks the user interface

Reported in	Resolved in	Ticket
4.5.0	4.5.1	CRIBL-23089

Problem: If Cribl Stream is configured with a custom baseUrl, Leader deployments sitting behind a reverse proxy server experience user interface errors. The user interface fails to load data correctly from the backend, URLs fail to display the custom baseUrl address in the address bar, and using an address with the custom baseURL results in a 404 error.

Workaround: None identified.

The API Reference automatic authorization doesn't work in Cribl.Cloud

Reported in	Resolved in	Ticket
4.5.0	4.5.1	CRIBL-22822

Problem: In Cribl.Cloud, the API Reference (under **Global Settings**) uses an invalid access token. Because of this, you will receive an HTTP 401 error when you attempt to run an API command.

Workaround: To obtain a valid token, do the following:

1. Open the Developer Tools network tab in your browser and copy the authorization bearer token from one of your requests. Alternatively, you can follow the docs steps here to create a Cribl.Cloud API credential and obtain a token. Copy the token.
2. On the API Reference page, click **Authorize**.
3. In the resulting modal, click **Logout**.
4. Enter your copied token in the **Value** field and click **Authorize**.

When in the context of a Pack, the Pipeline link in the routing table is broken

Reported in	Resolved in	Ticket
4.5.0	4.5.1	CRIBL-22762

Problem: In the Pack context, under **Routes**, if you click the hyperlinked Pipeline name in the table, you will get an `Item not found` error. Clicking `Try again` from the error page does not resolve the issue. However, the link icon at the end of the Pipeline field in the routing table works as expected and brings you to the intended Pipeline page.

Workaround: Use the link icon at the end of the Pipeline field in the Route to access the Pipeline.

OTLP Metrics function does not parse `__criblMetrics` when metric values are strings

Reported in	Resolved in	Ticket
4.5.0	4.5.1	CRIBL-22731

Problem: Documentation for the Publish Metrics Function indicates that it evaluates the **Metric Name Expression** to the **Event Field Name**, but it actually returns a `null`. As a result, the OTLP Metrics function is unable to properly parse `__criblMetrics` when the metrics values are strings.

Workaround: When using Publish Metrics and OTLP Metrics together, use the Numerify Function before the OTLP Metrics Function.

Fleet-level log searches no longer work

Reported in	Resolved in	Ticket
4.5.0	4.5.1	CRIBL-22716

Problem: The **Edge** > **Manage** > **Logs** UI no longer supports searching logs across entire Fleets. The option will be removed in an upcoming release.

Workaround: Search individual nodes or across Fleets in Cribl Search instead.

Unable to upgrade Leader from 4.3.0 to 4.4.0 when an external KMS is enabled

Reported in	Resolved in	Ticket
4.4.0	4.5.0	CRIBL-22299

Problem: When attempting to upgrade the Leader from 4.3.0 to 4.4.0 with an external KMS enabled, you will receive several `Secret failed to decrypt` errors and the web UI will fail to load. This is due to an issue with how `client.secret` is handled when an external KMS is enabled.

Workaround: None identified.

Notification targets created in one Cribl product can be deleted from another without warning

Reported in	Resolved in	Ticket
3.1.0	4.5.1	CRIBL-22292

Problem: When you create a Notification target, it will be made available to all products in the Cribl suite. When you attempt to delete a target from the same application you created it in (for example, Cribl Stream), the product will properly prevent the deletion when there is an active notification using the target. However, if you switch to a new application (for example, Cribl Search), you will be allowed to delete the target without error or warning. This will leave the active notification in the original product (Stream) with an undefined target. You should not be able to delete the target if it is used by any active notification in any Cribl suite product.

Workaround: None identified.

Packs installed in Fleets are not visible to Subfleets.

Reported in	Resolved in	Ticket
4.0.0	4.5.0	CRIBL-19676

Problem: When a Fleet has Subfleets, and you install a Pack in the parent Fleet, none of the Subfleet's Pipeline drop-downs make the Pack available. This is true for Routes, pre-processing Pipelines in Sources, and post-processing Pipelines in Destinations.

Workaround: Install the Pack both in the parent Fleet, and in any Subfleets that need to use the Pack.

Product-level Editor Permissions do not allow a commit/deploy action on the Worker Groups/Fleets page

Reported in	Resolved in	Ticket
4.2.0	4.5.0	CRIBL-18970, CRIBL-20113

Problem: Users with product-level Edge **Editor** or Stream **Editor** Permissions are unable to commit and deploy changes made to Worker Groups or Fleets from the Group or Fleet page. However, if the user navigates to the Group or Fleet where the change was saved, the **Commit and Deploy** button is available.

Workaround: Commit and deploy from the Worker or Group where you saved the change.

Special characters in Source or Destination auth tokens cause authentication failure

Reported in	Resolved in	Ticket
4.4.0	4.5.1	CRIBL-17047

Problem: When you include special characters in a Source or Destination auth token, those characters may cause an authentication failure.

Workaround: Use only alphanumeric characters or the underscore (`_`) in a Source or Destination auth token. Do not use any of the following characters: `<`, `>`, `"`, `` ` ``, `\r`, `\n`, `\t`, `{`, `}`, `|`, `\`, `^`, or `'`. Alternatively, upgrade to Cribl Stream 4.5.1.

Splunk Load Balanced Destination degradation with acks enabled

Reported in	Resolved in	Ticket
3.4.1	4.5.0	CRIBL-12066

Problem: On a Splunk Load Balanced Destination, enabling the **Minimize in-flight data loss** (acknowledgments) field can cause high CPU drain and backpressure.

Workaround: On the Splunk LB Destination's **Advanced Settings** tab, disable **Minimize in-flight data loss**.

Resolved in 4.4

The following issues were resolved in version 4.4 and its maintenance releases.

Windows Event Forwarder Source used up its allowed quota of connections

Reported in	Resolved in	Ticket
4.0.0	4.4.4	CRIBL-21965

Problem: When the Windows Event Forwarder (WEF) Source could not process a request coming from a Windows client, it failed to correctly close the socket or send an error response to the client. Eventually, maximum allowable active connections could be reached, stopping the flow of data.

Workaround: For any affected WEF Source, set **Advanced Settings** > **Max active requests** to `0` to allow unlimited requests. Note that this will eventually cause other problems as the number of open-inactive sockets

grows, meaning that the Worker nodes will eventually need to be restarted.

Sources incorrectly report failure

Reported in	Resolved in	Ticket
4.0.0	4.4.4	CRIBL-21690

Problem: When using OpenTelemetry HTTP, the Source always listens on the default address (either `0.0.0.0` or `::`, or both, depending on the network configuration of the host), ignoring the option you configured in **General Settings** > **Address**.

Workaround: None identified.

Certain Sources and Destinations are unavailable in Edge and Worker instances

Reported in	Resolved in	Ticket
4.4.0	4.4.2	CRIBL-21443

Problem: Some Sources and Destinations, notably Cribl HTTP and Cribl TCP, report an error of being "disabled in the current deployment" when attempting to edit their configuration from the teleport view or by direct UI access.

Workaround: Instead of modifying configurations for Edge or Worker nodes from the teleport view or using direct UI access, only use Leader nodes to modify configurations for Worker nodes.

Azure Data Explorer Destination exposes irrelevant PQ settings in Cribl.Cloud

Reported in	Resolved in	Ticket
4.4.0	4.4.4	CRIBL-21335

Problem: For Worker Nodes in Cribl.Cloud with Azure Data Explorer (ADX) Destinations: such Destinations' **Persistent Queue Settings** should expose only a **Clear Persistent Queue** button. They are incorrectly also exposing the PQ settings required for on-prem deployments.

Workaround: In Cribl.Cloud ADX Destinations, ignore all Persistent Queue settings except the **Clear Persistent Queue** button.

"Unsupported system page size" error when upgrading the Leader

Reported in	Resolved in	Ticket
4.4.0	4.4.4	CRIBL-21289

Problem: Fedora users can experience an "unsupported system page size" error when upgrading the Leader. This is due to an issue with `jemalloc`.

Workaround: You can manually remove `jemalloc.so`. Docker users can use the following:

```
docker ... -e CRIBL_BEFORE_START_CMD_0="rm /opt/cribl/bin/libjemalloc.so" ...
```

Go version update required

Reported in	Resolved in	Ticket
4.4.0	4.4.2	CRIBL-21155

Problem: The Go version requires an update.

Workaround: None identified.

Azure Data Explorer Destination fails to validate database settings in Streaming mode

Reported in	Resolved in	Ticket
4.4.0	4.4.2	CRIBL-21123

Problem: When Azure Data Explorer Destination is in **Streaming** mode and **Validate database settings** is turned on, database validation will fail unless **Ingestion service URI** has been set in **Batching** mode first.

Workaround: Switch to **Batching** mode, set the **Ingestion service URI** field, and save the Destination. Then switch back to **Streaming** mode and save the Destination again.

Stream Groups' Members indicators always show zero count

Reported in	Resolved in	Ticket
4.4.0	4.4.4	CRIBL-21099, CRIBL-22072

Problem: On a Stream Worker Group's **Manage** > **Overview** page, the **Members** counters show `0` in all Roles/Permissions, even when Members have been added.

Workaround: Navigate to **Group Settings** > **Members** for an accurate view of all Members and their access levels.

Worker Node generates an incomplete diagnostic bundle when Include git is enabled

Reported in	Resolved in	Ticket
4.4.0	4.4.2	CRIBL-21093

Problem: When you teleport to a Worker Node and create a diagnostic bundle, if you leave **Include git** toggled on in the **Create & Export Diag Bundle** modal, the bundle that the system creates will be malformed and missing information, and the UI will produce a fatal error notification.

Workaround: When you create diagnostic bundles, turn **Include git** off.

Azure Data Explorer Destination does not correctly turn off Validate database settings

Reported in	Resolved in	Ticket
4.4.0	4.4.2	CRIBL-21060

Problem: Once the Azure Data Explorer Destination has been saved with **Validate database settings** on, turning the setting off has no effect, and the Destination performs validation anyway.

Workaround: To ensure that **Validate database settings** is turned off, perform either of these two workarounds:

Option 1: Clone the Destination or create a new one, and turn **Validate database settings** off before saving.

Option 2: Turn off **Validate database settings**, then restart the Cribl Stream Worker Node.

Rapid logging causes Worker Node memory spikes and prevents logging

Reported in	Resolved in	Ticket
4.3.0	4.4.2	CRIBL-20607

Problem: A large number of logs written in a short time causes memory spikes in Worker Nodes and stops log output.

Workaround: None identified.

Upgrading to 4.3.0 or later causes Amazon Kinesis Data Streams and WEF Sources to lose state

Reported in	Resolved in	Ticket
4.3.0	4.4.2	CRIBL-20444

Problem:

After an upgrade to 4.3.0, Worker Nodes for a Cribl Stream Amazon Kinesis Data Streams Source or Windows Event Forwarder (WEF) Source can lose state upon init. This can be especially problematic for customers with large streams and high data ingestion.

An Amazon Kinesis Data Streams Source that loses state will fail to read a data stream from the point where it most recently left off. Instead, the Source will start reading from the location configured by **Optional Settings** > **Shard iterator start**.

- If **Shard iterator start** is set to `Earliest Record` (the default), the Source can start too far behind in the stream to ever catch up.
- If **Shard iterator start** is set to `Latest Record`, the Source can start later than where it left off, causing some records to be skipped.

A Microsoft Windows Event Forwarder (WEF) Source (with bookmarks configured for the subscription) that loses state will fail to request that upstream clients send events starting at a bookmarked location. Instead,

Cribl Stream will send no bookmark, prompting upstream clients to send **all** events that otherwise match the subscription. This can cause Cribl Stream to ingest duplicate events from WEF clients.

Workaround: If you have not yet upgraded to 4.3.0 or later, consider delaying the upgrade until this issue is fixed.

After upgrading, Monitoring dashboards are not visible for users with `GroupRead` and `GroupCollect` Policies

Reported in	Resolved in	Ticket
4.2.0	4.4.3	CRIBL-18925

Problem: Users that were assigned `GroupRead` and `GroupCollect` Policies in Cribl Stream 4.1.0 will no longer be able to access the **Monitoring** tab and dashboard after upgrading to Cribl Stream 4.2.

Workaround: For `GroupRead`, migrate the user to **Read Only** Permission at the Group-level in Members and Permissions. Assign the Member as Stream **User** then set their Permissions for the group as **Read Only**. For `GroupCollect`, there is no specific workaround but users can be assigned the `GroupEdit` Policy if they need to view Monitoring dashboards.

Unable to bind `CRIBL_DIST_MASTER_URL` to an IPv6 address

Reported in	Resolved in	Ticket
4.1.0	4.4.0	CRIBL-16284

Problem: Due to an issue with the `CRIBL_DIST_MASTER_URL` environment variable, Cribl will not bind to a specified IPv6 address.

Workaround: Manually update the settings in the two relevant configuration files, `instance.yml` and `cribl.yml`, for RPC and UI communication respectively.

For the UI, manually define the host setting in the `cribl.yml` file:

```
api:
  host: "::"
```

To configure the instance as a Leader node and listen on all IPv6 and IPv4 addresses, manually configure the `instance.yml` file:

```
distributed:
  mode: master
  master:
    host: "::"
    port: 4200
    tls:
      disabled: true
    authToken: criblmaster
```

Cascading problems when Windows Event Logs Source collects from `ForwardedEvents` channel

Reported in	Resolved in	Ticket
3.5.0	4.4.0	CRIBL-14869

Problem: Using the Windows Event Logs Source to collect events from a Windows `ForwardedEvents` channel can cause misattribution of logs to the local machine that hosts Cribl Edge, and undercollection of local logs from other logging channels (such as Security, System, or Application).

Workaround: Exclude the `ForwardedLogs` channel from your **Event Logs** selection.

Resolved in 4.3

The following issues were resolved in version 4.3 and its maintenance releases.

Microsoft Windows Installer (MSI) does not create an Edge desktop shortcut

Reported in	Resolved in	Ticket
4.3.0	4.3.1	CRIBL-20504

Problem: When you install Cribl Edge on Windows, the MSI doesn't create the expected desktop shortcut for Edge, even if you select **Create a shortcut for Cribl Edge on the desktop**.

Workaround: None identified.

Scheduled (cron-based) jobs fail to load for some Sources and Collectors

Reported in	Resolved in	Ticket
4.3.0	4.3.1	CRIBL-20088

Problem: Collection tasks for Office 365 Sources, the Splunk Search Source, the Prometheus Scraper Source, and scheduled Collectors fail to load when the Leader restarts, fails over, or upgrades. Collectors running jobs ad hoc are not affected.

Workaround: If you're using one of the listed Sources or use scheduled Collector jobs on-prem, do not upgrade to 4.3.0. If you are already on 4.3.0, downgrade to 4.2.2, or wait and upgrade to 4.3.1 when it's available.

You can also restart the config helper for on-prem installations using the command: `pkill -f CONFIG_HELPER`

You must run this command each time the Leader fails over, or is restarted (ideally, not too often).

Chain Function's link breaks when the chained Pipeline/Pack is resaved

Reported in	Resolved in	Ticket
4.3.0	4.3.1	CRIBL-20083

Problem: After linking a Chain Function to a Pipeline or Pack, resaving the target Pipeline/Pack triggers `Invalid link` errors.

Workaround: 1. Copy the Pipeline containing the Chain Function to your clipboard, delete the original Pipeline, and then paste the copy to resolve the error. 2. Alternatively, on-prem admins can restart the config helper that manages the Worker Group. (In the UI, navigate to **Settings** > **Global** > **System** > **Services** > **Processes**.)

In Cribl.Cloud, Admin Members cannot modify Global Settings

Reported in	Resolved in	Ticket
4.3.0	4.3.1	CRIBL-20038

Problem: After upgrading to 4.3.0, Members granted the Admin Permission cannot modify Global Settings.

Workaround: Members with the Owner Permission can still modify Global Settings.

Worker Nodes cannot be upgraded in Leader-managed upgrades

Reported in	Resolved in	Ticket
4.3.0	4.3.1	CRIBL-20086

Problem: In Stream and Edge, if you upgrade the Leader to 4.3.0, then use **Commit & Deploy** to push configs to Worker Groups before upgrading Worker Nodes to 4.3.0, you won't be able to upgrade the Worker Nodes from the Leader thereafter.

This issue affects only Leader-managed upgrades of Worker Nodes.

Workaround: If a Leader is on 4.3.0, you should upgrade all Worker Nodes to 4.3.0 before making any config changes or committing and deploying to the Nodes.

If you have already committed and deployed to Worker Nodes that are on a version prior to 4.3.0 (and the Leader is on 4.3.0), here are three workaround options:

- Revert and redeploy the last commit, then upgrade the Worker Nodes and deploy the most up-to-date changes, **OR**
- Upgrade the Worker Nodes via command line or script, **OR**
- Downgrade the Leader to 4.2.2 and then upgrade to 4.3.1 when it is available.

If you run into issues, contact support@cribl.io for resolution assistance.

Any Code Function before another Function breaks the Data Preview OUT tab display

Reported in	Resolved in	Ticket
4.3.0	4.3.1	CRIBL-20040

Problem: Any Code Function inserted before the end of a Pipeline prevents the Data Preview OUT tab from rendering properly. This occurs even if the Code Function contains only a single comment, or is blank. Adding a Code Function at the end of a Pipeline does not cause an issue. This is a Data Preview UI issue only – if you capture events to a Destination, Cribl Stream processes them as expected.

Workaround: None identified.

Numeric sub-second values sent over S2S v4 require care to avoid incorrect stringification

Reported in	Resolved in	Ticket
4.0.0	4.3.1	CRIBL-20017

Problem: Events received from S2S v4 can have sub-second granularity, meaning that the Splunk TCP Source reads a sub-second value from ingested events and uses it to set a `_subsecond` field added to outgoing events. If, for example, the Source sets the `_subsecond` field with a stringified numeric value instead of the actual number, problems can occur that affect downstream receivers such as Splunk indexers.

Workaround: Either of the following workarounds can be effective:

1. Upgrade to Cribl Stream 4.3.1 or newer.
2. In a Pipeline, drop or numerify any `_subsecond` field whose value is a string.

When in XML format, the Windows Event Logs Source doesn't accept log names that contain spaces

Reported in	Resolved in	Ticket
4.2.2	4.3.0	CRIBL-19818

Problem: When the Windows Event Logs Source is set to XML format, any configured log names that contain spaces (e.g., `Windows Powershell`) cause an error and the log can't be read.

Workaround: None identified.

PQ doesn't drain for the Event Hubs Destination when Acknowledgements is set to All or Leader

Reported in	Resolved in	Ticket
4.2.2	4.3.1	CRIBL-19756

Problem: When the `Acknowledgements` setting is set to `All` or `Leader`, Kafka-based Destinations (especially Azure Event Hubs) can fail to drain the persistent queue (PQ) and the logs are filled with `Attempting to send faster than the downstream can receive – consider checking the network connection and broker health` errors.

Workaround: You can set a limit using the `Persistent Queue Drain rate limit (EPS)` setting (for example, set it to `500`) to get the PQ to drain when the datagen is turned off. However, if the rate of data input continues to exceed the rate at which the Destination can send events downstream (which is slowed by the `Acknowledgements` setting), the PQ will continue to build. Alternatively, you can set the `Acknowledgements` setting to `None`, which significantly increases the rate at which data can be sent to Event Hubs.

Deleting a Source via QuickConnect doesn't refresh the view

Reported in	Resolved in	Ticket
4.2.0	4.3.0	CRIBL-19709

Problem: When using QuickConnect, if you delete a Source by opening its drawer and clicking `Delete Source`, the Source is deleted. However, it will continue to show on the page until you manually refresh the page.

Workaround: Manually refresh the page after deleting a Source.

When adding or editing a Route, typeahead misbehaves in the Filter field

Reported in	Resolved in	Ticket
4.2.2	4.3.0	CRIBL-19571

Problem: Entering text in the **Filter** field of a Route is difficult in Cribl Stream 4.2.2 because the typeahead function behaves erratically, sometimes moving the cursor around or inserting text fragments.

Workaround: 1. Assemble the filter expression in a different Cribl expression field, or in any text editor, then copy and paste it here. 2. Alternatively, click the Manage as JSON button at the **Data Routes** table's upper right.

Then, in the JSON editor, build the expression as the `"filter":` key's value.

Group Information for Cribl.Cloud Worker Groups not showing on summary page for SSO users

Reported in	Resolved in	Ticket
4.2.2	4.3.0	CRIBL-19107

Problem: On Cribl.Cloud Organizations, when you open a Stream Group's **Manage** > **Overview** page, the **Group Information** section is not populated for users imported using SSO from external identity providers. (This section populates correctly for users/Members configured natively within your Cribl Organization.)

Workaround: None identified.

When configuring an S3 Collector, JavaScript expressions break the "Auto-populate from" option for the Path field

Reported in	Resolved in	Ticket
2.3.0	4.3.0	CRIBL-18844

Problem: When automatically populating an S3 Collector from an S3 Destination, the Collector **Path** field won't resolve JavaScript expressions, even if the expression was valid on the Destination that the field was populated from. The S3 Collector path is treated like a literal string and the software fails to warn you that the path is invalid.

Workaround: None identified.

When configuring an HTTP Source, enabling Source PQ changes the inputId in events

Reported in	Resolved in	Ticket
4.1.3	4.3.0	CRIBL-18668

Problem: When Source-side Persistent Queueing is enabled on an HTTP Source, the trailing colon is dropped from `__inputId`. This will break Routes and filters that are based on the Input ID if it is copied from the configuration page. Live captures will also stop working until you modify them.

Workaround: None identified.

Default Pack is not visible to Project Editor when a Project is shared with them

Reported in	Resolved in	Ticket
4.2.0	4.3.0	CRIBL-18639

Problem: When a Cribl admin sets up a Project, a default Pack is included. If the Admin then shares that Project with a Project editor, the editor will not see the default Pack.

Workaround: In the Project view, the Project editor can add any Pack that has been made available by the admin, including the default Pack.

Users with Group-level Read Only Permissions can interact with logging level menus

Reported in	Resolved in	Ticket
4.2.0	4.3.1	CRIBL-18556

Problem: Users with the **Read Only** Permission at the Group-level can access the **Add Channel** and **Delete** buttons under **Group** > **Manage** > **Group Settings** > **Logging** > **Levels**. However, they are unable to save changes. When performing these actions, **Read Only** users will see a **Forbidden** message displayed in the UI and no changes will be saved. The setting should not be accessible to users with this Permission.

Workaround: None identified.

HTTP Destinations sometimes send oversized payloads

Reported in	Resolved in	Ticket
4.2.0	4.3.0	CRIBL-18218

Problem: HTTP-based Destinations do not strictly enforce the **Max Body Size** limit in all cases. This can cause payloads to be sent that exceed the maximum size some downstream receivers can accept.

Workaround: Experiment with lower **Max Body Size** values until downstream receivers are reliably accepting all events.

If a deployment fails, Workers will not automatically revert to the previous version

Reported in	Resolved in	Ticket
4.1.0	4.3.1	CRIBL-16203

Problem: When a deployment fails, Workers cannot revert `default/cribl` to a previous version because that directory is no longer backed up. The Worker will enter a broken state if you provide an invalid deploy bundle, because it cannot revert to the last valid state.

Workaround: To resolve any broken Workers, you must deploy a valid configuration. The Worker will resume working once it picks up the new configuration.

Cribl Edge/Windows Limitation: Cannot upgrade Edge Nodes from the Leader's UI

Reported in	Resolved in	Ticket
3.5.0	4.3.0	CRIBL-10870

Problem: Cribl Edge/Windows does not support upgrading Edge Nodes via the Leader's UI.

Workaround: Rerun the Windows installer on each Edge Node, specifying the same installation options/parameters you used when installing the preceding version.

Resolved in 4.2

The following issues were resolved in version 4.2 and its maintenance releases.

Inherited Packs in Fleets lose their configured Routes

Reported in	Resolved in	Ticket
4.0.0	4.2.0	CRIBL-19700

Problem: Routes in a Pack at the Fleet level revert to default Routes when inherited by a SubFleet.

Workaround: None identified.

File Monitor Source causes memory leaks and Worker Node crashes

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-19154

Problem: The File Monitor Source, when running in Manual Discovery mode, leaks memory and a file descriptor each time it rediscovers a file that it has already collected. The leaked resources increase with every polling interval, for every rediscovered file, eventually causing Worker Nodes to crash. This does not affect Auto Discovery mode, and does not affect deployments without an active File Monitor Source.

Workaround: File Monitor users should bypass (or roll back from) versions 4.2.0–4.2.1.

AppScope Source might reference a nonexistent config

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-19044

Problem: The 'sample_config' stock configuration was removed in 4.2.0. This missing config causes the Appscope Source to disappear from the UI, and changes to other Sources also fail with validation errors.

Workaround: For on-prem deployments, clone one of the existing AppScope configurations and rename it to `sample_config`. For Cribl.Cloud customers, there is no workaround yet.

Users with the Admin Permission cannot view Notifications

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-19015

Problem: Users with the **Admin** Permission receive a `You do not have sufficient permissions to access this resource` message when attempting to view Notifications. Users with this Permission should be able to access Notifications.

Workaround: None identified. Organization **Owners** can access these notifications.

Users with the Admin Permission cannot bootstrap a Worker due to a missing auth token

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-19014

Problem: Users with the **Admin** Permission can't add a Worker using **Add / Update Worker Node**, because the modal doesn't have the **Leader hostname/IP** or the **Auth token** fields populated. You can enter the hostname/IP into its field, but not the auth token. Users with the **Admin** Permission should see the auth token.

Workaround: Organization **Owners** can perform this action and share the auth token.

Credential encryption errors preventing user access to Cribl Stream Sources and Destinations

Reported in	Resolved in	Ticket
4.2.0	4.2.1	SAAS-4823

Problem: A critical regression caused Worker Groups to become unresponsive, preventing access to Sources and Destinations. This issue was caused by incorrectly encrypted credentials.

Workaround: Upgrade to Cribl Stream 4.2.1.

Users with the Edge Editor Permission cannot delete secrets under Fleet Settings

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18969

Problem: Users with the Edge **Editor** Permission can create secrets under **Fleet** > **Fleet Settings** > **Secrets** but they are unable to delete the secret once it is created. Edge **Editors** should have this capability.

Workaround: Assign the Edge **Admin** Permission to users that need to be able to delete secrets.

Edge Node Settings not visible when teleporting

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18963

Problem: When you teleport into an Edge Node, you can't view **Node Settings** in the UI.

Workaround: None identified.

Users with the Edge Editor Permission cannot delete Sources, Destinations, or Pipelines

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18951

Problem: If you assign a user the Edge **Editor** permission at the product-level, the user will not be able to delete Sources, Destinations, or Pipelines. Edge **Editors** should have this capability.

Workaround: Assign the Edge **Admin** Permission to users that need to be able to delete these items.

Change from Edge User to Edge Editor can fail to take effect

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18950

Problem: If you assign the **Editor** Permission to an Edge **User** at the Fleet-level and then later assign the Edge **Editor** Permission to the same User at the product-level (Edge **User** now becomes an Edge **Editor**), the **Editor** Permission at the product-level can fail to take effect. The user will have **Editor** access to the one Fleet at the Fleet-level but they will still show as an Edge User and will not have **Editor** Permissions at the product-level.

Workaround: None identified.

Product logins for users with product-level Read Only and Editor Permissions can result in misleading log entries

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18948

Problem: When users that are assigned product-level **Read Only** or **Editor** Permissions log in to a product, the browser incorrectly makes requests for resources that users at this level are not allowed to access. While these requests are correctly denied and there is no risk of compromising security, Cribl admins may see misleading log entries indicating that these users tried to access something they are not allowed to access.

Workaround: None identified.

Edge users with the Fleet-level Editor Permissions cannot use manual file discovery

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18923

Problem: When using manual file discovery in Cribl Edge, users that have been assigned the **Editor** Permission at the Group/Fleet-level will not see any results.

Workaround: You can assign the **Admin** Permission for users that require the manual file discovery feature.

Stream Users are able to access the Monitoring page

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18848

Problem: Stream **Users** with no Group-level Permissions are able to access the **Monitoring** page. The **Monitoring** menu item is hidden, but the page can be access manually using a URL.

Workaround: None identified.

Recent Actions endpoint returns results for certain unauthorized users

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18818

Problem: The Recent Actions endpoint `GET /api/v1/ui/recentActions` returns more recent actions than intended for non-admin users.

No Access to Subfleets for the Edge User Permission

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18784

Problem: Regardless of what Permissions are granted at the Fleet-level, Edge members assigned to the **User** Permission will not have access to Subfleets.

Workaround: At the (Edge) product level, you must grant your members **Read Only**, **Editor**, or **Admin** Permissions so that they can access Subfleets.

(Linux) System Metrics Source does not emit "Per interface" metrics when set to "All"

Reported in	Resolved in	Ticket
3.5.0	4.2.0	CRIBL-18473

Problem: In the (Linux) **System Metrics** Source > **Host Metrics** tab, selecting **All** does not emit **Per Interface** metrics.

Workaround: In the **Host Metrics** tab, select **Custom** > **Network** > **Custom** then toggle **Per interface metrics** to `Yes`.

Project editor can't delete Pipelines via Options menu

Reported in	Resolved in	Ticket
4.2.0	4.2.2	CRIBL-18447

Problem: In a Project's **Pipelines** modal, when a Project editor opens a Pipeline's ••• (Options) menu, the **Delete** option is unavailable. Cribl Stream displays a spurious error about insufficient permissions.

Workaround: Use the list's check boxes to select Pipelines, then click **Delete Selected Pipelines**.

High CPU usage in File Monitor Source's Manual mode

Reported in	Resolved in	Ticket
4.1.3	4.2.0	CRIBL-18400

Problem: In the **File Monitor** Source and the **Explore** > **Files** tab UI, the **Manual** mode does not honor the **Max depth** setting. The API process consumes high CPU resources because the discovery logic (used in the **File Monitor** Source and **Files** tab) recurses in the directory tree.

Workaround: None identified.

Using the Rename Function gives unexpected results due to skipped internal fields

Reported in	Resolved in	Ticket
3.5.2	4.2.0	CRIBL-18285

Problem: When internal fields are present in the `Rename fields` list, the Rename Function may incorrectly assign field keys or values.

Workaround: This function is not intended to operate on internal fields. Avoid this operation.

Amazon CloudWatch Destinations log error while flushing events older than 24 hours

Reported in	Resolved in	Ticket
4.1.3	4.2.0	CRIBL-18184

Problem: Amazon CloudWatch Destination doesn't filter batches of events to ensure all events in the batch are within 24 hours of each other as required by the API, resulting in the batch being rejected by Cloudwatch.

Workaround: Add a Post-Processing Pipeline with a Drop Function using a Filter Expression of `_time<(Date.now() / 1000) - 86400`.

The Office 365 Activity Source misses events

Reported in	Resolved in	Ticket
4.1.2	4.2.0	CRIBL-18164

Problem: The Office 365 Activity Source misses events due to the current collection system. For services such as Exchange, SharePoint, OneDrive, and Teams, Microsoft indicates that audit record availability is typically 60 to 90 minutes after an event occurs. Our current collector methodology does not account for this availability window. Instead, the Source completes runs as scheduled and collects only events it finds during the configured time range, which can lead to missed events.

Workaround: None identified.

GroupEdit is not able to commit changes

Reported in	Resolved in	Ticket
4.0.0	4.2.0	CRIBL-17939

Problem: Users having the `GroupEdit` policy are able to make changes (e.g. create new Sources) but are unable to **Commit** their changes. These users should be able to **Commit**, but not **Deploy**, changes.

Workaround: Apply the `GroupFull` policy for users that need to be able to **Commit** changes. These users will also have the ability to deploy a Worker Group or Fleet.

Worker Nodes don't update from Cribl Stream Leader

Reported in	Resolved in	Ticket
4.1.2	4.2.0	CRIBL-17792

Problem: In Cribl Stream 4.1.2–4.1.3, if you define the `baseURL` key on a Leader, Worker Nodes don't get the latest config version from the Leader. The log may also contain `checksum mismatch` warnings.

Workaround: Clear **URL base path** in **Settings** > **General Settings** > **Advanced** or specify an empty `baseURL` key in `cribl.yml`. If you need to define a base URL, do not upgrade to the affected versions.

Windows Event Forwarder Source causes duplicate events when experiencing backpressure

Reported in	Resolved in	Ticket
4.0.0	4.2.0	CRIBL-17614

Problem: In certain cases where the Windows Event Forwarder Source experiences backpressure from a downstream Pipeline or Destination, it will return an incorrect error message to the client that sent the events.

This causes that client to re-send the same events and results in duplicate events ingested in Stream.

Workaround: In cases where the cause of the backpressure can be resolved, this issue is mitigated. However if the backpressure cannot be completely removed, there is no additional workaround.

Kafka-based Destinations fail to report backpressure properly

Reported in	Resolved in	Ticket
4.1.0	4.2.2	CRIBL-16944

Problem: With a downstream receiver exerting backpressure, Kafka-based Destinations do not report backpressure promptly, even though they effectively exert backpressure. As a result, upstream data might stall for several minutes before appropriate errors surface in the Destination's health status, and PQ (if configured) will not engage promptly.

Workaround: Decreasing the value for the `Request timeout (ms)` setting within the `Advanced Settings` section of the destination configuration might lead to the Destination reporting backpressure more promptly.

The Chain Function has a 10% impact on performance

Reported in	Resolved in	Ticket
4.1.0	4.2.2	CRIBL-15538

Problem: Using the Chain Function to chain data processing from one Pipeline or Pack to another degrades performance by about 10%, compared to running the original Pipeline or Pack directly.

Workaround: None identified.

Azure Event Hubs Destination with PQ drops events when inbound data is interrupted

Reported in	Resolved in	Ticket
3.5.3	4.2.0	CRIBL-17661, replaces CRIBL-12649

Problem: When Azure Event Hubs (and other Kafka-based Destinations) have persistent queues (PQs) configured, an interruption of inbound data flow (e.g., due to network issues) can cause the Destination to start dropping events.

Workaround: On the Source whose events are being interrupted, configure an Always On persistent queue. This buffering will cause the Destination to drop fewer events. Note that persistent queuing will not engage until Cribl Stream has exhausted all attempts to send the data to the Kafka receiver.

Resolved in 4.1

The following issues were resolved in version 4.1 and its maintenance releases.

AES-256-GCM security vulnerability

Reported in	Resolved in	Ticket
4.1.2	4.1.3	CRIBL-18038

Problem: The AES-256-GCM encryption option introduced in 4.1.2 included a security vulnerability.

Workaround: Do not use this option in 4.1.2.

Kubernetes Logs Event Breaker Incorrectly Breaks Events

Reported in	Resolved in	Ticket
4.1.0	4.1.3	CRIBL-17907

Problem: The **Kubernetes Logs** Event Breaker incorrectly breaks events with out-of-order timestamps.

Workaround: In the Event Breaker, move the logic that adjusts `_raw` into a **Pre-Processing** Pipeline.

Perf bug: RPC consuming excessive CPU compiling expressions

Reported in	Resolved in	Ticket
4.1.1	4.1.3	CRIBL-17779

Problem: In 4.1.1, to improve product security, we changed how we manage our RPC traffic from Leaders and Workers. This change can have a negative impact in larger environments with many Worker Processes. Following a 4.1.1 or 4.1.2 upgrade, the Leader can become non-responsive to UI requests due to a steady 100% CPU utilization. When this happens, you cannot manage or monitor Cribl Stream environments.

Workaround: Roll back to a previous stable version, such as 4.1.0.

CrowdStrike Destination's "LogScale endpoint" field hidden from UI

Reported in	Resolved in	Ticket
4.1.2	4.1.3	CRIBL-17715

Problem: The CrowdStrike Falcon LogScale Destination's **LogScale endpoint** field is hidden from the 4.1.2 configuration modal, but can be restored.

Workaround: Follow these steps, in sequence, for each LogScale Destination. 1. Populate the LogScale config modal, and save once. 2. Reopen the modal, then select **Manage as JSON**. 3. Change the `"loadbalanced":` key's value from `true` to `false`. 4. Copy this default nested element: `"url": "https://cloud.us.humio.com/api/v1/ingest/hec",` 5. Paste it above the whole `"urls"` element (typically at line 21). 6. Click **OK** to restore the visual UI, with the **LogScale endpoint** field now visible. 7. Enter your actual endpoint URL, and save the config.

Expanding Status of Output Router Destination triggers error

Reported in	Resolved in	Ticket
4.1.1	4.1.3	CRIBL-17632

Problem: When you attempt to expand a node on the **Status** tab for an Output Router Destination, the page crashes and the error `Cannot convert undefined or null to object` appears.

Workaround: None identified.

The Kubernetes Logs Source drops events

Reported in	Resolved in	Ticket
4.0.0	4.1.3	CRIBL-17602

Problem: Events from a running container will stall when the underlying container runtime rotates the log file. Any further rotation of log files will result in data loss.

Workaround: Restart the Kubernetes Logs Source to reconnect.

S3 ingestion slows after upgrade

Reported in	Resolved in	Ticket
4.1.1	4.1.2	CRIBL-17317

Problem: After upgrading to Cribl Stream 4.1.1, ingesting using any `JSON` Array Event Breaker (such as AWS CloudTrail) will slow or stop due to high CPU usage.

Workaround: Roll back to a previous stable version, such as 4.1.0.

Worker Nodes integrated with `systemd/initd` can fail upon reconfig

Reported in	Resolved in	Ticket
4.1.1	4.1.2	CRIBL-17264

Problem: Where 4.1.1 customer-managed (hybrid or on-prem) Worker Nodes (on Linux) are integrated with `systemd/initd`, deploying new config bundles to those Worker Nodes can stop the Worker Nodes from processing data. The root cause is an incorrect backup step, which (depending on permissions) can also consume large amounts of disk space on their hosts.

Precondition: Cribl-managed Cloud instances are unaffected. This problem has been observed only if at least one of the following directories is populated, or exists with restricted permissions:

```
/data/
/default/cribl/
/default/edge/
/local/cribl/
/local/edge/
/default/<any-installed-Pack-name>/
/local/<any-installed-Pack-name>/
```

Workaround: Skip 4.1.1 or roll back to your last stable version. To run 4.1.1, this workaround is available on systemd's `Service` section: 1. In the script `/etc/systemd/system/cribl.service`, add the line: `WorkingDirectory=/opt/cribl`, (This is the default path – specify your own path equivalent to

`$CRIBL_HOME`). 2. Then reload the systemd daemon: `systemctl daemon-reload`. 3. Then restart the Cribl Stream instance using `systemctl restart <service name>`.

Requests from Office 365 Message Trace Source failed intermittently

Reported in	Resolved in	Ticket
2.2.0	4.1.0	CRIBL-16929

Problem: Microsoft has fixed this Office 365 Message Trace API problem with this patch (Microsoft login required). Before this patch, requests failed intermittently, often with `Non-whitespace` errors.

Workaround: None identified.

Monitoring incorrectly shows metrics for disconnected Subscriptions

Reported in	Resolved in	Ticket
4.1.1	4.1.2	CRIBL-16926

Problem: Selecting **Monitoring** > **Data** > **Subscriptions** will falsely show statistics even for Subscriptions that are not connected to a Destination, and therefore have no data flow.

Workaround: Ignore these Monitoring statistics.

Windows Event Logs Source should have a configurable Max Event Size

Reported in	Resolved in	Ticket
4.1.0	4.1.1	CRIBL-16549

Problem: Events aren't broken properly when collecting logs from the PowerShell event log. The Source contains a Max Event Limit of `51200`, which is a hard-coded breaker config. This limit should be configurable.

Workaround: None identified.

Cribl.Cloud API Credential's Roles aren't honored on tokens

Reported in	Resolved in	Ticket
4.1.0	4.1.2	SAAS-3681

Problem: API Bearer tokens obtained through the Cribl.Cloud portal are all granted the `Admin` Role, regardless of the scope specified on the parent Credential.

Workaround: Use the pre-4.0 workaround to obtain Bearer tokens from the in-app API Reference.

Splunk Load Balanced Destination incorrectly re-creates all connections during DNS resolution

Reported in	Resolved in	Ticket
4.1.0	4.1.1	CRIBL-16494

Problem: When **Minimize in-flight data loss** is enabled, the Splunk Load Balanced Destination re-creates all outbound connections during DNS resolution. This will cause the Destination to report a blocked status until the outbound connections refresh. If persistent queues (PQ) are enabled, PQ will engage while the Destination is blocked.

Workaround: Select the Destination's **Manage as JSON** option, to add the key-value pair: `"maxFailedHealthChecks": 1`.

Add Kubernetes and Docker modals in the UI aren't checking the `CRIBL_BOOTSTRAP_HOST` environment variable

Reported in	Resolved in	Ticket
4.1.0	4.1.1	CRIBL-16432

Problem: The Add Windows and Linux modals check for a bootstrap hostname to see if a user has configured a host override with the `CRIBL_BOOTSTRAP_HOST` environment variable. The Add Kubernetes and Docker modals aren't checking the environment variable as expected.

Workaround: None identified.

Leader's config deployments to pre-4.1 Workers silently fail

Reported in	Resolved in	Ticket
4.1.0	4.1.1	CRIBL-16339

Problem: A 4.1.0 Leader requires Workers to also be upgraded to – 4.1.0. If you attempt to deploy configs to Workers running earlier versions, the intended upgrade prompt might not appear. In this case, the deploy will silently hang.

Workaround: If you haven't enabled automatic upgrades of customer-managed (hybrid or on-prem) Workers, upgrade all Worker Groups to 4.1.0 before you deploy to them.

Cribl Stream Database Collector cannot connect with SQL Server using AD authentication

Reported in	Resolved in	Ticket
4.1.0	4.1.2	CRIBL-16304

Problem: On the indicated versions, the Database Collector cannot connect with SQL Server using Active Directory (AD) authentication. (Only local auth works.)

Workaround: Reverting to Cribl Stream 4.0.4 restores the Database Collector's ability to connect using AD authentication.

System Activity drawer on Windows Edge Nodes displays no data

Reported in	Resolved in	Ticket
3.5.0	4.1.1	CRIBL-16194

Problem: When you navigate to a Fleet's **List View** and click a row containing a Windows Edge Node, the System Activity drawer displays no data.

Workaround: None identified.

QuickConnect Pipeline Settings button fails

Reported in	Resolved in	Ticket
4.1.0	4.1.1	CRIBL-16142

Problem: When adding a new Pipeline using QuickConnect, clicking the gear ( ) button fails to open Pipeline Settings.

Workaround: After saving the Pipeline in QuickConnect, use **Manage** > **Processing** > **Pipelines** to select your new Pipeline. Click the gear button here to access Pipeline Settings as expected.

Duplicate data with Event Hubs

Reported in	Resolved in	Ticket
4.0.0	4.1.1	CRIBL-16102

Problem: When **Minimize Duplicates** is enabled, the Azure Event Hubs Source assigns partitions to multiple Worker Nodes in the same Worker Group, which generates duplicate data.

Workaround: Toggle **Minimize Duplicates** to `No` in **Azure** > **Event Hubs** > **Advanced Settings**.

Kafka-based Sources are omitting the `_time` field

Reported in	Resolved in	Ticket
4.0.4	4.1.0	CRIBL-15696

Problem: Kafka-based Sources (Kafka, Azure Event Hubs, Confluent Cloud) are not sending the `_time` field.

Workaround: If Cribl Stream is not retrieving the `_time` field, then in the affected Sources' config modals, use the **Processing Settings** > **Fields** tab to re-create `_time`. This new `_time` field will add the current (ingestion) time instead of the message time.

DNS Resolution reconnects Cribl TCP connections every time

Reported in	Resolved in	Ticket
4.0.0	4.1.0	CRIBL-15363

Problem: All Cribl TCP connections will reconnect every time DNS Resolution occurs, even when reconnection is not necessary.

Workaround: None identified.

Enable Automatic Upgrades deletes remote repo's Git Settings

Reported in	Resolved in	Ticket
4.0.4	4.1.3	CRIBL-15502

Problem: Enabling the Leader's **Upgrade** > **Enable Automatic Upgrade** setting deletes the corresponding remote repo's stored **Git Settings**.

Workaround: Reconfigure your repo at **Git Settings** > **Remote**.

Sending data to an inactive Kafka, Confluent Cloud, or Azure Event Hubs Destination triggers an endless series of log errors

Reported in	Resolved in	Ticket
4.0.4	4.1.1	CRIBL-15455

Problem: If you accidentally make a Kafka, Confluent Cloud, or Azure Event Hubs Destination inactive by putting a mismatched value in the **Advanced Settings** > **Environment** setting, Cribl Stream will send an endless series of errors to the log file.

Workaround: Correct the **Environment** value or leave it empty.

Logging-level changes do not take effect for services

Reported in	Resolved in	Ticket
4.0.0	4.1.1	CRIBL-15365

Problem: Changing logging levels in the Leader's Settings has no effect on the logs for the Connections, Lease Renewal, Metrics, or Notifications services.

Workaround: None identified.

On-prem Worker Nodes automatically upgrade, ignoring Leader settings

Reported in	Resolved in	Ticket
4.0.3	4.1.1	CRIBL-15367

Problem: Upgrading a Leader Node causes its customer-managed (on-prem) Worker Nodes to automatically upgrade, even when the Leader's **Enable automatic upgrades** option is set to `No` (the default). This problem does not affect Cribl-managed Worker Nodes in Cribl.Cloud.

Workaround: 1. Toggle **Enable automatic upgrades** to `Yes` and save the configuration; then slide it back to `No` and save again. Or: 2. Edit `local/cribl/cribl.yml` to explicitly set `upgradeSettings.disableAutomaticUpgrade` to `true`.

Pipeline is deselected in QuickConnect after modification

Reported in	Resolved in	Ticket
4.0.0	4.1.0	CRIBL-15246

Problem: If you add a Pipeline in the QuickConnect UI, then modify it in the **Edit Pipeline** modal, the Pipeline is deselected in the **Add Pipeline to Connection** modal. If you then close the **Add Pipeline to Connection** modal, the Pipeline will disappear from the Route.

Workaround: Select the modified Pipeline in the **Add Pipeline to Connection** modal before closing it.

Event Breaker timestamp extraction fails after configured time

Reported in	Resolved in	Ticket
4.0.0	4.1.1	CRIBL-15107

Problem: Event Breakers' timestamp extraction stops working after the Rule's configured **Future timestamp allowed** value (if set). All subsequent events received get the current time as their timestamp.

Workaround: Set a sufficiently large value for **Future timestamp allowed** – e.g., one year from the date you re/configure the rule. Alternately, restore normal timestamp extraction by restarting Worker Processes.

`CRIBL_DIST_WORKER_PROXY` env var is ignored when Leader Node's Master URL is set via `instance.yml`

Reported in	Resolved in	Ticket
3.0.3	4.1.0	CRIBL-15540

Problem: Setting the Cribl Stream Leader's Master URL via `instance.yml` causes Worker Nodes to ignore the `CRIBL_DIST_WORKER_PROXY` env var. Instead of trying to connect to the proxy configured in `CRIBL_DIST_WORKER_PROXY`, Worker Nodes will try to connect to other entities (e.g., Leader Nodes) directly, producing unexpected results.

Workaround: Set the Cribl Stream Leader's Master URL via the `CRIBL_DIST_MASTER_URL` env var, rather than via `instance.yml`.

Metrics blocklist can't be changed on a global level

Reported in	Resolved in	Ticket
4.0.0	4.1.0	CRIBL-15081

Problem: The Metrics blocklist cannot be modified from **Settings** > **Global Settings** > **General Settings** > **Limits**.

Workaround: Edit the `limits.yml` file's `metricsFieldsBlacklist` element. Add the event fields for which you want to disable metrics collection; remove any event fields for which you want to restore metrics collection.

GitOps Push/read-only confirmation banner has dead link

Reported in	Resolved in	Ticket
4.0.0	4.1.0	CRIBL-14681

Problem: After you enable GitOps `Push` mode, the resulting red confirmation banner contains a dead link labeled **GitOps Workflow**.

Workaround: To switch off `Push` mode, navigate to **Settings** > **Global** > **Git Settings**, and then set **GitOps workflow** back to `None`.

Kafka-based Sources' rebalancing is logged with exaggerated severity

Reported in	Resolved in	Ticket
4.0.2	4.1.0	CRIBL-14609

Problem: The Kafka, Azure Event Hubs, and Confluent Cloud Sources log `REBALANCE_IN_PROGRESS` events at the `error` level, even though only **frequent** rebalancing indicates a system-level or processing issue.

Workaround: Treat infrequent rebalancing events as `warn`.

Fix: Depends on a change to the underlying kafkajs library.

Worker Nodes show incorrect configurations after upgrade or commit/deploy from Leader

Reported in	Resolved in	Ticket
3.5.1	4.1.1	CRIBL-13863, CRIBL-15507

Problem: When you commit and deploy changes from the Leader, Worker Nodes sometimes fail to automatically restart with the correct configuration changes.

Workaround: Manually restart the Worker Nodes.

Source PQ in Smart mode can trigger excessive memory usage and OOM failures

Reported in	Resolved in	Ticket
3.4.0	4.1.0	CRIBL-13761

Problem: Enabling Source-side Persistent Queues in Smart mode can trigger excessive memory usage, leading to out-of-memory failures and Worker Node instability.

Workaround: If you encounter OOM failures (most likely with high throughput), set PQ to `Always On` mode instead.

Avg Thruput (Bytes Per Second) not displayed for internal logs or metrics

Reported in	Resolved in	Ticket
3.5.1	4.1.0	CRIBL-13530

Problem: No **Avg Thruput (Bytes Per Second)** data is displayed on Cribl Internal logs and metrics Sources' **Charts** tab, nor for these Sources on their attached Routes. This is by design, because Cribl Stream does not perform BPS calculations for internal logs or metrics. But the visual disparity can be confusing.

Workaround: None identified.

New Help drawers open under pinned Help drawers

Reported in	Resolved in	Ticket
3.5.3	4.1.0	CRIBL-12737

Problem: If you've pinned a Help drawer open, it's possible to open additional Help drawers behind the pinned drawer.

Workaround: Close the pinned drawer to see the newly opened drawer.

Cribl Edge/Windows: Upgrading ignores existing mode (etc.) settings

Reported in	Resolved in	Ticket
3.5.0	4.1.0	CRIBL-11467

Problem: When rerunning Windows installers on a system that hosts a previous Cribl version as a managed Edge Node, the installer does not read the distributed mode or other settings. The new version might install as a Leader instance.

Workaround: Run the new version's installer using the same mode and other options you used when installing the preceding version.

Edge Settings mistakenly display Process Count controls

Reported in	Resolved in	Ticket
4.0.0	4.1.1	CRIBL-10402

Problem: Edge Fleets' **Fleet Settings** > **Worker Processes** page incorrectly includes editable **Process Count** and **Minimum Process Count** controls. Each Edge Node is locked to `1` Worker Process, so changes to these fields' values will have no effect.

Workaround: Ignore these two fields.

Chain Function degrades CPU load and throughput

Reported in	Resolved in	Ticket
3.2.2	4.1.0	CRIBL-7445

Problem: Chaining Pipelines via the Chain Function can increase CPU load, and can signficantly slow down data throughput.

Workaround: Consolidate all Functions – per processing scenario – into a single Pipeline.

Resolved in 4.0

The following issues were resolved in version 4.0 and its maintenance releases.

Metrics service unavailable

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-13826

Problem: The Monitoring and Fleet pages don't load, due to the systemd-tmpfiles service cleaning some of the Cribl socket files from the `/tmp/` directory.

Workaround: Stop the host system from cleaning the socket files from the `/tmp/cribl-*` directory. For example, on an Amazon EC2 instance, add a new `tmp.conf` file to `/etc/tmp.conf` with the line `X /tmp/cribl-*`. Then restart the tmpfiles cleanup service with: `systemctl restart systemd-tmpfiles-clean.service`. Finally, restart the Cribl server.

Fix: This issue no longer applies to Cribl.Cloud as of 4.0.1. On-prem customers should use the workaround, which will be added to the deployment documentation as a standard practice.

Preview Full > Send Out does not capture events

Reported in	Resolved in	Ticket
3.5.0	4.0.4	CRIBL-14914

Problem: Selecting a Sample Data file's **Preview Full** > **Send out** option captures no events. This bug has been observed when capturing on Destinations.

Workaround: None identified.

Google Cloud Chronicle Destination drops changes in distributed deployments with custom log types

Reported in	Resolved in	Ticket
4.0.0	4.0.3	CRIBL-14453

Problem: A new Google Cloud Chronicle Destination with a custom log type might fail to save changes. This issue affects only distributed deployments.

Workaround: None identified.

Changes to a Lookup table on the Leader don't always propagate to Worker Nodes

Reported in	Resolved in	Ticket
3.5.4	4.0.4	CRIBL-14299

Problem: Modifying a Lookup table on the Leader doesn't always propagate the changes to Worker Nodes, even after clicking **Commit** and **Deploy**.

Workaround: Manually restart the Worker Nodes to refresh Lookup tables.

Users assigned the `owner_all` role cannot perform commits

Reported in	Resolved in	Ticket
4.0.1	4.0.3	CRIBL-14180

Problem: When a user with the `owner_all` role tries to perform a commit, the commit fails with the UI displaying a `Forbidden` modal.

Workaround: Modify the `GroupFull` policy, as follows:

1. As a user with the `owner_all` role, try a `POST /version/commit` API call with a request body of `{ "message": "test: hello" }`. The commit should fail, and the request payload should be `{ message: "test: hello" }`.
2. If `$CRIBL_HOME/local/cribl/policies.yml` does not exist, copy `$CRIBL_HOME/default/cribl/policies.yml` to `$CRIBL_HOME/local/cribl/policies.yml`.
3. If your OS is Linux, run the command `chmod 0744 policies.yml`.
4. In `$CRIBL_HOME/local/cribl/policies.yml`, edit the `GroupFull` policy to match the following:

```
GroupFull:
  args:
    - groupName
  template:
    - PATCH /master/groups/${groupName}/deploy
    - GroupEdit ${groupName}
    - POST /version/commit
    - GET /version
    - GET /version/*
```

5. Now retry the `POST /version/commit` API call, again with a request body of `{ "message": "test: hello" }`. The commit should succeed, and the request payload should be `{ message: "test: hello", "group": "default", "effective": true }`.

Landing page not displaying system metrics from Edge Nodes when teleporting from the Leader

Reported in	Resolved in	Ticket
4.0.1	4.0.3	CRIBL-14169

Problem: When you teleport from a Leader running 4.0.1 or 4.0.2 to an Edge Node that's running 4.0.0 or earlier, the system metrics for the landing page will not populate. This also affects the system metrics shown in the Node drawer for the honeycomb and Node List View pages.

Workaround: Upgrade Edge Nodes to 4.0.2 or higher.

Google Cloud Pub/Sub Source and Destination can break on field validation

Reported in	Resolved in	Ticket
4.0.1	4.0.2	CRIBL-14160

Problem: The Google Cloud Pub/Sub Source and Destination strictly validated entries in the **Topic ID** and **Subscription ID** fields. If you entered a full path (rather than the expected ID substring) in these fields, this strict validation broke the integration and broke the UI.

Workaround: Trim **Topic ID** and **Subscription ID** field values to just the ID.

CrowdStrike FDR Source needs 6-hour visibility timeout

Reported in	Resolved in	Ticket
4.0.2	4.0.3	CRIBL-14067

Problem: With its default **Visibility timeout seconds** setting of `600` (10 minutes), the CrowdStrike FDR Source can accumulate large backlogs when pulling data from Crowdstrike buckets.

Workaround: Set the **Visibility timeout seconds** to `21600` (6 hours), as CrowdStrike recommends. Leave both **Max messages** and **Num receivers** at their default `1` settings.

Amazon S3 Source stops receiving data after upgrade

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-14093

Problem: Upgrading to Cribl Stream 4.0.0 can cause the Amazon S3 Source to stop receiving data. This is due to a race condition between (premature) SQS messaging versus the Source's initialization.

Workaround: Skip 4.0.0 (or temporarily roll back to 3.5.4).

QuickConnect-configured Sources' misleading "Enabled" status while disconnected

Reported in	Resolved in	Ticket
4.0.2	4.0.3	CRIBL-14041

Problem: As you configure a new Source from the QuickConnect UI, the Source's **Enabled** slider will initially switch to `Yes`. This is misleading, because the Source is not yet connected to a Destination, so no data can flow.

Workaround: Save the Source in its config drawer. This resets the **Enabled** slider to its accurate `No` status, until you connect the Source to a Destination.

"Unknown config version" error can appear when deploying changes

Reported in	Resolved in	Ticket
4.0.0	4.0.3	CRIBL-13910

Problem: Attempting to commit and deploy a change can trigger errors of the form `Unknown config version: "[hash]"`.

Workaround: On the Leader's host, upgrade the `git` client to 1.9.1 or later.

Teleported Worker Nodes don't display Distributed Settings or Diagnostics Settings

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-13868

Problem: When displayed via remote access from the Leader ("teleporting"), a Worker's/Edge Node's **Settings** UI omits the **Distributed Settings** and **Diagnostics** left-nav links. This blocks remote access to features like configuring TLS communications between Worker Node and Leader.

Workaround: Access the Worker's UI directly on its host's port 9000 (or other configured port). As a precondition, you might need to undo any Disable UI Access setting on the parent Worker Group.

Chain Function creates extra Pipelines and Functions during initialization

Reported in	Resolved in	Ticket
3.2.0	4.0.1	CRIBL-13860

Problem: Under certain circumstances, when initializing, the Chain Function created multiple unneeded Pipelines and Functions.

Workaround: None identified.

License usage visible only for current day

Reported in	Resolved in	Ticket
4.0.0	4.0.4	CRIBL-13811

Problem: In the listed versions, selecting **Monitoring** > **System** > **License** displays usage only for the current day.

Workaround: None identified.

`Forbidden` error banners mistakenly displayed to non-admin users

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-13681

Problem: Non-admin users (with the `reader_all` Role) are mistakenly shown a continuous string of `Forbidden` error banners.

Workaround: Available upon request (documented in the ticket), but cumbersome. Cribl recommends upgrading instead.

Edge/Kubernetes Logs Source repeats logs due to incorrect timestamp

Reported in	Resolved in	Ticket
4.0.0	4.0.3	CRIBL-13900

Problem: The Kubernetes Logs Source is collecting redundant information for containers that don't emit their own timestamps. This Source assumes "current time" when the timestamps are missing, causing it to incorrectly stream older logs during restarts.

Workaround: None identified.

Cribl Edge honeycomb display doesn't render null values

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-13595

Problem: When you view Edge Nodes in **Map View**, a honeycomb displays values for each of the metrics you select in the **Measure** drop-down. When a value is null for a particular the Edge Node, the honeycomb should display `null`; instead, the value incorrectly renders as `ul i`.

Workaround: None identified.

Broken in-app doc links

Reported in	Resolved in	Ticket
4.0.0	4.0.1	DOC-100

Problem: The following Sources have broken in-app help links: Kubernetes Logs, Kubernetes Metrics, Windows Event Logs, and Windows Metrics.

Workaround: Use the above links to access these Sources' online documentation.

Spurious “Secret decrypt failed with error" log messages appear after upgrade

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-13554

Problem: After upgrading to Cribl Stream 4.0.0, multiple `Secret decrypt failed with error` messages might appear in logs. These are spurious, and you can disregard them.

Workaround: None identified.

Upgrade status shown on Group Upgrade page doesn’t match Global Settings

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-13566

Problem: The **Enable automatic upgrades** status shown on the **Settings** > **Group Upgrade** page doesn’t match the slider selection on the **Settings** > **Global Settings** > **Upgrade** tab.

Workaround: View the **Enable automatic upgrades** slider on the **Settings** > **Global Settings** > **Upgrade** tab to verify the current upgrade status.

Sorting by column on Manage > Worker Node page results in blank list

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-13505

Problem: When you click a column header on the **Manage** > **Worker Node** page, the list goes blank and rows are not sorted.

Workaround: Click the heading a couple of times to refresh the list.

Git settings don’t immediately populate Commit modals

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-13501

Problem: After you save Git settings (such as a default commit message), the new settings do not immediately appear in Commit/Git Changes modals.

Workaround: A hard or soft refresh will close the modal, but when you reopen it, it will reflect your new settings.

Manage Groups/Fleets pages count Packs in Pipeline totals

Reported in	Resolved in	Ticket
3.5.3	4.0.1	CRIBL-12602

Problem: On the **Manage Groups** and **Manage Fleets** pages, the **Pipelines** column overstates the actual number of Pipelines, because it includes Packs in each Worker Group's total count.

Workaround: For each Worker Group, click the link in its **Pipelines** column to see the Worker Group's actual list of Pipelines.

Subfleet search doesn't return parent Fleets

Reported in	Resolved in	Ticket
4.0.0	4.0.1	CRIBL-12465

Problem: On the **Manage Fleets** page's **Fleets** tab, searching for a Subfleet name returns only the Subfleet, without information about its parent Fleets.

Workaround: None identified.

Deleting or modifying default Mapping Rule reclassifies Cribl-managed Workers in Cribl.Cloud as hybrid Workers

Reported in	Resolved in	Ticket
3.2.0	4.0.4	CRIBL-11983

Problem: Cribl.Cloud's UI currently allows deleting or modifying the `default` Mapping Rule. By doing so, an admin can inadvertently reclassify Cribl-managed Workers in Cribl.Cloud as customer-managed (hybrid) Workers. These might not be supported by your Cribl.Cloud plan.

Workaround: If you have an Enterprise plan, create a hybrid Worker Group to manage the resulting hybrid Workers.

Lookup Functions intermittently fail

Reported in	Resolved in	Ticket
3.3.1	4.0.1	CRIBL-9539

Problem: Lookup Functions within some Pipelines were skipped up to ~20% of the time. Restarting Cribl Stream resolves this temporarily, but the failure eventually resurfaces as the new session proceeds.

Workaround: Where a Lookup Function fails, substitute an Eval Function, building a ternary JS expression around a `C.Lookup` method.

Won't Fix

The following issues are not expected to be fixed, either because they are working as designed, because they concern older or unmaintained features, or because they have satisfactory workarounds.

Cribl Copilot for KQL and Pipelines is disabled

Reported in	Resolved in	Ticket
4.8.2	won't fix	AI-797

Problem: With Cribl 4.8.2, the way we manage consent for AI features has changed. As a result, you might have access to Cribl Copilot for chat but not for KQL and Pipelines.

Workaround: Clear the cookies for Cribl.

Examples:

- **Chrome**: Go to **Settings** > **Privacy and security** > **Third-party cookies**, select **See all site data and permissions**, and then find and delete Cribl. Log back in to Cribl.
- **Safari**: Go to **Settings** > **Privacy** > **Manage Website Data**, and select Cribl and delete. Log back in to Cribl.

Cribl can't be upgraded in-product when the `CRIBL_VOLUME_DIR` environment variable is set

Reported in	Resolved in	Ticket
4.8.2	won't fix	CRIBL-28216

Problem: On Cribl Leaders, Cribl Edge, or Cribl Stream Linux instances that have the `CRIBL_VOLUME_DIR` environment variable set, you can't upgrade from 4.8.2 to 4.9.0 using the UI. This affects only upgrades from version 4.8.2. These scenarios are **not** impacted by this issue:

- Upgrading from versions 4.8.1 and older to 4.9.0.
- Installations where `CRIBL_VOLUME_DIR` is not set.
- Windows installations.
- Containers or RPM installs.

Workaround: Upgrade these instances manually. See Upgrading Cribl Edge on Linux (CLI) for instructions.

Edge Leaders running 4.5.1 can't use the Legacy upgrade method to upgrade 4.5.0 Nodes when jobs/tasks are disabled

Reported in	Resolved in	Ticket
4.5.1	won't fix	CRIBL-22801

Problem: Edge Leaders on version 4.5.1 that have Legacy upgrades enabled and **Enable Jobs/Tasks** toggled to `No` cannot upgrade their 4.5.0 Edge Nodes. The job finishes with the task timing out, and the Edge Node is not upgraded.

Workaround: On the 4.5.1 Leader, enable Legacy upgrades **and** toggle **Enable Jobs/Tasks** to `Yes`. Commit and deploy as necessary. The Leader will be able to create a job with the upgrade task and upgrade its Edge Nodes to 4.5.1.

Edge upgrades occasionally fail when Fleets contain a large number of Nodes

Reported in	Resolved in	Ticket
4.2.1	won't fix	CRIBL-20067

Problem: Leader-managed upgrades occasionally fail when a Fleet contains a large number of Nodes.

Workaround: Restart the upgrade operation to upgrade additional Nodes.

Source PQ in Smart mode could cause premature backpressure

Reported in	Resolved in	Ticket
3.4.0	won't fix	CRIBL-13414

Problem: Source-side persistent queuing enabled in `Smart` mode might trigger backpressure before the configured maximum queue size is reached. For TCP Sources, this will send backpressure back to the sender. For Sources using the UDP protocol, it will cause events to be dropped.

Workaround: None identified.

Default AppScope Config file can't be restored when in use

Reported in	Resolved in	Ticket
4.0.0	won't fix	CRIBL-13400

Problem: When the default AppScope Config file is assigned to an AppScope Source filter, you can't restore it to its default settings. You'll see an error message that the AppScope Config file is currently in use.

Workaround: On the AppScope Source's **AppScope Filter Settings** tab, delete the default AppScope Config from the **Allowlist**. Then, edit the AppScope Config Knowledge object to restore its default settings. You can now add this AppScope Config, with its restored settings, back to the AppScope Source's Allowlist.

`cidr-matcher` does not support IPv6 addresses

Reported in	Resolved in	Ticket
3.0.0	won't fix	CRIBL-11767

Problem: The version of `cidr-matcher` supported by Cribl only supports IPv4 CIDR matching.

Workaround: None identified.

Cribl.Cloud login page distorted on iPad

Reported in	Resolved in	Ticket
3.2.2	won't fix	SAAS-1141

Problem: On certain iPads, we've seen the Cribl.Cloud login page's left text column repeated twice more across the display. These unintended overlaps prevent you from selecting (or tabbing to) the **Log in with Google** button.

Workaround: If you encounter this, the only current workarounds are to either use Google SSO on a desktop browser, or else use a different login method.

19.2. Diagnose Issues

To help diagnose Cribl Stream problems, you can share a diagnostic bundle with Cribl Support. The bundle contains a snapshot of configuration files and logs at the time the bundle was created, and gives troubleshooters insights into how Cribl Stream was configured and operating at that time.

What's in the Diagnostic Bundle

The bundle includes the following subdirectories (and their contents) of `$CRIBL_HOME`:

- `.../default/*`
- `.../local/*` – except for `/local/cribl/auth/`, to exclude sensitive files.
- `.../log/*`
- `.../groups/*`
- `.../state/jobs/*` – will return all jobs if left empty.

As a security measure, the bundle excludes all `.crt`, `.pem`, `.cer`, and `.key` files from all `$CRIBL_HOME` subdirectories.

Create and Export a Diagnostic Bundle

If you're managing your own Cribl Stream deployment (single-instance Stream/Edge or distributed Stream/Edge), you can create and securely share bundles with Cribl Support, either from the UI or via the CLI.

With a Cribl.Cloud deployment, create bundles and securely share them with Cribl Support directly from the UI. In the Using the UI instructions below, **Send to Cribl Support** will always be enabled, and the **Export**/download option will be unavailable.

Requirements

Using either medium, you'll need outbound internet access to `https://diag-upload.cribl.io` and a valid support case number. The above URL works only when using the `cribl diag` command or uploading using the Cribl Stream UI. (So connecting directly to it with your web browser will fail.)

If your organization doesn't permit outbound access to `https://diag-upload.cribl.io` to upload from within Cribl, you can also submit diags directly via the Support Portal (login required). If none of

> these options work with your organization's policies, please work directly with your Support engineer to find a solution.

Open your support case before sending a diagnostic bundle to Cribl Support. Then, when creating the bundle, be sure to use the case number provided. Case numbers are 8 digits in length, and you must include any leading zeros. For example, `00001234`.

Use the UI

Depending on the issue you're debugging, you can create a bundle either from the Leader or from an individual Worker Node.

UI Options

The **Create & Export Diag Bundle** modal provides these additional options:

- **Rename .js files**: When enabled, appends `.txt` to JavaScript files in the bundle. Defaults to `Yes`.
- **Include metrics**: Includes metrics in the bundle. Defaults to `Yes`.
- **Include git**: Includes the last 14 days of git log in the bundle, identifying each commit's message, author, timestamp, and files changed. Defaults to `Yes`.
- **Latest number of jobs to include**: The number of jobs (and all tasks) the bundle will include. Defaults to empty, which means unlimited jobs.
- **Include install logs**: Includes Windows MSI logs, only available on Windows deployments of Cribl Edge. Defaults to `No`.
    - This option is not available for Linux deployments.
    - If MSI logs are available, the diag bundle will contain them. If no MSI logs are present, the bundle will not contain them even with this option toggled on.

Cribl Support will advise you on changing the defaults here. Disabling **Include metrics** can reduce the size of the diag bundle, where necessary.

From the Leader Node

To create a bundle from the Leader Node, go to **Settings** > **Global** > **Diagnostics** and select **Create Diagnostic Bundle**.

- To share the bundle with Cribl Support, toggle **Send to Cribl Support** to `Yes`. Enter your case number, and then select **Export**.
- To download the bundle locally to your machine (on-prem only), select **Export**.

From Worker Nodes

To create a bundle from individual Worker Nodes, you must be able to access the Worker Node's UI. You can easily use the Leader to get authenticated access to each Worker Node, if you first enable the parent Worker Group's UI Access (teleporting) setting:

1. In the Cribl Stream sidebar, select **Worker Groups**.
2. Make sure the relevant Worker Group's **UI Access** toggle is on.
3. Select the displayed number of Worker Nodes to access the **Worker Nodes** page.
4. In the **GUID** column, select the link for the Worker Node you're debugging.
5. Look for the purple border to confirm that you've teleported to that Worker Node.
6. Select **Worker Node Settings** (top right) > **Diagnostics** (lower left) > **Diagnostic Bundle**, and select **Create Diagnostic Bundle**.
7. Use the appropriate **Export** options listed above for the Leader.

On on-prem deployments, new and previously created bundles are stored in `$CRIBL_HOME/diag`. They're also listed in the UI, where you can re-download them or share them with Cribl Support.

Use the CLI

To create a bundle using the CLI, use the `diag` command. (This option is on-prem only.) Depending on the issue you're debugging, you can create a bundle either from the Leader host or from an individual Worker Node host.

diag command CLI

```
# $CRIBL_HOME/bin/cribl diag
Usage: [sub-command] [options] [args]

Commands:
create       - Creates diagnostic bundle for this instance, args:
  [-d]                  - Run create in debug mode
  [-j]                  - Do not append '.txt' to js files
  [-t <maxIncludeJobs>] - Latest number of jobs to include in bundle
  [-M]                  - Exclude metrics from bundle
  [-g]                  - Exclude git log from bundle
  [-i]                  - Include install logs
heapsnapshot - Generate heap snapshot of a Cribl process, args:
  [-p <pid>] - The pid of the process to dump the heap snapshot
list         - List existing diagnostic bundles
send         - Send diagnostics bundle to Cribl Support, args:
   -c <caseNumber> - Cribl Support Case Number
  [-p <path>]      - Diagnostic bundle path (if empty then new bundle will be create

## Creating a diagnostic bundle
# $CRIBL_HOME/bin/cribl diag create
Created Cribl Stream/Edge diagnostic bundle at /opt/cribl/diag/ <product>-<hostname>-

## Creating and sending a diagnostic bundle
# $CRIBL_HOME/bin/cribl diag send -c <caseNumber>
Sent Cribl diagnostic bundle to Cribl Support

## Sending a previously created diagnostic bundle
# $CRIBL_HOME/bin/cribl diag send -p /opt/cribl/diag/ <product>-<hostname>-<datetime
Sent Cribl diagnostic bundle to Cribl Support
```

For complete command syntax, see diag.

Include CPU Profiles

If Cribl Support asks you to grab CPU profiles of Worker Processes, follow these steps:

1. Use `top` or `htop` on the Worker Node to identify Worker Node PIDs consuming a lot of CPU.
2. See Measuring CPU or API Load for instructions on accessing the UI's **Profile** options (for your deployment type), and generating and saving profiles.
3. Find the Worker Processes matching the PIDs you identified above.
4. Select **Profile** on each. Start with the default 10-second **Duration**.

5. Once the profile is displayed, save it to a `.json` file. (See details at the above link.)
6. Repeat steps 3–5 for other CPU-intensive Worker Processes.
7. Upload the profile `.json` files to Cribl Support.

On an already CPU-starved Worker Node, profiling might fail with an error message, or just hang. In this case, you might need a few retries to get a successful profile.

Include Memory Snapshots

Cribl.Cloud does not support taking memory snapshots. This feature is for on-prem deployments only.

If you encounter a memory leak, Cribl Support might request a memory snapshot of a `cribl` process to better understand where the leak is occurring.

There are two ways to generate a memory snapshot:

- Automatically
- Manually

Automatically Capture a Memory Snapshot

To automatically capture memory snapshots when Worker Processes approach or exceed memory limits, turn on the **Enable heap snapshots setting** in the Worker Group's **General Settings**. Navigate to **Worker Group Settings** > **System** > **Worker Processes** and toggle the setting to `Yes`. Only the two most recent heap snapshots are retained. Older snapshots are automatically deleted. This behavior cannot be modified.

This setting should only be enabled if recommended by support or if you are experiencing out-of-memory issues. Be aware that enabling this setting may impact system performance and storage usage.

For details, see Worker Processes.

Manually Capture a Memory Snapshot

Prerequisites

To manually generate a reliable memory snapshot for Cribl Stream diagnostics, ensure two key conditions are met:

1. **Correct `CRIBL_HOME` Environment Variable**: This variable points to the Cribl Stream installation directory. Open a new terminal session and verify its value using `echo $CRIBL_HOME`. If empty, set it appropriately for your operating system (for example, `export CRIBL_HOME=/path/to/cribl` on Linux, `setex cribl C:\Program Files\Cribl /m` on Windows).
2. **Run as the `cribl` User**: The `diag heapsnapshot` command requires permissions to create the snapshot file within the run Cribl Stream directory. Use `sudo su - cribl` to switch to the cribl user before running the command. Remember to exercise caution with `sudo`. On Windows, if Cribl is set to run under a specific user account, log in as that user before running Cribl. Alternatively, you can run Cribl Stream as an `Administrator`.

Capture the Memory Snapshot

To capture the memory snapshot:

1. Note the PID of the process of interest.
2. In a terminal, `cd` to the directory where Cribl Stream is installed.

```
cd $CRIBL_HOME/bin
```

3. Run the `diag heapsnapshot` command with the PID you noted in step 1.

- For Linux:

```
./cribl diag heapsnapshot -p <pid>
```

Locate the PID on Windows

There are three methods to identify the Process ID (PID) for `cribl.exe`:

1. **Task Manager**: Open the Task Manager application. Locate the **Processes** tab and search for `cribl.exe` in the list. The PID will be displayed in the corresponding column.
2. **Command Line Interface (CLI)**: Open a Command Prompt window. Run the following command:

```
tasklist /FI "IMAGENAME eq cribl.exe"
```

This command will list all running processes. The line containing `cribl.exe` will also display the PID in the corresponding column (usually the second column).

3. **PowerShell**: Open a PowerShell window. Run the following command:

```
PowerShell
Get-Process -Name cribl
```

This command will list details about running processes. The output will include the PID for any process named `cribl`.

Once you locate the PID, run the `diag heapsnapshot` command:

1. Navigate to the Cribl Stream installation directory: For example, `C:\Program Files\Cribl\bin` or `$CRIBL_HOME\bin`.
2. Run the `diag heapsnapshot` command with the PID.

```
./cribl diag heapsnapshot -p <pid>
```

Cribl will capture the memory snapshot in `$CRIBL_HOME/diag/`.

Example output:

```
Heap-1690906031148-2458958.heapsnapshot
```

19.3. Get Product Help

This page has moved.

Please see Get Product Help in the Cribl Product Suite section of Cribl Docs.

19.4. Common Errors And Warnings

This page lists common error and warning messages that you might find in Cribl Stream's internal logs and/or UI. It includes recommendations for resolving the errors/warnings. Messages are grouped by component (Sources, Destinations, and so on).

Whole message texts are not listed in every case. They may have different capitalization than the messages you may encounter in the product.

Where events are written to log files, they might reside in different logs variously devoted to data processing, cluster communication, or the REST API. (For details, see Types of Logs.) We note the log type where necessary.

NodeJS serves as the Cribl Stream backend and has a large collection of well documented errors of its own. Some of system-level are listed on this page with the appropriate action to take. The remainder are documented at https://nodejs.org/api/errors.html, specifically in the `Common system errors` section of that page.

Web UI

Duplicate GUID

When you deploy and first run Cribl Stream software, it generates a GUID (globally unique identifier) and stores it in a `.dat` file located in `CRIBL_HOME/local/cribl/auth/`. For example:

```
# cat CRIBL_HOME/local/cribl/auth/676f6174733432.dat

{"it":1570724418,"phf":0,"guid":"48f7b21a-0c03-45e0-a699-01e0b7a1e061"}
```

When deploying Cribl Stream as part of a host image or VM, be sure to remove this file, so that you don't end up with duplicate GUIDs. The file will regenerate on the next run.

"Failed to fetch"

Occurs only when accessing **Data** > **Collectors**. It can occur with ad blockers, or in the Brave browser (because the newly loaded page's URL includes the string `collector`).

Recommendation

If you have an ad blocker, allowlist the `https://<hostname>:9000/jobs/collectors` (single-instance) URL or the `https://<leadernode>:9000/m/<group_name>/jobs/collectors` (Leader) URL.

"No workers registered"

Occurs during a live data capture, when there are no Workers available to fulfill the capture request. This error can be triggered if you attempt to capture events too quickly following a commit & deploy.

Recommendation

- If you recently committed and deployed changes, wait 30 seconds and retry the live capture.
- Navigate to the **Workers** page and confirm there are Workers currently registered with the Leader. Note that the error appears on a per-Group basis, which means that even if you have Workers registered, they may not be in the Group you're capturing live data from.

"The Config Helper service is not available..."

Full Text: "The Config Helper service is not available because a configuration file doesn't exist or the settings are invalid. Please fix it and restart Cribl server."

Occurs only on Leader Nodes. Each Worker Group relies on a config helper process that runs on its behalf on a Leader Node, and that process is not currently running. This error is usually triggered by restarting Cribl Stream on the Leader Node, and then trying to access one of these features before the Cribl Stream server is fully up:

- **Groups** or **Configure** link (3.x).
- **Worker Groups** menu (2.x).
- **Manage** > **Groups** or **Manage** > **Workers** tabs (4.x).

Recommendation

Try again in a few seconds. If you've made changes to the backend or filesystem permissions, stop Cribl Stream, and make sure the `cribl` user owns all relevant assets, before restarting: `sudo chown -R cribl.cribl /opt/cribl`

"KMS saved, but secret exists in destination location. No data was migrated."

This will appear when you attempt to save KMS Settings with a **Secret Path** entry that references a secret that already exists in HashiCorp Vault. It can also occur with OpenID Connect remote authentication. Cribl Stream has aborted the remote write to avoid overwriting an external shared secret.

Recommendation

Edit the Leader Node's `kms.yml` file to use `provider: local`. Then restart Cribl Stream to correct the path conflict.

"The number of Worker Processes has been limited by the license."

Workers use their local license until they connect to the Leader and download their current license data, which is why the message appears in Logs.

Recommendation

Ignore the message. Once the Worker checks in with the Leader and receives the production license, the rest of the Workers will start.

Sources

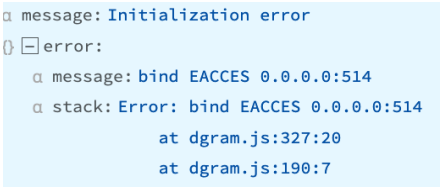
Here are some general errors that can occur with many Sources. When you encounter a problem with a specific Source, check the "Troubleshooting" section in its documentation as well for potential solutions.

"bind EACCES 0.0.0.0:514"

Cribl Stream doesn't have proper privileges to bind to the specified IP and port. Usually, this simply indicates that Cribl Stream is running as a non-root user, but a Source was accidentally configured to use a privileged port below 1024.

Recommendation

Check your Cribl Stream Sources' configuration. The error's `channel` field will indicate which input is affected. If you choose to enable access to the port range below 1024, see our configuration instructions for systemd and initd.



EACCES error

"bind EADDRINUSE 0.0.0.0:9514"

The interface and port combination is already in use by another process, which might or might not be Cribl Stream.

Recommendation

Check your Cribl Stream Sources' configuration. The error's `channel` field will indicate which Source is affected, but this error means that one or more other inputs are also using the same IP/port combination.

EADDRINUSE error

Destinations

Here are some general errors that can occur with many Destinations. When you encounter a problem with a specific Destination, check the "Troubleshooting" section in its documentation as well for potential solutions.

"Sending is blocked"

The Destination is blocking. This can occur with any TCP-based Destination, and is logged only after 1 second of blocking. This can also occur between Worker and Leader when the Worker can't connect to the Leader Node to send metrics data. When triggered by cluster communication, the warning will be in the Worker's API log.

"Begin backpressure" and "end backpressure"

The Destination is blocking. Like the "sending is blocked" message, "begin backpressure" is logged only after 1 second of blocking. It is logged only once while backpressure is occurring (at the start), and it will always be followed by the "end backpressure" message.

TLS

"Certificate has expired"

Validate server certs or **Validate client certs** is enabled, and the peer's certificate has expired.

Recommendation

Disable **Validate server certs** or **Validate client certs** (depending on whether Cribl Stream is serving as the client or server), so that encryption can still occur without authentication. Or renew the expired certificate.

"Client network socket disconnected..."

Full Text: "Client network socket disconnected before secure TLS connection was established"

Typically caused by a TLS protocol version mismatch between the client and server.

Recommendation

Verify that client's and server's TLS settings use the same minimum/maximum TLS version.

"Unable to get local issuer certificate"

Client can't validate the server certificate's CA (that is, the issuer) because it doesn't trust the CA certificate. Or vice versa (server can't validate client's certificate CA) if mutual auth is enabled.

Recommendation

The CA certificates used by the server's leaf certificate must be trusted by the client. See Configuring CA certs.

"Self signed certificate"

The client or server was presented with a self-signed cert from the peer, but that cert is not trusted.

Recommendation

The self-signed certificate must be trusted by the peer to which it's presented. See Configuring CA certs.

"Hostname/IP does not match certificate's altnames"

Full Text: "Hostname/IP does not match certificate's altnames: host: <server hostname> is not in the cert's list" or: "Hostname/IP does not match certificate's altnames: IP: <server IP> is not in the cert's list"

The server's hostname/FQDN used on the client is not found in the CN or SAN attribute of the server's certificate.

Recommendation

Examine the CN and/or SAN attribute, to see which names are listed that can be used as the server hostname/FQDN on the client. **CN values with spaces are not supported as hostnames/FQDNS.** If there isn't a SAN attribute, then a new cert will need to be issued.

“No protocols available”

Full Text: “140244944713600:error:141E70BF:SSL routines:tls_construct_client_hello:no protocols available:”

The highest TLS protocol available by the client is still too low for the server to support.

Recommendation

Review the minimum/maximum TLS version settings on the client and server, to ensure that they overlap.

“Wrong version number”

Full Text: “140251374995328:error:1408F10B:SSL routines:ssl3_get_record:wrong version number”

The client is using TLS but the server is probably not configured for TLS.

Recommendation

Review the TLS settings on the server.

Pipelines/Functions

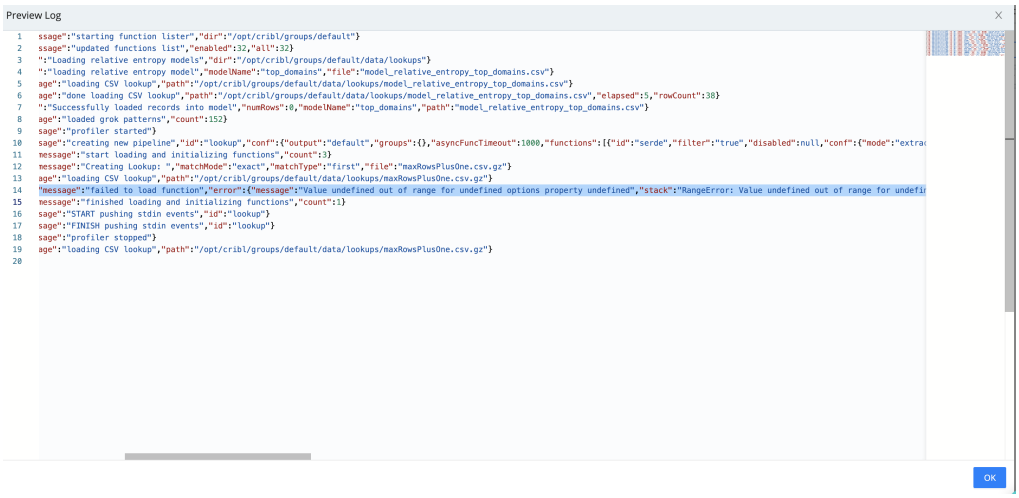
These events will be in the Worker Process logs.

“Failed to load function...Value undefined out of range...”

A Lookup Function attempted to load a Lookup table that exceeded Node.js’ hard size limit of 16,777,216 (that is, 2^{24}) rows.

Recommendation

Split the Lookup table to smaller tables, or use the Redis Function.



Oversized Lookup table error

Diag Command

“You are running Cribl Stream CLI as user=root…”

Full Text: “WARNING: You are running Cribl Stream CLI as user=root, while the binary is owned by the user=cribl. This may change the ownership of some files under CRIBL_HOME=/opt/cribl. Please make sure all files under CRIBL_HOME=/opt/cribl are owned by the user=cribl.”

This is caused by improper ownership on `$CRIBL_HOME`, and will cause some files to be missing from the diag.

Recommendation

Execute the `chown` command on the entire `$CRIBL_HOME` directory, so that everything can be owned by the proper user. Afterward, run the `./cribl diag create` command again.

Distributed Deployment

“Access denied”

The Worker’s authtoken (located in `$CRIBL_HOME/local/_system/instance.yml`) is missing or doesn’t match the Leader’s.

19.5. Git Push Errors

This page anticipates common errors you might see in Cribl Stream's UI, or in the `git` CLI, when pushing a commit.

Failed to Push Some Refs

Your first push to a remote repo might fail with one of several `failed to push some refs` errors.

As a first step in debugging these errors, edit the `$CRIBL_HOME/.git/config` file to make sure that its `name` and `email` key values match the credentials you've set on your repo provider or git server.

Also make sure that the `remote "origin"` key value matches the remote you set when you connected to the remote repo. This example shows all three keys, with placeholder values:

```
[user]
        name = <your-login-name>
        email = <email@example.com>
[remote "origin"]
        url = https://<user-name>:<token>@github.com/<username>/<repo-name>
```

Next, verify the remote repo from the command line, as follows:

```
cd $CRIBL_HOME/.git
git remote -v
```

In response, `git` should echo your configured remote twice – once for `fetch` and once for `push` operations.

If all of the above settings are correct, the `push` is very likely blocking because the remote repo has some commit history, or was simply created with a `readme.md` file. For command-line instructions to remedy this – by syncing your local repo to its remote – see GitHub's Dealing with Non-Fast-Forward Errors topic.

Large Files Detected

A push command might also trigger "large file" warnings or, more seriously, errors of this form (CLI/GitHub example):

```
remote: warning: File data/lookups/geo.mmdb is 60.12 MB; this is larger than GitHub's
remote: error: GH001: Large files detected. You may want to try Git Large File Storag
remote: error: Trace: [##########################################################
remote: error: See http://git.io/iEPt8g for more information.
remote: error: File groups/default/data/lookups/largelookup.csv is 313.91 MB; this ex
```

Cribl recommends adding such large files to `.gitignore`, to exclude them from subsequent `push` commands. As the above examples show, typical culprits are large `.csv` or `.mmdb` lookup files. A simple option is to place these files in a `$CRIBL_HOME` subdirectory that's already listed in `.gitignore` – for details, see Managing Large Lookups.

Other available workarounds include staging such files **outside** `$CRIBL_HOME`, or using plugins to accommodate the large files. For GitHub-specific options, see Working with Large Files.

See Also

- Git Remote Repos with Trusted CAs

19.6. Git Remote Repos & Trusted CAs

If you are using an internal Git server, a self-signed certificate might prevent Cribl Stream from successfully pushing commits to the origin. You might see errors like these when pushing (or pulling) via the CLI:

```
SSL certificate problem: self signed certificate in certificate chain
SSL certificate problem: unable to get local issuer certificate
```

Resolving the Errors

To ensure that Git trusts your self-signed certificate, follow these steps:

1. Obtain the certificate chain (root, intermediates, and leaf) for the Git server.
2. As the `cribl` user, run this command: `git config http.sslCAInfo /path/to/certs.pem`
3. Test with this command: `git push origin` Verify that this throws no errors.

Obtain the Certificate Chain (TLS/SSL)

Use these steps to enable Worker-to-Leader mutual authentication:

A. Validate the Client Certs

If you are using an internal certificate authority, obtain a copy of the CA public certificate, then add it to `/etc/systemd/system/cribl.service`:

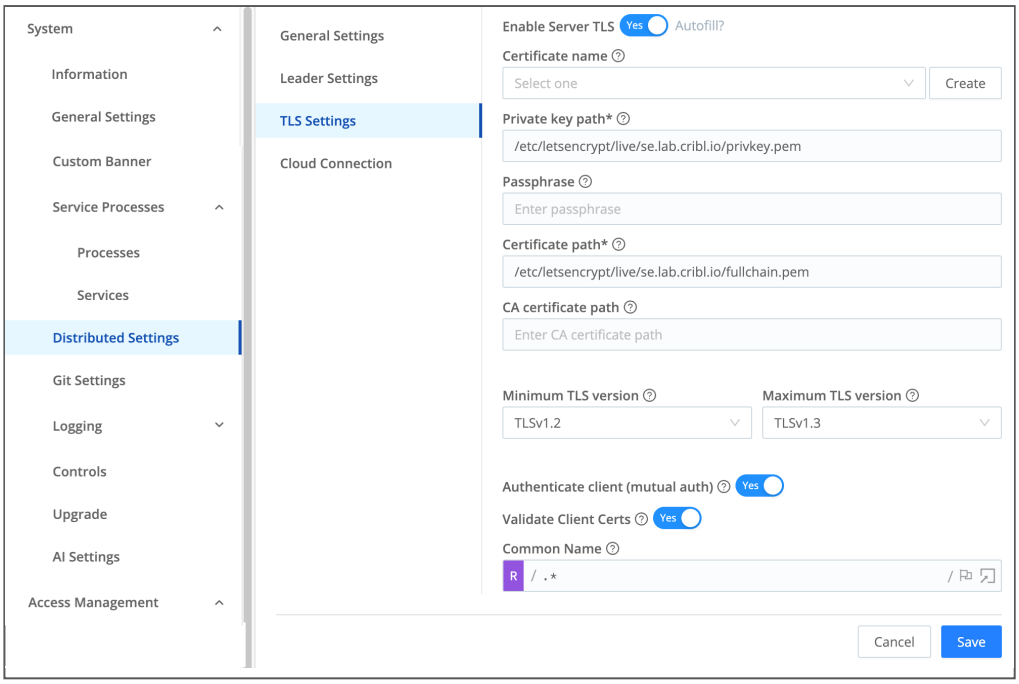
```
...
[Service]
Environment="NODE_EXTRA_CA_CERTS=/opt/cribl/local/cribl/auth/certs/ca.pem"
...
```

For details, see CA Certificates and Environment Variables.

B. Simplify the Common-Name Regex

The common-name regex (if required) should omit the `CN=` at the beginning of the **Common Name** field. The following example will match all immediate subdomains of `se.lab.cribl.io`, like `madsci.se.lab.cribl.io`.

If you disable **Validate Client Certs**, Cribl Stream will match only on common names.



Common Name example

C. Extract SSL Certificate Info

As in this example:

```
openssl x509 -in certificate.pem -text -noout
```

D. Dump the Certificate Chain from the Server

As in this example:

```
echo "" | openssl s_client -host www.google.com -port 443 -showcerts 2>&1 | sed -n '
```

19.7. Sample Logs For Login Scenarios

This page lists sample event series that Cribl Stream records in common login scenarios. Cribl Stream captures event series for both successful and failed login attempts. Note that these samples omit the following repeating fields that are captured in each log:

- `cid:api`
- `channel:cribl`
- `level:info`

Successful Authentication Using the `memberOf` Attribute
